Oxygen Carrier for Gas Chromatographic Analysis of Inert Gases in Propellants

The gas chromatographic determination of small quantities of inert gases dissolved in reactive propellants is not easily performed with carrier gases such as helium, nitrogen, or hydrogen. For example, the determination of helium in diborane with thermal conductivity detectors is complicated by traces of water in column packing materials, because hydrogen is formed by the hydrolysis of diborane, and the separation of hydrogen from helium is not readily accomplished on any column of convenient length. Moreover, hydrogen is not a satisfactory carrier gas because its thermal conductivity is nearly the same as helium. Oxidation of diborane by a hot cupric oxide bed placed in front of the gas chromatograph column proved to be only partially effective; however, when oxygen was used as the carrier, complete oxidation of the diborane was obtained and satisfactory determinations of 0.09 to 1.5 mol-percent of helium were obtained.

In another instance, the determination of nitrogen in oxygen difluoride by the usual gas chromatographic technique with helium as a carrier gas was unsuccessful because the oxygen which is produced by reaction of the propellant with column materials is not readily separated from nitrogen by the chromatographic columns ordinarily employed. However, it was found that oxygen could be used effectively as a carrier with glass-bead thermistor detectors, but the sensitivity of the determination was somewhat reduced.

Operating conditions used for these specific analyses are given in the table.
