Final Report for Period June 29, 1971 thru December 12, 1971

Prepared for

GODDARD SPACE FLIGHT CENTER
Greenbelt, Maryland 20771

The Lander Trajectory Reconstruction (LTR) computer program is a tool for analysis of the planetary entry trajectory and atmosphere reconstruction process for a lander or probe.

The program can be divided into two parts -- the data generator and the reconstructor. The data generator provides the "real" environment in which the lander or probe is presumed to find itself. The reconstructor reconstructs the entry trajectory and atmosphere using sensor data generated by the data generator and a Kalman-Schmidt consider filter. A wide variety of vehicle and environmental parameters may be either solved-for or considered in the filter process.
The Lander Trajectory Reconstruction (LTR) program is a computer program developed by the Martin Marietta Corporation to analyze the entry trajectory and atmosphere reconstruction process for the planetary entry of a lander or probe. The program was initially developed in the Viking lander contract, NAS1-9000. In Contract NAS5-11873, the program was modified and expanded to provide for more flexible atmosphere models, a wider variety of measurement types, and an arbitrary entry plane.

The program can be divided into two parts -- the data generator and the reconstructor. The data generator provides the "real" environment in which the lander or probe is presumed to find itself. Thus the data generator integrates the equation of motion from entry to landing using vehicle and atmosphere models that are assumed to model the "real" environment. These data are then used as inputs to the reconstructor.

The reconstructor reconstructs the entry trajectory and atmosphere using the sensor data generated by the data generator and a Kalman-Schmidt recursive estimation algorithm. The estimation algorithm generates an estimate of the state of the vehicle at each measurement time as well as the statistics associated with the estimate. In addition to the basic state of the vehicle, the state vector may be augmented with a wide variety of vehicle and environmental parameters. These augmented parameters may be treated as either solve-for parameters or consider parameters. The solve-for parameters are estimated along with the basic state variable, whereas the consider parameter uncertainties are used in generating the state and solve-for parameters statistics but are not estimated, i.e., their uncertainties are not improved.

The reconstructor can be operated in either of two modes. Mode A operation is designed for high-Mach number high-altitude regions. The principal atmosphere measurements of temperature and pressure are difficult to obtain accurately in these regions. Consequently vehicle acceleration, based on an atmosphere model and measurements of temperature and pressure, tend to be less accurate than direct accelerometer outputs. Therefore in mode A operation, no a priori atmosphere model is assumed and the vehicle acceleration terms in the equations of motion are obtained directly from accelerometer and, if available, gyro data. In low-Mach number regions, particularly as terminal velocity is approached, accurate temperature and pressure measurements are available and accelerometer
data yield less useful information. Mode B operation is designed for such regions. The vehicle accelerations are based on an a priori atmosphere model and accelerometer data are processed as observables.

The documentation for the LTR program is contained in two volumes: the Analytic/Users' Manual and the Programmers' Manual. Each of these manuals is self contained.

The Analytic/Users' Manual consists of two parts. The first part provides a unified treatment of the mathematical analysis of the LTR program. The general problem descriptions, formulation, and solution are given in a tutorial manner. This is followed by the detailed analysis of each LTR subroutine. The second part contains the information necessary to operate the program. The input and output quantities are described in detail. Example cases are also given and discussed.

The Programmers' Manual provides the reader with the information he needs to effectively modify the program. The overall structure of the program and the computational flow and analysis of the individual subroutines are described in this manual.

LTR ANALYTICAL MANUAL
I. INTRODUCTION

The Lander Trajectory Reconstruction (LTR) program is a planetary entry trajectory and atmosphere reconstruction program. Currently LTR is a preflight mission analysis tool that is used to perform error analyses and simulations of entry trajectory and atmosphere reconstruction processes. The LTR program can provide answers to questions such as How do modeling errors affect our ability to reconstruct the entry trajectory and planetary atmosphere? Is the reconstruction process convergent? What kind of reconstruction strategy and instrumentation accuracies are required to meet the scientific objectives of the mission?

The LTR program consists of a data generator program and a reconstruction program. The data generator can be run independently as an entry trajectory program, but is used primarily to generate the "actual trajectory and atmosphere" and "actual measurements" for use in the reconstruction program. The reconstruction program is primarily a simulation program that processes these "actual measurements" in an attempt to reconstruct the "actual trajectory and atmosphere." In designing an actual mission, of course, we can never obtain exact values of dynamic and measurement parameters, and our equations of motion always neglect certain dynamical effects and often embody certain simplifications in the interest of computational efficiency. It is important to know the significance of these inherent limitations on our ability to reconstruct the entry trajectory and the planetary atmosphere. This is the basis for the division of the LTR program into two parts. In essence, the mathematical models used in the data generator to compute the "actuals" represent the "real world," while those models used in the reconstruction program represent the "modeled world."

An independent error analysis mode is currently not available in the LTR reconstruction program. However, all the information that would be generated in an independent error analysis mode is always generated by the LTR reconstruction program. An independent error analysis mode could not be defined for the mode A reconstruction process because "actual" accelerometer measurements are required from the data generator. Although an independent error analysis mode could be defined for the mode B reconstruction process, it would not result in a significant reduction in program operation costs. Furthermore, it is always useful to have simulation information available because of the more difficult problems encountered in designing convergent filters for entry missions. The remainder of this chapter will summarize the contents of the remaining chapters in the Analytic section of this manual.
Chapter II presents the dynamic and measurement models that are used in the data generator to compute the "actuals." The equations of motion are written assuming an inverse square gravitational field and Mach number-dependent aerodynamic coefficients. Provision is available for including the dynamic effects of parachute deployment and release. The atmosphere model is a linear breakpoint model defined by temperature and molecular weight profiles and surface pressure. A linear breakpoint horizontal wind model is also available. During the terminal descent phase the dynamic model can be replaced with the quasi-static dynamic model. The quasi-static dynamic model improves computational efficiency and avoids certain integrator instabilities. Measurement models are defined in the data generator for the following measurement types: axial and normal accelerometers, gyro, radar altimeter, stagnation pressure, stagnation temperature, and range and range-rate from three earth-based tracking stations. "Actual" bias and scale factor errors can be incorporated into most of the dynamic and measurement parameters.

Chapter III presents the recursive linear estimation algorithm used in both reconstruction modes. The algorithm is the Kalman-Schmidt algorithm with a consider mode. The consider mode permits the uncertainties in certain parameters to be considered in the algorithm without actually attempting to estimate these parameters. This is a device for combating filter divergence. The state transition matrix computational method is also described in Chapter III. Quasi-linear filtering is discussed and the measurement noise models for all measurement types are summarized.

The two reconstruction modes available in the LTR reconstruction program differ primarily in the method employed for modeling aerodynamic forces. Since the mode A reconstruction process, which is described in Chapter IV, uses accelerometer and gyro data to model aerodynamic forces, it requires no model of the planetary atmosphere for its operation. The mode B reconstruction process, which is described in Chapter V, uses mathematical models similar to those used in the data generator to model aerodynamic forces and the planetary atmosphere. In either mode provision is available for estimating or considering various dynamic and measurement parameters.
II. MODELING OF ACTUAL TRAJECTORY, ATMOSPHERE, AND MEASUREMENTS

A. ENTRY GEOMETRY AND EQUATIONS OF MOTION

Figure II-1 defines the entry geometry modeled in the LTR program. The entry plane is defined relative to the planetocentric ecliptic coordinate system \( x_e, y_e, z_e \) by the longitude of the ascending node \( \Omega_e \) and the inclination \( i_e \). The reference line from which the downrange angle \( \phi \) is measured, is defined in the entry plane by the angle \( \psi \). Since only the planar translation and rotational dynamics of the entry vehicle are modeled in LTR, the state of the entry vehicle can be defined by the altitude \( h \), velocity \( v \), flightpath angle \( \gamma \), downrange angle \( \phi \), attitude \( \theta \), and angular velocity \( \omega \). Flightpath angle \( \gamma \) is measured from the instantaneous local horizontal. The position of the entry vehicle relative to the planet center is given by

\[
r = h + R_p
\]  

(II-1)

The vehicle body axes are denoted by the \( xyz \) coordinate system, where \( x \) is aligned with the vehicle longitudinal axis, \( y \) is normal to the entry plane, and \( z \) completes the orthogonal triad. The vehicle attitude angle \( \theta \) is measured from the local horizontal (corresponding to \( \theta = 0 \)) to the \( x \) body axis. The vehicle angle of attack \( \alpha \) is measured from the relative velocity \( v_r \) to the \( x \) body axis. Velocity \( v_a \) is the vehicle velocity relative to the planetary atmosphere, and is defined as the vector difference of the inertial velocity \( v \) and the atmosphere velocity \( v_a \), so that

\[
\frac{v - v_a \cos \gamma}{\cos \epsilon}
\]

(II-2)

where \( \epsilon \) is the angle between \( v \) and \( v_R \). The angle \( \epsilon \) is given by

\[
\epsilon = \tan^{-1} \left[ \frac{v_a \sin \gamma}{v - v_a \cos \gamma} \right]
\]

(II-3)
Figure II-1 Entry Geometry
If \( \dot{\omega}_p \) denotes the angular velocity vector of the planet, and if \( \hat{\mathbf{e}}_n \) denotes a unit vector normal to the entry plane, then the atmosphere velocity in the entry plane can be written as

\[
v_a = (\dot{\omega}_p \cdot \hat{\mathbf{e}}_n) \mathbf{r} + v_w
\]  

where \( v_w \) is the horizontal wind velocity. The angle of attack can be related to the other angular quantities according to

\[
\alpha = \theta + \phi - \gamma - \epsilon.
\]  

The entry vehicle geometry is defined in Figure II-2. The probe center of gravity (cg) has location \((x_p, z_p)\). When the parachute is deployed, its centerline is assumed to be aligned with the relative velocity vector so that the force \( F_d \) exerted by the parachute on the probe is also aligned with the relative velocity vector. The force \( F_d \) acts at location \((x_d, 0)\) relative to the body axis system.

Axial aerodynamic force \( A \), normal aerodynamic force \( N \), and aerodynamic (damping) moment \( M \) act at the center of pressure and are given by

\[
A = -C_A q S
\]

\[
N = -C_N q S
\]

\[
M = C_M \omega d^2 q S/v_r
\]  

The parachute force is given by

\[
F_d = C_D q S_D
\]  

In these equations \( C_A, C_N, \) and \( C_M \) are the axial force, normal force, and damping moment coefficients, respectively, and are tabulated functions of angle of attack \( \alpha \) and Mach number \( M \). The parachute drag coefficient \( C_D \) is a tabulated function of \( M \) only. The quantities \( S \) and \( S_D \) denote the reference areas of the probe and parachute,
Figure II-2 Entry Vehicle Geometry
respectively; the reference diameter of the probe is denoted by \( d \). Dynamic pressure \( q \) is given by

\[
q = \frac{1}{2} \rho \frac{v^2}{r}
\]

where \( \rho \) is the atmospheric density.

Assuming an inverse square gravitational force in addition to the previously discussed aerodynamic forces and moments, the translational and rotational equations of motion of the entry vehicle can be written as

\[
\dot{h} = v \sin \gamma \tag{II-11}
\]

\[
\dot{v} = -g \sin \gamma + \frac{A}{m} \cos (\alpha + \epsilon) + \frac{N}{m} \sin (\alpha + \epsilon) - \frac{F_d}{m} \cos \epsilon \tag{II-12}
\]

\[
\dot{\gamma} = \left( \frac{v}{r} - \frac{g}{v} \right) \cos \gamma + \frac{1}{v} \left[ \frac{A}{m} \sin (\alpha + \epsilon) - \frac{N}{m} \cos (\alpha + \epsilon) \right.
\]

\[
- \frac{F_d}{m} \sin \epsilon \tag{II-13}
\]

\[
\dot{\phi} = \frac{v}{r} \cos \gamma \tag{II-14}
\]

\[
\dot{\theta} = \omega \tag{II-15}
\]

\[
\dot{\omega} = \frac{1}{I} \left[ (z_p - z_g) A - (x_p - x_g) N + M + z_g F_d \cos \alpha \right.
\]

\[
- (x_g - x_d) F_d \sin \alpha \right] \tag{II-16}
\]

where \( I \) denotes the vehicle (pitch) moment of inertia about the center of gravity, and acceleration of gravity \( g \) is given by

\[
g = \frac{\mu}{r^2} \tag{II-17}
\]

where \( \mu \) is the gravitational constant. Vehicle mass is denoted by \( m \).
The parachute terms, of course, only appear in the above equations of motion when the parachute is deployed. The parachute can be deployed at a desired altitude, and then released at a lower altitude.

The derivation of the rotational equations of motion assumes that gravity-gradient and attitude control moments are negligible. Out-of-plane rotational dynamics are neglected and are assumed to have negligible coupling with in-plane rotational dynamics.

During certain flight regimes it becomes necessary to modify the equations of motion to avoid excessive computational time. During the terminal velocity regime, for example, it becomes desirable to increase the integration step size, especially when terminal velocities are rather low. Experience has shown, however, that very small step sizes are required during the terminal velocity regime to prevent the onset of an integrator instability. Although the terminal velocity regime is physically characterized by $|\dot{v}| \ll 1$, an unstable $\dot{v}$ oscillation can occur during this regime if the step size is not chosen small enough. A solution to this problem was obtained by assuming quasi-static motion during the terminal velocity regime. This entails replacing equation (II-12) for $\dot{v}$ with the approximate equation $\dot{v} = 0$, and replacing $v$ in the remaining equations with the terminal velocity $v_T$, which is computed from

$$v_T = \left[ \frac{2 mg |\sin \gamma|}{\rho \left( C_A S + C_D S_D \right)} \right]^{\frac{1}{2}} \quad \text{(II-18)}$$

This equation was obtained by setting $\dot{v}$, $\alpha$, and $\epsilon$ to zero and $v_T$ to $v_T$ in equation (II-12), and solving for $v_T$.

Yet another integrator instability can occur during the maximum dynamic pressure (max q) regime if integration step sizes are not sufficiently small. As the max q regime is entered, rotational oscillations with very high frequencies are induced by the aerodynamic moments acting on the entry vehicle. For the integrator to reproduce these oscillations accurately would require an extremely small step size; too large a step size would drive the integrator unstable. The instability normally becomes apparent in the unstable oscillation of the angle of attack during max q. A solution to this problem was devised by approximating the rotational motion during max q so small integration step sizes would not be required. If the actual entry vehicle is aerodynamically stable
during max q, it is reasonable to assume that the actual angle of attack oscillations are characterized not only by high frequencies, but very small amplitudes as well. This permits one to set the angle of attack $\alpha$ to zero during max q without significantly disturbing the accuracy of the computed translational motion. Setting $\alpha = 0$ in equation (II-5) yields

$$\theta = \gamma - \phi + \varepsilon$$  \hspace{1cm} (II-19)

Differentiating this equation, and assuming $\dot{\varepsilon}$ is negligible, we obtain

$$\omega = \dot{\gamma} - \dot{\phi}$$  \hspace{1cm} (II-20)

Thus, during max q we obtain the rotational state from equations (II-19) and (II-20), instead of by integrating equations (II-15) and (II-16). This approximation is also applied during the initial phase of parachute deployment to avoid integration instabilities in the rotational equations.

B. PLANETARY ATMOSPHERE MODEL

The planetary atmosphere modeled in LTR assumes only radial variations in all atmospheric parameters; horizontal gradients are neglected. The hydrostatic equation

$$\frac{dp}{dh} = -\rho g$$  \hspace{1cm} (II-21)

and the perfect gas law

$$\rho = \frac{pM}{RT}$$  \hspace{1cm} (II-22)

are also assumed to be valid. In these equations $p$ represents ambient pressure; $g$, acceleration of gravity; $\rho$, density; $M$, molecular weight; $T$, ambient temperature; and $R$, the universal gas constant.
Combining equations (II-21) and (II-22) yields

$$\frac{dp}{dh} = - \frac{P g M}{RT} \quad (II-23)$$

Assuming constant $g$, the integral of this equation has the form

$$p(h) = p(h_k) \exp \left[ - \frac{g}{R} \int_{h_k}^{h} \frac{M(c)}{T(c)} \, dc \right] \quad (II-24)$$

This integral is evaluated in LTR by assuming piece-wise linear variations of molecular weight $M$ and temperature $T$ with altitude:

$$T(h) = T(h_j) + \left[ \frac{T(h_{j+1}) - T(h_j)}{h_{j+1} - h_j} \right] (h - h_j)$$

$$h_j \leq h \leq h_{j+1} \quad (II-25)$$

$$M(h) = M(h_i) + \left[ \frac{M(h_{i+1}) - M(h_i)}{h_{i+1} - h_i} \right] (h - h_i)$$

$$h_i \leq h \leq h_{i+1} \quad (II-26)$$

where the set of altitudes $h_j$ define the temperature breakpoints, and the set of altitudes $h_i$ define the molecular weight breakpoints. Details of the evaluation of the integral in equation (II-24) are given in the subroutine ATMSET analysis section.

The molecular weight profile defined by equation (II-26) is computed from a set of mole fraction profiles for the component gases present in the planetary atmosphere. The same breakpoints $h_i$ are used to define these profiles. Letting $a_{j,i}$ denote the mole fraction of the $j$th gas at altitude $h_i$, the molecular weight at $h_i$ is given by

$$M(h_i) = \sum_j a_{j,i} m_j$$

$$where m_j is the molecular weight of the jth gas. Up to five gases can be defined in LTR.
A horizontal wind model is also available in LTR. Since a piece-wise linear variation of wind with altitude is assumed, the wind \( w \) at altitude \( h \) can be written as

\[
w(h) = w(h_n) + \frac{w(h_{n+1}) - w(h_n)}{h_{n+1} - h_n} (h - h_n)
\]

\( h_n \leq h \leq h_{n+1} \)  (II-28)

where the set of altitudes \( h_n \) define the horizontal wind break-points.

C. ACCELEROMETER AND GYRO MODELS

Two strapdown accelerometers, or velocity reference units, are modeled in LTR. A third accelerometer is not required because of the planar dynamic model assumed by LTR. The two accelerometers are nominally aligned with the \( x \) and \( z \) body axes of the entry vehicle and have location \( (x_m, z_m) \) relative to the origin of the body axes. Although a number of accelerometer error sources could be modeled, LTR assumes only misalignment, bias, and scale factor errors. The actual output from the accelerometer has quantized form and is not available as a continuous function of time. The derivation of the actual accelerometer output equation will be summarized in the following paragraphs.

The actual nongravitational acceleration at the location of the velocity reference unit (VRU) is given by

\[
a_x = a_{xg} - \omega^2 \bar{x} + \dot{\omega} \bar{z}
\]  \hspace{1cm} (II-29)

\[
a_z = a_{zg} - \omega^2 \bar{z} - \dot{\omega} \bar{x}
\]  \hspace{1cm} (II-30)

where \( \bar{x} \) and \( \bar{z} \) denote the offset of the VRU relative to the vehicle cg and are given by

\[
\bar{x} = x_m - x_g
\]  \hspace{1cm} (II-31)

\[
\bar{z} = z_m - z_g
\]  \hspace{1cm} (II-32)
and where $a_x$ and $a_z$ denote the $x$ and $z$ components of the actual nongravitational acceleration at the vehicle cg.

Because of accelerometer misalignment errors $\delta_1$ and $\delta_2$, the actual nongravitational acceleration experience by the VRU is given by

$$v_x = a_x \cos \delta_1 - a_z \sin \delta_1 \tag{II-33}$$

$$v_z = a_x \sin \delta_2 + a_z \cos \delta_2 \tag{II-34}$$

The actual output of the VRU in quantized form and is corrupted by bias errors $C_{bx}$ and $C_{bz}$ and scale factor errors $C_{sx}$ and $C_{sz}$. The equations for the quantized output are given by

$$v_{xq}(t_k) = Q \left\{ C_{sx} \int_0^{t_k} \hat{v}_x \, dt + C_{bx} \right\} \tag{II-35}$$

$$v_{zq}(t_k) = Q \left\{ C_{sz} \int_0^{t_k} \hat{v}_z \, dt + C_{bz} \right\} \tag{II-36}$$

where $Q$ denotes the quantizing operator. If we let $I$ denote the modified greatest integer operator, where $I(x)$ is the integer part of $x$ formed by truncating all digits to the right of the decimal, and $\Delta q$, the quantum level, then

$$Q(\cdot) = I\left\{ (\cdot) \right\} \times \Delta q \tag{II-37}$$

Note that $v_{xq}$ and $v_{zq}$ are not true velocities. Rather, they represent the contents of the $x$ and $z$ integrating accelerometer registers at time $t_k$. They would be true velocities only if the inertial orientation of the vehicle had remained constant over the time interval $[0, t_k]$. 

14
A single strapdown gyro, or attitude reference unit, is modeled in LTR. Three gyros are not required because of the planar dynamic model assumed by LTR. Although a number of gyro error sources could be modeled, LTR assumes only misalignment, bias, and scale factor errors. The actual output from the gyro, like that of the accelerometers, has quantized form and is not available as a continuous function of time. Derivation of the actual gyro output equation is summarized in the following paragraph.

The actual angular velocity of the vehicle and the attitude reference unit ARU in the plane of motion is denoted by $\omega$. Because of the gyro misalignment error $\delta_3$, the actual angular velocity experienced by the ARU is given by

$$\dot{\theta} = \omega \cos \delta_3.$$  \hspace{1cm} (II-38)

The actual output of the ARU is in quantized form and is corrupted by bias error $C_{b\theta}$ and scale factor error $C_{s\theta}$. The equation for the quantized output is given by

$$A_{q\theta}(t_k) = Q \left[ C_{s\theta} \int_0^{t_k} \dot{\theta}_0 \, dt + C_{b\theta} \, t_k \right].$$  \hspace{1cm} (II-39)

D. PREPROCESSING OF GYRO AND ACCELEROMETER MEASUREMENTS

The quantized accelerometer and gyro data are not processed directly by the navigation filter, but must first be preprocessed. This preprocessing consists of smoothing the quantized data to generate not only smoothed acceleration and attitude angle, but also angular velocity and angular acceleration. The smoothed angular quantities are particularly important for operation of the mode A reconstruction process. The LTR preprocessor employs a five-point central-point smoother, which simply means that five quantized data points are used to determine smoothed data and their derivatives at the center of the five-point interval. The smoothing of $A_{q\theta}$ data will be discussed in more detail in the following paragraph. The same method is used to smooth $v_{xq}$ and $v_{zq}$.
Suppose we wish to obtain smoothed attitude $\hat{\theta}_m$, angular velocity $\hat{\omega}_m$, and angular acceleration $\hat{\omega}_m$ at $t = t_k$. Then, as indicated in Figure II-3, smoothing will be performed using all quantized attitude data over the interval $[t_{k-2}, t_{k+2}]$. We assume $\hat{\theta}_m(t)$ can be expressed as a quadratic function over this interval, so that

$$\hat{\theta}_m(t) = C_1 + C_2 \left( t - t_k \right) + C_3 \left( t - t_k \right)^2 \qquad (II-40)$$

The coefficients $C_1$, $C_2$, and $C_3$ are chosen to obtain a least-squares fit to the data points $A_{\theta q}(t_{k-2})$ through $A_{\theta q}(t_{k+2})$. The solution to this problem is given by the following equations:

$$\begin{bmatrix} C_1 \\ C_2 \\ C_3 \end{bmatrix} = \left( B^T B \right)^{-1} B \begin{bmatrix} A_{\theta q}(t_{k-2}) \\ \vdots \\ A_{\theta q}(t_{k+2}) \end{bmatrix} \qquad (II-41)$$

where

$$B = \begin{bmatrix} 1 & -2\Delta & 4\Delta^2 \\ 1 & -\Delta & 2\Delta^2 \\ 1 & 0 & 0 \\ 1 & \Delta & 2\Delta^2 \\ 1 & 2\Delta & 4\Delta^2 \end{bmatrix} \qquad (II-42)$$

and $\Delta = t_k - t_{k-1}$. Having determined the coefficients $C_1$, $C_2$, and $C_3$, we evaluate equation (II-40) at $t = t_k$ to obtain:

$$\hat{\theta}_m(t_k) = C_1 \qquad (II-43)$$

Evaluating the first two derivatives of equation (II-40) at $t = t_k$ yields

$$\hat{\omega}_m(t_k) = C_2 \qquad (II-44)$$

$$\hat{\omega}_m(t_k) = 2 C_3 \qquad (II-45)$$
Figure II-3 Smoothing of Quantized Data
Smoothed acceleration data $a_{x m_k}(t_k)$ and $a_{z m_k}(t_k)$ are similarly obtained from the quantized accelerometer data. Additional information is available in the subroutine PRPR6S and SMOOTH documentation.

E. OTHER ONBOARD MEASUREMENT MODELS

In addition to the gyro and axial and normal accelerometers discussed in the previous section, several other onboard measurement types are modeled in the LTR program. These models are summarized below.

1. **Stagnation Temperature Measurement**

   The stagnation temperature measurement is given by
   
   $$ T_o = T \left(1 + \frac{\gamma - 1}{2} M^2 \right) $$(II-46)

   where $T$ is ambient temperature; $\gamma$, ratio of specific heats; and $M$, Mach number. The actual measurement is computed by multiplying the ideal measurement times a scale factor error, and adding on a bias and noise. The noise error is computed by sampling from a Gaussian distribution.

2. **Stagnation Pressure Measurement**

   The stagnation pressure measurement is a function of the Mach number regime and is computed using one of the following three equations:

   $M \geq 3$ :
   
   $$ p_o = \frac{1}{2} C_p \rho \frac{v^2}{r} + p $$ (II-47)

   $C_p = 2 - \epsilon$; (II-48)

   $1 \leq M < 3$ :
   
   $$ p_o = \frac{1}{2} C_p \rho \frac{v^2}{r} + p $$ (II-49)
\[ p = \frac{p}{8} \left[ \left( \frac{\gamma + 1}{2} \right)^{\gamma - 1} \times \left( \frac{\gamma + 1}{2\gamma M^2 - \gamma + 1} \right)^{1/\gamma - 1} - 1 \right] ; \quad (II-50) \]

\[ M < 1 : \]
\[ p_0 = p \left( 1 + \frac{\gamma - 1}{2} \right)^{1/\gamma - 1} \quad (II-51) \]

where \( p_0 \) is stagnation pressure; \( p \), ambient pressure; \( C_p \), coefficient of pressure; \( M \), Mach number; \( \gamma \), ratio of specific heats; and \( \varepsilon \), ratio of densities in front of and behind the shock wave. The ratio \( \varepsilon \) is a tabulated function of \( v_R \). The actual measurement is computed by multiplying the ideal measurement times a scale factor error, and adding on a bias and noise. The noise error is computed by sampling from a gaussian distribution.

3. Radar Altimeter Measurement

The onboard radar altimeter measurement is defined as the shortest distance between the spacecraft and the terrain of the planet within the limits of the altimeter sweep angle. Figure II-4 depicts the relevant radar altimeter and terrain height geometry. The spacecraft has altitude \( h \) above the mean planet surface. The altimeter has a symmetrical sweep angle of \( 2\theta \). Terrain height \( \tau \) above the mean surface is assumed to have the form

\[ \tau = C_1 + C_2 \sin \left( C_3 \phi' + C_4 \right) + C_5 \cos \left( C_6 \phi' + C_7 \right) \quad (II-52) \]

where constants \( C_1, C_2, ..., C_7 \) are chosen to approximate the terrain height profile of the planet, and \( \phi' \) represents the difference between the spacecraft downrange angle \( \phi \) and angular displacement of the terrain due to planet rotation, and is given by

\[ \phi' = \phi - \Omega_p \cdot \hat{e}_n (t - t_o) \quad . \quad (II-53) \]

In this equation \( \Omega_p \) denotes the planet inertial angular velocity \( \hat{e}_n \) is a unit vector normal to the entry plane (and in the direction of the spacecraft orbit angular momentum). The distance \( \bar{h} \) between the spacecraft and the terrain is given by

\[ \bar{h} = \left[ (h + R_p)^2 + w^2 - 2w (h + R_p) \cos (\bar{\phi} - \phi) \right]^{1/2} \quad (II-54) \]
Figure II-4 Altimeter and Terrain Height Geometry
where \( w \) is the distance from the center of the planet to the actual planet surface. Minimization of \( h \) is equivalent to minimization of the function

\[
f = w^2 - 2w (h + R_p) \cos (\phi - \phi)
\]

The function \( f \) is minimized using a direct search over the interval \([\phi-\delta, \phi+\delta]\) with respect to \( \phi \). The angle \( \delta \) is given by

\[
\delta = \sin^{-1} \left( \frac{(R_p + h) \sin \eta}{R_p} \right) - \eta
\]

The actual radar altimeter measurement is computed by multiplying the minimum \( h \) times a scale factor error and adding on a bias and noise. The noise error is computed by sampling from a gaussian distribution.

4. Angle of Attack

The ratio of measured accelerations \( a_z/a_x \) can be used to define an angle of attack measurement \( \alpha \). The ratio of vehicle lift \( L \) and drag \( D \) can be related to \( a_x \), \( a_z \), and \( \alpha \) according to the equation

\[
\frac{L}{D} = \frac{a_z \cos \alpha - a_x \sin \alpha}{a_z \cos \alpha + a_x \sin \alpha}
\]

Solving for \( \alpha \), we obtain

\[
\tan \hat{\alpha} = \frac{a_z - \frac{L}{D} a_x}{a_x \left( \frac{L}{D} \right)}
\]

The ratio \( L/D \) has the form

\[
\frac{L}{D} = k \hat{\alpha}
\]
where \( k \) is a tabulated function of Mach number. To compute the angle of attack measurement \( \theta \), equation II-58 is solved iteratively using

\[
\frac{a_x}{a_x} = \frac{a_x}{k + 1}
\]

(II-60)

as the initial guess.

F. EARTH-BASED RANGE AND DOPPLER MEASUREMENT MODELS

The geometry of earth-based tracking is shown in Figure II-5. The tracking station is located relative to the geocentric equatorial coordinate system \( x_0y_0z_0 \) by the latitude \( \theta \), longitude \( \lambda \), Greenwich hour angle GHA of the vernal equinox, earth radius \( R_o \), and altitude \( h \) above the mean earth sphere. The spacecraft has position \( \hat{r} \) and velocity \( \hat{r} \) relative to the target planet. These vectors are normally expressed relative to the planetocentric ecliptic coordinate system \( xsz_s \).

The range \( \rho \) between the spacecraft and the tracking station is given by

\[
\rho = \left| \hat{r} + \hat{r}_p - \hat{r}_e - \hat{r}_s \right|
\]

(II-61)

where \( \hat{r}_p \) and \( \hat{r}_e \) denote the position of the target planet and the earth, respectively, relative to the sun, and \( \hat{r}_s \) denotes the position of the tracking station relative to the center of the earth. The heliocentric ecliptic components of \( \hat{r}_s \) are given by

\[
x_s = (R_o + h) \cos \theta \cos G
\]

(II-62)

\[
y_s = (R_o + h) \left[ \cos \theta \cos \varepsilon \sin G + \sin \theta \sin \varepsilon \right]
\]

(II-63)

\[
z_s = (R_o + h) \left[ - \cos \theta \sin \varepsilon \sin G + \sin \theta \cos \varepsilon \right]
\]

(II-64)
Figure II-5 Earth-Based Tracking Geometry
where $e$ is the obliquity of the ecliptic, and

$$G = \lambda + \omega_e (t - t_o) + \text{GHA} (t_o).$$ \hspace{1cm} (II-65)$$

In this last equation, $\omega_e$ represents the inertial angular velocity of the earth; $t - t_o$, the time interval since epoch $t_o$; and $\text{GHA} (t_o)$, the Greenwich hour angle at epoch.

The range rate $\dot{p}$ between the spacecraft and the tracking station is given by

$$\dot{p} = \frac{\dot{\rho}}{\rho} \cdot e = \frac{\dot{\rho} \cdot \rho}{\rho}$$ \hspace{1cm} (II-66)$$

where $\dot{e}$ is a unit vector directed along the range vector $\dot{\rho}$, and $\dot{\rho}$ is given by

$$\dot{\rho} = \dot{r} + \frac{\dot{r}_p}{r_p} - \frac{\dot{r}_e}{r_e} - \frac{\dot{r}_s}{r_s}$$ \hspace{1cm} (II-67)$$

where $\frac{\dot{r}_p}{r_p}$ and $\frac{\dot{r}_s}{r_s}$ denote the velocity of the target planet and the earth, respectively, relative to the sun, and $\frac{\dot{r}_s}{r_s}$ denotes the velocity of the tracking station relative to the center of the earth.

The heliocentric ecliptic components of $\frac{\dot{r}_s}{r_s}$ are given by

$$\dot{x}_s = -\omega_e (R_0 + h) \cos \theta \sin G$$ \hspace{1cm} (II-68)$$

$$\dot{y}_s = \omega_e (R_0 + h) \cos \theta \cos \epsilon \cos G$$ \hspace{1cm} (II-69)$$

$$\dot{z}_s = -\omega_e (R_0 + h) \cos \theta \sin \epsilon \cos G.$$ \hspace{1cm} (II-70)$$

Actual range and doppler (range-rate) measurements are computed in LTR by incorporating the effects of various error sources in the range and doppler measurements computed from the previous equations. Three types of range and doppler error sources are modeled in LTR: (1) station location errors, (2) instrument bias and noise, and (3) refractivity effects of the planetary atmosphere. Station location errors are modeled as biases in station latitude, longitude, and altitude. Instrument noise is computed in LTR by sampling from a gaussian distribution.
III. RECURSIVE STATE ESTIMATION

A. RECURSIVE ESTIMATION ALGORITHM

The recursive estimation algorithm refers to the computational procedure that combines the dynamic model and measurement information to generate estimates of the deviation of the basic system state from the nominal and the covariances associated with these estimates. It is also possible to augment the state vector with parameters that are known with some uncertainty. The basic estimation algorithm treats all uncertain parameters as solve-for parameters, i.e., the estimation algorithm generates estimates of these parameters as well as estimates of the basic state. Continued processing of measurements will often reduce state covariances to unrealistically low values, a situation that can induce divergence in the estimation algorithm. One method used to prevent divergence is to incorporate a consider option in the algorithm and divide all uncertain parameters into either solve-for or consider parameters. Consider parameters are not estimated by the algorithm, nor can their covariance be reduced by measurement processing. In essence, by not solving for all parameters in the uncertain parameter set, the algorithm acknowledges that the nominal dynamic and measurement parameter values do not fully describe the real world, and that it is impossible to reduce parameter uncertainties indefinitely.

Thus the basic state vector is augmented with both solve-for parameters and consider parameters. The consider parameters are further categorized into dynamic-consider parameters, measurement-consider parameters, and dynamic/measurement-consider parameters. A dynamic-consider parameter appears in the dynamic equations only, whereas a measurement-consider parameter appears in the measurement equations only. Dynamic/consider parameters appear in both.

Before presenting the estimations algorithm, the dynamic and measurement models will be described. The set of dynamic equations is assumed to have been linearized about a nominal trajectory. The augmented state vector of deviations from nominal may be written in partitioned form as

\[
x^A = \begin{bmatrix} x \\
q \\
u \\
v \\
w \end{bmatrix}
\]  

(III-1)
where

\[ \begin{align*}
  x & \quad \text{basic state vector}, \\
  q & \quad \text{vector of solve-for parameters}, \\
  u & \quad \text{vector of dynamic-consider parameters}, \\
  v & \quad \text{vector of measurement-consider parameters}, \\
  w & \quad \text{vector of dynamic/measurement-consider parameters}.
\end{align*} \]

The linearized dynamic model is assumed to have the form

\[ x_{k+1}^A = \phi_{k+1,k}^A x_k^A + q_{N_{k+1,k}} \]  

(III-2)

where \( \phi_{k+1,k}^A \) is the augmented state transition matrix over the interval \([t_k, t_{k+1}]\) and \( q_{N_{k+1,k}} \) represents the effects of dynamic noise over the interval. Since the dynamic noise affects the basic state only,

\[
q_{N_{k+1,k}}^A = \begin{bmatrix}
q_{N_{k+1,k}} \\
0 \\
0 \\
0 \\
0
\end{bmatrix} \quad \text{(III-3)}
\]

The linearized measurement model is assumed to have the form

\[ y_k = H_k^A x_k^A + n_k \]  

(III-4)

where \( y_k \) represents the deviation of the observation from the nominal observation at \( t_k \), \( H_k^A \) relates changes in \( x_k^A \) to changes in the measurement \( y_k \), and \( n_k \) represents the measurement noise.

Under the usual assumptions of white noise, the dynamic and measurement noise statistics are described by
The equations constituting the recursive estimation algorithm are of two types — prediction equations and filtering equation. The prediction equations describe the behavior of the state and covariance matrix as they are propagated forward in time with no measurement processing. The state prediction equation is simply equation III-2 without the dynamic noise term. The filtering equations define the covariance updating procedure whenever a measurement is processed. Details of their derivation may be found in Reference 3.

The covariance of the augmented state is defined as

$$
P_{k}^A = E \left[ (\hat{x}_{k}^A - x_{k}^A)(\hat{x}_{k}^A - x_{k}^A)^{T} \right]
$$

where $\hat{x}_{k}^A$ is the estimated deviation from nominal and $x_{k}^A$ is the actual deviation from nominal. The covariance prediction equation that relates the covariance following the processing of a measurement at $t_{k}$, $P_{k}^{A^{+}}$, to the covariance prior to processing the next measurement at $t_{k+1}$, $P_{k+1}^{A^{-}}$, is given by

$$
P_{k+1}^{A^{-}} = \phi_{k+1,k}^{A} P_{k}^{A^{+}} \phi_{k+1,k}^{A^{T}} + Q_{k+1,k}^{A}
$$

Before presenting the filtering equations, the measurement residual at $t_{k}$ must be defined. The measurement residual, $e_{k}$, is the difference between the "actual" measurement $y_{k}^{a}$ and the estimated or expected measurement $y_{k}^{e}$. $y_{k}^{a}$ is composed of an error-free component, $y_{k}$, based on the actual state deviation, $x_{k}^{A}$ plus a random noise component $v_{k}$ and a bias component $b$

$$
y_{k}^{a} = y_{k} + v_{k} + b
$$
The estimated or expected measurement, \( y_k^e \), is composed of an error-free component \( \bar{y}_k \) based on the nominal state, plus a measurement deviation based on the estimated state deviation \( \hat{x}_k^A \)

\[
y_k^e = \bar{y}_k + H_k^A \hat{x}_k^A
\]  

(III-7)

The measurement residual is then simply

\[
\varepsilon_k = y_k^a - y_k^e
\]  

(III-8)

The filler equations involve equations for the measurement residual covariance matrix \( J \), the augmented Kalman gain matrix \( K^A \), the covariance update equation, and the state update equation. The first two equations are

\[
J_{k+1} = H_{k+1}^A P_{k+1}^A H_{k+1}^A + R_{k+1}
\]  

(III-9)

\[
K_{k+1}^A = P_{k+1}^A H_{k+1}^A (J_{k+1}^{-1})
\]  

(III-10)

Unfortunately there is no compact formulation for the state and covariance update equations in terms of the above matrices. This is true because the consider parameters and their covariances are not updated and thus require special handling. An artifice that may be used is to partition the rows of \( K_{k+1}^A \) corresponding to the partition of the augmented state vector in equation III-12:

\[
K_{k+1}^A = \begin{bmatrix}
K_{1, k+1} \\
K_{2, k+1} \\
K_{3, k+1} \\
K_{4, k+1} \\
K_{5, k+1}
\end{bmatrix}
\]  

(III-11)

If a modified gain matrix is defined by
then the estimated state update equation may be written

$$\hat{x}_{k+1} = \hat{x}_{k+1}^+ + K_{k+1}^A \epsilon_{k+1}$$

(III-13)

The covariance update equation may also be written in terms of $K_{k+1}^A$; however, only the partitions of $P_{k+1}^A$ on and above the diagonal are valid

$$P_{k+1}^A = P_{k+1}^A - K_{k+1}^A H_{k+1}^A P_{k+1}^A$$

(III-14)

To take advantage of the sparceness and symmetry of the above equations, they are computed in partitioned form. The partitioned equations are given in the subroutine FILTER analysis.

B. MEASUREMENT NOISE MODELS

This section discusses the measurement noise models used to compute the measurement noise covariance matrix $R$ appearing in equation (III-9).

The measurement noise covariance for an accelerometer, stagnation pressure, angle of attack, range, or doppler measurement is assumed to be a constant. For a stagnation pressure measurement $p_o$, $R$ is a two-valued function:

$$R_{p_o} = \begin{cases} C_1, & p_o \geq 20 \text{ millibars} \\ C_2, & p_o < 20 \text{ millibars} \end{cases}$$

(III-15)
The measurement noise covariance for a radar altimeter measurement $h$ can be either set to a constant or computed as a function of the measurement itself. Currently, with the latter option

$$R = \text{maximum} \begin{cases} [.005 \ h, .05] \ , \ h \geq 6 \\ [.015 \ h, .0005] \ , \ h < 6 \end{cases} \quad (III-16)$$

Although the doppler measurement noise is assumed to be constant, the modeled doppler noise can be adjusted to account for differences between the actual and modeled sample rates using the approximation

$$\sigma_{\rho}' = \sigma_{\rho_{\text{actual}}} \left( \frac{1}{T_s} \right) \quad (III-17)$$

where $\sigma_{\rho_{\text{actual}}}$ is the actual or original sample rate (typically 1 mm/s for a 1-minute count time), and $T_s$ is the spacing between successive doppler points used in the model. For additional information concerning this approximation, see Reference 4.

C. COMPUTATION OF STATE TRANSITION AND OBSERVATION MATRICES

The state transition matrices describe the behavior of a dynamic system in the neighborhood of a nominal trajectory. Before presenting the technique used in the LTP program for computing state transition matrices, the deviation of the general form of the dynamic system modeled in LTR will be summarized.

The nonlinear equations describing the motion of the lander or probe have the form

$$\dot{X}^A = f(X^A, t) \quad (III-18)$$

where $X^A$ denotes the augmented state vector. If equation (III-18) is linearized about a nominal trajectory, it takes the form

$$\dot{X}^A = \frac{\partial f}{\partial X^A} X^A \quad (III-19)$$
where \( x^A \) represents small deviations from the nominal augmented state \( x^A \). The partial derivative is evaluated along the nominal trajectory.

The discrete solution of equation (III-19) over the interval \([t_k, t_{k+1}]\) is given by

\[
x^A_{k+1} = \phi(t_{k+1}, t_k) x^A_k \quad \text{(III-20)}
\]

If the augmented state vector is partitioned into the basic state vector, \( x \); solve-for parameter vector, \( q \); dynamic-consider parameter vector, \( u \); measurement parameter vector, \( v \); and dynamic/measurement parameter vector, \( w \); it is possible to make a corresponding partition of the state transition matrix \( \phi \). Before writing \( \phi \) in partitioned form, it should be observed that all solve-for and consider parameters are assumed to be constant. This means that all partitions of \( \phi \) will be either zero matrices or identity matrices except for those associated with the basic state vector. Thus the partitioned form of \( \phi \) is

\[
\phi = \begin{bmatrix}
\phi & \psi & \theta & 0 & 0 \\
0 & I & 0 & 0 & 0 \\
0 & 0 & I & 0 & 0 \\
0 & 0 & 0 & I & 0 \\
0 & 0 & 0 & 0 & I
\end{bmatrix} \quad \text{(III-21)}
\]

The specification of the time interval has been dropped in equation (III-21) and will henceforth be assumed to be \([t_k, t_{k+1}]\) unless shown otherwise.

A numerical differencing technique was chosen for the computation of the partitions of the state transition matrix. This was done because of the resulting ease with which the solve-for/consider parameter set may be changed or expanded. Before describing the numerical differencing technique, let us adopt the following notation. Express the perturbation in the augmented state at time \( t_{k+1} \) due to a perturbation in the state at \( t_k \) or \( x_k \) as \( x^A(t_{k+1}; x_k, t_k) \) and let the \( j \)th column of \( \phi \) be designated by \( \phi_{\cdot j} \).

Now consider the special case of equation (III-20) in which \( x^A_k \) is a vector whose only nonzero element is the \( j \)th element:
\[
\mathbf{x}_k = [0, \cdots, 0, \delta_j, 0, \cdots, 0]^T = d_j \quad (III-22)
\]

Equation (III-20) becomes
\[
\mathbf{x}^A(t_{k+1}; d_j, t_k) = \phi_j \delta_j \quad (III-23)
\]

from which we obtain the \(j\)th column of \(\phi\) as
\[
\phi_j = \frac{\mathbf{x}^A(t_{k+1}; d_j, t_k)}{\delta_j} \quad (III-24)
\]

The numeration of this expression is evaluated by integrating the state equations over the interval \([t_k, t_{k+1}]\) as follows. Let
\[
I_j = \int_{t_k}^{t_{k+1}} f\left(\mathbf{x}^A(\tau) + d_j, \tau\right) d\tau = \mathbf{x}^A(t_{k+1}; x_k^A + d_j, t_k) - (x_k^A + d_j) \quad (III-25)
\]

and
\[
I = \int_{t_k}^{t_{k+1}} f\left(\mathbf{x}^A(\tau), \tau\right) d\tau = \mathbf{x}^A(t_{k+1}; x_k^A, t_k) - x_k^A \quad (III-26)
\]

then
\[
\mathbf{x}^A(t_{k+1}; d_j, t_k) = I_j - I + d_j \quad (III-27)
\]

Thus the state transition matrix is computed by evaluating the integral \(I\) once and the integral \(I_j\) once for each column of \(\phi\).

The computation of partitions of the state transition matrix is controlled by the subroutine STM.
Observation matrices relate the deviations from nominal in the augmented state variable to deviations in observables from their nominal values. The general nonlinear observation equation has the form

$$ Y = Y (X^A, t) \quad \text{(III-28)} $$

where $Y$ denotes the observable. The linearized versions of equation (III-28) is

$$ y = \frac{\partial Y}{\partial X^A} x^A = H^A x^A \quad \text{(III-29)} $$

where $y$ and $x^A$ represent deviations from the nominal values of $\bar{Y}$ and $\bar{x}^A$.

If we partition the augmented state vector as before, equation (III-29) may be written as

$$ y = [H : M : 0 : L : G] u + v $$

The third partition is zero since the dynamic-consider parameters do not affect the observables.

The columns of the augmented observation matrix $H^A$ are found by numerical differencing just as with the state transition matrix. However, this time the method is more direct since no integration of state equations is required. If we set $x^A = d_j$ as before, equation (III-29) may be written

$$ y = Y(x^A + d_j, t) - Y(x^A, t) = H^A d_j. \quad \text{(III-31)} $$
Thus

$$H^A_{j} = \frac{Y(X^A + d_j, t) - Y(X^A, t)}{j}$$

(III-32)

The computation of the partitions of the observation matrix are controlled by the subroutine HNM.

D. QUASI-LINEAR FILTERING EVENT

The quasi-linear filtering event option is included in the LTR program as an additional means to combat filter divergence. One of the several causes of filter divergence is the failure of the linearization assumption on which the entire estimation process is based. If the vehicle or the environment departs markedly from the current nominal value, the linearization assumptions can become invalid. The quasi-linear filtering event overcomes this difficulty by updating the nominal trajectory to correspond to the present estimate of the state. Specifically, updating the nominal trajectory results in better computation of the state transition and observation matrix partitions used in the recursive estimation algorithm.

Letting $t_j$ denote the time of the quasi-linear filtering event, and using the $(\,)^-$ and $(\,)^+$ notations to indicate values immediately before and after the event, respectively, the basic state and solve-for parameter vectors are updated as follows:

$$\begin{align*}
\tilde{x}^+ &= \tilde{x}^- + \delta_j \\
\tilde{q}^+ &= \tilde{q}^- + q_j \\
\delta_j &= 0 \\
q_j &= 0
\end{align*}$$

(III-33)

where the superscript $^-$ indicates the nominal value and the superscript $^+$ indicates an estimated value.
IV. MODE A STATE ESTIMATION AND ATMOSPHERE RECONSTRUCTION

A. MODE A DYNAMIC MODEL

A five-dimensional primary state vector is employed in the mode A reconstruction process. This state vector is defined by

\[ x = (h, v, \gamma, \phi, p)^T \]  \hspace{1cm} (IV-1)

where

- \( h \) = vehicle altitude
- \( v \) = vehicle velocity
- \( \gamma \) = vehicle flightpath angle
- \( \phi \) = vehicle downrange angle
- \( p \) = ambient atmospheric pressure.

The four vehicle state variables are defined in Figure II-1. These four state variables comprise the entire mode B primary state vector. In mode B, atmospheric pressure is not treated as a state variable.

The fundamental difference between the mode A and mode B reconstruction processes lies in the manner in which nongravitational forces are modeled. The general translational equations of motion can be written symbolically as

\[ \dot{x} = g(x) + f(x) \]  \hspace{1cm} (IV-2)

where in this case \( x \) represents the translational state; \( g(x) \), the gravitational acceleration acting on the vehicle; and \( f(x) \), the nongravitational acceleration. The mathematical form of \( g(x) \) is well known and can be used to accurately model gravitational acceleration. This is not the case for the nongravitational acceleration \( f(x) \), particularly when \( f(x) \) represents an aerodynamic acceleration as is the case for the planetary entry problem. Nevertheless, mode B does use a mathematical model for \( f(x) \), which also requires the selection of a mathematical model of the planetary atmosphere. Mode A, however, dispenses entirely with the attempt to mathematically model \( f(x) \). Instead, mode A uses acceleration...
and gyro data to model \( f(x) \). In other words, \( f(x) \) is replaced by

\[
f \left( a_x, a_z, \theta_m \right)
\]

where \( a_x \) and \( a_z \) represent (smoothed) axial and normal accelerometer (VRU) data, respectively, and \( \theta_m \) represents (smoothed) gyro (ARU) attitude data. Except for a nominal molecular weight profile, mode A requires no model of the planetary atmosphere. The axial acceleration \( a_x \), however, is essential for mode A operation.

The remainder of this section will treat the mode A dynamic model in more detail. The equations of motion are summarized as

\[
\hat{n} = v \sin \gamma \\
\dot{v} = -g \sin \gamma + a_x \cos (\alpha + \varepsilon) + a_z \sin (\alpha + \varepsilon) \\
\dot{\gamma} = \left( \frac{v}{r} - \frac{g}{v} \right) \cos \gamma + \frac{1}{v} \left[ a_x \sin (\alpha + \varepsilon) - a_z \cos (\alpha + \varepsilon) \right] \\
\dot{\phi} = \frac{v}{r} \cos \gamma \\
\dot{\theta} = -g \rho \dot{n}
\]

where \( a_x \) and \( a_z \) represent corrected axial and normal accelerometer data, respectively, and \( \alpha + \varepsilon \) can be obtained from equation (II-5)

\[
\alpha + \varepsilon = \theta_c + \theta_o + \phi - \gamma
\]

where attitude \( \theta \) has been represented as the sum of the initial attitude \( \theta_o \) and the change in (corrected) attitude \( \theta_c \) since \( t_o \). This permits the mode A filter to treat \( \theta_o \) as a solve-for or consider parameter. The angle \( \varepsilon \) is computed from equations (II-3) and (II-4). A nominal wind profile is assumed by mode A to compute the horizontal wind velocity \( v_w \). Equation (IV-7) is just the time-differential form of the hydrostatic equation, where \( \rho \) represents atmospheric density.
Accelerations $a_x$ and $a_z$ and attitude $\theta$ are referred to as corrected quantities since the measured accelerations $a_{x_m}$ and $a_{z_m}$ and the measured attitude $\theta_m$ have been corrected or calibrated for scale factor, bias, and misalignment errors. The equations relating corrected quantities to measured quantities are summarized as

$$a_x = \frac{1}{\cos(\delta_1 - \delta_2)} \begin{bmatrix} a_{x_m} - c_{sx} \\ a_{z_m} - c_{sz} \end{bmatrix} \cdot \begin{bmatrix} \cos \delta_2 \\ \sin \delta_2 \end{bmatrix} + \omega_c^2 x - \dot{\omega}_c z$$ (IV-9)

$$a_z = \frac{1}{\cos(\delta_1 - \delta_2)} \begin{bmatrix} a_{x_m} - c_{sx} \\ a_{z_m} - c_{sz} \end{bmatrix} \cdot \begin{bmatrix} \sin \delta_2 \\ \cos \delta_2 \end{bmatrix} + \omega_c^2 z + \dot{\omega}_c x$$ (IV-10)

$$\theta = \frac{1}{c_{d\theta}} \left\{ \theta_m - c_{d\theta} t \right\}$$ (IV-11)

where $c_{sx}$, $c_{sz}$, and $c_{d\theta}$ represent scale factors; $c_{bx}$, $c_{bz}$ and $c_{b\theta}$ biases; and $c_{d\theta}$, gyro drift error. Equations (II-31) and (II-32) define the accelerometer offsets $x$ and $z$. Corrected angular velocity $\omega_c$ and angular acceleration $\dot{\omega}_c$ are given by

$$\omega_c = \frac{1}{c_{d\theta}} \left\{ \omega_m - c_{d\theta} \right\}$$ (IV-12)

$$\dot{\omega}_c = \frac{\dot{\omega}_m}{c_{d\theta}}$$ (IV-13)
where $\omega_m$ and $\omega_m$ are measured angular velocity and angular acceleration, respectively. Misalignment angles $\delta_{1c}$ and $\delta_{2c}$ are calibrated using

$$\delta_{1c} = \delta_1 - c_b\delta_1$$

(IV-14)

$$\delta_{2c} = \delta_2 - c_b\delta_2$$

(IV-15)

where $\delta_1$ and $\delta_2$ are the nominal misalignment angles, and $c_b\delta_1$ and $c_b\delta_2$ are misalignment biases.

Returning to equation (IV-7), it is apparent that a method for obtaining density $\rho$ must be available before this final state equation can be integrated. Unlike mode B, an atmospheric model cannot be used for generating $\rho$. Instead, in mode A an approximate relationship between $\rho$ and $a_x$ is used. Comparing equations (IV-4) and (II-12), neglecting temporarily the parachute term in equation (II-12), and using equation (II-6), we obtain

$$q = -\frac{m}{C_a S} a_x$$

(IV-16)

The parachute effect can be incorporated approximately by writing

$$q = -\frac{m}{(C_A S + C_D S_D)} a_x$$

(IV-17)

Having related dynamic pressure $q$ to $a_x$, it is a simple matter to relate $\rho$ to $a_x$ since

$$\rho = \frac{2q}{v_r^2}$$

(IV-18)

where $v_r$ is the relative velocity given by equation (II-2). With density $\rho$ available from equations (IV-17) and (IV-18), equation (IV-7) can be integrated to obtain atmospheric pressure $p$. Atmospheric temperature is then directly available from the equation
of state

\[ T = \frac{p}{\rho} M \]  \hspace{2cm} (IV-19)

where \( M \) is the molecular weight and \( R \) is the universal gas constant. Molecular weight \( M \) is computed from the nominal mole fraction profiles of the component gases in the planetary atmosphere.

If a normal accelerometer is not available, the following substitutions must be made in the previous equations:

\[
\begin{align*}
\dot{a}_c &= 0 \\
\delta_2 &= 0
\end{align*}
\]  \hspace{2cm} (IV-20)

If a gyro is not available, we assume

\[
\begin{align*}
\omega_c &= 0 \\
\delta_\omega &= 0
\end{align*}
\]  \hspace{2cm} (IV-21)

and delete equation (IV-11).

A quasi-static dynamic model option is also available in mode A. When quasi-static motion is assumed, equation (IV-4) is deleted and velocity is computed from equation (II-18).

B. MODE A RECURSIVE TRAJECTORY AND ATMOSPHERE RECONSTRUCTION

The equations presented in Section A are used to compute the nominal trajectory and state transition matrices (via numerical differencing) required by the linear recursive estimation process described in Chapter VII. Nominal observations and observation matrices are computed using the equations presented in Chapter II.D and II.E (Part I), with "actual" parameter values replaced by nominal parameter values. Since mode A already employs accelerometer data in its dynamic model, accelerometer data are not treated as a (filtered) measurement in mode A as in mode B. Neither are gyro data treated as a (filtered) measurement in mode A.
Parameters listed in Table II-1 (Chapter II, Part I) and checked in the mode A column can be augmented to the mode A primary state vector as either solve-for or consider parameters. Note that accelerometer and gyro scale factors, biases, and misalignments can also be treated as augmented parameters, and can thus influence the propagation and update of estimates and covariance matrices.

Estimates of certain parameters that do not appear in the mode A parameter augmentation list can nevertheless be obtained as derived estimates. These estimates are referred to as derived (or secondary) estimates since they are derived from estimates generated by the recursive estimation process, and in no way influence this recursive process. Derived estimates are presently available for atmospheric density and temperature. The required equations for both the derived estimates and their variances follow.

The nominal density computed from equations (IV-17) and (IV-18), when combined, yield

\[ \rho = \frac{2m_a a}{v_f (C_A S + C_D S_D)} \quad \text{(IV-22)} \]

To obtain a derived estimate of the density deviation from its nominal value, we should, strictly speaking, take the first variation of equation (IV-22) with respect to the primary state variables and all explicit and implicit augmented parameters on which \( \rho \) depends through equation (IV-22). Denoting all such parameters as \( w \), we would obtain a first variation of equation (IV-22) having the form

\[ \delta \rho = \Gamma_1 (\delta x, \delta \omega)^T \quad \text{(IV-23)} \]

where \( \Gamma_1 \) is the Jacobian matrix

\[ \Gamma_1 = \left[ \frac{\partial \delta \rho}{\partial (x, \omega)} \right] \quad \text{(IV-24)} \]

Then the derived estimated deviation of density would be given by

\[ \delta \rho = \Gamma_1 (\delta x, \delta \omega)^T \quad \text{(IV-25)} \]
where estimates $\delta \hat{x}$ and $\delta \hat{\phi}$ are available from the recursive estimation process (estimates of any elements of $w$ that are treated as considered parameters are, of course, zero). The variance of the derived estimate $\delta \hat{\phi}$ can be found from

$$
\sigma_{\phi}^2 = \Gamma_1 \left[ \begin{array}{cc} P & C_{XW} \\ C_{XW}^T & W \end{array} \right] \Gamma_1^T
$$

where $P$ is the primary state covariance matrix, $W$ the augmented parameter covariance matrix, and $C_{XW}$ represents the correlation between $x$ and $w$.

We could operate on equation (IV-19) in similar fashion to obtain a derived estimate of temperature. Such an estimate would have the form

$$
\delta \hat{T} = \Gamma_2 (\delta \hat{x}, \delta \hat{\phi})^T
$$

where

$$
\Gamma_2 = \left[ \begin{array}{c} \frac{\partial \hat{T}}{\partial \hat{x}} \\ \frac{\partial \hat{T}}{\partial \hat{\phi}} \end{array} \right]
$$

The variance of $\delta \hat{T}$ would be given by

$$
\sigma_{\hat{T}}^2 = \Gamma_2 \left[ \begin{array}{cc} P & C_{XW} \\ C_{XW}^T & W \end{array} \right] \Gamma_2^T
$$

Currently, however, derived estimates $\delta \hat{\phi}$ and $\delta \hat{T}$ are computed from considerably simplified expressions. The first variation of $\phi$ is taken only with respect to $\nu$, and then $\delta \hat{\phi}$ itself is replaced with $\delta \hat{\phi}$ to obtain

$$
\delta \hat{\phi} = \frac{2\rho}{\nu} \delta \hat{\phi}
$$
and

\[ \sigma_p^2 = \frac{4\delta^2}{v_r^2} \sigma_v^2 \]  

(IV-31)

The first variation of \( T \) is taken with respect to \( p, M, \) and \( v_r \) (with \( \delta \) replaced with \( \delta v \)) to obtain

\[ \delta \hat{T} = T \left( \frac{\delta p}{p} + 2 \frac{\delta v}{v_r} + \frac{\delta M}{M} \right) \]  

(IV-32)

and

\[ \sigma_T^2 = \frac{T^2}{p^2} \sigma_p^2 + \frac{4T^2}{v_r^2} \sigma_v^2 + \frac{T^2}{M^2} \sigma_M^2 \]  

(IV-33)

Eventually equations (IV-30) through (IV-33) should be replaced with equations (IV-25), (IV-26), (IV-27), and (IV-29) to obtain improved derived estimates \( \delta \hat{p} \) and \( \delta \hat{T} \) and more realistic variances of \( \sigma_p^2 \) and \( \sigma_T^2 \).

The entire mode A trajectory and atmosphere reconstruction process is based on the method presented in Reference 1.
V. MODE B STATE ESTIMATION AND ATMOSPHERE RECONSTRUCTION

A. MODE B DYNAMIC MODEL

A four-dimensional primary state vector is employed in the mode B reconstruction process. This state vector is defined by

\[ x = (h, v, \gamma, \phi)^T \]  

(V-1)

where

- \( h \) = altitude
- \( v \) = velocity
- \( \gamma \) = flightpath angle
- \( \phi \) = downrange angle.

These variables are defined in Figure II-1.

The fundamental difference between the mode A and mode B reconstruction processes, which was explained fully in Chapter IV.A, consists in the manner in which the nongravitational forces acting on the entry vehicle are treated. Unlike mode A where all information on the aerodynamic forces and planetary atmosphere are imbedded in the accelerometer and gyro data, mode B assumes a mathematical representation for both aerodynamic forces and the planetary atmosphere.

The remainder of this section will treat the mode B dynamic model in more detail. The equations of motion are summarized below:

\[ \dot{h} = v \sin \gamma \]  

(V-2)

\[ \dot{v} = -g \sin \gamma + \frac{A}{m} \cos (\alpha + \varepsilon) + \frac{N}{m} \sin (\alpha + \varepsilon) - \frac{F_d}{m} \cos \varepsilon \]  

(V-3)

\[ \dot{\gamma} = \left( \frac{v - \frac{F_d}{m}}{v} \right) \cos \gamma + \frac{1}{v} \left[ \frac{A}{m} \sin (\alpha + \varepsilon) - \frac{N}{m} \cos (\alpha + \varepsilon) \right. 
\left. - \frac{F_d}{m} \sin \varepsilon \right] \]  

(V-4)
\[
\dot{\phi} = \frac{v}{r} \cos \gamma \tag{V-5}
\]

where axial aerodynamic force \( A \), normal aerodynamic force \( N \), and parachute drag force \( F_d \) are given by

\[
A = -C_A q S \tag{V-6}
\]
\[
N = -C_N q S \tag{V-7}
\]
\[
F_d = C_D q S_D \tag{V-8}
\]

where dynamic pressure \( q = \frac{1}{2} \rho v^2 \). These equations of motion have the same form as the translational equations of motion used by the data generator to compute the "actual" entry trajectory. These latter equations are presented in Chapter II.A. However, mode B uses assumed nominal values of all parameters to integrate these equations, whereas the data generator uses "actual" values. In addition, mode B does not model rotational motion, assumes gyro information is not available, and that the nominal angle of attack \( \alpha \) is zero.

Before the aerodynamic forces given by equations (V-6) through (V-8) can be evaluated, it is necessary to obtain density \( \rho \). Unlike mode A that extracts density from the axial accelerometer measurement \( x_c \), mode B assumes that the planetary atmosphere can be modeled by piece-wise linear temperature and molecular weight profiles. In fact, the mathematical atmosphere model employed by mode B has the same form as the model employed by the data generator to compute the "actual" atmospheric properties. The equations that define such an atmosphere model are presented in Chapter II.B. Of course, mode B uses assumed nominal values of all parameters to define its atmosphere model, whereas the data generator uses "actual" values to define its atmosphere model.

A quasi-static dynamic model option is also available in mode B. When quasi-static motion is assumed, equation (V-3) is deleted and velocity is computed from equation (II-18).
B. MODE B RECURSIVE TRAJECTORY AND ATMOSPHERE RECONSTRUCTION

The equations presented in Section A (and related equations in Chapter II.A and II.B) are used to compute the nominal trajectory and state transition matrices (via numerical differencing) required by the linear recursive estimation process described in Chapter III. Nominal observations and observation matrices are computed using the equations presented in Chapter II.D and II.E, with "actual" parameter values replaced by nominal parameter values. Unlike mode A, mode B treats accelerometer data as measurements to be used directly in the recursive estimation process. Mode B uses the following equations to compute nominal accelerometer measurements and accelerometer observation matrices:

\[ a_x = \left( \frac{A}{m} \cos \delta_1 - \frac{N}{m} \sin \delta_1 \right) C_{sx} + C_{bx} \]  \hspace{1cm} (V-9)

\[ a_z = \left( \frac{A}{m} \sin \delta_2 + \frac{N}{m} \cos \delta_2 \right) C_{sz} + C_{bz} \]  \hspace{1cm} (V-10)

where aerodynamic forces A and N are given by equations (V-6) and (V-7), \( \delta_1 \) and \( \delta_2 \) are axial and normal accelerometer misalignment angles, \( C_{sx} \) and \( C_{sz} \) are scale factors, and \( C_{bx} \) and \( C_{bz} \) are biases.

Parameters listed in Table II-1 (Chapter II, Part II) and checked in the mode B column can be augmented to the mode B primary state vector as either solve-for or consider parameters. Unlike mode A, which can treat only one atmospheric parameter — pressure, in the recursive estimation process, mode B can treat several — surface pressure, temperature profile parameters, and mole fraction profile parameters. If mode B solves for any of these atmospheric parameters, the final estimates can be used to compute pressure and density as a function of altitude. This could be accomplished by rerunning the data generator program with an atmosphere model defined by these new atmospheric parameter estimates.

The mode B trajectory and atmosphere reconstruction process is an adaptation of the method presented in Reference 2.
VI. INDIVIDUAL SUBROUTINE ANALYSES

Individual subroutine analyses are found in Chapter V of the Programmers' Section of the manual.
VII. REFERENCES

PART II

LTR USERS' MANUAL
I. INTRODUCTION

The LTR Users' Manual provides the user of the LTR data generator and reconstruction programs with all the information necessary to input these programs and interpret the output.

Chapter II describes the input of the LTR program. This includes a description of the data deck and tape structure, namelist variable definitions, measurement and event scheduling, and restrictions on the use of the programs. Chapter III describes the output of the LTR data generator and reconstruction programs. Chapter IV discusses actual sample cases run using the LTR programs. These sample cases are presented primarily to demonstrate the operation and versatility of the LTR programs and to assist the user in the input/output procedure for these programs.
II. INPUT DESCRIPTION

A. DATA DECK AND TAPE STRUCTURE

The first card of an LTR data deck must have an integer 1 or 2 in CC 10, followed by another card with Hollerith problem identification information, such as case number, landing date, etc. If the first card has set RUNNO = 1, the data generator namelist section ERAN must be input and the data generator and preprocessor will be executed. If the first card has set RUNNO = 2, the reconstruction program namelist ERAN must be input and:

1) The data generator must have been executed immediately before, or;

2) The data generator must have written logical units 10 and 16 onto magnetic tape during a previous run;

3) The plotting and summary table namelist PLTVAR must be input before the reconstruction and summary modes can be run.

If the reconstruction program is to be executed, a measurement schedule in fixed-field format must follow the PLTVAR section of data. See Section C.3 for a description of the measurement schedule. If the first card has set RUNNO = 3, the program terminates execution.

B. DATA GENERATOR INPUT VARIABLE DEFINITIONS

1. Namelist Variable Definitions

The namelist variables appearing in the data generator namelist ERAN and read from subroutine SETUP1 are defined below according to several categories. Most of these variables will be preset by the program if they do not appear in the namelist input; these preset values are the quantities enclosed by parentheses in the namelist variable definitions. The required input units are specified in the last column.

If ICNTR = N, a print occurs every (N * DT) seconds

RESTRT Logical variable that indicates if subroutine RSTART has punched re-start cards for this input deck (false)

2. Error Definitions

Most of the namelist variables defined in subsection 1 represent nominal values. Actual errors in these variables are specified by inserting the proper C(j) variables in the same namelist. All C(j) variables are defined in Table II-1, along with their required input units. The same table also indicates in which programs the C(j) variables presently have meaning. The use of the C(j) variables in the mode A and mode B reconstruction programs is treated in Section C.2. Room for more than 70 new C(j) variables is still available in the table. All C(j) scale factors are preset to 1., while all C(j) biases are preset to 0.

As an example of the use of the C(j) variables, suppose one wished to define errors in the initial vehicle state, the scale factor in the aerodynamic coefficient $C_A$, and the altimeter bias.

The errors in the initial vehicle state are specified as:
\[
\begin{align*}
C(101) &= 10., \text{ altitude error} \\
C(102) &= .05, \text{ velocity error} \\
C(103) &= 1.2, \text{ flightpath angle error} \\
C(104) &= .5, \text{ downrange angle error} \\
C(140) &= -2., \text{ attitude error} \\
C(106) &= -.03, \text{ angular velocity error}. \\
\end{align*}
\]

If the actual $C_A$ scale factor error were $+1\%$, we would set
\[
C(20) = 1.01,
\]
and if the altimeter bias were 0.75 kilometer, we would set
\[
C(72) = .75.
\]

</table>
Any number of actual errors can be defined in the data generator namelist.

The \( C(j) \) variables can also be used to alter the nominal aerodynamic characteristics of the entry vehicle. Currently all aerodynamic tables are defined in the \texttt{BLOCK DATA} subroutine. One could, of course, remove the existing aerodynamic tables from \texttt{BLOCK DATA} and replace them with the desired aerodynamic tables. This, however, is a cumbersome task that is not really required until the aerodynamic characteristics of a particular vehicle have been finalized. For preliminary studies it is far easier to manipulate certain \( C(j) \) variables in such a way that the existing \texttt{BLOCK DATA} aerodynamic tables approximate the desired aerodynamic tables. For example, the \( C_A \) table can be modified by using the \( C_A \) scale factor \( C(20) \) and the scale factor bias \( C(16) \). Suppose that \( C(20) = 0.9 \) and \( C(16) = -0.1 \) would transform the existing \( C_A \) table to the desired \( C_A \) table. Then if there were no actual \( C_A \) errors, one would simply insert \( C(20) = 0.9 \) and \( C(16) = -0.1 \) in the data generator (and reconstructor) namelist. If, however, actual errors are defined, say a +1\% \( C_A \) scale factor error and a \( C_A \) bias of 0.03, then one would insert

\[
C(20) = 0.9 (1.01) = 0.909
\]

and

\[
C(16) = -0.1 + 0.03 = -0.07
\]

in the data generator namelist. \( C(20) = 0.9 \) and \( C(16) = -0.1 \) would still appear in the reconstructor namelist.

3. Restrictions

A successful data generator run depends on selection of proper values for namelist variables \( DT \), \( QSALT \), \( QSDT \), and \( \Phi DB \). Improper values can lead to integrator instability in the data generator. Since integrator step size \( DT \) is used to integrate both translational and rotational equations of motion, \( DT \) must be chosen small enough to prevent instability or inaccuracies in the integration of the rotational equations, but large enough to avoid exorbitant computational time. High-frequency rotational oscillations, which are likely to occur in the maximum dynamic pressure regime, would require extremely small values of \( DT \). To circumvent this problem, the variable \( \Phi DB \) has been defined. This variable represents the
maximum dynamic pressure permitted for the integration of the complete set of equations of motion. Whenever dynamic pressure exceeds ODB, the motion of the entry vehicle is assumed to be described by the point mass equations of motion so the rotational equations of motion need not be integrated. This same approximation is currently employed whenever the parachute is deployed.

Another type of integrator instability can occur during the terminal velocity regime when $|\dot{\textbf{v}}| \ll 1$. To avoid using very small integration step sizes to prevent this instability, an option for using the quasi-static dynamic model has been developed. When the quasi-static model is used, the $\dot{\textbf{v}}$ equation is not integrated and velocity is computed using equation (II-18). The user sets QSALT to the altitude at which the quasi-static model is to be used, and QSDT to the step-size to be used in the integration of the quasi-static equations of motion. QSDT can be chosen up to 10 times larger than DT, depending, of course, on DT and the particular entry problem. The user should be certain that QSALT is chosen so the quasi-static assumptions are satisfied over the entire altitude range from 0. to QSALT. The quasi-static assumptions are (1) $|\dot{\textbf{v}}| \ll 1$, and (2) $\gamma \approx -90^\circ$. Since the vehicle motion normally violates the quasi-static assumptions for a few minutes after parachute release, it is recommended that the restriction QSALT < HR < HD be applied.

C. RECONSTRUCTION PROGRAM INPUT VARIABLE DEFINITIONS

1. Namelist Variable Definitions

The namelist variables appearing in the reconstruction program namelist ERAN and read from subroutine SETUP are defined in the following subsections according to several categories. Many of these variables that are identical to those appearing in the data generator namelist are not defined. Refer to Section B.1 for their definitions. As in Section B.1, preset values of namelist variables are enclosed in parentheses, and required input units are specified in the last column.
### a. Trajectory Variables

b. Planet and Atmosphere Variables - All planet and atmosphere variables defined in Section B.1 for the data generator namelist are also defined for the reconstruction program namelist, with the exception that variables NTPTS, ATM08S(1), and ATM08S(18) through ATM08S(33) are not used when the reconstruction program is run in mode A. The following variable, which is not defined for the data generator namelist, appears in the reconstruction program namelist:
Table of specific heat ratios as a function of molecular weight.

GAMTBL (1) = n, number of molecular weight breakpoints; GAMTBL (2) through
GAMTBL (1 + 2n) define the corresponding sequence of specific heat ratios.
Up to four breakpoints can be defined (2., 0., 1000., 1.4, 1.4)

c. Entry Vehicle Variables - All entry vehicle variables defined in Section B.1 for the data generator namelist are also defined for the reconstruction program namelist. The following variable, which is not defined for the data generator namelist, appears in the reconstruction program namelist:

\[ BKTBL \]

Table of \( k \) (see equation (II-59)) as a function of Mach number; required only if angle of attack measurements are scheduled. BKTBL has same structure as GAMTBL; up to nine breakpoints can be defined (2., 0., 1000., -0.922, -0.922)

\[ d. \text{ Measurement Variables} - \text{ Most measurement variables defined in Section B.1 for the data generator namelist are also defined for the reconstruction program namelist. Those not defined for the reconstruction program namelist are XSTE', ZSTEP, TSTEP, VXQA, VZQA, THTQA, and NOFRAC. The following variables, which are not defined for the data generator namelist, appear in the reconstruction program namelist:} \]

\[ \text{CDEL} \]

Logical variable that indicates if misalignment errors are to be treated (true)
\[
= \text{true, misalignment errors will be treated}
\]
\[
= \text{false, misalignment errors will not be treated}
\]

\[ \text{NACCEL} \]

Logical variable that indicates if the normal accelerometer is to be deleted (false)
\[
= \text{true, normal accelerometer deleted}
\]
\[
= \text{false, normal accelerometer not deleted}
\]
NGYRØ

Logical variable that indicates if gyro is to be deleted; applies only
to mode A (false)
= true, gyro deleted
false, gyro not deleted

e. Parameter Augmentation Variables - Parameters appearing in
the C(j) table of Section B.2 can be augmented to the entry vehicle
state vector as either solve-for, dynamic-consider, measurement-
consider, or dynamic/measurement-consider parameters. This is ac-
complished by inserting the index j associated with parameter C(j)
in one of the parameter lists defined below. Although the order
of indices in a given list is arbitrary, once the order has been
defined the related covariance matrix partitions (to be defined
subsequently) must correspond to this order.

NQ

Number of solve-for parameters;
must not exceed 10 (0)

NU

Number of dynamic-consider parameters;
must not exceed 20 (0)

NV

Number of measurement-consider param-
eters; must not exceed 20 (0)

NW

Number of dynamic/measurement-
consider parameters; must not exceed
10 (0)

LISTQ

List of augmented solve-for param-
eters

LISTU

List of augmented dynamic-consider
parameters

LISTV

List of augmented measurement-
consider parameters

LISTW

List of augmented dynamic/measurement-
consider parameters
<table>
<thead>

</tr>
</tbody>
</table>
CQU Solve-for parameter/dynamic-consider parameter covariance matrix. Dimension NQ x NU

CQV Solve-for parameter/measurement-consider parameter covariance matrix. Dimension NQ x NV

CQW Solve-for parameter/dynamic-measurement-consider parameter covariance matrix. Dimension NQ x NW

SDMW T Molecular weight standard deviation used in mode A derived estimation process (this variable will be deleted when the option for augmenting mole fraction parameters in mode A has been developed)

### g. Measurement Noise Statistics

**REDRR2** Logical variable used to compute altimeter noise (false)

- true, use user-specified measurement noise
- false, compute measurement noise in subroutine OBSM

**RR** Three-dimensional measurement noise variance array: 1st index I, indicates measurement type; 2nd index J, measurement component; 3rd index K, regime. Only the accelerometer measurement currently requires more than one component (axial and normal). Only the pressure measurement currently depends on the (Mach number) regime. RR values represent variances whose units are assumed to be internal units. The correspondence between index I and measurement type is indicated:

- I = 1, accelerometer (mode B only)
- 2, gyro (nonfunctional currently)
- 3, altimeter
- 4, stagnation pressure
- 5, stagnation temperature
6, angle of attack (mode A only)
11, doppler, station 1
12, range, station 1
13, doppler, station 2
14, range, station 2
15, doppler, station 3
16, range, station 3

SD
Two-dimensional actual measurement noise standard deviation array:
1st index I, indicates measurement type; 2nd index J, measurement component. Only the accelerometer measurement currently requires more than one component (axial and normal). SD values represent standard deviations whose units are assumed to be internal units. The correspondence between index I and measurement type is identical to that for the preceding RR array.

h. Other Variables

LTR2
Logical mode A variable (true)
= true, mode A
false, not mode A

LTR1
Logical mode B variable (false)
= true, mode B
false, not mode B

ICNTR
Measurement print code. Print will occur after every ICNTR measurements or groups of simultaneous measurements.

MCNTR
Counter on the TMN and MCØDE event arrays. Whenever MCNTR reaches 250, another batch of 250 events is read from tape 20 into these arrays and MCNTR is reset to 1. Should be input only if restarting.

RESTRT
See Section B.1

NMEAS
Counter on the number of measurements taken up to the current time. Non-functional currently.
2. Use of C(j) Table in Reconstruction Program

Just as the C(j) variables defined in Table II-1 can be used to specify actual errors to be incorporated in nominal values of the variables in the data generator, so can the C(j) variables be used in the reconstruction program to change previously defined nominal values to new nominal values. Normally this option is not employed, however, since nominal scale factors are usually set to 1 and nominal biases are usually set to zero, if the C(j) associated with the aerodynamic coefficients are selected in the data generator to alter the nominal aerodynamic tables appearing in BLOCK DATA, the same C(j) variables must be used in the reconstruction program to change the existing aerodynamic tables in BLOCK DATA to the desired nominal values (see Section B.2 for an example).

The primary use of the C(j) table in the reconstruction program lies in parameter augmentation. The final two columns in Table II-1 indicate which parameters can be augmented to the state vector in each of the two reconstruction modes. Augmentation is accomplished by inserting the index j of the appropriate parameter C(j) in one of the four parameter lists. For example, if the user wished to treat the CA scale factor as a solve-for parameter, the CN scale factor and the vehicle mass bias as dynamic-consider parameters, doppler biases for all three tracking stations as measurement-consider parameters, and the axial accelerometer scale factor as a dynamic/measurement-consider parameter, the following should appear in the namelist:

\[
\begin{align*}
\text{LISTQ} & = 20, & \text{NQ} & = 1 \\
\text{LISTU} & = 21, 30, & \text{NU} & = 2 \\
\text{LISTV} & = 67, 68, 69, & \text{NV} & = 3 \\
\text{LISTW} & = 51, & \text{NW} & = 1 .
\end{align*}
\]

Whether a consider parameter is to be treated as a dynamic-, measurement-, or dynamic/measurement-consider parameter is a function of the measurement types scheduled and the reconstruction mode. If in doubt, it is always safe to treat the questionable parameter as a dynamic/measurement-consider parameter and insert the associated index j in LISTW. If NACCEL is true (i.e., when the normal accelerometer is deleted), C(53) and C(54) cannot be treated as solve-for parameters although it is still meaningful to treat them as consider parameters. If NGYRØ is true (i.e., when the gyro is deleted in mode A), C(124), C(125), and C(140) can only be treated as consider parameters.
3. Measurement/Event Types and Schedules

Measurements and events are input with fixed field formats immediately after the PLTVAR namelist section. Each card contains the following formats and information:

```
F10.3  F10.3  F10.3  I10
START  TIMEND  TIMDIF  CODE
```

where

- **START** is the time (in seconds) to start a measurement or event,
- **TIMEND** is the time (in seconds) to end a measurement or event,
- **TIMDIF** is the time (in seconds) between measurements or events,
- **CODE** is the type of measurement or event to be processed, and can take on any of the following values,
  - 1 accelerometer measurement
  - 2 gyro measurement (not functional)
  - 3 altimeter measurement
  - 4 pressure measurement
  - 5 temperature measurement
  - 6 angle of attack measurement
  - 7 to 10 not used
  - 11 prediction event (not functional)
  - 12 quasi-filtering event
  - 13 print increment set event
  - 14 set internally
  - 15 set internally
= 16 set internally
= 17 print without measurement
= 18 set internally
= 19, 20 not used
= 21 range-rate measurement from station 1
= 22 range measurement from station 1
= 23 range-rate measurement from station 2
= 24 range measurement from station 2
= 25 range-rate measurement from station 3
= 26 range measurement from station 3.

The last card of the measurement schedule must have a START value of 100000, to signify the end of measurement input.
4. Restrictions

Restrictions on the use of the quasi-static dynamic model and the selection of integration step sizes and measurement schedules in the LTR reconstruction program are discussed in this section.

The use of the quasi-static dynamic model in the reconstruction program is subject to the same restrictions that apply in the data generator program. In fact, the values selected for DT and QSDT in the data generator must be small enough that the step sizes of 2*DT and 2*QSDT do not lead to integrator instabilities in the reconstruction program because the step sizes used in the reconstruction program must be twice the size of the corresponding step sizes used in the data generator.

The quasi-static dynamic model should be used with care when a wind model has been defined since the quasi-static assumptions are not always satisfied when the entry vehicle encounters winds of sufficient magnitude. This restriction applies to the data generator as well as to the two modes of the reconstruction program.

Since the LTR program performs trajectory reconstruction utilizing data already generated (by the data generator), the user cannot arbitrarily select integration step sizes. Since the present integrator is a two-step Runge-Kutta package, the basic step size in the reconstructor must be an even multiple of the basic step size used in the data generator. In addition, the use of the quasi-static dynamic model introduces more problems:

1) The switch to the quasi-static model in the data generator must occur at a time that corresponds to an even multiple of the basic integration step size so the two-step Runge-Kutta integrator can be used in the reconstructor;

2) The data generator quasi-static integration step size QSDT must be a multiple of the basic data generator step size DT to insure proper measurement processing in the reconstructor;

3) The switch to the quasi-static model in the data generator must occur at a time that corresponds to an even multiple of the quasi-static model step size to be used by the data generator to prevent improper measurement sequencing in the reconstructor.
The user must also sequence measurements in the reconstructor with care. If, for example, the user wished to process altimeter measurements from 5 seconds to 100 seconds every 1 second, the reconstructor could not integrate with a step size of 0.75 seconds, either before or after a change to the quasi-static model. The reconstructor step size of 0.75 seconds would require a data generator step size of 0.375 seconds for the same time period and therefore no altimeter data would be available to the reconstructor at 5,000 seconds. The user could choose a reconstructor step size for the quasi-static model of 1.0 second and a basic step size of 0.1 second, thereby requiring step sizes in the data generator of 0.5 second and 0.05 second for the quasi-static and basic models, respectively. This would ensure that all necessary data had been calculated in the data generator. The general rule, then, is that the measurement times must be at even multiples of the data generator quasi-static model step size.

An additional user problem concerns state transition matrices. The assumption of linearity is not valid for all integration step sizes. The user, for example, could not expect linear matrices over an interval of 60 seconds but can assume linearity over a 1-second interval. Given the integration step sizes used by the data generator, the measurement sequencing subroutine SCHED will allow an interval between measurements or events of no more than 10 times the step size used at a given time point. The user must therefore determine what step sizes can be used in both the basic and quasi-static dynamic models that will not violate linear assumptions.

The user restrictions on integration step sizes are summarized as:

1) The integration step size in the reconstructor must be an even multiple of the step size used in the data generator, regardless of the dynamic model chosen. The program currently sets the step sizes internally in the reconstructor to twice the step sizes used in the data generator;

2) In the data generator the quasi-static step size QSDT must be a multiple of the basic integration step size DT;

3) Measurement and/or event times (see subroutine SCHED) must be at even multiples of the data generator quasi-static model integration step size QSDT;

4) Integration step sizes must be chosen so the linearity assumption used in the computation of state transition matrices in the reconstructor is not violated.
If the quasi-static dynamic model is not used, the restrictions are fewer:

1) Reconstructor step sizes are still even multiples of data generator step sizes;

2) Measurement/event times must occur at even multiples of the data generator integration step size DT;

3) State transition matrix linearity must still be considered when choosing step sizes.
III. OUTPUT DESCRIPTION

A. DATA GENERATOR OUTPUT DESCRIPTION

The initial data generator output consists of the following:

1) Namelist ERAN;

2) Initial actual state vector -- altitude, velocity, flightpath angle, downrange angle, attitude angle, angular velocity, unquantized axial VRU output, unquantized normal VRU output, unquantized ARU output, ambient pressure;

3) Planet and vehicle constants;

4) Initial and final trajectory times in seconds;

5) Actual planet atmosphere model.

At each trajectory printout time, the following output is printed:

1) Trajectory time and integration step size in seconds -- entry phase;

2) Actual state vector;

3) Actual state vector derivatives;

4) Actual trajectory, atmosphere, and aerodynamic parameters, i.e.,
   a) Vehicle relative velocity,
   b) Horizontal wind velocity,
   c) Dynamic pressure,
   d) Molecular weight of atmosphere,
   e) Ambient temperature of atmosphere,
f) Ambient pressure of atmosphere,
g) Density of atmosphere,
h) Angle of attack,
i) Aerodynamic coefficient, $C_A$,
j) Aerodynamic coefficient, $C_N$,
k) Mach number,
l) Axial aerodynamic force (does not include parachute effect),
m) Normal aerodynamic force (does not include parachute effect),
n) Center of pressure location along x body axis,
o) Aerodynamic damping moment acceleration (does not include parachute effect),
p) Angle between inertial and relative velocity vectors,
q) Aerodynamic coefficient, $C_{M_q}$,
r) Aerodynamic damping moment (does not include parachute effect),
s) Local acceleration of gravity,
t) Total axial aerodynamic acceleration,
u) Total normal aerodynamic acceleration;

5) Actual measurements,
a) Axial accelerometer (km/s$^2$),
b) Normal accelerometer (km/s$^2$),
c) Stagnation pressure (kg/km$^2$s$^2$),
d) Rate gyro (rad/s),
e) Radar altimeter (km),
f) Stagnation temperature (°K),
g) Range from three earth-based tracking stations,
h) Range-rate from three earth-based tracking stations,
i) Refraction effects on range and range-rate measurements (not functional currently);

6) Auxiliary trajectory information (computed in subroutine AUXIL),
   a) Communication angle,
   b) Angle between entry plane and plane of the sky,
   c) Latitude/longitude ground trace relative to the planetocentric equatorial, subsolar orbital plane, and planetocentric geographic coordinate systems.

B. RECONSTRUCTION PROGRAM OUTPUT DESCRIPTION

The initial reconstruction program output consists of the following:

1) Namelist ERAN;
2) Array of measurement noise variances for all measurement types;
3) Initial nominal vehicle state vector -- altitude, velocity, flightpath angle, downrange angle;
4) Planet and vehicle constants;
5) Initial and final trajectory times in seconds;
6) Number and list of solve-for parameters (appear only if NQ ≠ 0);
7) Number and list of dynamic-consider parameters (appear only if NU ≠ 0);
8) Number and list of measurement-consider parameters (appear only if NV ≠ 0);
9) Number and list of dynamic/measurement-consider parameters (appear only if NW ≠ 0);

10) Primary state covariance matrix -- primary state refers to the unaugmented state used in the recursive estimation process;

11) Solve-for parameter covariance matrix (appears only if NQ ≠ 0);

12) Vector of dynamic-consider parameter variances (appears only if NV ≠ 0);

13) Vector of measurement-consider parameter variances (appears only if NV ≠ 0);

14) Vector of dynamic/measurement-consider parameter variances (appears only if NW ≠ 0);

15) Array of nominal C.'s;

16) Initial original nominal, most recent nominal, and actual vehicle state vectors;

17) Initial most recent nominal and actual atmosphere state vectors -- ambient pressure, density, ambient temperature molecular weight (appear only in mode A);

18) Initial actual and reconstructed VRU and ARU data -- attitude angle, angular velocity, axial nongravitational acceleration, normal nongravitational acceleration, normal nongravitational acceleration (appear only in mode A);

19) Entry parameters based on most recent nominal trajectory;

20) Initial estimated and actual vehicle state deviations from most recent nominal and initial vehicle state estimation errors;

21) Initial estimated and actual atmosphere state deviations from most recent nominal and initial atmosphere state estimation errors (appear only in mode A);
22) Initial estimated and actual solve-for parameter deviations from most recent nominal and initial solve-for parameter estimation errors;

23) Initial estimated solve-for parameter deviations from original nominal;

24) Additional entry parameters based on most recent nominal trajectory;

25) Initial primary state, solve-for parameter, and consider parameter correlation matrix partitions. Standard deviations appear along diagonals of the symmetric partitions and correlation coefficients comprise the remaining elements;

26) Measurement and event data cards;

27) Measurement schedule;

28) Event schedule;

29) Number of measurements to be processed for each measurement type;

30) Number of events to be executed for each event type.

When measurement information is to be printed, the output summarized below will be available. Items 1 through 20 also appear for a type 17 or when a "print without measurement" event occurs:

1) Measurement type and trajectory time;

2) Message "quasi-static model" if quasi-static dynamic model is being used at current trajectory time;

3) Original nominal, most recent nominal, and actual vehicle state vectors;

4) Most recent nominal and actual atmosphere state vectors (appear only in mode A);

5) Actual and reconstructed VRU and ARU data (appear only in mode A);

6) Entry parameters based on most recent nominal trajectory;
7) Estimated and actual vehicle state deviations from most recent nominal and vehicle state estimation errors immediately before processing the measurement;

8) Estimated and actual atmosphere state deviations from most recent nominal and atmosphere state estimation errors immediately before processing the measurement (appear only in mode A);

9) Estimated and actual solve-for parameter deviations from most recent nominal and solve-for parameter estimation errors immediately before processing the measurement;

10) Estimated solve-for parameter deviations from original nominal immediately before processing the measurement;

11) Additional entry parameters based on most recent nominal trajectory;

12) State transition matrix for primary state vector;

13) Remaining state transition matrix partitions and lists of all solve-for and consider parameters. The order of elements in each parameter list corresponds to the order of columns in each state transition matrix partition;

14) Diagonal of dynamic noise covariance matrix;

15) Primary state, solve-for parameter, and consider parameter correlation matrix partitions immediately before processing the measurement. Standard deviations appear along diagonals of the symmetric partitions and correlation coefficients comprise the remaining elements;

16) Measurement noise covariance matrix;

17) Primary state and solve-for parameter gain matrices;

18) Density and temperature estimation error standard deviations immediately before processing the measurement (appear only in mode A and then only if MACHNO is true. MACHNO is an internally set logical that is set true when sufficient aerodynamic decelerations have been attained to make density and temperature estimation feasible);
19) Measurement residual covariance matrix;
20) Nominal measurement;
21) Observation matrix partitions;
22) Estimated and actual measurement deviations from nominal and actual measurement residuals;
23) Estimated and actual vehicle state deviations from most recent nominal and vehicle state estimation errors immediately after processing the measurement;
24) Estimated and actual atmosphere state deviations from most recent nominal and atmosphere state estimation errors immediately after processing the measurement (appear only in mode A);
25) Estimated and actual solve-for parameter deviations from most recent nominal and solve-for parameter estimation errors immediately after processing the measurement;
26) Primary state, solve-for parameters, and consider parameter correlation matrix partitions immediately after processing the measurement. Standard deviations appear along diagonals of the symmetric partitions and correlation coefficients comprise the remaining elements;
27) Measurement noise covariance matrix (redundant; identical to item 17);
28) Primary state and solve-for parameter gain matrices (redundant; identical to item 18);
29) Density and temperature estimation error standard deviations immediately after processing the measurement (appear only in mode A and then only if MACHNO is true);
30) Actual measurement noise;
31) Actual measurement noise standard deviations.
Quasi event output consists of the following:

1) Original nominal, most recent nominal, and actual vehicle state vectors immediately after quasi event has been executed;

2) Most recent nominal and actual atmosphere state vectors immediately after quasi event has been executed (appear only in mode A);

3) Estimated and actual vehicle state deviations from most recent nominal and vehicle state estimation errors;

4) Estimated and actual ambient pressure deviation from most recent nominal and ambient pressure estimation error (appear only in mode A);

5) Most recent nominal solve-for-parameters immediately after quasi event has been executed;

6) Estimated and actual solve-for parameter deviations from most recent nominal and solve-for parameter estimation errors immediately after quasi event has been executed;

7) Estimated solve-for parameter deviations from original nominal.
IV. SAMPLE CASES

A. LTR MODE A SAMPLE CASE

The sample case presented here demonstrates the application of the mode A reconstruction process to a Venusian entry problem, and is primarily presented to aid the user in defining the required input data and interpreting the resulting output. Before the reconstruction program can be run, the "actual" trajectory, atmosphere, and measurements used in the reconstruction program must be available from a previous data generator run. For this reason, the input and output for the associated data generator run is presented first.

1. Data Generator

a. Input Discussion - The input data for the data generator consist of the following namelist ERAN cards:

\[
\begin{align*}
XN & = 248.9, \quad 11.08, \quad -38.8, \quad 0, \quad -38.8, \quad 0, \\
DT & = .19, \quad TF = 500, \\
IYR & = 1977, \quad LM0 = 5, \quad IDAY = 16, \quad IHR = 23, \quad IMIN = 54, \\
SECSI & = 41, \\
ICOOR & = 3, \quad PHIR = 0, \quad ECLINC = 140.61, \quad ECLONG = 68.2, \\
\Omega B & = 15. E+5, \\
G0 & = 8.867 E-3, \quad RM = 6050, \quad \Omega MEG = 2.997 E-7, \quad MU = 3.2486 E5, \\
ATMOS(1) & = 1.104 E10, \quad ATMOS(18) = 0, \quad 60, \quad 115, \quad 125, \quad 137, \quad 175, \quad 2 E0, \quad \\
ATMOS(26) & = 738.0, \quad 260.0, \quad 170.0, \quad 2 E210.0, \quad 710.0, \quad \\
NTPS & = 6, \quad NMP = 4, \\
WDTBL & = 2, \quad 0, \quad 10, \quad 0, \quad 0, \\
TERHT & = .FALSE., \quad AGAM = 1.4, \\
VMAS & = 174, \quad 122, \quad 100, \\
VSA & = 1.474 E-6, \quad .292 E-6, \quad .292 E-6, \\
VRIA & = 1.37 E-3, \quad .61 E-3, \quad .61 E-3, \\
VR & = 1.7 E-5, \quad .5 E-5, \quad .5 E-5, \\
XG & = 0, \quad XM = 0, \quad ZG = 0, \quad ZMM = 0, \\
XSTEP & = 1.5 E-5, \quad ZSTEP = 1.5 E-5, \quad TSTEP = .004, \\
IGNTR & = 20, \\
RESTR & = .FALSE.,
\end{align*}
\]
C(101)=-10., .025, .4, .5, C(140)=1.5,  
C(16)=-.1, C(20)=1.034, 2.1, 4., .23,  
C(51)=1.00066, C(53)=1.00066,  
C(64)=.25, C(67)=1.E-6, C(71)=1.001, C(81)=1.01,  
C(83)=1.01, C(91)=.99, C(96)=.97,  
C(111)=1.2E-3, -1.3E-7, 5.E-7,  
C(152)=6., C(156)=.03, -.03, C(161)=.01, -.01,  

The first group of cards defines the nominal entry conditions and certain integration variables. The initial nominal entry state is specified by the XN vector and the variables ICOOR through ECLONG. These latter variables define the orientation of the entry plane, while XN defines the vehicle state in that plane. An integration step size of .1 second will be used in generation of the "actual" trajectory. Point-mass motion will be assumed whenever dynamic pressure q exceeds 15 millibars, as is indicated by ODB. This is necessary to maintain integrator stability through the max q regime.

Planetary physical characteristics are specified by the next group of cards, including the planetary atmosphere model. This planetary atmosphere model is defined by the surface pressure ATMOS(1), a sequence of six temperature breakpoints defined by the ATMOS(18) vector, and the six corresponding temperatures defined by the ATMOS(26) vector. Mole fraction profiles are also required to complete definition of the atmosphere model. Since the desired mole fraction profiles are preset by the program, they need not appear in the above namelist.

The third group of cards specifies vehicle and certain instrumentation characteristics. The mass (VMASS), reference area (VSA), etc are given as three vectors, which correspond to the three available phases of entry in LTR--aeroshell, parachute, and terminal (with parachute released). However, since variables HD and HR do not appear in the above namelist, the entire sample case deals with only the aeroshell phase.

The final group of cards defines the "actual" dynamic and measurement errors and other differences between the "actual" and nominal models. Elements C(101) through C(104) define initial errors in the vehicle translational state and C(140) defines an initial vehicle attitude error. Use of the aerodynamic coefficient C(J)s to alter preset nominal aerodynamic coefficient tables, as well as to define "actual" errors in the vehicle aerodynamic coefficients, has been explained in Chapter II of this section. In this particular sample case C(16), C(22), and C(23) are used only to alter the
preset nominal coefficient tables; \( C(20) \) is used only to specify an "actual" error; while \( C(21) \) performs both functions. To convert the preset \( C_N \) table to the desired table requires that the preset table be multiplied by a factor of 2. We also desire to introduce a 5% "actual" \( C_N \) table factor error into this table. Thus we set
\[
C(21) = 2 \times (1.05) = 2.1
\]
The remaining \( C(J) \) elements are used to specify "actual" errors in certain sensors and in the nominal mole fraction profiles.

b. Output Discussion - Selected pages from the output of the data generator portion of this sample case appear in section D, where it is referred to as case A-1. The selected pages show the "actual" state and state derivatives, various vehicle and atmosphere parameters corresponding to this state, and "actual" values of all measurement types available in the LTR program at selected trajectory times. A trajectory time of 24. seconds corresponds to \( m \times q \). Since dynamic pressure obviously exceeds \( \Phi DB \), the point-mass dynamic model was used to generate the information shown at 24. seconds. This also explains why \( \Phi LPHA \) and the normal acceleration are zero at this point. The output for this sample case was generated at the CDC 6400/6500 computer at the Martin Marietta Corporation.

2. Reconstruction Program

a. Input Discussion - The input data for the reconstruction program consist of a namelist and a measurement/event schedule. The namelist, which is also entitled ERAN, consists of the following cards:

\[
\begin{align*}
XN &= 248.0, \quad 11.08, \quad -38.8, \quad 0.0, \quad 5.4E-9, \\
X\phi &= 248.8, \quad 11.08, \quad -38.8, \quad 0.0, \quad 5.4E-9, \\
\text{THETI} &= -38.8, \quad \text{TP}=500, \\
\text{IYR} &= 1977, \quad \text{IDACE}=5, \quad \text{IDAY}=16, \quad \text{IHR}=23, \quad \text{IMIN}=54, \quad \text{SECSI}=41, \\
\text{ICOOR} &= 3, \quad \text{PHIR}=0, \quad \text{ECLINC}=140.61, \quad \text{ECLONG}=68.2, \\
G\phi &= 8.867E-3, \quad \text{RM}=6050, \quad \text{MEG}=2.997E-7, \quad \text{MU}=3.2486E-5, \\
\text{WDTBL} &= 2, \quad 0.0, \quad 10.0, \quad 0.0, \quad \text{TERHT}=.\text{FALSE},. \\
\text{VMASS} &= 174.0, \quad 122.0, \quad 100.0, \quad \\
\text{VSA} &= 1.474E-6, \quad .292E-6, \quad .292E-6, \quad \\
\text{VDIA} &= 1.37E-3, \quad .61E-3, \quad .61E-3,
\end{align*}
\]
VRI=1.76E-5, .5E-5, .5E-5, 
XG=0., XM=0., ZG=0., ZMM=0., 
ICNTR=1, RESTRT=.FALSE., 
NGYRØ=.TRUE., LTR2=.TRUE., 

C(16)=-.13, C(21)=2.4, .23,
P=200., 003, 003, 0.9, 0.91, 0.4, 2.5E-41, 0.3, 00,

NW=5, LISTW=140, 20, 96, 51, 53, 
SMT=3., 
REDR2=.TRUE., 
RR(11,1,1)=1.3E+10, .001, 
SD(11,1)=1.3E-12, .001, 
RR(3,1)=1.22E-3, 0., 0., 
SD(3,1)=.05, 1.3E-5, .5, 

The first group of cards defines the initial nominal primary state used in the mode A reconstruction process. The first four elements of the XN vector define the vehicle translational state and are identical to the first four elements of the XN vector appearing in the data generator namelist. The fifth element of the primary state and the fifth element of XN is the ambient pressure. The variable THETI defines the initial nominal vehicle attitude.

Planetary physical characteristics are specified by the next group of cards. Note that an atmosphere model does not appear since the mode A reconstruction process does not employ such a model.

The third group of cards is essentially the same as the third group appearing in the data generator namelist except for the addition of NGYRØ and LTR2. Setting NGYRØ true indicates that gyro measurements will not be processed. Setting LTR2 true indicates that the mode A reconstruction process will be used.
The four C(J) elements appear next and are used solely to alter the preset nominal aerodynamic coefficient tables.

The remaining cards define the statistics of the error sources acknowledged in the design of the filter. The F-array is the initial covariance matrix for the primary state XN. The filter considers nine measurement-consider parameters and five dynamic/measurement-consider parameters. These parameters are defined in LISTV and LISTW, respectively, and their variances are given in the DV and DW vectors, respectively. The assumed molecular weight standard deviation is given by SDMWT. Measurement noise variances assumed by the filter are defined by the RR variables while the "actual" measurement noise standard deviations are defined by the SD variables.

The measurement/event schedule cards used in this sample case are listed.

</table>

Not all these measurements and events will be processed in the sample case since TF was set to 500. in the previous namelist.

b. Output Discussion - Selected pages from the reconstruction program portion of this sample case appear in section D, where it is referred to as case A-2. The measurement output for a range measurement at 10. seconds and a doppler measurement at 121. seconds is shown. The range measurement at 10. seconds reduced altitude errors from 8.718 to 8.171 kilometers, flightpath angle errors from -.943 to -.515°, and downrange angle errors from -.38 to .090°. The velocity error increases slightly. Reconstructed ARU data are zero, and will remain zero since NGYRØ was set true in the name-list. Reconstructed VRU data are zero since sufficient axial aerodynamic deceleration has not yet developed. According to the data generator output at 10. seconds, the axial aerodynamic deceleration is only on the order of 10^-7. However, a reconstructed axial
acceleration appears in the doppler measurement at 121. seconds. The reconstructed normal acceleration is still zero, and will remain so since the integrated normal acceleration never exceed the normal accelerometer quantum level ZSTEP. The output for this sample case was generated on the CDC 6400/6500 computer at the Martin Marietta Corporation.

B. LTR MODE B SAMPLE CASE

The sample case presented here demonstrates the application of the mode B reconstruction process to a Venusian entry problem, and is presented primarily to aid the user in defining required input data and interpreting the resulting output. As in Section A, the input and output of the associated data generator run is presented first.

1. Data Generator

a. Input Discussion - The input data for the data generator consists of the following namelist ERAN cards.

XN=248., 11.06, -74., 0., -65., 0.,
DT=1., QSALT=55., TF=500.,
IYR=1977, IMO=5, IDAY=16, IHR=23, IMIN=54, SECSI=41.,
ICOOR=3, PHIR=14.624, ECLONG=137.82,
ECLINC=89.36,
ΩDE=15. E+5,
GΘ=8.867E-3, RM=6050., MEG=2.997E-7, MU=3.2486E+5,
ATMOS(1)=1.104E+10,
ATMOS(18)=0., 60., 115., 125., 137., 175., 2*0.,
ATMOS(26)=738., 260., 170., 2*210., 710.,
NTPTS=6, NMPTS=4,
AGAM=1.4,
WDTBL=2., 0., 10., 0., 0.,
TERHT=.FALSE.,
VMASS=22.6, VDIA=.448E-3, VSA=.158E-6,
VR=1.085E-6,
XG=0., XM=0., ZG=0., ZMM=0.,
XSTEP=1.5E-5, ZSTEP=1.5E-5, TSTEP=.004,
ICNTR=20,
RESTRT=.FALSE.,
Since these data are very similar to the data presented for the mode A sample case (data generator) in Section A, only the differences will be explained here.

The first difference concerns the appearance of the variables QSDT and QSALT in the above namelist. These variables indicate that the quasi-static dynamic model will be used when the vehicle descends to an altitude of 55 kilometers. The integration step size will be increased from .1 second to .5 second. The second difference concerns the physical characteristics of the entry vehicle. The mode A sample case involves an entry vehicle representative of the Planetary Explorer main probe, while the mode B sample case involves an entry vehicle representative of the Planetary Explorer miniprobe. This accounts for the different values used for the variables VMASS through VRI in each case.

b. Output Discussion - Selected pages from the output of the data generator portion of this sample case appear in section D, where it is referred to as case B-1. The data at the trajectory time of 40 seconds were generated with the standard dynamic model, although the point-mass assumption was employed since the dynamic pressure exceeded the input value of ODB. This is still true at the trajectory time of 228 seconds. In addition, the data at this latter time were generated using the quasi-static dynamic model since the vehicle altitude is less than the input value of QSALT. The fact that the derivative of the velocity is zero is a consequence of using the quasi-static dynamic model. The output for this sample case was generated in the CDC 6400/6500 computer at the Martin Marietta Corporation.

2. Reconstruction Program

a. Input Discussion - The input data for the reconstruction program consist of a namelist and a measurement/event schedule. The namelist, which is also entitled ERAN, consists of the following cards.

\[ XN=248., 11.06, -74., 0., X\theta=248., 11.06, -74., 0. \]
IYR=1977, ID=5, IDAY=16, IHR=23, IMIN=54, SECSI=41,
ICOR=3, FHR=-14.624, ECLONG=137.82, ECLINC=89.36,
TF=500,,
G=8.867E-3, RM=6050., OMEG=2.997E-7,
MU=3.2486E+5,
ATMOS(1)=1.104E+10,
ATMOS(18)=0., 60., 115., 125., 137., 175., 2*0.,
ATMOS(26)=738., 260., 170., 2*210., 710.,
NTPTS=6, NMPTS=4,
AGAM=1.4,
TERM=.FALSE.,
WDTHI=2., 0., 10., 0., 0.,
VMASS=22.6, VDIA=.448E-3, VSA=.158E-6,
VR=1.085E-6,
XG=0., XM=0., ZG=0., ZMM=0.,
IGNTR=1,
RESTR=.FALSE.,
NACCEL=.TRUE., NGYR=TRUE.,
LIRI=.TRUE.,
C(16)=.1, C(21)=2., 4., .23,
P=200., 0., 0., 0.,
0., 2.5E-4, 0., 0.,
0., 0., 1.22E-3, 0.,
0., 0., 0., 3.234E-4,
NQ=4, LISTQ=3, 5, 7, 9,
Q=25., 0., 0., 0.,
0., 10., 0., 0.,
0., 0., 1.5, 0.,
0., 0., 0., 40.,
NU=2, LISTU=20, 140,
DU=2.78E-4, .25E-2,
NV=7, LISTV=67, 111, 112, 113, 81, 83, 91,
DV=.12E-8, .15E-5, .19E-13, .33E-13, 1.E-4, 1.E-4, 1.E-4,
NW=8, LISTW=4, 6, 8, 152, 153, 156, 161, 1,
DW=4., 8., 14., 25., 50., 6.E-4, 1.E-4, 2.E+9,
SDMWT=3.
RR(4,1,1)=1.E8, RR(4,1,2)=1.3E10, SD(4,1)=1.E5,
RR(5,1,1)=1., SD(5,1)=.5,
RR(11,1,1)=1.E-8, SD(11,1)=1.E-5.

Since these data are very similar to the data presented for
the mode A sample case (reconstruction program) in part A, only the
differences will be discussed here.

The mode B primary state vector consists of only four components.
This explains why the XN vectors in the two cases have different
dimensions. Since the mode B reconstruction process, unlike mode
A, requires an atmosphere model, the pertinent ATMOS variables must
appear in the above name list.

Both NACCEL and NGYRO are set true to remove both the normal
accelerometer and the gyro from the reconstruction process. Setting
LTR1 true indicates that the mode B reconstruction process will be
employed.

The 4x4 P-array defines the initial covariance matrix corres-
ponding to the primary mode B four-dimensional state vector. The
mode B filter in this sample case also solves for the temperatures
at the first four temperature breakpoints. The second, third, and
fourth temperature breakpoints are treated as consider parameters
by the filter. Certain of the component mole fraction profile pa-
rameters are also considered by the filter.

The measurement/event schedule cards used in this sample case
are listed.

Not all these measurements and events will be processed in the
sample case since TF was set to 500. in the previous namelist.
b. Output Discussion - Selected pages from the reconstruction portion of this sample case appear in section D where they are referred to as case B-2. The output for a temperature measurement at 40. seconds, a quasi-event at 200. seconds, and a pressure measurement at 230. seconds is shown. The temperature measurement at 40. seconds reduces the velocity and downrange estimation errors, although the altitude and flightpath angle errors have increased. The temperature estimation errors at the temperature breakpoints of 0. and 60. kilometers have been reduced, while those at the higher temperature breakpoints have not been significantly affected. This is to be expected since the vehicle is at an altitude of 66.6 kilometers when this temperature measurement was made. The nominal trajectory is updated at the quasi-event at 200. seconds, but only the altitude and downrange angle components of the nominal trajectory have been improved as a result. Examining all estimation errors at this quasi-event shows that all initial errors, except for the temperature error at the third temperature breakpoint, have been reduced at 200. seconds. The pressure measurement at 230. seconds, which is the first measurement following the previous quasi-event, does not have much of an effect on the temperature solve-for parameters, although altitude and velocity estimation errors are reduced. Note that all state and solve-for parameter estimation errors at this point easily fall within the ±3σ range predicted by the filter. For example, compare the altitude error of -0.751 kilometer with the predicted 1-σ standard deviation of 0.823 kilometer, and the surface temperature error of -4.55°K with the predicted 1-σ standard deviation of 4.97°F. This indicates that the filter is convergent at this point in the reconstruction process. The output for this sample case was generated on the CDC 6400/6500 computer at the Martin Marietta Corporation.

C. QUASI-STATIC DYNAMIC MODEL SAMPLE CASE

The results of a study performed to establish the validity of the quasi-static dynamic model in the terminal descent phase of a Vernusian entry mission are presented here. The assumptions and equations defining the quasi-static dynamic model are given in Chapter II of the Analytic Section of this manual. The LTR data generator program was used to compute the true vehicle velocity. The quasi-static velocity, of course, was computed from the analytic terminal velocity solution.
Vertical motion (γ = -90°) was assumed for this study. The initial vehicle velocity was 863 m/s at an 85-kilometer altitude. A ballistic coefficient of 30.01 x 10^6 kg/km² was assumed until the parachute was deployed at the 50-kilometer altitude, after which the ballistic coefficient was changed to 25.539 x 10^6 kg/km².

The Venusian atmosphere model used in this study was based on the GSFC No. 3609 Venusian model. In LTR, atmosphere models are approximated with a surface pressure and linear temperature and molecular weight breakpoint models. The validity of the hydrostatic equation and the perfect gas law is also assumed. The temperature profile used in the study is defined.

<table>
<thead>
<tr>
<th>Altitude (km)</th>
<th>Temperature (°K)</th>
</tr>
</thead>
<tbody>
<tr>
<td>0.</td>
<td>738.</td>
</tr>
<tr>
<td>13.5</td>
<td>640.</td>
</tr>
<tr>
<td>42.</td>
<td>387.</td>
</tr>
<tr>
<td>60.</td>
<td>256.</td>
</tr>
<tr>
<td>115.</td>
<td>170.</td>
</tr>
</tbody>
</table>

A constant molecular weight of 43.2 over the altitude range under consideration was assumed. Surface pressure was set to 1.104 x 10^5 millibars.

The results of the study are summarized. True velocity (computed by LTR) and quasi-static velocity (computed analytically) are shown as functions of altitude.

<table>
<thead>
<tr>
<th>Altitude (km)</th>
<th>Quasi-Static Velocity (m/s)</th>
<th>True Velocity (m/s)</th>
</tr>
</thead>
<tbody>

<td>4.30</td>
</tr>
<tr>
<td>10.</td>
<td>3.17</td>
<td>3.21</td>
</tr>
</tbody>
</table>

The initial disagreement at the 80-kilometer altitude is due to the fact that the initial velocity at the 85-kilometer altitude was chosen to be 863 m/s, which is much greater than the terminal velocity at that altitude. However, after 70 kilometers, the agreement between the quasi-static and true velocities is quite good.

PART III
LTR PROGRAMMERS' MANUAL
I. INTRODUCTION

This Lander Trajectory Reconstruction Programmers' Manual is intended to supply the reader with sufficient information about the lander trajectory reconstruction (LTR) program to enable him to modify it for his own uses. Both the overall structure of the program and the computational flow of individual subroutines are presented in this manual.

Chapters II and III describe the overall flow and operation of the program and present the graphical structure of the various segments.

Chapter IV of this volume contains the definitions of common variables. The variables are defined in the order of appearance within the common block, and the common blocks are presented alphabetically.

Chapter V documents each of the subroutines in detail. The purpose of the subroutine is given, and subroutines required by the subroutine are listed. Arguments to the subroutine and local variables of interest are defined, and usage of common variables is noted. The mathematical analysis and a flow chart are provided whenever necessary for a thorough understanding of the subroutine.
II. SUMMARY OF LTR OPERATION

The LTR program is segmented by an overlay structure to conserve core storage. There are five overlay sections, which are discussed in the following sections.

A. MAIN

The executive subroutine MAIN controls overall program execution and calls the remaining sections according to values from input data. The rest of the subroutines in this overlay section are called from several of the remaining overlay sections and appear in the main overlay to conserve core.

B. DATGEN

The data generator overlay section generates the actual trajectory, the actual measurements, the quantized ARU-VRU data, and the actual atmosphere experienced by the vehicle as it descends. Several input/output files are written for use by subsequent overlay sections in reconstructing the atmosphere and trajectory.

C. PRPROS

The preprocessor overlay section operates on the quantized ARU-VRU data generated by DATGEN and filters them using a least-squares curve-fitting technique. File 16 is written with the smoothed data for use by the reconstructor.
D. LTRCON

The reconstructor overlay section utilizes the I/O files written by DATGEN and PRPR5S to reconstruct the atmosphere and descent trajectory. It is presumed that files 10 and 16 have been previously written on magnetic tape or are generated immediately prior to the start of reconstruction. Derived measurements are used to drive the dynamic equations, and a Kalman-Schmidt filter is employed to refine the estimated errors between "actual" and "assumed" parameters. Up to 15 data files may be written for plotting purposes, according to data supplied from NAMELIST input.

E. SUMMARY

The summary overlay section prints the summary tables from I/O files written by LTRCON and calls the user-written plot package according to information supplied by LTRCON. A sample plot package is described in Appendix A.
III. LTR Program Structure

A. LTR SUBROUTINE CLASSIFICATION

The subroutines that make up the LTR program are listed according to category in Table III-1. Table III-2 lists the subroutines again with a brief summary of their purposes. The individual subroutines are documented in detail in alphabetical order in Chapter V.

B. LTR SUBROUTINE HIERARCHY

As described in Chapter II, the LTR program is composed of three distinct parts. Each part is governed by an executive routine that is called from the main routine according to the value of RUNN0. The calling hierarchy of the LTR program is given in Figure III-1. Each of the three parts is broken down separately in Figures III-2 thru III-4. Subroutines in parentheses are called by the preceding subroutine. An asterisk indicates an expansion elsewhere in the hierarchy charts. BLOCK DATA in Figure III-1 is adjoined to LTR by dotted lines, indicating that data initialized there are available to all subroutines.

## IV. COMMON VARIABLE DEFINITIONS

### A. COMMON VARIABLES BY BLOCKS

In this section common blocks are listed in alphabetical order. Variables within these blocks are defined in the order they appear within the block.

<table>
<thead>
<tr>
<th>Block</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>/ACCEL/</td>
<td></td>
</tr>
<tr>
<td>ACCLX</td>
<td>Actual acceleration along the X-axis (written in DATGEN)</td>
</tr>
<tr>
<td>ACCLZ</td>
<td>Actual acceleration along the Z-axis (written in DATGEN)</td>
</tr>
<tr>
<td>/ACT/</td>
<td></td>
</tr>
<tr>
<td>RHÔA</td>
<td>Actual density (read in READAC)</td>
</tr>
<tr>
<td>TÔMPA</td>
<td>Actual stagnation temperature (read in READAC)</td>
</tr>
<tr>
<td>ACCLXC</td>
<td>Actual acceleration along the X-axis (read in READAC)</td>
</tr>
<tr>
<td>ACCLZC</td>
<td>Actual acceleration along the Z-axis (read in READAC)</td>
</tr>
<tr>
<td>NWTA</td>
<td>Actual molecular weight (read in READAC)</td>
</tr>
<tr>
<td>/ALREDY/</td>
<td></td>
</tr>
<tr>
<td>GENDAT</td>
<td>Flag to determine if data generator has been run before reconstructor (set .TRUE. in SETUP1)</td>
</tr>
<tr>
<td>RESTRT</td>
<td>Flag to determine if data generator and reconstructor are being restarted (read in SETUP1, SETUP)</td>
</tr>
</tbody>
</table>
/AM/

MWTM Nominal molecular weight (input in SETUP)

THETI Initial attitude angle (input in SETUP)

/ATMS/

BKTBL(20) Breakpoints of ratios of lift to drag versus Mach number used to calculate angle of attack measurement

GAMTBL(20) Breakpoints of ratios of specific heats versus molecular weight used to calculate Mach number and speed of sound

/AX/

AXC Reconstructed acceleration along X-axis as experienced by VRU

AZC Reconstructed acceleration along Z-axis as experienced by VRU

THTC Change in inertial pitch attitude since TZERO

ØMGC Reconstructed angular velocity as experienced by ARU

ALPHA Reconstructed angle of attack

/BM/

EDNBM(30) Estimated deviations from most recent nominal trajectory before a measurement

QEDNBM(30) Estimated deviations in solve-for parameters from most recent nominal before a measurement
### /COVARE/

</table>
HM(24) Partition of observation matrix relating observables to state

MM(40) Partition of observation matrix relating observables to solve-for parameters

LM(80) Partition of observation matrix relating observables to measurement-consider parameters

GM(40) Partition of observation matrix relating observables to dynamic/measurement-consider parameters

JM(16) Kalman filter J matrix

W1(24) Working matrices for filter equations

W2(40)

W3(80)

W4(80)

W5(40)

K1(24) Kalman gain matrix for state parameters

K2(40) Kalman gain matrix for solve-for parameters

W0RK(400) Working matrices for filter equations

W(120)

R(16) Measurement noise matrix

DYN(36) Dynamic noise matrix

PP(36) Correlation matrix of P matrix

QQ(100) Correlation matrix of Q matrix

JIN(16) J inverse of Kalman filter equations

SQDU(20) Standard deviations of dynamic-consider parameters
SQDV(20) Standard deviations of measurement-consider parameters
SQDW Standard deviations of dynamic/measurement-consider parameters
PPC(36) PP matrix converted to output units
QEDN(10) Estimated deviations of solve-for parameters from nominal values
QEDNBC(10) QEDN matrix before a quasi-event

/DET/

CDELT1 Cosines of calibrated misalignments of the VRU and ARU after biasing
CDELT2
CDELT3
SDELT1 Sines of calibrated misalignments of the VRU and ARU after biasing
SDELT2
SDELT3
SUBDL1 Intermediate term used to calculate axial and normal acceleration

/DOPPLER/

TZERØ Trajectory time TC at start of data generator and reconstructor
DATEJ Julian date, epoch 1900, corresponding to TZERO (calculated in SETUP1, SETUP)
SALT(3) Station location altitudes for DSN tracking in kilometers
SLAT(3) Station location latitudes for DSN tracking in radians
SLON(3) Station location longitudes for DSN tracking in radians
RANGE(3) Actual range measurement (km)
RANGER(3) Actual range-rate measurements (km/s)
ØMEGAE Angular velocity of earth (rad/s)
ØBLIC Obliquity of the ecliptic (radians)
REARTH Radius of the earth (kilometers)
GHATØ Greenwich hour angle of the vernal equinox at TZERO
SCPEC(6) Spacecraft planetocentric ecliptic coordinates based on ECLØNG(1), ECLINC(1), PHIR(1)
PHIR(3) Reference angle phi for ecliptic, planetoequatorial, and subsolar orbital planes, respectively
ECLØNG(3) Reference longitude for ecliptic, planetoequatorial, and subsolar orbital planes, respectively
ECLINC(3) Reference inclination for ecliptic, planetoequatorial, and subsolar orbital planes, respectively
DELRR(3) Range perturbations due to refractivity
DELRRR(3) Range-rate perturbations due to refractivity
RØTNØ The target planet angular velocity component normal to the entry plane
NTP Integer number of the target planet (see EPHEM for range of values)

/DERIV/

VA Velocity of atmosphere at vehicle position
SGAM Sine of vehicle flightpath angle
CGAM Cosine of vehicle flightpath angle
V Velocity of vehicle
GAM  Vehicle flightpath angle
FE   Vehicle range angle

/GYRACC/

NACCEL  Flag used to delete accelerometer data from
dynamic equations
NGYRØ  Flag used to delete gyro data from dynamic
equations

/INTCOM/

GEND  Integer to indicate number of gyro elements
IAA  Indicates which accelerometer data partition to
use to calculate state derivatives
ICNTR  Indicates number of increments between print points
IEND  Indicates end of accelerometer data partitions
       for a given interval
IGYRØ  Indicates which gyro data partition to use to
calculate state derivatives
INDEP(15)  Indicators of independent variables for plot
package
IPRINT  Print increment counter used with ICNTR to control
       print points
IX  Not used
LASTIM  Not used
LICNTR(15)  Array of values for ICNTR
LISTSM  Not used
LISTS(6)  List of state parameters
LISTQ(10) List of solve-for parameters
LISTU(20) List of dynamic-consider parameters
LISTV(20) List of measurement-consider parameters
LISTW(10) List of dynamic/measurement-consider parameters
M Parameter used to quantize VRU and ARU data
MCNTR Indicates which measurement or event is currently being processed
MCODE(250) Array of values of MCNTR
MØDE Not used
N Parameter used to quantize VRU and ARU data
NE Number of state parameters in LISTS
NICNTR Indicates LICNTR value of interest
NM Number of observables in a measurement
NMEAS Not used
NMPTS Number of breakpoints of altitude versus molecular weight
NPRED Not used
NQS Set to NQ and used to set up plot package
NQUASI Not used
NTPTS Number of breakpoints of altitude versus ambient temperature
NVAR(15) Array of number of dependent variables for plot package
NS Number of state parameters in LISTS
NQ Number of solve-for parameters in LISTQ
NU  Number of dynamic-consider parameters in LISTU
NV  Number of measurement-consider parameters in LISTV
NW  Number of dynamic/measurement-consider parameters in LISTW
PROB(40)  Array of Hollerith data for problem identification
RUNNØ  Indicates which part of LTR is being executed (data generator, reconstructor, etc)
SUM  Not used
SUMFAR  Not used
SIZEP  Not used
TYPE  Current value of MCØDE used to process event or measurement

/LØGØRA/

CDEL  Logical to reduce time needed to compute state derivatives when C(55), C(56), C(63) are not perturbed
HITGND  Logical set to .TRUE. when vehicle impacts the planet
LASTYM  Logical used to quantize VRU and ARU data
LINEAR(15)  Array of logicals to set linear scales for plot package
LØG(15)  Array of logicals to set log scales for plot package
LTR1  Logical to control mode B logic
LTR2  Logical to control mode A logic
MACHNØ  Logical to control updating of Mach number for LTR2 mode of reconstructor
<table>

</table>
TIMEF  Final trajectory time reached by the reconstructor

/TRAJ/

AROTBL(316,4)  Table of vehicle aerodynamic coefficients for integrators divided into four parts:
   A. CA table of ALPHA versus Mach number
   B. CN table of ALPHA versus Mach number
   C. CMQ table of ALPHA versus Mach number
   D. CP table of ALPHA versus Mach number

AF  Axial force calculated from surface area and dynamic pressure

AGAM  Ratio of specific heats used to calculate Mach number and speed of sound

ALPH  Computed angle of attack assuming an atmosphere stationary with respect to the rotating planet

AM  Moment acceleration computed by data generator

AR  Universal gas constant

ATM\$SS(33,5)  Five tables of breakpoints of molecular weights and temperatures versus altitude

ATM\$S(33)  ATM\$S table chosen according to NATM\$S

AX  Axial aerodynamic acceleration

AY  Normal aerodynamic acceleration

C(200)  Biases and scale factors used to calculate "real world" model in the data generator and to calculate sensitivity matrices and state deviations in the reconstructor (for a breakdown of the elements of the C array, see input description of the Users' Manual)
CA     Axial force coefficient computed from AROTBL tables
CACT(200)   Data generator values of the C array used by the
            reconstructor to compute actual deviations from
            most recent nominal values of solve-for parameters
CBQ(30)   Scale factors and biases before a quasi-event
            used to compute estimated deviations from most
            recent nominal values of solve-for parameters
CDTBL(50) Parachute drag coefficient table
CMQ    Moment coefficient computed from AROTBL tables
CN     Normal force coefficient computed from AROTBL tables
CO(200) Original reconstructor C array values used to cal-
            culate estimated deviations from original nominal
            values of solve-for parameters
DIA    Vehicle base diameter
DP     Dynamic pressure
DT     Integration step size (seconds) for data generator
            and reconstructor
DXN(30) First derivatives of state parameters, actual VRU-
            ARU data, and ambient pressure derivative
EDN(30) Estimated deviations from most recent nominal
            trajectory after a measurement
EDNBQ(30) EDN array before a quasi-event
EPS    Epsilon, the angle between the inertial velocity
            and relative velocity vectors
FD     Parachute drag force
GA     Local gravitational acceleration
GØ     Gravitational acceleration at zero altitude
MACH  Mach number

FUNCTION CALLED: TAN
ATMOSP Analysis

Subroutine ATMOSP computes Mach number and atmospheric density and temperature for the mode A reconstruction process. The required equations are derived in Chapter IV.

Dynamic pressure $q$ can be related to the calibrated axial accelerometer measurement $a_x$ according to

$$q = \frac{(m + C_{30}) a_x}{(C_{20} \cdot C_A + C_{16}) + (C_{96} \cdot C_D + C_{97})}$$

so that density can be immediately obtained from

$$\rho = \frac{2q}{v^2}$$

These equations correspond to equations (IV-17) and (IV-18), respectively, but with relevant scale factors and biases incorporated. These scale factors and biases are defined as follows:

- $C_{16}$ = axial aerodynamic coefficient $C_A$ bias
- $C_{20}$ = $C_A$ scale factor
- $C_{30}$ = mass $m$ bias
- $C_{96}$ = parachute drag coefficient $C_D$ scale factor
- $C_{97}$ = $C_D$ bias.

Mach number $M$ is computed from the equation

$$M = \left[\frac{2q}{\gamma p}\right]^{\frac{1}{2}}$$

where $\gamma$ is the ratio of specific heats and $p$ is the ambient pressure, which has been obtained by integrating the hydrostatic equation in subroutine DERIVE.
Temperature is obtained from the equation of state

\[ T = \frac{pM}{\rho R} \]  \hspace{2cm} (4)

where \( M \) denotes molecular weight and \( R \) denotes the universal gas constant.
Set MACHNO false

Use DTAB to interpolate on AROTBL to compute $C_A$ as a function of Mach number and the absolute value of the angle of attack.

Incorporate scale factor and bias into $C_A$

Use TAB to interpolate on CDTABL to compute parachute $C_D$ as a function of Mach number.

Incorporate scale factor and bias into $C_D$

Compute the product of $C_A$ and the vehicle reference area $S$. Include the contribution of the parachute if it is deployed.

Compute dynamic pressure $q$ and density $p$ using equations (1) and (2), respectively.
Use TAB to interpolate on GAMTBL to compute the ratio of specific heats as a function of molecular weight

Set MACHNO true if
  a. \( t_c - t_0 > 0.5 \),
  b. \( q \geq 1 \times 10^{-5} \),
  c. \( p > 0 \)

Compute Mach number using equation (3) if MACHNO is true

Compute temperature using equation (4) if \( q \geq 1 \times 10^{-5} \)

| ENTRY PNT --- | ATMOAT | ATMSET |
ATMSET Analysis

ATMSET determines the temperature, molecular weight, pressure, density, and speed of sound of the atmosphere as a function of height above the mean surface, \( h \). The atmosphere is modeled by assuming piece-wise linear representation for the temperature and molecular weight versus height. The remaining atmospheric parameters are then found from the hydrostatic equations and the perfect gas law.

The temperature \( T \) at height \( h \) between the \( j \) and \( j+1 \) temperature breakpoints is given by

\[
T(h) = T_{i,j}^h + T_{b,j}
\]  

(1)

The molecular weight \( M \) at height \( h \) between the \( i \) and \( i+1 \) molecular weight breakpoints is given by

\[
M(h) = M_{i,j} h + M_{b,j}
\]  

(2)

The hydrostatic equation

\[
\frac{dP}{dh} = -\rho g
\]  

(3)

where \( g \) = acceleration due to gravity, and the perfect gas law,

\[
\rho(h) = \frac{P(h)}{R} \cdot \frac{M(h)}{T(h)}
\]  

(4)

where \( R \) = gas constant, may be integrated from the atmosphere breakpoint (temperature or molecular weight) immediately below the height \( h \) to give the pressure \( P(h) \)

\[
P(h) = P(h_{k}) \exp \left[ -\frac{g}{R} \int_{h_{k}}^{h} \frac{M(\zeta)}{T(\zeta)} d\zeta \right] .
\]  

(5)
\[
\int_{h_k}^{h} \frac{M(z)}{T(z)} \, dz = \begin{cases} 
\frac{1}{T_b} (h - h_k) \left\{ M_{s_4} + \frac{1}{2} M_{s_4} (h - h_k) \right\}, & T_s_j = 0 \\
\frac{M_{s_4}}{T_s_j} (h - h_k) + \frac{M_{s_4} - T_{s_j} - T_b \cdot M_{s_3}}{T_s_j} \ln \frac{T_b}{T_b + T_s_j h_k}, & T_s_j \neq 0
\end{cases}
\]

where

\( i \) = the index of the molecular weight breakpoint immediately below \( h \),

\( j \) = the index of the temperature breakpoint immediately below \( h \).

For a given surface pressure \( P(h_0) \), the pressure \( P(h) \) may be found by repeated application of the above expression

\[
P(h) = P(h_0) \left\{ \frac{P(h_k)}{P(h_0)} \right\} \exp \left[ - \frac{R}{M} \int_{h_k}^{h} \frac{M(z)}{T(z)} \, dz \right].
\]

The density is then found from equation (4) and the speed of sound at height \( h \) is given by

\[
\rho_s(h) = \gamma_s \left[ \frac{RT(h)}{M(h)} \right]^{\frac{1}{2}}.
\]

where \( \gamma_s \) = ratio of specific heats.

The subroutine has two entry points — ATMST and ATMDAT. Entry ATMSET computes and stores the ratios \( P(h_k)/P(h_0) \) for each atmosphere breakpoint. Entry ATMDAT computes the temperature, molecular weight, pressure, density, and speed of sound at height \( h \).

The flow of the ATMSET subroutine is illustrated.
ENTRY ATMSET

Compute the slopes (MS,TS) and zero height intercepts (MB,TB) for each linear segment of the molecular weight and temperature vs height functions.

Order atmosphere breakpoint heights in ascending height and store in E array.

Compute \( P(h_x) \) ratio for each atmosphere breakpoint, \( k \), and store in CUMPRD array.

RETURN

ENTRY ATMDAT

Determine the atmosphere breakpoint index, \( k \), the temperature breakpoint index, \( J \), and molecular weight breakpoint index, \( i \), immediately below the height, \( h \).

Compute temperature (TEMP), molecular weight (MWT), pressure (PRES), density (RHO), and speed of sound (SS) at height, \( h \).

RETURN
ATTACK-A

SUBROUTINE ATTACK

PURPOSE: COMPUTE VEHICLE ANGLE OF ATTACK

SUBROUTINES CALLED: DERIVE

COMMONS: AX, ATMS, TRAJ, GYRACC

LOCAL SYMBOLS:
- BK: INTERPOLATED VALUE OF LIFT OVER DRAG VERSUS MACH NUMBER
- DALPHA: INTERMEDIATE VARIABLE FOR ITERATIVE SOLUTION
- FALPHA: INTERMEDIATE VARIABLE FOR ITERATIVE SOLUTION
- I: INDEX
- ZETA: RATIO OF MEASURED ACCELERATIONS

USED/COMMON: ALPHA, AX, AZC, BKTBL, MACH, NACCEL

SET/COMMON: ALPHA

FCT CALLED: TAR

LOADED: MACHNO
ATTACK Analysis

Subroutine ATTACK computes the actual angle of attack measurement, which is currently defined only for the mode A reconstruction process. The ratio of calibrated accelerations $a_{c}/a_{x}$ is used to define the angle of attack measurement $\alpha$. The vehicle lift/drag ratio can be related to $a_{c}$, $a_{x}$, and $\alpha$ as follows:

$$L = a_{c} \cos \alpha - a_{x} \sin \alpha$$
$$D = a_{c} \cos \alpha + a_{x} \sin \alpha$$

Furthermore, $L/D$ has the form

$$\frac{L}{D} = k \alpha$$

where $k$ is a tabulated function of Mach number. Eliminating $L/D$ from equations (1) and (2) yields

$$\tan \alpha = \frac{1 - k \alpha}{1 + \zeta k \alpha}$$

where

$$\zeta = \frac{a_{c}}{a_{x}}.$$ 

Equation (3) is solved iteratively for $\alpha$ using a standard Newton iteration technique. Rewriting equation (3) as

$$F = (1 + \zeta k \alpha) \tan \alpha + k \alpha - \zeta = 0$$

the iteration process is defined by

$$\alpha_{i+1} = \alpha_{i} - \left( \frac{F}{\partial F/\partial \alpha} \right)_{i}$$

where

$$\frac{\partial F}{\partial \alpha} = k + 1 + \alpha \left[ -2 \zeta k + \alpha \left( 1 - \frac{4}{3} k \zeta \alpha \right) \right]$$

$$\alpha_{o} = \frac{\zeta}{k + 1}$$

which is an approximate solution of equation (3) for small $\alpha$ and $\zeta$. 

SUBROUTINE AUXIL

PURPOSE: PRINT AUXILIARY INFORMATION FROM THE DATA GENERATOR

THETA LATITUDE GROUND TRACE RELATIVE TO REFERENCE PLANE
XNU ANGLE BETWEEN THE ENTRY PLANE AND PLANE OF THE SKY

USED/COMMONS: CARCOR RA D

WRITTEN --- PSI RLONG THETA XNU
AUXIL Analysis

Subroutine AUXIL computes the following auxiliary information:

1. Latitude and longitude ground trace relative to three coordinate systems:
   a. Planetocentric equatorial,
   b. Subsolar orbital-plane,
   c. Planetocentric geographical;
2. Communication angle;
3. Angle between the entry plane and the plane of the sky.

Given the spacecraft position components \((x,y,z)\) relative to an arbitrary orthogonal coordinate system, the latitude and longitude are given by the following equations:

a. Latitude (relative to xy-plane)
   \[
   \theta = \tan^{-1}\left(\frac{z}{\sqrt{x^2 + y^2}}\right)
   \]

b. Longitude (relative to x-axis)
   \[
   \lambda = \tan^{-1}\left(\frac{y}{x}\right)
   \]

The communication angle \(\psi\) is defined as the angle between the spacecraft and earth position vectors relative to the center of the target planet. Thus

\[
\psi = \cos^{-1}\left[\frac{\hat{r} \cdot (\hat{r}_e - \hat{r}_p)}{|\hat{r}| \cdot |\hat{r}_e - \hat{r}_p|}\right], \quad 0 \leq \psi \leq \pi
\]

where \(\hat{r}\) is the spacecraft position relative to the target planet, and \(\hat{r}_e\) and \(\hat{r}_p\) are the position vectors of the earth and the target planet, respectively, relative to the sun.
The angle $\eta$ between the entry plane and the plane of the sky is defined as the angle between the normals of each plane. The unit vector $\hat{e}_n$ normal to the entry plane is given by

$$
\hat{e}_n = \begin{bmatrix}
\sin i \cos \Omega \\
-\sin i \sin \Omega \\
\cos i
\end{bmatrix}
$$

relative to the planetocentric ecliptic system, where inclination $i$ and longitude of the ascending node $\Omega$ define the orientation of the entry plane relative to the same system (see subroutine ECLIP). The plane of the sky is defined as the plane perpendicular to the range vector $\hat{r}$ from the earth to the spacecraft. The unit vector normal to this plane is

$$
\hat{e}_\rho = \frac{\hat{r}}{\rho}
$$

Then

$$
\eta = \cos^{-1} \left( \hat{e}_\rho \cdot \hat{e}_n \right)
$$

$$
0 \leq \eta \leq \pi
$$

DERIV1 Analysis

Subroutine DERIV1 is the dynamic model subroutine used in the generation of the actual trajectory, actual VRU and ARU outputs, and actual atmospheric parameters. Subroutine DERIV1 computes derivatives of the variables h, v, γ, φ, θ, ω, v_x, v_z, A_g, and p for use in the integration subroutine RKUTDG.

Certain preliminary calculations are required before the required derivatives can be evaluated. First, the local acceleration of gravity is computed from

\[ g = \frac{\mu}{r^2} \]  

where \( \mu \) is the planet gravitational constant and \( r \) is the radial distance from the planet center. Atmosphere velocity \( v_a \), vehicle relative velocity \( v_r \), and the angle \( \varepsilon \) between the inertial velocity \( v \) and the relative velocity are computed from the following relations:

\[ v_a = r \omega_n + v_w \]  
\[ v_r = \frac{v - v_a \cos \gamma}{\cos \varepsilon} \]  
\[ \varepsilon = \tan^{-1} \left( \frac{v_r \sin \gamma}{v - v_a \cos \gamma} \right) \]

where \( \omega_n \) denotes the component of the planet rotational velocity in the entry plane. Angle of attack is given by

\[ \alpha = \theta + \phi - \gamma - \varepsilon \]

Axial, normal, and parachute drag forces are given, respectively, by

\[ A = -C_A q S \]  
\[ N = -C_N q S \]  
\[ F_d = C_D q S_D \]
The aerodynamic damping moment is computed from

$$M = C_M q \omega \frac{d^2 q}{dt^2} \frac{S}{v}$$  \hspace{1cm} (9)$$

The equations of motion which constitute the dynamic model used to compute the actual entry trajectory are summarized below:

$$\dot{h} = v \sin \gamma$$  \hspace{1cm} (10)$$

$$v = -g \sin \gamma + \frac{A}{m} \cos (\alpha + \epsilon) + \frac{N}{m} \sin (\alpha + \epsilon) - \frac{F_d}{m} \cos \epsilon$$  \hspace{1cm} (11)$$

$$\gamma = \left(\frac{v}{r} - \frac{\dot{r}}{v}\right) \cos \gamma + \frac{1}{v} \left[ \frac{A}{m} \sin (\alpha + \epsilon) - \frac{N}{m} \cos (\alpha + \epsilon) - \frac{F_d}{m} \cos \epsilon \right]$$  \hspace{1cm} (12)$$

$$\phi = \frac{v}{r} \cos \gamma$$  \hspace{1cm} (13)$$

$$\dot{\theta} = \omega$$  \hspace{1cm} (14)$$

$$\omega = \frac{1}{I} \left[ \left( z_p - z_g \right) A - \left( x_p - x_g \right) N + M + z_g F_d \cos \alpha \right. \right.$$  
$$- \left. \left( x_g - x_d \right) F_d \sin \alpha \right]$$  \hspace{1cm} (15)$$

The parachute terms, of course, appear only when the parachute is deployed (IPHAS = 2).

The actual nongravitational acceleration experienced by the VRU is given by

$$\dot{v}_x = a_x \cos \delta_1 - a_z \sin \delta_1$$  \hspace{1cm} (16)$$

$$\dot{v}_z = a_x \sin \delta_2 + a_z \cos \delta_2$$  \hspace{1cm} (17)$$

The actual angular velocity experienced by the ARU is given by

$$\dot{\omega} = \omega \cos \delta_3$$  \hspace{1cm} (18)$$

The rate of change of ambient pressure is computed from

$$\dot{p} = -\rho g \dot{h}$$  \hspace{1cm} (19)$$
which is just the time-differential form of the hydrostatic equation.

If the quasi-static dynamic model is to be used, equation (11) is replaced with

\[ \dot{v} = 0 \]  \hspace{1cm} (20)

and \( v \) is computed from the terminal velocity solution

\[ v = \frac{2m \ g \ |\sin \gamma|}{\rho \ (C_A \ S + C_D \ S_D)} \]  \hspace{1cm} (21)

The logical variable COND is set to true if either dynamic pressure exceedsODB or if the parachute is deployed. Whenever COND is true, the angle of attack and the rotational state are computed as follows:

\[ \alpha = 0 \]  \hspace{1cm} (22)

\[ \theta = \gamma - \phi + \varepsilon \]  \hspace{1cm} (23)

\[ \omega = \gamma - \phi \]  \hspace{1cm} (24)
DERIV1 Flow Chart

DERIV1-4

ENTER

Set local state variables to the XNEW vector

Compute cosine and sine of $\gamma$, radial distance of vehicle from planet center, and the local acceleration of gravity

Use WINDV to compute the local horizontal wind velocity $v_W$

Compute atmosphere velocity $v_a$, vehicle relative velocity $v_r$, and the angle $\epsilon$ between $v$ and $v_r$

Call ATMDAT to compute the local atmospheric temperature, pressure, density, molecular weight, and speed of sound

Compute Mach number and dynamic pressure

Set condition COND false

Set COND true if dynamic pressure exceeds ODB, or if parachute is deployed

A

213
Compute angle of attack

Is COND true

YES

Set $\alpha = 0$ and $X_{NEW(5)} = \gamma - \phi + \varepsilon$

Compute cosine and sine of $\alpha + \varepsilon$

Use DTAB to interpolate on AROTBL to compute $C_A$, $C_N$, $C_M$, and $X_p$ as functions of Mach number and the absolute value of the angle of attack

Is parachute deployed

YES

Use TAB to interpolate on CDTBL to compute $C_D$ as a function of Mach number. Compute the parachute drag force $F_D$

Set $Z_p$, the cp location along the z-axis, to zero

B
Change the sign of $C_N$ if $\alpha > 0$

Compute the vehicle aerodynamic forces, moments, and accelerations

Evaluate the $\dot{V}$ equation. If the parachute is deployed, incorporate its effect into the $\dot{V}$ equation.

Is the quasi-static dynamic model being used?

- **YES**
  - Set $\dot{v} = 0$ and compute the quasi-static velocity. Include parachute terms if parachute is deployed. Set $XNEW(2)$ equal to the quasi-static velocity.
  - Evaluate the $\dot{h}$, $\gamma$, $\phi$, and $\dot{\phi}$ equations.
  - Include parachute terms in $\dot{\gamma}$ equation if parachute is deployed.
  - If $COND$ is true, set $\dot{\theta} = \dot{\gamma} - \dot{\phi}$

- **NO**
Evaluate the \( \dot{\omega} \) equation. Include parachute terms if parachute is deployed.

If COND is true, set \( \omega = \dot{\gamma} - \dot{\phi} \) and \( X\text{NEW}(6) = \omega \).

If parachute is deployed, incorporate its effect into the aerodynamic accelerations.

Evaluate the \( \dot{x} \), \( \dot{z} \), \( \dot{\alpha} \), and \( \dot{\beta} \) equations.

DERIV3 Analysis

Surbourne DERIV3 is the filter dynamic model subroutine employed in the mode B reconstruction process. The primary purpose of DERIV3 is to evaluate the derivatives of the state variables \( h, v, \gamma, \) and \( \phi \) for use in the integration subroutine RKUTL3 in the computation of both the nominal trajectory and the state transition matrix partitions. State transition matrices are computed by perturbing the relevant \( C_j \)'s that appear in the DERIV3 equations.

Certain preliminary calculations are required before the derivatives of the state variables can be evaluated. The local acceleration of gravity is computed from

\[
g = \frac{\mu}{r^2} \tag{1}
\]

where \( \mu \) is the planet gravitational constant and \( r \) is the radial distance from the planet center. Atmosphere velocity \( v_a \), vehicle relative velocity \( v_r \), and the angle \( \epsilon \) between the inertial velocity \( v \) and the relative velocity are computed from the following relations:

\[
v_a = r \omega_n + v_w \tag{2}
\]

\[
v_r = \frac{v - v_a \cos \gamma}{\cos \epsilon} \tag{3}
\]

\[
\epsilon = \tan^{-1} \left[ \frac{v_a \sin \gamma}{v - v_a \cos \gamma} \right] \tag{4}
\]

where \( \omega_n \) denotes the component of the planet rotational velocity in the entry plane.

Angle of attack \( \alpha \) is given by

\[
\alpha = \theta + \phi - \gamma - \epsilon \tag{5}
\]

However, attitude angle \( \theta \) is not available in the mode B reconstruction process since gyro measurements are not permitted in this mode. Thus, in mode B \( \alpha \) is nominally set to zero. It is
still necessary, however, to compute the perturbations in a result-
ing from perturbations in the state variables and other parameters
in order to compute valid state transition matrix partitions. The
perturbation $\delta \alpha$ is given by

$$\delta \alpha = \delta \theta + \delta \phi - \delta \gamma - \delta \epsilon$$

(6)

where $\delta \theta = C_{140}'$, $\delta \phi = C_{104}'$, $\delta \gamma = C_{103}'$, and

$$\delta \epsilon = \frac{\sin^2 \epsilon}{\nu_a^2 \sin^2 \gamma} \left[ -v \omega_n \sin \gamma \cdot \delta h + (v \cos \gamma - v_a) \nu_a \delta \gamma - \nu_a \sin \gamma \cdot \delta \nu \right]$$

(7)

In this latter equation, which was derived by differentiating equa-
tion (4), $\delta h = C_{101}'$ and $\delta \nu = C_{102}'$.

Axial, normal, and parachute drag aerodynamic forces are given,
respectively, by

$$A = -C_A q S$$

(8)

$$N = -C_N q S$$

(9)

$$F_d = C_D q S_D$$

(10)

The equations of motion that constitute the mode B filter dynamic
model are summarized as

$$\hat{h} = v \sin \gamma$$

(11)

$$\dot{v} = -g \sin \gamma + \frac{A}{m} \cos (\alpha + \epsilon) + \frac{N}{m} \sin (\alpha + \epsilon) - \frac{F_d}{m} \cos \epsilon$$

(12)

$$\dot{\gamma} = \left( \frac{v}{r} - \frac{R}{v} \right) \cos \gamma + \frac{1}{v} \left[ \frac{A}{m} \sin (\alpha + \epsilon) - \frac{N}{m} \cos (\alpha + \epsilon) \right. \left. - \frac{F_d}{m} \sin \epsilon \right]$$

(13)

$$\dot{\phi} = \frac{v}{r} \cos \phi$$

(14)
The parachute terms, of course, appear only when the parachute is deployed (IPHAS = 2).

If the quasistatic dynamic model is to be used, equation (12) is replaced with

\[ \dot{v} = 0 \]  

(15)

and \( v \) is computed from the terminal velocity solution

\[ v = \left[ \frac{2 (m + C_{30}) g \sin \gamma}{\rho (C_A S + C_D S_D)} \right]^{\frac{1}{2}} + C_{102} \]  

(16)
Add the appropriate $C_j$ perturbations to the vehicle state.

Compute the radial distance of the vehicle from the planet center and the local acceleration of gravity.

Use WINDV to compute the local horizontal wind velocity $v_w$.

Compute atmosphere velocity $v_a$, vehicle relative velocity $v_r$, angle $\epsilon$ between $v$ and $v_r$, perturbation $\delta \epsilon$, and angle of attack $\alpha$.

Call ATMDAT to compute the local atmospheric temperature, pressure, density, molecular weight, and speed of sound.

Compute Mach number and dynamic pressure.
Use DATAB to interpolate on ARBL to compute $C_A$ and $C_N$ as functions of Mach number and the absolute value of the angle of attack.

Is parachute deployed? 

Yes

Use TAB to interpolate on CDTBL to compute $C_D$ as a function of Mach number. Compute the parachute drag force $F_D$.

Change the sign of $C_N$ if $\alpha > 0$.

Compute the aerodynamic forces and accelerations.

Evaluate the $\dot{v}$ equation. If the parachute is deployed, incorporate its effect into the $\dot{v}$ equation.

No
Is the quasistatic dynamic model being used?

Yes

Set \( \dot{\gamma} = 0 \) and compute the quasistatic velocity. Include parachute terms if parachute is deployed.

Set XNEW(2) equal to the quasistatic velocity if the unperturbed nominal trajectory is being computed.

Evaluate the \( \dot{h}, \dot{\gamma}, \) and \( \dot{\phi} \) equations. Include parachute terms if parachute is deployed.

DERIVE Analysis

Subroutine DERIVE is the filter dynamic model subroutine employed in the mode A reconstruction process. The primary purpose of DERIVE is to evaluate the derivatives of the state variables h, v, γ, φ, and p for use in the integration subroutine RKUT3 in computation of the nominal trajectory and ambient pressure and the state transition matrix partitions. State transition matrices are computed by perturbing the relevant C_j's that appear in the DERIVE equations.

Certain preliminary calculations are required before the derivatives of the state variables can be evaluated. The first computation concerns the calibration of cg and VRU offsets and VRU and ARU misalignments using the following equations:

$$\begin{align*}
\bar{x}_c &= (x_m + C_{28}) - (x_g + C_{26}) \\
\bar{z}_c &= (z_m + C_{29}) - (z_g + C_{27}) \\
\delta_1 &= \delta_1 - C_{55} \\
\delta_2 &= \delta_2 - C_{56} \\
\delta_3 &= \delta_3 - C_{63}
\end{align*}$$

where x_m and z_m define the nominal VRU location; x_g and z_g, the nominal cg location; δ_1 and δ_2, the nominal VRU misalignment angles; δ_3, the nominal ARU misalignment; and C_{26}, C_{27}, C_{28}, C_{29}, C_{55}, C_{56}, and C_{63}, biases in all these quantities.

The measured VRU and ARU data are obtained from the AA(I, J, K) array, which contains the coefficients a_{ij} generated by the preprocessor smoothing process. Index I specifies the sensor type:

I = 1 : axial VRU;
I = 2 : normal VRU;
I = 3 : ARU.
Index J refers to the coefficient in the quadratic function that is fitted in a least-squares sense to five quantized data points (see Section II.D). Index K is the time index in the AA(I, J, K) array. The measured axial and normal VRU data are obtained from

\[ a_{x_m} = a_{12} \]  
\[ a_{z_m} = a_{22} \]  

The measured ARU data are obtained from

\[ \theta_m = a_{31} \]  
\[ \omega_m = a_{32} \]  
\[ \dot{\omega}_m = 2a_{33} \]  

If normal VRU data are not available, \( a_{z_m} \) and misalignment \( \delta_2 \) are set to zero. In this situation it is no longer meaningful to treat the normal VRU scale factor \( C_{53} \) as a solve-for or consider parameter. For this reason \( C_{53} \) has a fixed value of 1. and cannot be perturbed. However, the normal VRU bias \( C_{54} \) can still be treated as a consider parameter representing the anticipated, but not measured, normal accelerations. Since these normal accelerations are not constant, \( C_{54} \) cannot be treated as a solve-for parameter when normal VRU data are not available. If ARU data are absent, \( \omega_m \), \( \dot{\omega}_m \), and misalignment \( \delta_3 \) are set to zero and the nominal angle of attack \( \alpha \) is assumed to be zero.

The measured VRU and ARU data are calibrated for scale factor, bias, and misalignment errors using the following equations:
\[ a_x = \cos \left( \delta_{1c} - \delta_{2c} \right) \left[ \frac{a_{x_m} - C_{52}}{C_{51}} \cos \delta_{2c} + \frac{a_{z_m} - C_{54}}{C_{53}} \sin \delta_{1c} \right] \\
+ \omega_c^2 \ddot{x}_c - \dot{\omega}_c \ddot{z}_c \]  

(11)

\[ a_z = \cos \left( \delta_{1c} - \delta_{2c} \right) \left[ -\frac{a_{x_m} - C_{52}}{C_{51}} \sin \delta_{2c} + \frac{a_{z_m} - C_{54}}{C_{53}} \cos \delta_{1c} \right] \\
+ \omega_c^2 \ddot{z}_c + \dot{\omega}_c \ddot{x}_c \]  

(12)

\[ \theta_c = \frac{1}{C_{124}} \left[ \theta_m - C_{125} \left( t - t_0 \right) \right] \]  

(13)

\[ \omega_c = \frac{1}{C_{124}} \left( \omega_m - C_{125} \right) \]  

(14)

\[ \dot{\omega}_c = \frac{\dot{\omega}_m}{C_{124}} \]  

(15)

The local acceleration of gravity is computed from

\[ g = \frac{\mu}{r} \]  

(16)

where \( \mu \) is the planet gravitational constant and \( r \) is the radial distance from the planet center. Atmosphere velocity \( v_a \), vehicle relative velocity \( v_r \), and the angle \( \epsilon \) between the inertial velocity \( v \) and the relative velocity are computed from the following relations:

\[ v_a = r \omega_n + v_w \]  

(17)
\[ \v_r = \frac{v - v_a \cos \gamma}{\cos \v} \]

\[ \v = \tan^{-1} \left[ \frac{v_a \sin \gamma}{v - v_a \cos \gamma} \right] \]

where \( \omega_n \) denotes the component of the planet rotational velocity in the entry plane.

Angle of attack \( \alpha \) is given by

\[ \alpha = \theta_c + \theta_o + \phi - \gamma - \v + C_{140} \]  

(20)

where \( \theta_o \) is the initial attitude angle and the calibrated attitude measurement \( \theta_c \) represents the change in attitude since initial time to \( t \). Parameter \( C_{140} \) represents the initial attitude error.

When nominal \( \alpha \) is chosen to be zero, as it is when ARU data are not available or when the parachute is deployed, perturbations in \( \alpha \) resulting from perturbations in the state variables and other parameters are computed from

\[ \delta \alpha = \delta (\theta_c + \theta_o) + \delta \phi - \delta \gamma - \delta \v \]

(21)

where \( \delta (\theta_c + \theta_o) = C_{140}, \delta \phi = C_{104}, \delta \gamma = C_{103}, \) and

\[ \delta \v = \frac{\sin^2 \v}{v_a \sin^2 \gamma} \left[ -v \omega_n \sin \gamma \cdot \delta h + (v \cos \gamma - v_a) v_a \delta \gamma \right. \]

\[ \left. -v_a \sin \gamma \cdot \delta v \right] \]

(22)

In this latter equation, which was derived by differentiating equation (19), \( \delta h = C_{101} \) and \( \delta v = C_{102} \).
Subroutine ATMOSP is not called until significant axial aerodynamic deceleration has developed. Currently, ATMOSP is called when

\[ a_x \leq -0.5 \times 10^{-3} \text{ km/s}^2 \]

in order to compute Mach number and atmospheric density and temperature.

The equations of motion that constitute the mode A filter dynamic model are summarized as

\[ \dot{\mathbf{r}} = v \sin \gamma \]

\[ \dot{v} = -g \sin \gamma + a_x \cos (\alpha + \varepsilon) + a_z \sin (\alpha + \varepsilon) \]

\[ \dot{\gamma} = \left( \frac{v}{r} - \frac{\mathbf{r}}{v} \right) \cos \gamma \overline{v} \left[ a_x \sin (\alpha + \varepsilon) - a_z \cos (\alpha + \varepsilon) \right] \]

\[ \dot{\phi} = \frac{v}{r} \cos \gamma \]

\[ \dot{\rho} = -g \rho \dot{h} \]

If the quasistatic dynamic model is to be used, equation (24) is replaced with

\[ \dot{v} = 0 \]

and \( v \) is computed from the terminal velocity solution

\[ v = \sqrt{\frac{2 (m + C_{30}) g \left| \sin \gamma \right|}{\overline{v} \left( C_A S + C_D S_D \right)^2}} + C_{102} \]

DTAB Analysis

**TABLE** is a partitioned matrix, each submatrix containing:

1) $N_1$ - The number of values in the X table;
2) $N_2$ - The number of values in the Y table;
3) The $N_1$ values of the X table;
4) The $N_2$ values of the Y table;
5) The first $N_1$ values of X versus Y;
6) The second $N_1$ values of X versus Y;
7) The last ($= N_2$) $N_1$ values of X versus Y.

Thus, each partition contains $N_1 \times N_2 + N_1 + N_2 + 2$ elements. If $X_1, X_2$ from 3) above are the bounds of X so $X_1 \leq X \leq X_2$ and $Y_1, Y_2$ from 4) above are the bounds of Y so $Y_1 \leq Y \leq Y_2$, then $W_1$ represents $A(I)$ only if $Y = Y_1$ and $W_2$ represents $A(I)$ only if $Y = Y_2$. That is, $W_1$ and $W_2$ are lower and upper bounds of $A(I)$, which are computed according to standard single table lookup schemes. $A(I)$ is then computed by

$$A(I) = \text{FRAC}(2) \times (W_2 - W_1) + W_1$$

as in the standard formulae.

ECLIP Analysis

Subroutine ECLIP transforms the standard LTR spacecraft state variables $h$, $v$, $\gamma$, $\phi + \phi_c$, $\Omega_c$, and $i_c$ to planetocentric ecliptic Cartesian components $r_x$, $r_y$, $r_z$, $v_x$, $v_y$, and $v_z$. In the figure below $x_c$, $y_c$, $z_c$ denotes the planetocentric ecliptic coordinate system and $R_p$ denotes the planet radius.
The transformation equations are summarized as:

\[
\begin{align*}
    r_x &= r \left( \cos \theta \cos \Omega - \sin \theta \cos \iota \sin \Omega \right) \\
    r_y &= r \left( \cos \theta \sin \Omega + \sin \theta \cos \iota \cos \Omega \right) \\
    r_z &= r \sin \theta \sin \iota \\
    v_x &= v \left( \cos \psi \cos \Omega - \sin \psi \cos \iota \sin \Omega \right) \\
    v_y &= v \left( \cos \psi \sin \Omega + \sin \psi \cos \iota \cos \Omega \right) \\
    v_z &= v \sin \theta \sin \iota
\end{align*}
\]

where

\[
\begin{align*}
    r &= R_p + h, \\
    \theta &= \phi + \phi_e, \\
    \psi &= \phi + \phi_e - \gamma + \frac{\pi}{2}.
\end{align*}

ELCAR Analysis

ELCAR transforms the standard conic elements of a massless point referenced to a gravitational body to Cartesian position and velocity components with respect to that body.

Let the gravitational constant of the body be denoted \( u \) and the given conic elements \((a, e, i, \omega, \Omega, f)\). The semilatus rectum \( p \) is

\[
p = a (1 - e^2) . \tag{1}
\]

Then the magnitude of the radius vector is given by

\[
r = \frac{p}{1 + e \cos f} . \tag{2}
\]

The unit vector in the direction of the position vector is

\[
\begin{align*}
  u_x &= \cos (\omega + f) \cos \Omega - \cos i \sin (\omega + f) \sin \Omega \\
  u_y &= \cos (\omega + f) \sin \Omega + \cos i \sin (\omega + f) \cos \Omega \\
  u_z &= \sin (\omega + f) \sin i 
\end{align*} \tag{3}
\]

The position vector \( \mathbf{r} \) is therefore

\[
\mathbf{r} = ru \mathbf{u} . \tag{4}
\]

The velocity vector \( \mathbf{v} \) is given by

\[
\begin{align*}
  v_x &= \sqrt{\frac{u}{p}} [(e + \cos f)(-\sin \omega \cos \Omega - \cos i \sin \Omega \cos \omega) \\
       &\quad - \sin f (\cos \omega \cos \Omega - \cos i \sin \Omega \sin \omega)] \\
  v_y &= \sqrt{\frac{u}{p}} [(e + \cos f)(-\sin \omega \sin \Omega + \cos i \cos \Omega \cos \omega) \\
       &\quad - \sin f (\cos \omega \sin \Omega + \cos i \cos \Omega \sin \omega)] \\
  v_z &= \sqrt{\frac{u}{p}} [(e + \cos f) \sin i \cos \omega - \sin f \sin i \sin \omega] . \tag{5}
\end{align*}
\]

The conic time from periapsis \( t_p \) is computed from different formulae, depending on the sign of the semimajor axis. For \( a > 0 \)
(elliptical motion)

\[ t_p = \sqrt{\frac{a^3}{\mu}} \left( E - e \sin E \right) \]

\[ \cos E = \frac{e + \cos f}{1 + e \cos f} \quad \sin E = \frac{\sqrt{1 - e^2} \sin f}{1 + e \cos f} . \quad (6) \]

For \( a < 0 \) (hyperbolic motion), the time from periapsis is

\[ t_p = \sqrt{\frac{a^3}{\mu}} \left( e \sinh H - H \right) \]

\[ \tanh \frac{H}{2} = \sqrt{\frac{e - 1}{e + 1}} \tan \frac{f}{2} . \quad (7) \]

**SET/COMMON--- CARGOR CONEL**

**LOADED --- AU PI PMU RAD TM**
Subroutine EPHEM computes the heliocentric ecliptic position and velocity components of an arbitrary planet at a given Julian date. The elements are referred to the mean equinox and ecliptic of date except for Pluto. The time interval from the epoch is denoted by T when measured in Julian centuries of 36,525 ephemeris days, by \( D = 3.6525 \ T \) when measured in units of 10,000 ephemeris days. Times are measured with respect to the epoch 1900 January 0.5 E.T. = J.D. 2415020.0. Angular relations are expressed in radians.

The first step in this process consists of computing the six mean orbital elements of the planet using standard ephemeris polynomials. The six orbital elements are semimajor axis \( a \), eccentricity \( e \), inclination \( i \), longitude of the ascending node \( \Omega \), argument of periapsis \( \omega \), and mean anomaly \( M \). Kepler's equation

\[
M = E - e \sin E
\]

is then solved iteratively to determine the eccentric anomaly \( E \). Subsequent computations are basic conic manipulations:

\[
\begin{align*}
p &= a (1 - e^2) \\
r &= a (1 - e \cos E) \\
v &= \sqrt{\frac{2}{\mu} - \frac{1}{a}} \\
\cos f &= \frac{p - r}{er} \\
\sin f &= \sqrt{1 - \cos^2 f} \cdot \text{sgn} (\sin E) \\
\cos \gamma &= \frac{\sqrt{\mu p}}{rv} \\
\sin \gamma &= \sqrt{1 - \cos^2 \gamma} \cdot \text{sgn} (\sin E) \\
\omega &= \omega - \Omega.
\end{align*}
\]

The heliocentric ecliptic position and velocity components of the planet are then

\[
\begin{align*}
\dot{r} &= r_x \hat{i} + r_y \hat{j} + r_z \hat{k} \\
r_x &= r \cos (\omega + f) \cos \Omega - r \sin (\omega + f) \sin \Omega \cos i \\
r_y &= r \cos (\omega + f) \sin \Omega + r \sin (\omega + f) \cos \Omega \cos i \\
r_z &= r \sin (\omega + f) \sin i \\
\dot{v} &= \frac{v}{r} [(\dot{\omega} \times \dot{r}) \cos \gamma + \dot{r} \sin \gamma]
\end{align*}
\]

where \( \dot{\omega} = (\sin i \sin \Omega) \hat{i} - (\sin i \cos \Omega) \hat{j} + (\cos i) \hat{k} \).

USED/COMM--- INM NODEM
Subroutine EQUATR computes the coordinate transformation matrix $A$ from geocentric equatorial to planetocentric equatorial coordinates. Matrix $A$ is computed from

$$A = A_1 A_2$$

where $A_2$ is the coordinate transformation matrix from geocentric equatorial to geocentric ecliptic coordinates and is given by

$$A_2 = \begin{bmatrix} 1 & 0 & 0 \\ 0 & \cos \varepsilon & \sin \varepsilon \\ 0 & -\sin \varepsilon & \cos \varepsilon \end{bmatrix}$$

Matrix $A_1$ is the coordinate transformation matrix from geocentric ecliptic to planetocentric equatorial coordinates. The derivation of $A_1$ is summarized below.

The coordinate transformation $A_1$ is defined by

$$A_1 = [\hat{X} | \hat{Y} | \hat{Z}]^T$$

where $\hat{X}$, $\hat{Y}$, and $\hat{Z}$ are unit vectors aligned with the planetocentric equatorial coordinate axes and referenced to the geocentric ecliptic coordinate system. Unit vector $\hat{Z}$ is aligned with the planet pole. Unit vector $\hat{X}$ lies along the intersection of the planet equatorial and orbital planes and points at the planet vernal equinox. Unit vector $\hat{Y}$ completes the orthogonal triad and is given by

$$\hat{Y} = \hat{Z} \times \hat{X}.$$ 

It remains to obtain expressions for $\hat{X}$ and $\hat{Z}$. Let $\hat{N}$ denote the unit vector normal to the planet orbital plane, and let $\hat{P}$ denote the unit vector aligned with the planet polar axis. Then

$$\hat{Z} = \hat{P}$$

and

$$\hat{X} = \frac{\hat{P} \times \hat{N}}{|\hat{P} \times \hat{N}|}$$
The unit vector \( \hat{N} \), referred to the ecliptic coordinate system, is given by

\[
\hat{N} = \begin{bmatrix} \sin i \sin \Omega \\ -\sin i \cos \Omega \\ \cos i \end{bmatrix}
\]  

(7)

where \( i \) and \( \Omega \) are the inclination and longitude of the ascending node, respectively, of the planet orbital plane. The unit vector \( \hat{P} \), referred to the ecliptic system, is given by

\[
\hat{P} = \begin{bmatrix} \cos \alpha \cos \delta \\ \cos \epsilon \sin \alpha \cos \delta + \sin \epsilon \sin \delta \\ -\sin \epsilon \sin \alpha \cos \delta + \cos \epsilon \sin \delta \end{bmatrix}
\]  

(8)

where \( \alpha \) and \( \delta \) are the right ascension and declination, respectively, of the planet polar axis relative to the geocentric equatorial coordinate system, and \( \epsilon \) is the obliquity of the ecliptic. Expressions for \( \alpha \) and \( \delta \) for each planet were obtained from JPL TR 32-1306, Constants and Related Information for Astrodynamie Calculations, 1968, by Melbourne, et al.

The use of subroutine EQUATR is restricted to planets other than the earth and moon.
Compute the coordinate transformation matrix $A$.

Call EPHM to compute the orbital elements of the target planet.

Target planet = moon?

Yes

Target planet = earth?

No

Compute the obliquity of the ecliptic $\varepsilon$.

Compute coordinate transformation matrix $A_2$.

Target planet = earth?

Yes

Compute the right ascension $\alpha$ and declination $\delta$ of the target planet pole.

Compute the coordinate transformation matrix $A_1$.

Compute the coordinate transformation matrix $A$.

RETURN

Earth and moon cannot be treated with EQUATR. Write error message.

SET/COMMON: ELEMENTS FROM COMMON/COVARP/.

ENTRY PNT: FILM, FILTER, PREM, QUASI, SIMM.
FILTER Analysis

The augmented state deviation vector is defined as

\[ x^A = \begin{bmatrix} x \\ q \\ u \\ v \\ w \end{bmatrix} \]  

where
- \( x \) = basic state vector,
- \( q \) = vector of solve-for parameters,
- \( u \) = vector of dynamic consider parameters,
- \( v \) = vector of measurement consider parameters,
- \( w \) = vector of dynamic/measurement consider parameters.

The dynamic model for the linearized equations has the form

\[ x_{k+1}^A = \phi_{k+1,k}^A x_k^A + Q_{N,k+1,k}^A \]  

where the augmented state transition matrix, \( \phi_{k+1,k}^A \), may be partitioned as

\[ \phi^A = \begin{bmatrix} \phi & \psi & \theta & u & v & w \\ 0 & I & 0 & 0 \\ 0 & 0 & I & 0 & 0 \\ 0 & 0 & 0 & I \\ 0 & 0 & 0 & 0 & I \end{bmatrix} . \]  

Henceforth the state transition matrix partitions will be written without stating the associated time interval, which will always be assumed to be \([t_k, t_{k+1}]\). The augmented dynamic noise vector \( Q_{N,k+1,k}^A \) may be partitioned.
where the associated time interval is again understood to be $[t_k, t_{k+1}]$.

The measurement deviation vector is related to the augmented state deviations through the relation

$$y_k = H_k^A x_k^A + \eta_k$$

where the augmented measurement matrix may be partitioned as

$$H_k^A = [H M 0 L G]$$

and $\eta_k$ is the measurement noise.

The augmented state covariance matrix may be written in partitioned form as

$$P^A = \begin{bmatrix}
P & C_{xq} & C_{xu} & C_{xv} & C_{xw} \\
T & Q & C_{qu} & C_{qv} & C_{qw} \\
T & C_{xu} & D_u & 0 & 0 \\
T & C_{xv} & 0 & D_v & 0 \\
T & C_{xw} & 0 & 0 & D_w \\
\end{bmatrix}.$$  (6)

Prediction and filtering equations for the partitions appearing in the previous equations will be written below. Equations need not be written for the consider parameter covariances $D_u, D_v,$ and $D_w$ since they remain constant. A minus superscript on a covariance partition indicates its value immediately prior to processing a
measurement; a plus superscript indicates its value immediately after processing a measurement. To improve numerical accuracy and to avoid nonpositive definite covariance matrices, $P$ and $Q$ are symmetrized after the computations.

At entry point FILM, the following computations are made. First, the measurement residual covariance matrix

$$J_{k+1} = H_A^{k+1} P A^{k+1} H_A^{k+1} + R_{k+1}$$

$$= H_{k+1} \left\{ P_{k+1} H_{k+1}^T + C_{xq_{k+1}}^T M_{k+1} + C_{xv_{k+1}}^T L_{k+1}^T + C_{xw_{k+1}}^T C_{k+1} \right\}$$

$$+ M_{k+1} \left\{ C_{xq_{k+1}}^T H_{k+1} + C_{xv_{k+1}}^T Q_{k+1} M_{k+1} + C_{xw_{k+1}}^T L_{k+1} + C_{xw_{k+1}}^T G_{k+1} \right\}$$

$$+ L_{k+1} \left\{ C_{xq_{k+1}}^T H_{k+1}^T + C_{xv_{k+1}}^T Q_{k+1} M_{k+1}^T + D_v L_{k+1}^T \right\}$$

$$+ G_{k+1} \left\{ C_{xv_{k+1}}^T H_{k+1} + C_{xw_{k+1}}^T Q_{k+1} M_{k+1}^T + D_w L_{k+1} \right\} + R_{k+1}.$$  \( \text{(7)} \)

The Kalman gain matrix

$$K_{k+1}^A = P_{k+1} A^T (J_{k+1})^{-1} = \begin{bmatrix} K_{1, k+1} \\ K_{2, k+1} \\ K_{3, k+1} \\ K_{4, k+1} \\ K_{5, k+1} \end{bmatrix}$$  \( \text{(8)} \)

$$K_{AM}^{k+1} = \begin{bmatrix} K_{1, k+1} \\ K_{2, k+1} \\ 0 \\ 0 \\ 0 \end{bmatrix}.$$  \( \text{(8A)} \)
Only the $K_{1k+1}$ and $K_{2k+1}$ partitions are used,

$$K_{1k+1} = \left\{ p_{k+1}^{-T} H_{k+1}^{-T} + C_{xq_{k+1}}^{-} M_{x_{k+1}}^{-T} + C_{x_{k+1}}^{-} L_{x_{k+1}}^{-T} + C_{xw_{k+1}}^{-} G_{k+1}^{-T} \right\} (J_{k+1})^{-1}$$  (9)

$$K_{2k+1} = \left\{ C_{xq_{k+1}}^{-T} H_{k+1}^{-T} + Q_{k+1}^{-} M_{x_{k+1}}^{-T} + C_{x_{k+1}}^{-} L_{x_{k+1}}^{-T} + C_{xw_{k+1}}^{-} G_{k+1}^{-T} \right\} (J_{k+1})^{-1}$$  (10)

The partitions of the covariance update equation

$$p_{A+}^{A+} = p_{A-}^{A-} - K_{k+1}^{A} H_{k+1}^{A} p_{A-}^{A-}$$  (11)

are given by

$$p_{k+1}^{+} = p_{k+1}^{-} - K_{1k+1}^{-1} \left\{ H_{k+1}^{-1} p_{k+1}^{-} + M_{k+1}^{-1} C_{xq_{k+1}}^{-T} + L_{k+1}^{-1} C_{xv_{k+1}}^{-T} + C_{x_{k+1}}^{-1} C_{xw_{k+1}}^{-} \right\}$$  (12)

$$C_{xq_{k+1}}^{+} = C_{xq_{k+1}}^{-} - K_{1k+1}^{-1} \Delta_{k+1}$$  (13)

$$C_{xu_{k+1}}^{+} = C_{xu_{k+1}}^{-} - K_{1k+1}^{-1} \Gamma_{k+1}$$  (14)

$$C_{xv_{k+1}}^{+} = C_{xv_{k+1}}^{-} - K_{1k+1}^{-1} \Omega_{k+1}$$  (15)

$$C_{xw_{k+1}}^{+} = C_{xw_{k+1}}^{-} - K_{1k+1}^{-1} \Lambda_{k+1}$$  (16)

$$Q_{k+1}^{+} = Q_{k+1}^{-} - K_{2k+1}^{-1} \Delta_{k+1}$$  (17)

$$C_{qu_{k+1}}^{+} = C_{qu_{k+1}}^{-} - K_{2k+1}^{-1} \Gamma_{k+1}$$  (18)

$$C_{qv_{k+1}}^{+} = C_{qv_{k+1}}^{-} - K_{2k+1}^{-1} \Omega_{v_{k+1}}$$  (19)

$$C_{qw_{k+1}}^{+} = C_{qw_{k+1}}^{-} - K_{2k+1}^{-1} \Lambda_{w_{k+1}}$$  (20)
where
\[
\Delta_{k+1} = H_{k+1} C_{xq_{k+1}}^- + M_{k+1} Q_{k+1}^- + L_{k+1} C_{qv_{k+1}}^- + G_{k+1} C_{qw_{k+1}}^-
\] (21)

\[
\Gamma_{k+1} = H_{k+1} C_{xu_{k+1}}^- + M_{k+1} C_{qu_{k+1}}^-
\] (22)

\[
\Omega_{k+1} = H_{k+1} C_{xv_{k+1}}^- + M_{k+1} C_{qv_{k+1}}^- + L_{k+1} D_v
\] (23)

\[
\Lambda_{k+1} = H_{k+1} C_{xw_{k+1}}^- + M_{k+1} C_{qw_{k+1}}^- + G_{k+1} D_w
\] . (24)

The remaining partitions, \(D_u, D_v, D_w\), are not updated since they are associated with consider parameters.

At entry point PREM, the following computations are made. First the partitions of the covariance prediction equation
\[
p_{A-}^{k+1} = p_{A+}^{k+1} \phi_{k+1, h}^{k+1, h}
\] (25)

are given by
\[
P_{k+1} = \left\{ \phi_{A+}^{k+1} + \psi_{A+}^{k+1} + \theta_{u}^{T} u_{k} + \theta_{w}^{T} w_{k} \right\} \phi_{T}^{k+1} \bigg| \begin{array}{l}
C_{xq_{k+1}}^- \psi_{T}^{k+1} + C_{xu_{k+1}}^- \theta_{u}^{T} u_{k} + C_{xw_{k+1}}^- \theta_{w}^{T} w_{k} \\
\end{array}
\] (26)

\[
C_{xq_{k+1}}^- = \phi_{C}^{+}_{xq_{k}} + \psi_{C}^{+}_{xq_{k}} + \theta_{u}^{T} u_{k} + \theta_{w}^{T} w_{k}
\] (27)

\[
C_{xu_{k+1}}^- = \phi_{C}^{+}_{xu_{k}} + \psi_{C}^{+}_{xu_{k}} + \theta_{u}^{T} u_{k}
\] (28)

\[
C_{xv_{k+1}}^- = \phi_{C}^{+}_{xv_{k}} + \psi_{C}^{+}_{xv_{k}}
\] (29)

\[
C_{xw_{k+1}}^- = \phi_{C}^{+}_{xw_{k}} + \psi_{C}^{+}_{xw_{k}} + \theta_{w}^{T} w_{k}
\] . (30)
Since all solve-for and consider parameter deviations are assumed to be constant between measurements, the following relations are used:

\[ Q_{k+1}^- = Q_k^+ \]  

(31)

\[ C_{qu_{k+1}}^- = C_{qu_k}^+ \]  

(32)

\[ C_{qv_{k+1}}^- = C_{qv_k}^+ \]  

(33)

\[ C_{qw_{k+1}}^- = C_{qw_k}^+ \]  

(34)

Again since the solve-for and consider parameter deviations are constant between measurements, only the basic state partition of the estimated state prediction or propagation equation is required:

\[ \Tilde{x}_{k+1}^- = \Tilde{x}_k^+ + \psi_q^+ \]  

(35)

At entry point SIMM, the following computations are made. First the measurement residual is computed as:

\[ \epsilon_{k+1} = y_{k+1}^a - \{ \hat{y}_{k+1} + H_{k+1} \Tilde{x}_{k+1}^- + M_{k+1} \delta_{k+1}^- \} \] .

Then the partition of the estimated state update equation:

\[ \Tilde{x}_{k+1}^{A+} = \Tilde{x}_{k+1}^{A-} + \psi_{Am} \epsilon_{k+1} \]

where

\[ K_{k+1}^{Am} = \begin{bmatrix} K1 \\ K2 \\ 0 \\ 0 \\ 0 \end{bmatrix} \]
is given by

\[ \hat{x}_{k+1}^+ = \hat{x}_{k+1}^- + K_{1k+1} e_{k+1}^- \]

\[ \hat{q}_{k+1}^+ = \hat{q}_{k+1}^- + K_{2k+1} e_{k+1}^- \]

At entry point QUASI, the computations associated with a quasi-linear filtering event are made

\[ \hat{x}^+ = \hat{x}^- + \hat{x}^- \]

\[ \hat{q}^+ = \hat{q}^- + \hat{q}^- \]

\[ \hat{x}^+ = 0 \]

\[ \hat{q}^+ = 0 \]

where the superscript - indicates the nominal value of the state or solve-for parameter. The + superscript indicates the value after the quasi-linear filtering event, whereas the - superscript indicates the value before.

The flow of the FILTER subroutine is illustrated.
\( J_{k+1} = H_{k+1}^A R_{k+1} + H_{k+1}^T (J_{k+1})^{-1} \)

\( P_{k+1} = P_k + H_k^T (J_k)^{-1} \)

\( H_{k+1} = H_k - H_k^T H_k J_k^{-1} \)

\( A_{k+1}^+ = P_{k+1} - A H_{k+1} - H_{k+1} P_{k+1}^T A^+ \)

\( A_{k+1}^- = A_{k+1} - A \cdot P_{k+1} - P_{k+1}^T A_{k+1} \)

\( X_{k+1}^- = X_k^A - X_{k+1}^A \)

\( Y_{k+1} = Y_k^A - X_{k+1} \)

\( A_{k+1}^+ = A_{k+1}^+ + A_{k+1}^+ \)

\( X_{k+1}^- = X_{k+1}^- + X_{k+1}^- \)

\( \hat{x}^+ = \hat{x}^- + \hat{x}^- \)

\( \hat{q}^+ = \hat{q}^- + \hat{q}^- \)

\( \hat{x}^+ = 0 \)

\( \hat{q}^+ = 0 \)

FILTER Flow Chart
SUBROUTINE GEOG

PURPOSE: COMPUTE THE CO-ORDINATE TRANSFORMATION FROM PLANETOCENTRIC EQUATORIAL PLANE TO PLANETOCENTRIC GEOGRAPHICAL PLANE

ENTRY PARAMETERS:
NP	TARGET PLANET CODE
D	JULIAN DATE, EPOCH JANUARY 0, 1900
EQGF	CO-ORDINATE TRANSFORMATION FROM PLANETOCENTRIC EQUATORIAL TO PLANETOCENTRIC GEOGRAPHICAL

LOCAL SYMBOLS:
ED	JULIAN DATE, EPOCH 4713 B. C.
DGTR	CONVERTS DEGREES TO RADIANS
VEHA	HOUR ANGLE OF THE VERNAL EQUINOX
GEØG Analysis

Subroutine GEØG computes the coordinate transformation from planetocentric equatorial to planetocentric geographical coordinate for an arbitrary planet. The geographical coordinate system is defined so the z-axis is aligned with the planet spin vector and the x-axis lies in the plane of the planet prime meridian. The prime meridian is oriented relative to the planet vernal equinox T by the hour angle of the vernal equinox V. In the figure shown below the xyz axes define the planetocentric geographical system, the $x_{eq} \ y_{eq} \ z_{eq}$ axes define the planetocentric equatorial system.

The expressions used to evaluate V for each planet were obtained from JPL TR32-1306, Constants and Related Information for Astrodynamical Calculations, 1968, by Melbourne et al.
The coordinate transformation matrix is given by

$$A = \begin{bmatrix}
\cos V & \sin V & 0 \\
-sin V & \cos V & 0 \\
0 & 0 & 1
\end{bmatrix}.$$ 

Thus

$$\mathbf{x}_{\text{geographical}} = A \mathbf{x}_{\text{equatorial}}.$$ 

GEØG Flow Chart

1. ENTER
2. Convert Julian date, epoch 1900, to Julian date, epoch 4713 BC
3. Compute the known angle $V$ of the vernal equinox for the specified planet
4. Reduce $V$ to modulo 360
5. Compute coordinate transformation matrix $A$
6. RETURN
SUBROUTINE GHA

PURPOSE: Computes Greenwich Hour Angle of the Vernal Equinox

ENTRY PARAMETERS:
- DATEJ: Julian date, epoch at January 0, 1900
- GH: Greenwich Hour Angle of the Vernal Equinox in radians

LOCAL SYMBOLS:
- EOMEG: Earth rotation rate in degrees/day
- REFJD: Julian date of 1950 January 1, epoch at 4713 B.C.
- TSTAR: Julian date, epoch at 1950 January 1
- ID: Integer part of TSTAR
- D: ID converted to real
- TFRAC: Fractional part of TSTAR
Subroutine GHA computes the Greewich hour angle GHA of the vernal equinox at a given Julian date (JD), epoch 1900 January 0\(^d\) 12\(^h\), using

\[
GHA = 100.0755426 + 0.985647346 \ d + 2.9015 \times 10^{-13} \ d^2 + \omega t
\]

where

- \(\omega = \text{Earth's rotation rate (deg/day)}\)
- \(d = \text{integer part of } T^*\)
- \(t = \text{fractional part of } T^*\)

and

\(T^* = \text{Julian date, epoch 1950 January } 1^d \ 0^h\).

The Julian dates relative to epochs 1900 and 1950 are related as follows:

\[
T^* = JD + 2415020.0 - 2433282.5
\]

where

- 2415020.0 = 1900 January 0\(^d\) 12\(^h\) referenced to 4713 BC January 0\(^d\) 12\(^h\)

and

- 2433282.5 = 1950 January 1\(^d\) 0\(^h\) referenced to 4713 BC January 0\(^d\) 12\(^h\)
SUBROUTINE HMM

PURPOSE: CONTROLS COMPUTATION OF OBSERVATION MATRIX PARTITIONS

SUBROUTINES CALLED: JACORN

COMMONS: TRAJ, COVARP, INTCOM

LOCAL SYMBOLS:

EXTERNAL VARIABLE NAME USED BY JACORN FOR COMPUTATION OF MEASUREMENT VALUES

USED/COMMON--- C

LSTQ LISTS LISTV LISTW LM MM

NM NO NS NV NW P
Subroutine HMM is an executive routine that controls the computation of the partitions of the observation matrix. The matrix partitions are all computed by numerical differencing, which is carried out by calling JACORN. The indices of the variables to be perturbed to compute columns of the observation matrix are stored in LISTS, LISTQ, LISTV, and LISTW for the H, M, L, and G partitions, respectively. The size of the perturbations are governed by the variance of the parameters that are stored in arrays P, Q, DV and DW. The unperturbed measurement values are stored in the MEAS array.

The linearized measurement equation in partitioned form is given by

\[ y = \begin{bmatrix} H & M & 0 & L & G \end{bmatrix} \begin{bmatrix} x \\ q \\ u \\ v \\ w \end{bmatrix}. \]
SUBROUTINE INVPO?

PURPOSE: INVERTS A POSITIVE DEFINITE SYMMETRIC MATRIX

ENTRY PARAMETERS

A: A WORKING MATRIX (N X N)
J: VECTOR OF DIAGONAL ELEMENTS OF AN N X N MATRIX
L: LOWER TRIANGULAR MATRIX WITH ONES ON THE DIAGONAL
N: DIMENSION OF S
S: POSITIVE DEFINITE SYMMETRIC MATRIX TO BE INVERTED
SI: INVERSE OF S

SUBROUTINES CALLED: EXIT MATOUT

LOCAL SYMBOLS

I: INDEX
I1: I - 1
J: INDEX
J1: J - 1
J11: J + 1
K: INDEX
SUM: INTERMEDIATE SUM
INVPD2 Analysis

This subroutine inverts a positive definite symmetric matrix by a modified Cholesky method. Let S be the positive definite matrix to be inverted. The method proceeds by determining matrices L and D so L is lower triangular with 1s on the diagonal, D is diagonal, and

\[ S = LD L^T \]

L and D may be found recursively from the relations

\[
d_j = s_{jj} - \sum_{k=1}^{j-1} d_k \kappa_{jk}^2
\]

\[
\kappa_{ij} = \left[ \frac{\sum_{k=1}^{j-1} d_k \kappa_{ik} \kappa_{jk}}{d_j} \right], \quad i > j
\]

The inverse of S is then given by

\[ S^{-1} = (L^T)^{-1} D^{-1} L^{-1} \]
Compute the L and D matrices recursively

Invert L

Compute

\[ S^{-1} = (L^T)^{-1} D^{-1} L^{-1} \]

LOADED --- TMLAST
MEAZUR Analysis

Subroutine MEAZUR is the executive measurement processing subroutine. It controls the computation of all quantities required to generate a new estimate of the state and the associated error covariance matrix partitions. Subroutine MEAZUR also computes the actual angle of attack measurement for mode A and the actual accelerometer measurements for mode B. Unlike other measurement types available in the LTR program, the actual values of these two measurement types cannot be computed in the data generator since they are computed from information generated in the preprocessor, which is always run after the data generator has been run.
Increment the measurement counter NMEAS

Increment the measurement print counter if the time interval since the last measurement exceeds 0.001 seconds

Set TMLAST to the current measurement time

Call GBSM to compute the nominal value of the measurement and the measurement noise covariance matrix

Call HMM to compute all observation matrix partitions

Call FILM to update all covariance matrix partitions immediately following the measurement processing

If measurement is an angle of attack measurement, call ATTACK to compute the actual angle of attack measurement

If measurement is an accelerometer measurement, obtain the actual accelerometer measurement from the appropriate elements of the AA array.

Call SIMM to update all estimates immediately following the measurement processing

RETURN

SET/COMMON: IAA  IEND  TEND
NEXTAA Analysis

Subroutine NEXTAA reads from file 16 the smoothed accelerometer and gyro coefficients (as determined by subroutine PREPROS) required to cover the time interval to the next event.

The first time NEXTAA is called, IEND is zero, which causes the coefficients for time zero to be read. Thereafter, the coefficients for the beginning of the interval are obtained from the last point of the previous interval.

Subroutine NEXTAA also determines the number NG of records to be read to cover the interval from TC through TEND. However, if an end-of-file is encountered while these coefficients are being read, then the number IEND of coefficient records read is adjusted and TEND is reset to correspond to the last record read.

NEXTIM Analysis

Subroutine NEXTIM computes the next event time and the time difference between the current time and the next event time. The logic proceeds as follows:

a. If the event schedule buffer has been used up, as determined by MCNTR = 250, then another 250 elements of the schedule is read from file 20 and MCNTR is set to zero.

b. Current time TC is updated, schedule index MCNTR is incremented, and the time TEND and type TYPE of the next event are taken from the schedule.

c. If the current time TC is equal to the time QST to change to the quasi-static dynamic model, then QSMCHG is set to true and the integration step size is changed to the quasi-static integration step size.

d. The entry phase IPHAS is determined by comparing current time TC to the time of parachute deployment TD and the time of parachute deployment TD and the time of parachute release TR. The vehicle parameters MASS, RI, SA, and DIA are then selected for this phase.
SUBROUTINE NORMN7

PURPOSE: COMPUTES RANDOM VARIABLES FROM A DISTRIBUTION WITH ZERO MEAN AND STANDARD DEVIATION ONE

ENTRY PARAMETERS
SIGMA
OUTPUT RANDOM VARIABLE

LOCAL SYMBOLS
A SUM OF THE VALUES OF RR
N INTEGER PORTION OF SS MULTIPLIED BY 1.E-7
NX CONTROLS START OF RANDOM SELECTION
RR DIFFERENCE OF SS AND N
SS INTERMEDIATE SUM OF SS, WW, YY, AND ZZ
WW SEED VALUE FOR BUILDING SS
YY SEED VALUE FOR BUILDING SS
ZZ SEED VALUE FOR BUILDING SS

LOADED --- NX
NORMNZ Analysis

NORMNZ builds a random number from a distribution with a mean of zero and standard deviation of one. From preset seed values (NX = 0) or from values stored in a previous call (NX = 1), the variables WW, YY, ZZ are always positive and, when summed with SS, yield a number X such that X is in the open interval between 1.E + 7 and 1.E + 8, with occasional (i.e., greater than 3 sigma) values outside this interval. RR is then found as

RR = X modulo (integer portion of X)

so that RR is normally distributed over (0,1). Finally,

\[
\text{SIGMA} = \left( \sum_{i=1}^{12} \text{RR} \right) - 6.
\]
SUBROUTINE NTM

OBSM Analysis

Subroutine OBSM has three functions:

a. Compute nominal measurement for each measurement type.

b. Compute perturbed measurement for use in the numerical differencing computation of observation matrix partitions.

c. Compute measurement noise covariance matrix for each measurement type.

The computation of nominal measurements in OBSM is very similar to the computation of actual measurements in OBSM1. The equations used to compute nominal radar altimeter, stagnation pressure, stagnation temperature, range, and range-rate measurements have the same form as those used to compute the corresponding actual measurements in OBSM1 and will not be discussed further (see subroutine OBSM1 for details).

The $C_j$ in subroutine OBSM1 represent actual errors. In OBSM, however, the $C_j$ represent both nominal and perturbed values of the errors. The $C_j$ are perturbed only when OBSM is being used in the numerical differencing computation of observation matrix partitions.

If a measurement is being processed, OBSM also computes the measurement noise covariance matrix. The equations used to compute the measurement noise covariance matrix for each measurement type are summarized in section 3.2 of the Analytic Manual.

Accelerometer and angle of attack measurements require further discussion since their treatment in OBSM differs from their treatment in OBSM1. Accelerometer measurements are used in the filter observation model only for the mode B reconstruction process. In mode A accelerometer measurements are treated as part of the dynamic model and all computations relating to mode A accelerometer measurements are performed in subroutine DERIVE; none are performed in OBSM. The following equations are used in OBSM to compute the accelerometer measurements for mode B:
\[ a_x = \left( \frac{A}{m + C_{30}} \cos (\delta_1 + C_{55}) - \frac{N}{m + C_{30}} \sin (\delta_1 + C_{55}) \right) C_{51} + C_{52} \]

\[ a_z = \left( \frac{A}{m + C_{30}} \sin (\delta_2 + C_{56}) + \frac{N}{m + C_{30}} \cos (\delta_2 + C_{56}) \right) C_{53} + C_{54} \]

where \( A \) and \( N \) are the axial and normal aerodynamic forces (including effect of parachute), \( \delta_1 \) and \( \delta_2 \) are misalignment angles, and \( m \) is vehicle mass. Bias terms \( C_{30}, C_{52}, C_{54}, C_{55} \), and \( C_{56} \) are readily identifiable, as are scale factors \( C_{51} \) and \( C_{53} \).

The angle of attack measurement, which is currently defined only for mode A, is defined as the angle of attack \( \alpha \) computed in subroutine DERIVE.

Prior to computing any measurement, ØBSM calls the relevant dynamic model subroutines (DERIVE, if mode A; DERIV3 and ATMSET, if mode B) to ensure that all dynamic quantities have the proper values at the time of the measurement, since many of these quantities are required in the computation of measurements.

OBSM1-1

OBSM1 Analysis

Subroutine OBSM1 computes the actual measurements for most measurement types available in the LTR program and incorporates the effects of all error sources except noise into these measurements. Those measurements not computed in OBSM1 are the quantized VRU and ARU measurements, which are computed in subroutine SENSOR. The equations used to compute the actual measurements in OBSM1 are summarized below.

If the terrain height model is not used, the radar altimeter measurement is given by

\[ h = C_71 h + C_72 \] (1)

where \( h \) is the vehicle altitude, \( C_71 \) is the altimeter scale factor, and \( C_72 \) is the altimeter bias. If the terrain height model is used, the radar altimeter measurement is defined as the shortest distance between the vehicle and the planet terrain within the altimeter sweep angle \( 2\eta \). The altimeter measurement is computed from

\[ h = C_71 \left[ \left( h + R^2_p \right) + \tilde{f} \right]^{\frac{1}{2}} + C_72 \] (2)

where \( \tilde{f} \) is the minimum value of

\[ f = W^2 - 2W(h + R_p) \cos (\tilde{\phi} - \phi) \] (3)

with respect to \( \tilde{\phi} \), and is found using a direct search technique. For more details see section 2.4 of the Analytic Manual.

Unquantized accelerometer (VRU) and rate gyro (ARU) measurements, which are currently not used in the LTR reconstruction program, are given by

\[ \dot{v}_x = a_x \cos \delta_1 - a_z \sin \delta_1 \] (4)

\[ \dot{v}_z = a_x \sin \delta_2 + a_z \cos \delta_2 \] (5)

and

\[ \dot{\alpha} = \omega \cos \delta_3 \] (6)
where $\delta_1$, $\delta_2$, and $\delta_3$ are the axial accelerometer, normal accelerometer, and rate gyro misalignment angles, respectively, $\omega$ is the vehicle angular velocity, and $a_x$ and $a_z$ are the axial and normal nongravitational accelerations at the VRU location. These latter accelerations are computed from

$$a_x = a_{xg} - \omega^2 \bar{x} + \omega \bar{z}$$  \hspace{1cm} (7)

$$a_z = a_{zg} - \omega^2 \bar{z} - \omega \bar{x}$$  \hspace{1cm} (8)

where $a_{xg}$ and $a_{zg}$ are the axial and normal nongravitational acceleration at the vehicle cg location, and $\bar{x}$ and $\bar{z}$ denote the offset of the VRU relative to the cg. Scale factor and bias errors for these unquantized measurements are currently undefined.

The stagnation pressure measurement $p_o$ is a function of Mach number regime. If Mach number $M > 3$, then

$$p_o = C_{81} \left[ \frac{1}{\gamma} C_p \rho \frac{v^2}{r} + p \right] + C_{82}$$  \hspace{1cm} (9)

where $\rho$ is the density, $p$ is the ambient pressure, and the coefficient of pressure $C_p$ is given by

$$C_p = 2 - \epsilon$$  \hspace{1cm} (10)

where $\epsilon$ is the ratio of densities in front of an behind the shock wave. Scale factor $C_{81}$ and bias $C_{82}$ are the error terms used in the supersonic regimes. If $1 \leq M < 3$, then $p_o$ is again given by equation (9), but $C_p$ is now given by

$$C_p = \frac{\gamma}{2} \left[ \left( \frac{\gamma + 1}{2} \frac{\gamma - 1}{\gamma + 1} \right) \left( \frac{\gamma + 1}{2\gamma \frac{\gamma - 1}{\gamma + 1} - \gamma + 1} \right) - 1 \right]$$  \hspace{1cm} (11)

where $\gamma$ is the ratio of specific heats. If $M < 1$, then

$$p_o = C_{83} \left[ p \left( 1 + \frac{\gamma - 1}{2} \frac{\gamma}{\gamma - 1} \right) \right] + C_{84}$$  \hspace{1cm} (12)

where $C_{83}$ and $C_{84}$ are the subsonic scale factor and bias errors, respectively.
The stagnation temperature measurement is computed from

\[ T_o = C_{g1} \left[ T \left( 1 + \frac{\gamma - 1}{2} M^2 \right) \right] + C_{g2} \]  

(13)

where \( T \) is the ambient temperature and \( C_{g1} \) and \( C_{g2} \) are the scale factor and bias errors, respectively.

Range and range-rate measurements are given by

\[ \rho = | \dot{\rho} | \]  

and

\[ \dot{\rho} = \frac{\rho \cdot \dot{\rho}}{\rho} \]  

respectively, where

\[ \dot{\rho} = \dot{r} + \dot{r}_p - \dot{r}_p - \dot{r}_s \]  

(16)

\[ \dot{\rho} = \dot{r} + \dot{r}_p - \dot{r}_p - \dot{r}_s \]  

(17)

\((\dot{r}, \dot{r}) = \) vehicle state relative to target planet

\((\dot{r}_p, \dot{r}_p) = \) target planet state relative to Sun

\((\dot{r}_s, \dot{r}_s) = \) Earth state relative to Sun

\((\dot{r}_s, \dot{r}_s) = \) tracking station state relative to Earth.

All vectors are assumed to be referred to an ecliptic coordinate system. The geocentric ecliptic coordinates of the \(i\)-th tracking station state are given by

\[ x_s = (R_o + h_i) \cos \theta_i \cos G_i \]  

(18)

\[ y_s = (R_o + h_i) \left[ \cos \theta_i \cos \epsilon \sin G_i + \sin \theta_i \sin \epsilon \right] \]  

(19)

\[ z_s = (R_o + h_i) \left[ -\cos \theta_i \sin \epsilon \sin G_i + \sin \theta_i \cos \epsilon \right] \]  

(20)

\[ \dot{x}_s = -\omega_x (R_o + h_i) \cos \theta_i \sin G_i \]  

(21)
\[ \dot{y}_s = \omega_z \left( R_0 + h_i^r \right) \cos \theta_i^r \cos G_i^r \]
\[ z_s = -\omega_i \left( R_0 + h_i^r \right) \cos \theta_i^r \sin \epsilon \cos G_i^r \]

where

\[ h_i^r = h_i + C_{108+31} \]
\[ \theta_i^r = \theta_i + C_{109+31} \]
\[ G_i^r = \lambda_i^r + \omega_z \left( t - t_0 \right) + \text{GHA} \left( t_0 \right) \]
\[ \lambda_i^r = \lambda_i + C_{110+31} \]

In these equations, \( R_0 \) denotes the Earth radius; \( h_i \), the altitude of the \( i \)-th station; \( \theta_i \), the latitude; \( \lambda_i \), the longitude; \( \omega_z \), the Earth's angular velocity; \( t \), the current time; \( t_0 \), the initial time; \( \text{GHA} \left( t_0 \right) \), the initial Greenwich hour angle of the vernal equinox; \( \epsilon \), the obliquity of the ecliptic; and \( C_{108+31} \), \( C_{109+31} \), and \( C_{110+31} \), station location errors. A range bias \( C_{63+1} \) is added to the range computed using equation (14), and a range-rate bias \( C_{66+1} \) is added to the range-rate computed using equation (15).

PLANE Analysis

Given the orientation of the entry plane and the \( \phi \) reference line relative to 1 of 3 coordinate systems, subroutine PLANE computes the orientation of the entry plane and the \( \phi \) reference line relative to the remaining two coordinate systems. The orientation of the entry plane is defined by the inclination \( i \) and the longitude of the ascending node \( \Omega \), and the location of the \( \phi \) reference line in the entry plane is defined by \( \phi_{\text{ref}} \) (see subroutine ECLIP).

These quantities are computed relative to the following three coordinate systems: (1) planetocentric ecliptic, (2) planetocentric equatorial, and (3) subsolar orbital plane.

Given \( i \), \( \Omega \), and \( \phi_{\text{ref}} \) relative to one of the three coordinate systems, the unit vector \( \hat{e}_n \) normal to the entry plane and the unit vector \( \hat{e}_r \) aligned with the \( \phi \) reference line can be computed from

\[
\begin{align*}
\hat{e}_n &= \left[ \begin{array}{c}
\sin i \sin \Omega \\
-\sin i \cos \Omega \\
\cos i 
\end{array} \right] \\
\hat{e}_r &= \left[ \begin{array}{c}
\cos \phi_{\text{ref}} \cos \Omega - \sin \phi_{\text{ref}} \cos i \cos \Omega \\
\cos \phi_{\text{ref}} \sin \Omega + \sin \phi_{\text{ref}} \cos i \cos \Omega \\
\sin \phi_{\text{ref}} \sin i
\end{array} \right]
\end{align*}
\]

The coordinate transformations from the given coordinate system to the remaining two coordinate systems are then computed, and \( \hat{e}_n \) and \( \hat{e}_r \) are transformed to these systems.

Denoting the components of the transformed \( \hat{e}_n \) and \( \hat{e}_r \) as

\[
\begin{align*}
\hat{e}_n &= \left( e_{n_x}, e_{n_y}, e_{n_z} \right) \\
\hat{e}_r &= \left( e_{r_x}, e_{r_y}, e_{r_z} \right)
\end{align*}
\]
the angles $i'$, $\Omega'$, and $\phi'_\text{ref}$ defining the entry plane and $\phi$ reference line relative to the new coordinate system can be computed as follows:

$$
\begin{align*}
\Omega' &= \tan^{-1}\left(\frac{e_{n_x}}{-e_{n_y}}\right) \\
i' &= \cos^{-1}\left(e_{n_z}\right) \\
\phi'_\text{ref} &= \tan^{-1}\left(\frac{\sin \phi'_\text{ref}}{\cos \phi'_\text{ref}}\right)
\end{align*}
$$

where

$$
\begin{align*}
\sin \phi'_\text{ref} &= \frac{e_{z}}{\sin i'} \\
\cos \phi'_\text{ref} &= \frac{\hat{e}_z \times \hat{e}_n}{|\hat{e}_z \times \hat{e}_n|}, \hat{e}_r
\end{align*}
$$

and $\hat{e}_z$ is a unit vector aligned with the $z$-axis of the new coordinate system.

Subroutine PLANE also computes the component of the planet inertial angular velocity normal to the entry plane. Letting $\omega_p$ denote the inertial angular velocity of the planet and $\omega_n$, the component normal to the entry plane, we can compute $\omega_n$ as follows:

$$
\omega_n = \omega_p \cdot \hat{e}_\omega \cdot \hat{e}_n
$$

where $\hat{e}_\omega = (0,0,1)$ is a unit vector aligned with the planet spin axis and $\hat{e}_n$ is a unit vector normal to the entry plane. Both unit vectors are referred to the planetocentric equatorial coordinate system.
SUBROUTINE PLOTS

PURPOSE:

Plot \( n \) frames of graphic information on the DD280 plotter from data stored during the trajectory.

ENTRY PARAMETERS:

- **JJ**: Number of elements used in each column of XMAT
- **LABEL**: List of Hollerith names of independent and dependent variables
- **LINEAR**: Logical variable - if true, plot a linear grid with scale numbers
- **LOG**: Logical variable - if true, plot a semi-log grid with x-axis linear
- **N**: Number of frames to be plotted for each independent variable
- **NI**: Number of independent variables (1 or 2)
- **TITLE**: List of Hollerith titles for plot identification

PRINT1 Analysis

The problem identification is printed. If the parachute has been deployed, a message is printed. The current time, actual state vectors, and state derivatives are printed in appropriate output units. The following atmospheric and acceleration terms are printed:

1) Relative velocity (km/s);  11) Mach number (unit free);
2) Stagnation pressure (millibars);  12) Coefficient of moment (unit free);
3) Wind velocity (km/s);  13) Axial force (kg·km/s²);
4) Atmospheric density (kg/km³)  14) Moment (kg·km/s²);
5) Dynamic pressure (millibars)  15) Normal force (kg·km/s²);
6) Angle of attack (degrees);  16) Gravitational acceleration (km/s²);
7) Molecular weight (kg-mol);  17) Center of pressure (km);
8) Coefficient of axial force (unit free);  18) Axial acceleration (km/s²);
9) Stagnation temperature (degrees K);  19) Moment acceleration (km/s²);
10) Coefficient of normal force (unit free);  20) Normal acceleration (km/s²);

Measurement values that do not affect the dynamic equations are also printed.

PRPRWS Analysis

Subroutine PRPRWS is the executive preprocessor subroutine and controls computation of the coefficients used to smooth quantized VRU and ARU data. The operation of PRPRWS is more easily described by including a description of the operation of SMOOT2.

As quantized VRU and ARU data are input into PRPRWS, the quantized data arrays are shifted up and the new data are inserted in the bottom of each array (in SMOOT2) so the arrays hold exactly the five most recent data points. The coefficients of the smoothing quadratic for each data array are determined as follows:

\[
\begin{bmatrix}
    C_1 \\
    C_2 \\
    C_3
\end{bmatrix} = E \cdot \begin{bmatrix}
    q_{k-2} \\
    \vdots \\
    q_{k+2}
\end{bmatrix}
\]

where

\[
E = (B^T B)^{-1} B
\]

\[
B = \begin{bmatrix}
    1 & -2\Delta & 4\Delta^2 \\
    1 & -\Delta & 2\Delta^2 \\
    1 & 0 & 0 \\
    1 & \Delta & 2\Delta^2 \\
    1 & 2\Delta & 4\Delta^2
\end{bmatrix}
\]

\[
\Delta = t_k - t_{k-1}
\]

and the \(C_j\) are the desired coefficients and \(q_{k-2}, \ldots, q_{k+2}\) represent a set of five evenly spaced quantized data points over the time interval \([t_{k-2}, t_{k+2}]\). The matrix \(E\) is computed only twice—at the initial time, and when the dynamic model is changed to the quasistatic dynamic model.
An exception to this scheme occurs when PRPROS is first called. In this case the coefficients are not determined until three data points are available. The two preceding data points are assumed to be zero by the five-point smoother.

Another exception occurs at the end of the process. After all quantized data have been input, the coefficients for the last two time points must still be computed. This is accomplished by calling SMOOTH twice in succession without reading any more quantized data. This is equivalent to assuming that the final two quantized data points are equal to the last quantized data point actually read.
initialize variables

compute E matrix required by SMOOT2

read quantized VRU and ARU data

if EOF is yes, set LASTYM true. call SMOOT2 twice in succession to obtain final set of smoothing quadratic coefficients

if NOT EOF, call SMOOT2 to compute coefficients of smoothing quadratic

if NOT time to change to quasi-static model, set step size to quasi-static step size. set QSMCHG true

return

RKUTDG Analysis

Subroutine RKUTDG is the integration subroutine employed in the LTR data generator program. The algorithm employed is a modified Runge-Kutta method, although the classical fourth-order Runge-Kutta is used to start the integration process.

The system of equations to be integrated has the form

\[ \dot{x} = f(x, t) \]

where \( x \) is the \( n \)-dimensional state vector and \( t \) is the time. The classical fourth-order Runge-Kutta algorithm is summarized as:

\[
\begin{align*}
  k_1 &= h \cdot f(x_k, t_k) \\
  k_2 &= h \cdot f(x_k + \frac{1}{2} k_1, t_k + \frac{h}{2}) \\
  k_3 &= h \cdot f(x_k + \frac{1}{2} h_2, t_k + \frac{h}{2}) \\
  k_4 &= h \cdot f(x_k + k_3, t_k + h) \\
  x_{k+1}^* &= x_k + \frac{1}{6} (k_1 + 2k_2 + 2k_3 + k_4) \\
  x_{k+1} &= x_k + \frac{1}{6} (k_1 + 2k_2 + 2k_3 + k_4)
\end{align*}
\]

where \( h \) is the step size, \( x_k \) is the state at the beginning of the interval, and \( x_{k+1} \) is the state at the end of the interval. The state \( x_k^* \) is required by the modified Runge-Kutta algorithm, which is summarized as:

\[
\begin{align*}
  k_1 &= 1.1 \\
  k_2 &= 3.6 k_1 - 4.2 (x_{k+1}^* - x_k) + 1.6 k_1 \\
  k_3 &= h \cdot f(x_{k+1} + \frac{1}{4} k_1 + \frac{1}{4} k_2, t_{k+1} + \frac{h}{2})
\end{align*}
\]
The advantage of using the modified Runge-Kutta algorithm lies in the fact that the state derivatives need be evaluated only three times, and not four times as is required in the classical Runge-Kutta algorithm.

Another function of RKUTDG is to determine when the vehicle hits the planet surface. The first component of the state $x$, which is the vehicle altitude, is compared with the terrain height. If the two are equal, RKUTDG sets the logical variable HITGND to true, sets TEND to the current time, and returns.

SUBROUTINE RKUTL3

USED/COMMON: DT DXM NE
RKUT3 Analysis

Subroutine RKUT3 is the integration subroutine employed in the mode A reconstruction program. The Runge-Kutta algorithm is the same as that employed in subroutine RKUTDG, except that the classical Runge-Kutta algorithm is used initially whenever RKUT3 is called. This procedure is required since RKUT3 is used to integrate more than one trajectory (original nominal, most recent nominal, and perturbed trajectories) and the local variables that contain information from the last integration may not correspond to the desired trajectory. Because the total interval TEND−TSTART may not be an exact multiple of the step size DT, DT is always adjusted so an exact multiple is attained.

Subroutine RKUT3 also computes the variable XADD, which is used in the computation of the state transition matrix and is defined as

\[ XADD = x_{k+1} - x_k \]

where \( x_k \) and \( x_{k+1} \) are the states at the beginning and end, respectively, of the integration interval.

Subroutine RKUT3 does not have the hit-ground test appearing in RKUTDG since impact occurs when the actual trajectory, not the nominal trajectory, impacts the planet surface.

SCHED-B
SCHED Analysis

SCHED reads and sequences measurements and other events for use by the reconstructor. START, TIMEND, TIMDIF, and CODE(N) are read and written for identification purposes. START, TIMEND, and TIMDIF are converted to integer numbers of integration steps DT and stored. The process is repeated until a START value of 100000. or some other hard-wired value is read. All values read are then separated into groups according to CODE(N) and written with identifiers. Groups of 250 measurements and events are then ordered on time, with TNN and MODE used as storage. TNN and MODE are written on unit 20 for processing by subroutine NEXTIM. The process continues until the final measurement time exceed TF. Whenever a start time exceeds an end time for an event type (start times are incremented), the start time is set to 1.E+10. The last group of times and codes is then written, unit 20 is rewound, and the total number of events and total number of each type of event are printed with identifiers.
If ISTART (low) > IEND (low) set ISTART (low) = 1.E+10

When K = 250, write TMN, MCODE arrays. Set LASTT = TMN(K) go to 60
SUBROUTINE SENSOR

PURPOSE: COMPUTES THE QUANTIZED OUTPUT OF ACCELEROMETER AND GYRO SENSORS

SUBROUTINES CALLED: ALTFILE

COMMONS: TRAJ, SNO, SIZE, DOPPLER

LOCAL SYMBOLS: NALT, DUMMY ARGUMENT

USED/COMMON--- C, XSTEP, TC, ZSTEP, TSTEP, TZERO, XN

WRITTEN --- TQ, THTQ, VXQ, VZQ

SET/COREM--- THTQ, VXQ, VZQ
Subroutine SENSOR computes the quantized output of an accelerometer or gyro sensor. The quantized output of a sensor is found by first modifying the integral of the actual sensor input by appropriate scale factor, $C_s$, and bias, $C_b$, terms. This is then divided by the quantization step size, $\Delta$. The greatest integer contained in this number is the sensor output count. The quantized output is then the output count times the quantization step size.

Let the operation of finding the largest integer contained in a number be designated by enclosing the number in brackets, $\{\}$. The quantized accelerometer outputs are given by

$$V_{ax} = \left\{ \frac{C_{sx} V_x + C_{bx}}{\Delta_x} \right\} \Delta_x$$

$$V_{az} = \left\{ \frac{C_{sz} V_z + C_{bz}}{\Delta_z} \right\} \Delta_z$$

where $V_x$ and $V_z$ are the integrals of the actual accelerations experienced by the x and z accelerometers, respectively. The quantized output of the gyro is found similarly except that the bias term is also integrated,

$$A_{\theta q} = \left\{ \frac{C_{s\theta} A_\theta + C_{b\theta} t}{\Delta_\theta} \right\} \Delta_\theta$$

where $A_\theta$ is the integral of the actual angular rate experienced by the gyro and $t$ is the time since the instrument was last initialized.
SUBROUTINE SETPLT

PURPOSE: Initializes plot variables and reads plotting namelist

SUBROUTINES CALLED: ALTFULL INIT280

COMMONS: INTCOM LOGCOM

LOCAL SYMBOLS:
- I: INDEX
- J: INDEX AND LOGICAL DISK FILE NUMBER
- NALT: DUMMY CALL ARGUMENT
- PLTVAR: PLOTTING NAMELIST SECTION NAME

USED/COMMON--- NQS:

SETPLT-A
SUBROUTINE SETIC

PURPOSE: Initializes PRINT INCREMENT COUNTERS at an ITERATION COUNTER SET EVENT

COMMONS: INTCOM

LOCAL SYMBOLS: NONE

USFD/COMM--- IICNTR NICNTR
SET/COMMON--- IICNTR IPRINT NICNTR
SETICN Analysis

IPRINT is reset to 0 for later incrementing and usage. NICNTR is the counter for the N-th iteration counter set event, incremented by 1. ICNTR is the N-th value of LICNTR, a vector of print increments that allows the user to change print increments for denser print at critical trajectory intervals. SETICN is called whenever TYPE = 13 in LTRCON. TYPE is set in subroutine NEXTIM. IPRINT, the counter for groups of measurements, is updated in subroutine MEASUR.
SUBROUTINE SETUP

PURPOSE: READ AND INITIALIZE DATA FOR THE RECONSTRUCTOR

SUBROUTINES CALLED: ALTFILE, BEGIN, COPY, EXIT, GHA

COMMONS: SMO, OBSERV, ACT, AX, TRAJ, LOGCOM

LOCAL SYMBOLS:

| LOADED --- ICOMM | L1 | L2 | MNAME | ULAB | ULABEL | 357 |
SETUP Analysis

Subroutine SETUP reads and initializes the data necessary for the reconstruction program. Subroutine BEGIN is called to reset data changed by the data generator. Print counters, logic variables, and dynamic equation parameters are initialized. Scale factors are set to one and standard deviations and bias factors are set to zero. Subroutine NORMNZ is called to seed the random noise generator. If logic variable GENDAT is .FALSE., the data generator was not run (i.e., the actual trajectory resides on previously generated data tapes), and the ABSTBL array must be converted. A series of data cards containing Hollerith information is read and printed. If the first character was a C, the card is presumed to be a comment card. Successive cards are read until the array PRØB contains the problem identification.

The matrices associated with the Kalman filter equations are set to zero, and the namelist section ERAN is read and written. The basic integration step size DT is set to twice the step used in the computation of the actual trajectory in the data generator, and the vehicle physical properties are chosen according to IPHAS. The number of state parameters NS is set according to mode A or mode B, the LISTS array is initialized, and subroutine SETPLT is called to read the plot package variables. SETUP then checks the deletion of accelerometer or gyro data for the mode A dynamic equations. If such data are deleted, C(54) or C(140) must appear as a consider parameter if either appears at all.

Subroutine TIME is called to calculate the Julian date at TZERO, the earth's obliquity is computed, and GHA is called to find the Greenwich hour angle at TZERO. Subroutine PLANE is called to calculate the orientation of the entry plane to the three reference coordinate systems. If GENDAT is .FALSE., the DSN station locations are converted to radians.

The initial trajectory conditions, vehicle characteristics, planetary values, and problem identification are printed. The lists of augmentation parameters and associated covariance matrices are printed. The nominal values of the C array are printed, the trajectory state is stored in the XNS and XS arrays, and the actual atmospheric variables at TZERO are read from unit 10. If the trajectory is not being restarted, the most recent nominal trajectory is also the original nominal trajectory and XN is stored in XØ. Covariance and correlation matrices are stored in saving matrices, and initial accelerometer values are read from unit 16. Subroutine PRINT is called to print the trajectory and atmosphere values at TZERO, and subroutine SCHED is called to read and sequence measurement and event information. Control then returns to LTRCON.
SUBROUTINE SETUP

PURPOSE: INITIALIZE AND READ DATA FOR THE DATA GENERATOR

SUBROUTINES CALLED: ALTFILE, ATMSET, COPY, DATE, DERIV

359
SETUP1 Analysis

SETUP1 is called from DATGEN to initialize and read data via NAMELIST for the data generator. Elements of the AROTBL array are converted to radians and the variable GENDAT is set .TRUE. so that the reconstructor (see subroutine SETUP) will not convert AROTBL elements. Problem identification and namelist ERAN are read and subroutine TIME is called to calculate the Julian date, epoch 1900, from the input calendar date. The obliquity of the ecliptic is calculated and trajectory time TC is stored as TZERO. Subroutine GHA is called to compute the Greenwich hour angle at TZERO. Since one set has been read into the first elements of PHIR, ECLANG, and ECLINC regardless of the value of IC00R, subroutine PLANE computes the orientation of the remaining reference planes. DSN tracking station latitudes and longitudes are converted to radians, and the desired target planet atmosphere is stored according to NATM0S. ARU-VRU misalignment errors are added to nominal location values. If RESTRT is false, state parameter values are perturbed with nominal errors read from input. Input data are converted to internal units and the atmosphere and vehicle characteristics are written, together with the perturbed state parameters and problem identification. Subroutines ATMSET, DERIV1, SENS0R, and OBSM1 are called to initialize the trajectory integration at TZERO and PRINT1 is called to print the data generator output at TZERO. Control then returns to DATGEN for the data generator execution.
SUPROUTINE SMOOT2

SUBROUTINE STM

PURPOSE: CONTROLS THE CALCULATION OF THE AUGMENTED STATE TRANSITION MATRIX PARTITIONS

ENTRY PARAMETERS:

ZADD: NOMINAL CHANGE IN THE STATE VECTOR OVER THE INTERVAL OF INTEREST

SUBROUTINES CALLED: JACOB

COMMONS: TRAJ, COVARP, INTCOM

LOCAL SYMBOLS:

I: INDEX
NTM: EXTERNAL VARIABLE FOR INTEGRATION OF STATE EQUATION
N1: NUMBER OF BASIC STATE VARIABLES SQUARED
N2: NUMBER OF BASIC STATE VARIABLES PLUS 1

USED/COMMON: NS, PHI

SET/COMMON: PHI
STM Analysis

STM is an executive routine that controls the calculation of the partitions of the augmented state transition matrix.

The augmented state vector, $\bar{X}$, may be partitioned into the basic state vector, $X$; solve-for parameter, $q$; dynamic consider parameter, $U$; measurement consider parameters, $V$; and dynamic/measurement consider parameters, $W$. When the state transition matrix is partitioned to correspond with the augmented state vector partitions, the state equation may be written

$$X(t_F) = \begin{bmatrix} \phi_{t_F, t_0} & \psi_{t_F, t_0} & \theta_{u_{t_F, t_0}} & 0 & \theta_{w_{t_F, t_0}} \\ 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} x(t_0) \\ q(t_0) \\ u(t_0) \\ v(t_0) \\ w(t_0) \end{bmatrix}$$

The partitions $\phi$, $\psi$, $\theta_u$, and $\theta_w$ are computed by numerical differencing, i.e., the value of the $j$-th element of $X(t_F)$ is perturbed by an amount $\delta_j$, and the resulting change in $X(t_F)$ is found by integrating the equations of motion. The $j$-th column of $\phi$ is then given by $\Delta X(t_F)/\delta_j$.

The actual computation of the partitions of $\phi$ are obtained by calling JACOBN once for each partition. The elements of $X(t_0)$ to be perturbed are indicated by indices stored in the arrays LISTS, LISTQ, LISTU, and LISTW. The magnitude of the perturbation $\delta_j$ is determined from the variance of the parameter, $\sigma_j^2$. These variances are stored in the covariance matrices $P$, $Q$, $D_u$ and $D_w$. 

STM-1

365
SUBROUTINE SUB

PURPOSE: TO SUBTRACT ONE RECTANGULAR MATRIX FROM ANOTHER AND STORE INTO A THIRD RECTANGULAR MATRIX.

ENTRY PARAMETERS:
- NCX: NUMBER OF COLUMNS OF X, Y, AND Z MATRICES.
- NRX: NUMBER OF ROWS OF X, Y, AND Z MATRICES.
- X: MATRIX TO SUBTRACT FROM Y.
- Y: MATRIX TO BE SUBTRACTED FROM.
- Z: OUTPUT MATRIX (Y - X).

LOCAL SYMBOLS:
- I: INDEX.
- N: TOTAL NUMBER OF ELEMENTS OF X, Y, AND Z MATRICES.
SUBROUTINE SUBSOL

PURPOSE: COMPUTES THE CO-ORDINATE TRANSFORMATION FROM PLANETOCENTRIC ECLIPTIC PLANE TO SUB-SOLAR PLANET-ORBITAL PLANE

SUBROUTINES CALLED: EPHEM

ENTRY PARAMETERS:

NP  TARGET PLANET CODE
D  JULIAN DATE, EPOCH JANUARY 0, 1900
EQSS  CO-ORDINATE TRANSFORMATION FROM PLANETOCENTRIC ECLIPTIC PLANE TO SUB-SOLAR PLANET-ORBITAL PLANE

COMMONS:

LOCAL SYMBOLS:

EZS  CROSS PRODUCT OF PLANET POSITION AND VELOCITY VECTORS, OR UNIT VECTOR ALLIGNED WITH Z-AXIS OF SUB-SOLAR PLANET-ORBITAL PLANE
C1  MAGNITUDE OF EZS
C2  MAGNITUDE OF PLANET POSITION VECTOR
EXS  UNIT VECTOR ALLIGNED WITH X-AXIS OF SUB-SOLAR PLANET-ORBITAL PLANE
EYS  UNIT VECTOR ALLIGNED WITH Y-AXIS OF SUB-SOLAR PLANET-ORBITAL PLANE
XP  PLANET POSITION AND VELOCITY VECTORS

USED COMMONS: CARCOR
Subroutine SUBSOL computes the transformation from planetocentric ecliptic coordinates to subsolar planet orbital plane coordinates for an arbitrary planet. The subsolar planet orbital plane coordinate system is defined as the planetocentric system whose x-axis points directly at the sun, whose z-axis is normal to the planet's orbital plane, and whose y-axis is normal to the xz-plane and lies in the planet's orbital plane. In the figure below \( \vec{r} \) and \( \vec{v} \) denote the position and velocity vectors, respectively, of the planet relative to the sun. Unit vectors \( \vec{e}_x, \vec{e}_y, \) and \( \vec{e}_z \) are aligned with the axes of the subsolar planet orbital plane system.

These unit vectors are defined as

\[
\begin{align*}
\vec{e}_x &= -\frac{\vec{r}}{r} \\
\vec{e}_y &= \vec{e}_z \times \vec{e}_x \\
\vec{e}_z &= \frac{\vec{r} \times \vec{v}}{|\vec{r} \times \vec{v}|}
\end{align*}
\]
If these unit vectors are referred to the ecliptic coordinate system, the coordinate transformation $A$ from planetocentric ecliptic to subsolar planet orbital plane coordinates is given by

$$
A = \begin{pmatrix}
    e^T_{x_S} \\
    e^T_{y_S} \\
    e^T_{z_S}
\end{pmatrix}
$$

Thus

$$
\hat{x}_{\text{sub} \text{solar}} = A \hat{x}_{\text{ecliptic}}
$$

**SUBSØL Flow Chart**

1. **ENTER**
2. Call EPHEM to compute the ecliptic position/velocity state of the planet at the current Julian date (epoch 1900)
3. Compute the ecliptic components of the unit vectors $\hat{e}_{x_S}$, $\hat{e}_{y_S}$, and $\hat{e}_{z_S}$
4. Compute coordinate transformation matrix $A$
5. **RETURN**
SUBROUTINE SUMMRY

PURPOSE: WRITES SUMMARY PRINT AND CALLS PLOT PACKAGE

SUBROUTINES CALLED: ALTFILE, PLOTS

COMMONS: SUMRY, PLOT2, INTCOM, LOGCOM

LOCAL SYMBOLS:

- TITLE   HOLLERITH LIST OF SECTION TITLES

USED/COMMON--- NVAR, PLOTL, SMT9
READ     --- ITAPE, XMAT
WRITTEN  --- LABEL, PROB, TIMEF, TITLE, XMAT
SET/COMMON--- PROB
LOADED   --- LABEL, TITLE, TARONE, TARTWO
SUMMARY Analysis

If SUMTB(I) is .TRUE., the I-th summary table is written (containing problems identification, title, and label information) and plot values are stored on unit 10. Subroutine PLOTS is called to plot using the system plot package.
SUBROUTINE SYMTRZ

PURPOSE: TO DETERMINE THE SYMMETRIC COMPONENTS OF A SQUARE MATRIX BY TAKING ONE HALF THE SUM OF THE MATRIX AND ITS TRANSPOSE

ENTRY PARAMETERS

N  DIMENSION OF X
X  SQUARE MATRIX WHICH IS REPLACED BY ITS SYMMETRIC COMPONENT

LOCAL SYMBOLS

I  INDEX
J  INDEX
FUNCTION TAB

PURPOSE: TO PERFORM A LINEARLY INTERPOLATED TABLE LOOKUP

ENTRY PARAMETERS

TABLE: SINGLY DIMENSIONED ARRAY WHOSE FIRST ENTRY INDICATES
THE NUMBER N OF BREAK POINTS. THE N BREAK POINTS
OF THE INDEPENDENT VARIABLE ARE NEXT AND THE REMAINING
N VALUES ARE THE BREAK POINTS OF THE DEPENDENT VARIABLE

X: VALUE OF THE INDEPENDENT VARIABLE

LOCAL SYMBOLS

K: INDEX
L: INDEX
The index $K$ is set to $\text{TABLE}(1)+1$, and $X$ is tested against $\text{TABLE}(L)$, $L = 3, K$. If $X \leq \text{TABLE}(L)$,

$$M = K + L - 1$$

and

$$\text{TAB} = \frac{(X - \text{TABLE}(L-1))}{(\text{TABLE}(L) - \text{TABLE}(L-1))} \ast (\text{TABLE}(M) - \text{TABLE}(M-1) + \text{TABLE}(M-1))$$

where $\text{TABLE}$ is a singly dimensioned array whose first entry indicates the number $N$ of break points. The $N$ break points of the independent variable are next, and the remaining $N$ values are the break points of the dependent variable.
SUBROUTINE TIME

PURPOSE: TRANSFORM CALENDAR DATE TO/FROM JULIAN DATE, EPOCH 1900

ENTRY PARAMETERS

JAY JULIAN DATE, EPOCH 1900
IYR CALENDAR YEAR
MO CALENDAR MONTH
IDAY CALENDAR DAY
IMH HOUR OF THE DAY
MIN MINUTE OF THE HOUR
SEC FRACTIONAL SECONDS
ICODE OPERATIONAL MODE
   =1, JULIAN DATE IS INPUT, CALENDAR DATE IS OUTPUT
   =0, CALENDAR DATE IS INPUT, JULIAN DATE IS OUTPUT

LOCAL SYMBOLS

IA NUMBER OF CENTURIES
IB YEARS IN PRESENT CENTURY
IP NUMBER OF MONTH (BASED ON MARCH AS NUMBER ZERO)
IQ NUMBER OF YEARS
IR NUMBER OF CENTURIES DIVIDED BY 4
IS NUMBER OF YEARS SINCE LAST 400 YEAR SECTION BEGAN
IT NUMBER OF LEAP YEARS IN PRESENT CENTURY
IU NUMBER OF YEARS SINCE LAST LEAP YEAR
IV NUMBER OF DAYS IN LAST YEAR
IX INTERMEDIATE VARIABLE
J INTERMEDIATE VARIABLE
JD NUMBER OF DAYS IN JULIAN DATE
P JULIAN DATE
R FRACTIONAL PORTION OF DAY IN JULIAN DATE
SUBROUTINE TIMEX

PURPOSE: TO PRINT TIME ELAPSED SINCE LAST CALL

ENTRY PARAMETERS
NAME A HOLLERITH NAME OF A SUBROUTINE

SUBROUTINES CALLED: CPWMS XRCL

LOCAL SYMBOLS
N LOGIC VARIABLE SET TO +1 OR -1
T ELAPSED TIME IN SECONDS (T2-T1)
T1 PREVIOUS TIME IN SECONDS
T2 CURRENT TIME IN SECONDS

WRITTEN --- NAME T
LOADED --- N
TIMEX Analysis

XRCL and CPWMS are Martin Marietta/CDC system routines that, together, return real clock time in seconds. If N < 0, elapsed time and a Hollerith subroutine name are printed. T1 is set to T2 and N to -N prior to return.
SUBROUTINE TMULT

PURPOSE: TO MULTIPLY THE TRANSPOSE OF A RECTANGULAR MATRIX BY ANOTHER RECTANGULAR MATRIX AND STORE IN A THIRD MATRIX

ENTRY PARAMETERS:
NCX  NUMBER OF COLUMNS OF X AND NUMBER OF ROWS OF Z
NCY  NUMBER OF COLUMNS OF Y AND Z MATRICES
NRX  NUMBER OF ROWS OF X AND Y MATRICES
X    INPUT Rectangular Matrix (TO BE TRANSPOSED)
Y    INPUT Rectangular Matrix
Z    OUTPUT Matrix (X TRANSPOSED TIMES Y)

LOCAL SYMBOLS:
I    INDEX
J    INDEX
K    INDEX
SUM  PRODUCT OF I-TH COLUMN OF X AND J-TH COLUMN OF Y
SUBROUTINE TMULTT

PURPOSE: TO MULTIPLY THE TRANSPOSES OF TWO RECTANGULAR MATRICES AND STORE INTO A THIRD RECTANGULAR MATRIX

ENTRY PARAMETERS
- NCX: NUMBER OF COLUMNS OF X AND NUMBER OF ROWS OF Z

APPENDIX A

CDC 280 SOFTWARE PACKAGE
1. INTRODUCTION

This document has been written to provide the user with software information that he might require in using the CDC 280 for producing microfilm or hardcopy.

These routines are a part of the CDC 6000 MACE Operating System and utilize the CDC 280 as an on-line peripheral device.
2. THE CDC 6000 OPERATION SYSTEM INTERFACE

2.1 Interfacing the 280 Display and Recorder with the MACE Operation System requires the addition of two special file names, Film Plot (FILMPL) and Film Print (FILMPR). Film Plot files (FILMPL) and other I/O files, such as OUTPUT, that are used by the program must be declared on the program name card for the particular job. The Film Print file (FILMPR) can be declared in the same manner, or it can be established via a control card. Data sent to either of these files during job execution is written on the system disk in the same manner as print data.

Each file being filmed can be controlled by Output control point commands. The commands are: END, REPEAT, and SUPPRESS.

280 CONSOLE OPERATION

When the RUN mode is selected on the console, output data directed to the 280 is transferred to both the console CRT and the recorder CRT. (The RUN mode should not be confused with the RUN control card. By use of the 280 console keyboard, the operator has the options to stop the 280 and monitor each page of output. The operator accomplishes this by selecting the STEP mode on the console and stepping through successive pages of output display until he desires to return to the normal RUN mode. The operator can change modes by pressing keys in the following manner:

<table>
<thead>
<tr>
<th>TYPE KEY</th>
<th>ACTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>R</td>
<td>Return to RUN mode</td>
</tr>
<tr>
<td>S</td>
<td>Change to STEP mode</td>
</tr>
<tr>
<td>G</td>
<td>Go to next page if in STEP mode</td>
</tr>
</tbody>
</table>

Jobs can automatically be put in the STEP mode by keying in (1. ON SW1.) at the 6000 console. This STEP mode of operation can then be removed by keying in (1. OFF SW1.).

2.2 Examples of Job Generation Film Print and Film Plot Files

2.3 The IDENTIFY card is the method by which the device and type of microfilm and/or hardcopy is specified for non-standard options.

Standard: FILMPR(BCD) TO MICROFILM = (no IDENTIFY card required)
FILMPL(BINARY) TO HARDCOPY = (no IDENTIFY card required)

Nonstandard: IDENTIFY (FILE1, FORM)

FILE1 = FILMPL(BINARY FILE)
= FILMPR(BCD FILE)

FORM = 1 (HARDCOPY)
= 2 (MICROFILM)
= 3 (BOTH)

Example: Binary and BCD files to both hardcopy and microfilm.

New Method
IDENTIFY(FILMPL,3)
IDENTIFY(FILMPR,3)

3. PLOTTING

3.1 DD202

These FORTRAN subroutines have been rewritten to produce a file (FILMPL) for plotting on the CDC 280. The only change required in a user's program is to identify the file FILMPL in the PROGRAM statement in place of TAPE44.

DD202 has five entries: BPLT, SPLT, FPLT, EPLT, REVPL.
3.1.1 BPLT

The function of BPLT is to provide initialization and need be called only at the start of the job.

CALL BPLT(A,B)

CALL BPLT (2HNB, 2HLC) where
2HNB indicates no background grid lines.
2HLC indicates a larger character size.

3.1.2 SPLT

The function of SPLT is to provide frame identification for the data that are to be plotted. This frame identification is repeated for as many frames as are necessary to plot the data. The frame identification consists of a title, symbolic names of the dependent and independent variables, the scales of the dependent variables, and the scale of the independent variable properly incremented on all frames produced. Thus, SPLT should be called only whenever it is desired to change any of the frame identification variables. The frame identification information is supplied by:

CALL SPLT (XO,XS,XN,TITLE,O_,T,YMIN1,YMAX1,
YNL,...........YMIN1,YMAX1,YN1)

where

XO is the value of the independent variable at which plotting is to begin.

XS is the scale of the independent variable. Since each frame of a plot is divided into 10 major divisions, 10*XS = total range of the independent variable over one frame. If the value of the independent variable exceeds the value of 10*XS, plotting is continued onto a new frame with the frame identification repeated as already noted.
In this case, plotting may not be resumed on a previous frame, i.e., subsequent values of the independent variable may not be less than that value which caused a new frame to be produced. If the user attempts to do this or if the user inadvertently supplies an XS of 0.0, an error message is printed. The job is not terminated, but no more plotting will be done.

XN is the name of the independent variable in Hollerith and many consist of one to six alphanumeric characters.

TITLE is a 60 contiguous character Hollerith array which will be printed below each frame generated.

0. is self evident, and at present is a dummy argument.

T is a flag specifying whether point plots (T=0) or vector plots (T=1 or T=1.) are desired. If the plots are Secret or Confidential, the Secret or Confidential label is generated by setting the last four characters of the sixty-character TITLE parameter of SPLT to either "SECR" or "CONF".

YMIN1 is the minimum grid value for the first dependent variable.

YMAX1 is the maximum grid value of the first dependent variable.

(If the dependent variable goes out of the interval (YMIN-YMAX) no plotting is done off the grid, but is resumed normally at the point where Y reenters the interval)

YN1 is the name of the first dependent variable in Hollerith and may consist of one to six alphanumeric characters.
The number of remaining arguments for SPLT depends on the number of dependent variables to be plotted. A maximum of \( i = 10 \) dependent variables is allowed and three arguments are required for each additional variable in the same order as \( \text{YMIN}1, \text{YMAX}1, \text{YN}1 \). The scale of each dependent variable is computed as

\[
\text{YMAX}_i - \text{YMIN}_i = \frac{1}{10}\text{ per major grid division;}
\]

however if more than three dependent variables are requested, all \( N \) variables will be plotted at the

\[
\text{YMAX}_i = \text{YMIN}_i = \frac{1}{10}\text{ scale but the BCD name of the first variable is the only one that will appear as part of the frame identification.}
\]

If \( \text{YMAX}_i = \text{YMIN}_i \), the action taken is identical to that described under the XS argument discussion.

### 3.1.3 FPLT

The third entry to be called is FPLT. FPLT must be called once for each point (or set of points) to be plotted.

FPLT is used by a:

\[
\text{CALL FPLT (X,Y1......Y}_i\text{)}
\]

where:

\( X \) is the value of the independent variable.

\( Y1 \) is the value of the first dependent variable at point \( X \). Again, there may be a maximum of \( i = 10 \) dependent variable values. The number of dependent
variable values specified in FPLT must agree with the number specified by the SPLT arguments. The FPLT arguments must have floating point values.

3.1.4 EPLT

The function of EPLT is to terminate the plot information. Thus, it must be called before the user program terminates to insure that all plotting information is put on the file. It must also be called before a new SPLT is called to insure that all of the previous frame identifications are processed before the new frame identification specs are input through SPLT. EPLT is called by

CALL EPLT (0)

3.1.5 REVPL

The function of REVPL is to provide an option for switching from vector to print plotting or vice versa. Each time the REVPL entry is called, the mode of plotting is reversed. The applications for this option might be in plotting discrete functions to eliminate a vector between points of discontinuity.

CALL REVPL

3.1.6 FRAMECT

The function of FRAMECT is to place on the dayfile the number of frames that have been advanced. FRAMECT is automatically called by EPLT.

CALL FRAMECT (N,I)

where:

N is the number of frames
I = 0 - no dayfile message
1 - a dayfile message.
Most of this report was taken from "CRT Plotting Routines in Use at LRL-Livermore" written by Judith D. Ford and Marilyn J. Welsh (UCRL-14427-T), and modified by Lt. Peter R. Keller of KAFB.

This report describes a system of plotting routines. These FORTRAN routines provide a flexible package for point, line, and character plotting via a CDC 280 display device.

This report gives detailed descriptions of the 280 routines, including purpose, operation, usage, and examples. The routines are separated into the following classes:

1. Mapping routines.
   These routines set up scale factors for converting the user's coordinates to the 280 raster point coordinates (raster point defined later). These routines may also draw scales with grid lines or short marks along the axes.

2. Arrow, line, and point plotting routines.
   These routines provide the facility for plotting various types of curves.

3. Character plotting routines.
   These routines provide the facility for plotting alphanumeric information.

4. Absolute plotting routines.
   These routines position the beam independent of the scaling defined by the mapping routines.

5. Utility routines.
   These routines give the facilities for framing and initializing the plot package.
6. Internal routines.

Internal routines perform various functions necessary to the operation of the system, and the user is normally not aware of their existence.

The CDC 280 plane is defined to be a (1024 by 1024) square of addressable points on the face of a cathode ray tube (CRT). These points are called raster points. Information is displayed by unblanking the CRT beam. The beam may be moved to a new position without unblanking (i.e., without plotting a line). Points may only be positioned at a raster point. Lines may only be drawn between two raster points (i.e., the beam unblanked between these two raster points may or may not intersect other raster points).

In the following description of the 280 routines, it is assumed that all arguments are given in the same mode as the dummy arguments, using the standard FORTRAN conventions for the names of integer and floating point variables. The dummy arguments spelled -DUM- are not used by the routine. These arguments are reserved in some cases for future options.

For the purposes of these routines this 280 plane is regarded as having the usual X, Y cartesian coordinates, both of which range from 0. to 1. with the origin at the lower left corner. If no mapping routine is called all coordinates for the plotting routines are assumed to be between 0. and 1.

3.2.2 This group of routines makes it unnecessary for the user to scale his own numbers for plotting on the 280. This is accomplished by establishing a mapping from the user's coordinate plane onto some portion of the 280 plane. This, by the way, allows more than one graph to be plotted on a frame.
CALL MAP (XMIN, XMAX, YMIN, YMAX, XM1, XMA, YMI, YMA)

XMIN, XMAX, YMIN, YMAX are the user's maximum and minimum cartesian coordinates.

XM1, XMA, YMI, YMA are the maximum and minimum coordinates of the 280 plane desired to be used.

This description encompasses a group of twelve routines, each of which establishes a mapping from the rectangle in the user's plane with corners (XMIN, YMIN), (XMAX, YMAX) onto the rectangle in the 280 plane with corners (XM1, YMI), (XMA, YMA). Unless reset, this mapping applies to all subsequent plotting, except the absolute plotting routines.

Linear mappings are established by -MAP-, -MAPG-, and -MAPS-.

MAP establishes a mapping only.

MAPG plots a grid with scale numbers.

MAPS plots a rectangle with scale numbers and short marks along the axes.

The suffixes -LL-, -SL-, and -LS- may be used with any of -MAP-, -MAPG-, or -MAPS- to modify the mapping as follows:

LL establishes a log-log mapping.

SL establishes a semi-log mapping with the X-axis linear.

LS establishes a semi-log mapping with the Y-axis linear.

The cycles are determined automatically.
Examples:

CALL MAP (0., 1., 0., 1., 0., 1., 0., 1.)
sets up a linear-linear mapping,

CALL MAPGLL (1., 10., 1., 100000., .1, .999, .1, .999) sets up a 1 cycle by 5 cycle scale, and

CALL MAPGSL (-100., 10., 1., 100., .1, .5, .1, .999) sets up a linear by 2 cycle grid.

The mapping function is initially set

XMIN - YMIN = XMI = YMI = 0. and XMAX = YMAX = 1.

The scale numbers will overplot the grid lines if XMI or YMI is less than .078125 for linear scaling or .043 for logarithmic scaling.

Plotting routines specifying point(s) out of the defined user domain are handled in two ways.

1. If the scaled coordinate is within the 280 range then the routine is executed at the scaled coordinate.

2. If the scaled coordinate is outside of the 280 range then this coordinate is projected on the nearest extreme edge and the routine executes there.

An error message is printed whenever a mapping routine is called with

XMIN > XMAX, YMIN > YMAX, XMI > XMA, YMI > YMA

or a log mapping is called with a nonpositive argument.
CALL MAPP (RMAX, XMI, XMA, YMI)

RMAX is the maximum radius for the user's polar coordinates.

XMI, XMA, YMI are the same as in -MAP- above.

-MAPP- establishes a mapping from the circle of radius RMAX in the user's polar coordinate plane into the square in the 280 plane with corners (XMI, YMI), (XMA, YMA) where YMA = YMI + (XMA - XMI).

Vertical and horizontal reference axes will be plotted, with scale numbers along the zero-degree axis, and with the origin at the center of the square. All (X,Y) pairs given in later plotting routines will be interpreted as polar coordinates (R, θ) until another mapping routine is called.

CALL MAPX (XMIN, XMAX, YMIN, YMAX, XMI, XMA, YMI, YMA, I)

I is an integer 1 ≤ I ≤ 13.

The remaining arguments are the same as in -MAP- above.

-MAPX- allows the mapping to be specified at execution time, according to the value of I. A call to -MAPX- is equivalent to a call to one of the above mapping routines, with the integers 1-13 corresponding to these routines in the following order:

MAP, MAPSL, MAPLS, MAPLL, MAPG, MAPGL, MAPGLS, MAPGLL, MAPS, MAPSSL, MAPSLS, MAPSSL, MAPP.

When I = 13 the arguments in MAPX correspond to MAPP as follows

CALL MAPX (DUM, RMAX, DUM, DUM, XMI, XMA, YMI, DUM, 13).
ARROW, LINE AND POINT PLOTTING Routines

These routines may be used to display and/or photograph data in graphic form. The user's (X,Y) coordinates in these plotting routines are scaled by the scale factors set up by a mapping routine. If no mapping routine has been called, these coordinates are assumed to be in the range 0. to 1.

CALL ARROW (X1, Y1, X2, Y2, Z)

(X1, Y1) and (X2, Y2) are coordinates of two points.

Z is a floating point number 1.

-ARROW- sweeps a line from (X1, Y1) to (X2, Y2) and draws an arrowhead at (X2, Y2). The arrowhead measures Z raster points in length. Z = 10 is a normal size arrowhead. The intensity is set by -LINEOPT-. The final beam position is (X2, Y2).

CALL LINE (X1, Y1, X2, Y2)

(X1, Y1) and (X2, Y2) are the coordinates of two points. -LINE- will sweep a line from (X1, Y1) to (X2, Y2) with intensity set by -LINEOPT-.

CALL LINEOPT (DUM, INTEN)

DUM is a dummy argument.

INTEN is the intensity at which all arrows, lines, points, and vectors will be plotted.

0 low intensity (fine line).

1 high intensity (heavy line).

-LINEOPT- is initially set to low intensity.

The mapping routines reset -LINEOPT- from within.
CALL LINEP (XI, Y1, X2, Y2, K)

(X1, Y1) and (X2, Y2) are the coordinates of two points.

K is an integer.

-LINEP- plots a line consisting of every Kth raster point between (X1, Y1) and (X2, Y2). Intensity is set by -LINEOPT-.

CALL LINES (X,Y,N)

X and Y are the names (first word addresses) of arrays of the X and Y coordinates of points.

N is the number of points.

-LINES- connects the N points given by the arrays X and Y with line segments. The final beam position is (X(N), Y(N)). The lines are swept with intensity as set by -LINEOPT-.

CALL POINT (X,Y)

X and Y are the coordinates of a point.

-POINT- will plot a point at (X, Y) with intensity set by -LINEOPT-.

CALL POINTS (X, Y, N)

X and Y are the names (first word addresses) of arrays of the X and Y coordinates of points.

N is the number of points.

-POINTS- plots the N points given by the arrays X and Y. The intensity is set by -LINEOPT-.
CALL SETBEAM (X, Y)

X is the abscissa at which the beam is to be positioned.

Y is the ordinate at which the beam is to be positioned.

-SETBEAM- causes the beam to be positioned at (X, Y) without unblanking.

CALL VECTOR (X2, Y2)

(X2, Y2) is the coordinate of a point.

-VECTOR- sweeps a line from the current beam position to (X2, Y2) with intensity set by -LINEOPT-.

3.2.3 Character Plotting Routines

This group of routines allows the plotting of alphanumeric information, either to label the various curves, lines, etc., produced by the point and line plotting routines, or as a more versatile alternative to an off-line printer (this is distinct from the -FILMPR- option. -FILMPR- merely simulates the printer). This versatility derives from:

1) The capability of positioning a line of alphanumeric information anywhere on the current frame (vs the top-to-bottom progression of a page printer).

2) The two orientations, two intensities and four character sizes that are available, and

3) The expanded character set, which includes many non-key punchable characters (not immediately available).
CALL CHAROPT (DUM, DUM, ISIZE, IOR, DUM)

ISIZE = 0 miniature
       1 small
       2 medium
       3 large

IOR = 0 horizontal (0°)
       1 vertical (90°)

-CHAROPT- specifies the size (ISIZE) and orientation (IOR) of all characters to be plotted. The option is changed by a second call to -CHAROPT-.

The maximum string length and line limits for the various sizes are:

<table>
<thead>
<tr>
<th></th>
<th>Lines/</th>
<th></th>
<th>Frames</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Symbols</td>
<td>Line</td>
<td></td>
</tr>
<tr>
<td>Miniature</td>
<td>128</td>
<td>64</td>
<td></td>
</tr>
<tr>
<td>Small</td>
<td>86</td>
<td>43</td>
<td></td>
</tr>
<tr>
<td>Medium</td>
<td>64</td>
<td>32</td>
<td></td>
</tr>
<tr>
<td>Large</td>
<td>43</td>
<td>22</td>
<td></td>
</tr>
</tbody>
</table>

In the character plotting routines, the 280 plane is considered to be a grid of rectangles, each containing one character of the chosen size. The number and dimensions of these rectangles depend on the character size and orientation. Characters are drawn within the rectangle. The rectangle is positioned such that the current beam position is in the center of the rectangle. After the character has been drawn the beam is positioned in the center of the next rectangle.

CALL NUMBER (X, F)

X is a variable (fixed or floating).

F is any allowable FORTRAN format 10 characters.

-NUMBER- converts the variable X under the given format, determines the field width and plots the resulting characters as -SYMBOL- would.
Example:

```
X = 1.0E5
CALL NUMBER (X, 5HE10.2)
```

would plot
```
bbbl.00E05
```
and
```
I = 42
CALL NUMBER (I, 9H4HIN = , I3)
```

would plot
```
INb = b42
```

CALL SYMBOL (A)

or

CALL SYMBOL (MH...$.)

A is the first word of BCD data. The end of string is designated by $.

MH...$ is a Hollerith text of M characters. The last two characters must be $., which designates the end of string.

-SYMBOL- encodes BCD data into the 280 character set and plots it starting at the current beam position with options as given by -CHAROPT-.

If $ does not appear at the end of string -SYMBOL- attempts to plot words up to the field length.
3.2.4 Absolute Plotting Routines

These routines position the beam independently of the defined mapping function. The arguments range from 0. to 1. Out of range points are projected on the nearest extreme edge of the plotting area.

CALL ABSBEAM (X, Y)

X, Y are coordinates of a point.

-ABSBEAM- causes the beam to be positioned at (X, Y) without unblanking.

CALL ABSLINE (X1, Y1, X2, Y2)

(X1, Y1), (X2, Y2) are coordinates of two points.

-ABSLINE- draws a line from (X1, Y1) to (X2, Y2).

CALL ABSPT (X, Y)

X, Y are coordinates of a point.

-ABSPT- plots a point at (X, Y).

CALL ABSVECT (X, Y)

X, Y are coordinates of a point.

-ABSVECT- draws a vector from the last beam position to (X, Y).

3.2.5 Utility Routines

CALL INIT280

-INIT280- initializes the 280 routines and must be called before any of the plotting routines.

CALL FRAME

-FRAME- advances the microfilm to the next blank frame after emptying the buffer.

-FRAME- should be the last routine called in order to empty the buffer.
3.2.6 Internal Routines

These routines are essential to the plotting routines, but are not called directly by the user, only by other routines in the system.

-GRID80- is called by the mapping routines which draw scale marks or grid lines and label them with scale number.

-GTRF-, -GEQF-, -EQLF-, -SEQF-, -SMLF-, -UNQF-, and -ZGTRF- are functions which are used in -GRID80-. Each has two arguments and returns a value of 1 if the first argument stands in the indicated relation to the second, a value of 0 otherwise.

<table>
<thead>
<tr>
<th>FUNCTION</th>
<th>RELATION</th>
</tr>
</thead>
<tbody>
<tr>
<td>GTRF</td>
<td>greater than</td>
</tr>
<tr>
<td>GEQF</td>
<td>greater than or equal to</td>
</tr>
<tr>
<td>EQLF</td>
<td>equal to</td>
</tr>
<tr>
<td>SEQF</td>
<td>less than or equal to</td>
</tr>
<tr>
<td>SMLF</td>
<td>less than</td>
</tr>
<tr>
<td>UNQF</td>
<td>not equal to</td>
</tr>
</tbody>
</table>

These functions call -ZGTRF- to establish the value.

-TEST- is called by the mapping routines to establish legal arguments.

-ADJUST- is called by some of the plotting routines to convert nonlinear arguments to linear before scaling.

-LENGTH- is called by number to count the number of characters to be plotted.

-STREND- is called by symbol to test for end of string symbol.
-PSCALE- is called by the mapping routines to establish the scaling.

-PLOTQ- is called by the plotting routines and forms the 280 instructions.

3.3 SC4020 Conversion

3.3.1 SC4020 Binary PLOT Files may be converted to a CDC 280 FIIMPL File by calling the FORTRAN Subroutine SCDD. The calling sequence is:

```
CALL SCDD (I,J,K)
```

where I = Number of files to be converted.

J = Tape number of SC4020 FILE

K = 0, debug printout is inhibited

1, debug printout is not inhibited

3.3.2 Example:

```
PROGRAM TEST (OUTPUT, TAPE45, FILMPL)

CALL ENDPLOT
ENDFILE 45
REWIND 45
CALL SCDD(1, 45, 0)

```

3.3.3 SC4020 Binary Plot Tapes produced on the IBM 360 or 7094 must be processed by program DD219. This program will read tapes written in 36-bit increments.
4. PRINTING

4.1 CDC 6000 Print Files

4.1.1 Print files may be recorded by the CDC 280 with the following format:

Up to 128 characters per line are accepted.

The first character of each line is interpreted as the vertical spacing control and is replaced with a space code. The control characters are:

0 = 12 (BCD) Double Sp.
1 = 01 (BCD) Eject
+ = 60 (BCD) Suppress Sp.

Any other character causes single spacing.

Vertical spacing control is accomplished before the line is filmed (preprint spacing).

A maximum of 64 lines per frame is admissible. More than 64 lines force an automatic frame advance.

*40 FR will produce 40 blank frames of microfilm for spacing purposes.

4.2 Non-CDC 6000 Print Files

4.2.1 Print Files may be created on other computers for recording on the CDC 280.

Tapes must be written in the following manner:

Unlabeled 7 track tape (BCD)

Single blocked records of 130 characters (Last 2 characters blank).

Blocked records:

Maximum size is 1820 characters.

An END OF FILE terminates processing.
4.3 Forms Flash

A Forms Flash may be programmed for use as an outline for each frame of CDC 280 recording of Print Data.

Those desiring the use of a Forms Flash should design a Forms Flash on a grid layout with the following specifications.

Grid size allows 128 characters per line and 64 lines per page for data.

Symbol sizes may be:

- 128 characters per line
- 86 characters per line
- 64 characters per line
- 43 characters per line

Symbols may be oriented horizontally (left to right) or oriented 90° clockwise.

The Grid Layout should be submitted to Dept. 6643 for programing and implementation.

4.4 Special Capabilities

Jobs requiring Secret or Confidential output on microfilm or hardcopy may be obtained as follows:

FILMPR - If this file is utilized to generate secret or confidential output, a forms flash must be used to label the microfilm or hardcopy as secret or confidential. This forms flash is generated by initializing FILMPR with one of the following BCD records:

Col 1
FORMSFLASH6A3 For a secret file.
FORMSFLASH6A4 For a confidential file.
Example to initialize FILMPR with secret forms flash:

Job Card
CHARGE.
REQUEST TAPE1,HY.
COPYCR (INPUT, FILMPR, 1)
RUN(S)
LGO
...
...
789
FORMSFLASH6A3
789
...
...
5. ILLUSTRATIONS

CALL FRAME

Figure A-2 was generated by the following sequence of instructions:

CALL MAPGSL (-1., 1., 1., 100000., .1, .5, 1, 1.)
CALL MAPGLL (1., 10., 100., 1000., .6, 1., .1, .5)
CALL MAPS (-10., 10, 6., 1., 1000000., 1., .5)
CALL CHAROPT (0, 0, 0, 0, 0)
CALL ABSBEAM (.45, .001)
CALL SYMBOL (11HFIGURE 2.$.)
CALL FRAME
Figure A-3 was generated by the following sequence of instructions:

```
DIMENSION X(100), Y(100)
DO 1 I=1, 100
  X(I)=1
  Y(I)=7.2
1  CALL MAPP (100., 0., .5, 0.)
  DO 2 I=1, 100
2  CALL POINT (X(I), Y(I))
    CALL MAPP (100., .5, 1., .5)
  DO 3 I=1, 98, 4
3  CALL ARROW (X(I), Y(I), X(I+2), Y(I+2), 8.)
    CALL CHAROPT (0, 0, 0, 0, 0)
    CALL ABSBEAM (.45, .001)
    CALL SYMBOL (11HFIGURE 3.$.)
    CALL FRAME
```
