THE POPOP4 LIBRARY AND CODES FOR PREPARING SECONDARY GAMMA-RAY PRODUCTION CROSS SECTIONS

W. E. Ford, III
Oak Ridge National Laboratory
Oak Ridge, Tennessee

The POPOP4 code for converting secondary gamma-ray yield data to multigroup secondary gamma-ray production cross sections and the POPOP4 library of secondary gamma-ray yield data are described. Recent results in the "testing" of uranium and iron data sets from the POPOP4 library are given. The data sets were tested by comparing calculated secondary gamma-ray pulse-height spectra with spectra measured at the ORNL TSR-II reactor.

One of the primary considerations in the design of shields for reactors on spacecraft is the dose rate due to secondary gamma rays produced by neutron interactions in the fuel and in the structural and shielding materials. The importance of secondary gamma rays is illustrated by the calculated dose distribution shown in figure 1 for a three-cycle W-LiH shield for a SNAP-8 ZrH reference reactor (ref. 1). The design objectives were to limit the dose rate on the outer surface of the shield to a maximum value of $1.55 \times 10^3$ mrem/hr and to minimize the weight of the spherical shield. Note from the figure that before the constraint dose is obtained, the secondary gamma-ray dose rate predominates. These dose rates were calculated by coupling the transport of the neutrons and secondary gamma rays in a single discrete ordinates calculation. One of the requirements for a coupled calculation is accurate secondary gamma-ray production cross sections (SGRFXS's). To satisfy this requirement, the shield designer must have a readily accessible library of secondary gamma-ray yield data for the elements used in shield design, the means to convert the yield data to SGRFXS's in a format for use with the standard transport codes, and confidence in the accuracy of the data.

POPOP4, a FORTRAN-IV code, was written to convert secondary gamma-ray yield data as found in the literature for $(n,\gamma)$, $(n,x\gamma)$, etc., reactions to any required neutron-gamma multigroup energy structure (ref. 2). If the yield data are in terms of gamma-ray intensity per neutron induced reactions, the code multiplies the converted multigroup yields by input multigroup neutron-reaction cross sections to give the SGRFXS's. [The neutron reaction cross sections are obtained from codes such as GAM-II or XSDRN (refs. 3 and 4).] POPOP4 sums the SGRFXS's for the various neutron-induced reactions to give total SGRFXS's for the nuclide of interest. Using codes such as the Sample Simple Coupling Code (ASSCC) (ref. 5), the POPOP4 cross sections are coupled with $F_N$ neutron and gamma-ray cross-section sets for use in coupled neutron-gamma transport calculations. Discrete ordinates codes such as ANISN (ref. 6) and DOT (ref. 7) and Monte Carlo codes such as MORSE (ref. 8) use multigroup coupled cross sections produced as described above.

![Dose Distribution in SNAP-8 Reactor With Three-Cycle W-LiH Shield](https://ntrs.nasa.gov/search.jsp?R=19720010016)
A compendium of neutron-induced secondary gamma-ray yield and cross-section data has been compiled for use with POPOP4. This collection of data is known as the POPOP4 library (ref. 9). Included in the library are capture and inelastic-scattering yield data sets from the United Nuclear Corporation publications (refs. 10, 11, and 12), Maerker's and Muckenthaler's measured secondary gamma-ray yields due to thermal-neutron captures in the elements found in soils, concretes, and structural materials (ref. 13), the yields for thermal-neutron captures in a large number of elements as compiled in the Nuclear Data publications (refs. 14, 15, and 16), the isotropic components of the gamma-ray production cross sections for Na, Mg, Cl, K, and Ca reported by Drake et al. (ref. 17), and many other \((n,\gamma)\) and \((n,x\gamma)\) data sets from the literature and from the private files of contributors. At present there are 223 data sets in the library for 79 elements or nuclides. The library is available on magnetic tape from the Radiation Shielding Information Center (RSIC). [POPOP4, the Sample Simple Coupling Code, and POPOP4 Library Tape Maker (ref. 5) — a code to make or update the POPOP4 library tape — are also available from RSIC.]

One of the most important objectives of the POPOP4 project is the "testing" of secondary gamma-ray yield data for use in shielding calculations. The data are tested by comparing measured secondary gamma-ray pulse-height spectra with spectra calculated using POPOP4 multigroup SGRPXS's prepared with data sets from the POPOP4 library.

A series of experiments was conducted by Muckenthaler et al. of ORNL's Neutron Physics Division to measure secondary gamma-ray pulse-height spectra resulting from the exposure of various slabs of reactor core, structural, and shielding materials to collimated neutron beams (refs. 13 and 18). The slabs were exposed to bare, Cd-filtered, and \(^{10}\)B-filtered neutron beams emanating from the ORNL TSR-II reactor. A simplified illustration of the experimental configuration is shown in figure 2. Differential pulse-height spectra due to secondary gamma rays produced by neutron-induced reactions in the slabs were measured at a point 20 ft from the slabs. A borated polyethylene filter was placed between the NaI(Tl) detector and the slab to reduce thermal-neutron effects in the detector. Some materials required an additional LiH filter in front of the borated polyethylene to thermalize scattered neutrons. These experiments provided the standards for testing the data sets from the POPOP4 library.

![Figure 2 - TSR-II Experimental Configuration for Measuring Secondary Gamma-Ray Pulse-Height Spectra.](image)

The FORTRAN-IV code LINFOLD (ref. 5) was used to correct the ANISN angular flux for the geometric attenuation and for the attenuating effect of the detector neutron shield(s) - giving the intensity of secondary gamma rays striking the detector within each gamma group. One-fifth of the intensity within each group was assumed to be the intensity of five equally spaced discrete gamma energies within the group. Using Maerker's experimentally determined response functions for the NaI(Tl) detection system (ref. 13), the intensities of the discrete gammas were folded with LINFOLD to give the calculated spectra. Plots of the calculated and measured spectra were produced as the means for comparison.

Initial efforts in the data testing program were concentrated on the 23 Al, Fe, Ni, Cu, and Pb (n,γ) and (n,n'γ) data sets from refs. 11, 12, 13, 14, and 16. Pictorial comparisons of the calculated and measured pulse-height spectra resulting from the exposure of slabs of these materials to the TSR-II neutron beams are shown in ref. 20. The comparisons provide a means of evaluating the validity of the data sets for various incident neutron energy ranges. Recent efforts have been directed to the testing of the U, W, and Ta data sets in the library and to the testing of a newly acquired Fe (n,γ) data set. To illustrate the testing procedure, recent results for U and Fe are described below.

Muckenthaler et al. measured the spectra resulting from the exposure of a 10.44 x 5.75 x 0.0304-in.-thick depleted uranium foil to the collimated TSR-II beams. Background was determined for each beam by measuring the spectra without the foil in place. The 235U and 238U number densities in the sample were 8.305 x 10^{-5} and 5.02 x 10^{-2} nuclei/barn cm, respectively. The foil was oriented as shown in figure 2 above. Since gamma rays are produced by the fission capture, non-fission capture, and the inelastic-scattering reactions in both 235U and 238U, and since the SGRPXS's depend on the resonance characteristics of the nuclides, the spectra comparisons for the foil provided an interesting challenge. XSDRN was used to calculate 235U and 238U P3 neutron cross sections for the 27 neutron group structure. This calculation included the resonance self-shielding effects in both nuclides. Booth has shown that the secondary gamma-ray spectrum resulting from exposure of the foil to the Cd-filtered neutron beam minus 1.377 times the 10B-filtered spectrum eliminates the effect of high-energy (fission) neutrons (ref. 21). Sample comparisons for the (Cd-1.377 10B) and bare neutron beams are shown in figure 4. The data sets used in the preparation of the SGRPXS's for the transport calculations are listed in Table I. Calculation B is a bare beam calculation which included SGRPXS's for all 235U and 238U neutron induced reactions except the 238U (n,γ) reaction. SGRPXS's for all 235U and 238U neutron induced reactions were used in calculation D. The 238U SGRPXS's for calculation D were prepared from data sets 928112, 928301, 928901, 925801, and 925804 as indicated in Table I. Calculation A is a (Cd-1.377 10B) calculation which included SGRPXS's for all reactions except the 238U (n,γ) reaction, whereas, calculation C included SGRPXS's for all 235U and 238U reactions. A report describing similar tests of twelve uranium data sets from the POPOP4 library is in the final stages of preparation (ref. 25).

Measured spectra resulting from the exposure of an approximately 5-ft-square by 1/16-in.-thick Fe slab to the TSR-II beams were used as the standards for testing Fe data sets. Since the Cd-filter has a "cutoff" at 0.5 eV and a constant attenuation of 0.986 to neutrons above 1 MeV, and since the boron filter "cuts off" at approximately 10 keV and has

a constant attenuation of 0.75 to neutrons above 1 MeV, the spectra from the (Cd-^{10}B) neutron beam provide a test of the epithermal Fe capture yield data (ref. 18). Two calculated spectra resulting from exposure of the slab to the (Cd-^{10}B) beam are compared with the measured spectrum in figure 5. The data sets used in the preparation of SGRPXS for the calculations are identified in Table II. Neutron cross sections for the calculations were calculated with GAM-II.

Results of these studies have proven that the conversion technique used in POPOP4 is satisfactory for the conversion of yield data to a required multigroup energy structure. Since the SGRPXS's are only as accurate as the yield data and the neutron reaction cross sections, the neutron cross sections must be properly weighted prior to being used. The growth envisioned for the POPOP4 library depends on the continued support of individuals who are willing to share their efforts with others.
