NATIONAL AERONAUTICS AND SPACE ADMINISTRATION - WASHINGTON, D. C. - APRIL 1972
NEWRAP, an improved version of a previous multiple linear regression program called RAPIER, CREDUC, and CRSPLT, allows for a complete regression analysis including cross plots of the independent and dependent variables, correlation coefficients, regression coefficients, analysis of variance tables, t-statistics and their probability levels, rejection of independent variables, plots of residuals against the independent and dependent variables, and a canonical reduction of quadratic response functions useful in optimum seeking experimentation. A major improvement over RAPIER is that all regression calculations are done in double precision arithmetic.

AN IMPROVED MULTIPLE LINEAR REGRESSION AND DATA ANALYSIS COMPUTER PROGRAM PACKAGE
by Steven M. Sidik
Lewis Research Center

SUMMARY

NEWRAP is a digital computer program which can be used with ease to perform extensive regression analyses or a simple least-squares curve fit. The program is written in FORTRAN IV, version 13, for the IBM 7094/7044 DCS. The major value of the program is the comprehensiveness of its calculations and options.

NEWRAP computes the variance-covariance matrix of the independent variables, regression coefficients, t-statistics for individual tests, and analysis of variance tables for overall testing of regression. There is a provision for a choice of three strategies for the variance estimate to be used in computing t-statistics.

Also, more than one set of responses of dependent variables can be analyzed for the same set of independent variables.

A backward rejection option method based on the first dependent variable may be used to delete nonsignificant terms from the model. In this case, a critical significance level is supplied as input. The least significant independent variable is deleted and the regression recomputed. This process is repeated until all remaining variables have significantly nonzero coefficients.

The NEWRAP program uses the triangular form of symmetric matrices throughout. It also allows for the use of weighted regression, computation of predicted values at any combination of independent variables, a table of residuals, and plots of residuals.

By use of CRSPLT, a preregression analysis may be performed which may aid in the choice of model to use in NEWRAP. This program accepts the same raw data in the same format and computes the variance-covariance matrix and correlation matrix of all the variables and an eigenvector decomposition of the variance-covariance matrix corresponding to the independent variables. Microfilm plots are then printed of specified pairs of variables. Punched output of residuals and predicted values from NEWRAP can also be used for more complicated residual plots than the direct use of the plotting option NEWRAP permits.

When a quadratic response function has been estimated (as for example in optimum-seeking experimentation) CREDEC may be used to obtain all information necessary for a canonical analysis of the function.

The three programs together provide a useful data analysis package that can be applied to a large variety of common research and development situations.
**INTRODUCTION**

RAPIER (ref. 1) is a very flexible multiple linear regression analysis computer program which has been in frequent use at the NASA Lewis Research Center. It was tested with the data presented in Wampler (ref. 2) and performed quite poorly. This alone was not very disturbing since real data are seldom even nearly as ill-conditioned as that set of data. A second factor, however, is that Wampler's data leads to a 5 by 5 matrix to be inverted whereas RAPIER is designed to handle matrices of up to 60 by 60. With real data it is not uncommon for the matrix to become more ill-conditioned as the dimension increases. Often the user increases the size of the model by adding terms which are functions of the original independent variables (as for example in polynomial models) and this often leads to increased correlations and ill-conditioning.

For this reason, RAPIER was modified primarily by rearranging the storage of variables in COMMON blocks and performing all the regression calculations in double precision. This was done without losing any of the capabilities of the original program (in fact adding new options). The resulting version is called NEWRAP.

It may be of interest to some RAPIER users that in a number of sample calculations the major numerical inaccuracies arising in the regression calculations were not involved in the actual inversion of the $X'X$ matrix but in the calculation of the inner products which give

$$\hat{b} = (X'X)^{-1}(X'y)$$

Thus a major improvement might be made by computing inner products in double precision arithmetic and truncating to single precision answers without going to complete double precision arithmetic although the latter alternative would further increase the accuracy. As a matter of fact, the double precision inner product calculation is used in a different least-squares method proposed by Golub (ref. 3) which is reference 19 of Wampler's paper.

It should be pointed out that in estimation problems an alternative to the obvious step of more accurate routines is provided by Hoerl and Kennard (ref. 4). They present a technique called "ridge regression" which uses the method of minimum mean squared error estimation in place of minimum variance unbiased estimation. The ridge regression technique should have some definite appeal to statisticians, because it recognizes the fact that existence of ill-conditioned data indicates a problem which should be accounted for statistically as well as computationally. They do consider the problem of rejecting terms but their methods are not amenable to incorporation in NEWRAP in its present form.

A second reason for modifying the program was the desire to provide plots of the residuals as was strongly recommended in chapter 3 of Draper and Smith (ref. 5).
the microfilm plotting capabilities provided by CINEMATIC (ref. 6) available at the Lewis Research Center computer facility, this feature was also added to NEWRAP without significantly increasing printed output. CINEMATIC is a very specialized set of routines for the 7094/7044 DCS and 360/67 systems. If microfilm plotting is not available at other computer installations, the subroutines used in plotting may readily be changed to routines which produce line printer plots or CALCOMP plots however.

The RAPIER program used an algorithm for the coefficient calculations that inverted the correlation matrix and then converted this to the \((X'X)^{-1}\) matrix to calculate \(\hat{b}\). After inspection of several test cases, it seemed that this method did not improve the accuracy of the calculation of \((X'X)^{-1}\). Thus it was dropped and NEWRAP inverts \(X'X\) directly.

As with the RAPIER report, only the statistics and mathematics necessary to explain the program capabilities will be presented along with illustrative input and output listings and listings of the programs.

**SYMBOLS**

- \(B\) matrix
- \(b\) vector (column)
- \(b_i\) true regression coefficient
- \(\hat{b}_i\) estimated regression coefficient
- \(b_0\) constant term
- \(b_1, \ldots, b_J\) unknown parameters
- \(C\) correlation matrix
- \(C_{ij}\) elements of \(C\)
- \(D\) indicator variable, equal to 0 if no \(b_0\) coefficient is estimated and equal to 1 if \(b_0\) is estimated
- \(E(x)\) expected value of \(x\) (i.e., mean of \(x\) over all possible values of \(x\))
- \(e\) vector of observed values minus predicted values
- \(F_{a,d}\) statistic distributed as variance ratio with \(a\) and \(d\) degrees of freedom
- \(f_j(z_1, \ldots, z_K)\) term of regression equation
- \(H_0\) statistical hypothesis to be tested
$H_1$ alternate hypothesis to be accepted if $H_0$ is judged to be false
$J$ number of coefficients estimated, excluding $b_0$
$K$ number of independent variables observed
$k$ number of segments or cells in range of possible studentized residuals
LOF lack of fit
$M$ total number of independent and dependent variables
$MS(source)$ mean square due to source, where source is REG, RES, etc.
$N$ number of observations
NPDEG pooled degrees of freedom for replication error
$N(\mu, \sigma^2)$ normal distribution with mean $\mu$ and variance $\sigma^2$
$R$ number of sets of replicates
REG regression
REP replication
RES residual
$r_i$ number of replicates in set $i$
$S$ diagonal matrix
$S_c$ sum of squares correction if $D = 1$, and 0 if $D = 0$
$SSQ(source)$ sum of squares due to source, where source is REG, RES, etc.
$s_j$ elements of diagonal matrix
TOT total
$t_n$ statistic distributed as Student's $t$ with $n$ degrees of freedom
$V(x)$ variance of $x$, expected value of $(x - E(x))^2$
$W, X$ matrices
$w, x$ vectors (column)
$X_s$ stationary point of estimated quadratic surface
$x(J)$ $x_J$
$ar{x}_{i,j}$ $\frac{1}{N} \sum_{i=1}^{N} x_{ij}$
$y$ vector (column)
$Z_i$ studentized residual
4
In multiple linear regression, a dependent or response variable \( Y \) (such as temperature or pressure) measured on an object or experiment is assumed to be correlated with a function of one or more other variables \( (z_1, \ldots, z_K) \) measured on the same object or experiment. This function includes a number of unknown parameters \( (b_1, \ldots, b_J) \) and can be represented as

\[
y = h(b_1, \ldots, b_J, z_1, \ldots, z_K) + \epsilon
\]  

(1)

The only restriction imposed on this function is that it be linear in the parameters; that is, the function is of the form

\[
y = \sum_{j=1}^{J} b_j f_j(z_1, \ldots, z_K) + \epsilon
\]  

(2)

where \( f_j(z_1, \ldots, z_K) \) is a TERM of the regression equation. (A TERM is a quantity which may be a variable or a function of a variable, e.g., \( T \) is a TERM and \( Z \), after it is defined as \( Z = \log T \), is also a TERM.)

Suppose that there are \( N \) observations of the dependent variable. Let the subscript \( i \) indicate that the values are associated with the \( i \)th observation; in particular, the value of the response variable \( y_i \) would depend on the observed values of the variables \( (z_{i1}, \ldots, z_{iK}) \). Also, let the subscript \( j \) denote the \( j \)th term in the regression
model so that $x_{ij} = f_j(z_{i1}, \ldots, z_{iK})$ describes the transformations of the $z_{i1}, \ldots, z_{iK}$ to produce the value of $x_{ij}$ for the $j$th term at the $i$th observation.

The regression model can now be rewritten as

$$y_i = b_1 x_{i1} + b_2 x_{i2} + \ldots + b_J x_{iJ} + \epsilon_i \quad i = 1, \ldots, N$$

(3)

where $\epsilon_i$ denotes the difference between the observed value and the expected value of $y_i$. For the $N$ observations, it is convenient to write this regression model in matrix notation as $y = Xb + \epsilon$ where

$$y = \begin{pmatrix} y_1 \\ \vdots \\ y_N \end{pmatrix}, \quad b = \begin{pmatrix} b_1 \\ \vdots \\ b_J \end{pmatrix}, \quad \epsilon = \begin{pmatrix} \epsilon_1 \\ \vdots \\ \epsilon_N \end{pmatrix}$$

$$X = \begin{pmatrix} x_{11} & \cdots & x_{1J} \\ \vdots & \ddots & \vdots \\ x_{N1} & \cdots & x_{NJ} \end{pmatrix}$$
More often than not, the analyst feels the following model is more appropriate:

\[ y_i = b_0 + b_1 x_{i1} + \ldots + b_J x_{iJ} + \epsilon_i \quad i = 1, \ldots, N \]  

(5)

Let \( a_0 = b_0 + b_1 \bar{x}_1 + \ldots + b_J \bar{x}_J \). Then, the result of adding this equation to and subtracting it from equation (5) and rearranging the terms is

\[ y_i = (b_0 + b_1 \bar{x}_1 + \ldots + b_J \bar{x}_J) + b_1 (x_{i1} - \bar{x}_1) + \ldots + b_J (x_{iJ} - \bar{x}_J) + \epsilon_i \quad i = 1, \ldots, N \]  

(6)

If, then, a dummy variable \( x_0 \) is introduced such that, for all values of \( i \), \( x_{i0} = 1.0 \), equation (6) may be written as

\[ y_i = a_0 x_{i0} + b_1 (x_{i1} - \bar{x}_1) + \ldots + b_J (x_{iJ} - \bar{x}_J) + \epsilon_i \quad i = 1, \ldots, N \]  

(6a)

Equation (6a) now resembles equation (3) and may be written in matrix notation, similar to equation (4), as \( y = Xb + \epsilon \) where now

\[
\begin{align*}
    y &= \begin{pmatrix} y_1 \\ \vdots \\ y_N \end{pmatrix} \\
    x &= \begin{pmatrix} 1.0 & x_{11} - \bar{x}_1 & \ldots & x_{1J} - \bar{x}_J \\ 1.0 & x_{21} - \bar{x}_1 & \ldots & x_{2J} - \bar{x}_J \\ \vdots & \vdots & \ddots & \vdots \\ 1.0 & x_{N1} - \bar{x}_1 & \ldots & x_{NJ} - \bar{x}_J \end{pmatrix} \\
    b &= \begin{pmatrix} a_0 \\ b_1 \\ \vdots \\ b_J \end{pmatrix} \\
    \epsilon &= \begin{pmatrix} \epsilon_1 \\ \vdots \\ \epsilon_N \end{pmatrix}
\end{align*}
\]  

(7)
Equations (4) and (7) are similar in form and for \( N > J \) are an overdetermined set of linear equations. There will be some vector \( \hat{b} \) which is a "best" vector to use. If the vector \( \epsilon \) is composed of random variables \( \epsilon_i \) such that \( \mathbb{E}(\epsilon_i) = 0 \), \( \mathbb{V}(\epsilon_i) = \sigma^2 < +\infty \), and the \( \epsilon_i \) are uncorrelated, then as is well known, the method of least squares gives the linear minimum variance unbiased estimators \( \hat{b} \) for \( b \). And \( \hat{b} \) is given by

\[
\hat{b} = (X'X)^{-1}X'y
\]  

(8)

The matrix \( X'X \) divided by \( N - 1 \) is called the moment matrix of the experiment. The variance-covariance matrix of \( \hat{b} \) is given by

\[
\mathbb{V}(\hat{b}) = \sigma^2(X'X)^{-1}
\]  

(9)

It is important to note that when the form of equation (7) is used, \( X'X \) is given by

\[
X'X = \begin{pmatrix}
N & 0 & \cdots & 0 \\
0 & \sum_{i=1}^{N} (x_{i1} - \bar{x}_1)^2 & \cdots & \sum_{i=1}^{N} (x_{i1} - \bar{x}_1)(x_{iJ} - \bar{x}_J) \\
\vdots & \vdots & & \vdots \\
\vdots & \vdots & & \vdots \\
0 & \sum_{i=1}^{N} (x_{i1} - \bar{x}_1)(x_{iJ} - \bar{x}_J) & \cdots & \sum_{i=1}^{N} (x_{iJ} - \bar{x}_J)^2
\end{pmatrix}
\]  

(10)

This is seen to be symmetric and of the form

\[
X'X = \begin{pmatrix}
A & 0 \\
0 & B
\end{pmatrix}
\]

Hence,

\[
(X'X)^{-1} = \begin{pmatrix}
A^{-1} & 0 \\
0 & B^{-1}
\end{pmatrix}
\]
NEWRAP uses this relation to advantage by storing only the lower triangular part of $B$ and computing only the coefficients $b_1, \ldots, b_J$ by matrix manipulations. Then $b_0$ is given by the simple equation

$$b_0 = \bar{y} - \hat{b}_1 \bar{x}_1 - \hat{b}_2 \bar{x}_2 - \ldots - \hat{b}_J \bar{x}_J$$

where $\bar{y} = \sum y_i / N = \hat{a}_0$. It can also be shown that

$$V(\hat{b}_0) = V(\bar{y}) + V(\hat{b}' \bar{x}) = \left[\frac{1}{N} + \bar{x}'(X'X)^{-1} \bar{x}\right]\sigma^2$$

$$\text{COV}(\hat{b}_0, \hat{b}) = -(X'X)^{-1} \bar{x} \sigma^2$$

When there is no $b_0$ term in the regression model,

$$X'X = \begin{bmatrix}
\sum_{i=1}^{N} x_{i1}^2 & \sum_{i=1}^{N} x_{i1}x_{i2} & \cdots & \sum_{i=1}^{N} x_{i1}x_{iJ} \\
\sum_{i=1}^{N} x_{i2}x_{i1} & \sum_{i=1}^{N} x_{i2}x_{i2} & \cdots & \sum_{i=1}^{N} x_{i2}x_{iJ} \\
\sum_{i=1}^{N} x_{iJ}x_{i1} & \sum_{i=1}^{N} x_{iJ}x_{i2} & \cdots & \sum_{i=1}^{N} x_{iJ}x_{iJ}
\end{bmatrix}$$

Comparing this to equation (10) shows this form of $X'X$ to be similar to the lower right submatrix in equation (10). This similarity is used to simplify notation by assuming that $X'X$ represents either the form of equation (12) or the lower right portion of equation (10) and considering the calculation of $b_0$ as a special case. Thus, further reference to $b$ implies

$$b = \begin{pmatrix} b_1 \\ \vdots \\ b_J \end{pmatrix}$$

There are two different methods of computing the regression coefficients which may
be used in NEWRAP. The first method uses bordering (ref. 7) on the full $X'X$ matrix. If $X'X$ is a nearly singular matrix, there may be problems with accuracy resulting in overflows or underflows causing execution to terminate without any results being printed. The second method uses a method of bordering which enters one term at a time into the model equation. After each term is entered, a full regression analysis is printed. Typically, if $X'X$ is nearly singular, a number of terms will have been added to the model before the results become unreliable or cause execution to be terminated. Thus, at least a partial analysis of the full model is available to aid in selection of further models to submit. After all the terms have been entered, the program then switches to the procedure which inverts the appropriate full $X'X$ matrix at each stage for further analyses.

The use of the bordering method leads to a large volume of printed output and is not recommended as a standard procedure. Through use of CRSPLT as a preregression analysis program it may be easier to determine if bordering should be used. CRSPLT can also help indicate the order of arrangement of the terms of the model so that those thought to be most important can be entered into the model first.

Also note that the individual observations may be weighted to perform a weighted regression analysis. NEWRAP permits the use of weights (ref. 5). In this case, the $X'X$ and $X'y$ matrices take the following form:

$$\begin{pmatrix}
\sum_{i=1}^{N} [(x_{i1} - \bar{x}_1)^2 w_i] & \cdots & \sum_{i=1}^{N} [w_i(x_{i1} - \bar{x}_1)(x_{iJ} - \bar{x}_J)] \\
\vdots & \ddots & \vdots \\
\sum_{i=1}^{N} [(x_{iJ} - \bar{x}_J)(x_{i1} - \bar{x}_1)w_i] & \cdots & \sum_{i=1}^{N} [(x_{iJ} - \bar{x}_J)^2 w_i]
\end{pmatrix}$$

$$X'X =$$

$$\begin{pmatrix}
\sum_{i=1}^{N} x_{i1} y_i w_i \\
\vdots \\
\sum_{i=1}^{N} x_{iJ} y_i w_i
\end{pmatrix}$$

$$X'y =$$
CORRELATION MATRIX

Another matrix of interest both computationally and statistically in the correlation matrix $C$. The elements of $C$, which are denoted $C_{ij}$, are the sample correlation coefficients between the terms $X_i$ and $X_j$. These are

$$C_{ij} = \frac{\sum_{l=1}^{N} (x_{lj} - \bar{x}_i)(x_{lj} - \bar{x}_j)}{\sqrt{\sum_{k=1}^{N} (x_{ki} - \bar{x}_i)^2 \sum_{k=1}^{N} (x_{kj} - \bar{x}_j)^2}}$$

and all these numbers are between 1.0 and -1.0.

The calculation of $C$ can be expressed in matrix notation conveniently by defining a diagonal matrix $S = \text{diag}(s_1, s_2, \ldots, s_J)$ with elements

$$s_j = \frac{1.0}{\sqrt{(X'X)_{jj}}} \quad j = 1, \ldots, J$$

Then

$$C = S(X'X)S$$

It may also be that the independent variables are random variables. Then $X'X$ divided by $N - 1$ represents the sample variance-covariance matrix and $C$ the sample correlation matrix. If the independent variables are considered to be from a multivariate distribution, it is useful in some cases to consider the eigenvalues and eigenvectors of $X'X$. For these reasons, NEWRAP includes options to compute and print these quantities. These may also be computed and printed through use of the CRSPLT program.

ESTIMATING $\sigma^2$

For any regression model $y = Xb + \epsilon$, there are possibly two methods of estimating $\sigma^2$. First, if the assumed regression model is, in reality, the true model, it is well known that an unbiased estimator is given by
Second, where there are replicated data points, another estimator of \( \sigma^2 \), depending only on \( V(\epsilon_i) = \sigma^2 \) for all \( i \) and not on the validity of the assumed model, is the pooled mean squares computed from the replicated data points.

Assume the observations are grouped into replicate sets in sequence. Let \( R \) be the number of sets of replicates and \( r_i \) be the number of replicates in the \( i \)th replicate set. Let

\[
SSQ(i) = \sum_{k=r^*+1}^{r^*+r_i} (y_k - \bar{y}_i)^2
\]

where

\[
r^* = \sum_{j=1}^{i-1} r_j
\]

It is assumed \( y_n \) is from the \( i \)th replicate set and \( \bar{y}_i \) is calculated only from those \( y_n \) in the \( i \)th replicate set. Then define the pooled sum of squares due to replication as

\[
SSQ(REP) = \sum_{i=1}^{R} SSQ(i)
\]

and the pooled degrees of freedom as \( NPDEG = \sum_{i=1}^{R} (r_i - 1) \). The second estimator of \( \sigma^2 \) becomes

\[
\sigma^2_{REP} = \frac{SSQ(REP)}{NPDEG}
\]

\[
= MS(REP)
\]

It can be shown (ref. 5, p. 26) that the sums of squares due to residuals can be partitioned into a component due to replication and a component due to lack of fit; that is,

\[
SSQ(RES) = SSQ(LOF) + SSQ(REP)
\]
This partitioning is used later to determine the estimate of $\sigma^2$ to use in tests of hypotheses.

**HYPOTHESIS TESTING**

**NORMALITY OF $\epsilon$**

As stated before, the only assumption necessary for $\hat{\beta}$ to be a linear minimum variance unbiased estimator is that $E(\epsilon_i) = 0.0$, $V(\epsilon_i) = \sigma^2 < +\infty$, and $\epsilon_i$ be uncorrelated. If it can further be assumed that $\epsilon_i \sim N(0, \sigma^2)$, a number of standard tests become available. NEWRAP computes a chi-squared statistic which can be used as an approximate test.

Under the hypothesis $\epsilon_i \sim N(0, \sigma^2)$, the studentized residuals defined by

$$Z_i = \frac{y_i - \hat{y}_i}{\hat{\sigma}} = \frac{\epsilon_i}{\hat{\sigma}}$$

will be distributed as Student's $t$ with the degrees of freedom associated with the estimate $\sigma$. If the degree of freedom is 30 or more, the $t$ distribution is very close to the normal.

The range of possible studentized residuals is $(-\infty, +\infty)$ and may be divided into $k$ segments or cells each with probability $p_i$, so that each segment will have $Np_i$ as the expected number of observations falling into it. Let $n_i$ denote the number of studentized residuals in the $i^{th}$ cell. Then a chi-squared goodness-of-fit statistic may be calculated as

$$\chi^2_{k-1} = \sum_{i=1}^{k}\frac{(n_i - Np_i)^2}{Np_i}$$

NEWRAP computes this statistic by using an even number of cells greater than or equal to four and less than or equal to 20, such that the expected numbers of observations per cell is five or more. This statistic is not computed when there are less than 20 observations. The bounding values for the $i^{th}$ cell are $Z_{i-1}, Z_i$ where $F(Z_i) = (i \cdot k)/N$ and $F(Z)$ is the cumulative normal distribution function. Then each cell has the same expected number of observations, say $f = N/k$. Then
There is a point to be made concerning the chi-squared calculations. The validity of the use of the chi-squared statistic in a test depends upon the residuals forming a sample of independent and identically distributed random variables. This is not usually the case for regression residuals. Although the tail probabilities of the chi-squared tests might be in error, they should still be able to tell the statistician whether one intended normalizing transformation was more successful than another.

**ANALYSIS OF VARIANCE TABLE**

For most hypothesis testing of the regression model, it is convenient to summarize the available information in an Analysis of Variance (ANOVA) table, as follows:

<table>
<thead>
<tr>
<th>Source</th>
<th>Sums of squares</th>
<th>Degrees of freedom</th>
<th>Mean squares</th>
</tr>
</thead>
<tbody>
<tr>
<td>Regression (REG)</td>
<td>SSQ(REG) = ( b'X'y - S_c^a )</td>
<td>( J )</td>
<td>MS(REG) = SSQ(REG) ( J )</td>
</tr>
<tr>
<td>Residual (RES)</td>
<td>SSQ(RES) = ( y'y - b'X'y )</td>
<td>( N - J - D^b )</td>
<td>MS(RES) = SSQ(RES) ( N - J - D )</td>
</tr>
<tr>
<td>Total</td>
<td>SSQ(TOT) = ( y'y - S_c )</td>
<td>( N - D )</td>
<td></td>
</tr>
</tbody>
</table>

\[ a \quad S_c = \begin{cases} 
0 & \text{if no } b_0 \text{ coefficient is estimated.} \\
N y^2 & \text{if a } b_0 \text{ coefficient is estimated.}
\end{cases} \\
\]

\[ b \quad D = \begin{cases} 
0 & \text{if no } b_0 \text{ coefficient is estimated.} \\
1 & \text{if } b_0 \text{ is estimated.}
\end{cases} \\
\]

If there are replicated data points, another ANOVA table can be constructed to show the separation of the residual sums of squares into components from lack of fit and replication, as in the following table:
As mentioned previously, there are two possible methods of estimating $\sigma^2$ depending on whether there are replicated data points. This is true for any given model equation. When the backward rejection option of NEWRAP is used, there is no longer one hypothetical model but a series of models. Thus, there is the choice of estimator for $\sigma^2$ to be made after each rejection of a term in the previous model.

As an example, consider the model

$$y = b_0 + b_1x_1 + b_2x_2 + b_3x_3 + \epsilon$$

(20)

with replicated data points. The first step is to estimate $b_0$, $b_1$, $b_2$, and $b_3$. There will then be the estimators $\hat{\sigma}^2_{\text{RES(J)}}$ and $\hat{\sigma}^2_{\text{REP}}$. If the model in equation (20) has not left out any important terms, $\hat{\sigma}^2_{\text{RES(J)}}$ as well as $\hat{\sigma}^2_{\text{REP}}$ is a valid estimator.

The ratio $F = \text{MS(LOF)}/\text{MS(REP)}$ can be used to test the hypothesis that there is no lack of fit, where $F \sim F_{a,d}$ with $a = N - J - D - \text{NPDEG}$ and $d = \text{NPDEG}$ degrees of freedom. If the test accepts the hypothesis of no lack of fit, MS(RES) is a pooled estimate of $\sigma^2$ with more degrees of freedom. But there is the possibility that the hypothesis was accepted as a result of random fluctuation when there really is some lack of fit; that is, there is the possibility that $\hat{\sigma}^2_{\text{RES(J)}}$ is a biased estimator. If lack of fit is not concluded to be significant, the decision to pool or not is usually made on the basis of the number of degrees of freedom for replication. If this is "large" (no definition of large is given herein), $\hat{\sigma}^2_{\text{REP}}$ is used. If "small," the pooled estimate $\hat{\sigma}^2_{\text{RES(J)}}$ is used.

In testing equation (20), should it be decided that $b_3$ is not significantly different from zero (see section t-TESTS), the coefficients of the following model would be estimated:

$$y = b_0 + b_1x_1 + b_2x_2 + \epsilon$$
From this model there is an estimate $\hat{\sigma}^2_{RES(J-1)}$. This estimate could also be biased since $b_3$ may be small but nonzero and the decision of $b_3 = 0$ may have been due to the low power of the test.

At the first step, the lack of fit can be considered a random sample of an infinite possibility of biases. But the biases due to pooling mean squares after rejecting terms can be considered to be systematic biasing. In such a case the use of Cochran's test for "the largest of a set of estimated variances as a fraction of their total" might be appropriate.

NEWRAP provides three strategies of pooling estimates for use in the decision procedure:

1. Never pool. This is usable only when there are replicated data points. The estimator used in all t-tests is $\hat{\sigma}^2_{REP}$.

2. Pool initial residual. This will pool the lack of fit and replication (if any) from the first model only. Additional mean squares due to rejected terms will be ignored.

3. Always pool. This strategy will always use $\hat{\sigma}^2_{RES(J-i)}$ for the model with $i$ rejected terms.

Wherever a $\hat{\sigma}$ or $\hat{\sigma}^2$ is indicated, NEWRAP always uses the value calculated according to the strategy chosen by the user.

**TEST OF OVERALL REGRESSION**

One of the first tests usually applied to a regression model is the test of the overall significance of the model. In the notation of hypothesis testing this is stated $H_0$: $b = 0$; $H_1$: $b \neq 0$ where

$$b = \begin{pmatrix} \hat{b}_1 \\ \vdots \\ \hat{b}_j \end{pmatrix}$$

The statistic for this test is $F = \frac{MS(\text{REG})}{\hat{\sigma}^2}$. The $F \sim F_{a, d}$ with $a = J - D$, and $d$ equals the degrees of freedom associated with $\hat{\sigma}^2$.

Another useful statistic for judging the significance of overall regression is $R^2 = SSQ(\text{REG})/SSQ(\text{TOT})$. The sampling distribution of $R$ does not lend itself to very simple tests except in the case of $H_0$: $b = 0$. The main value of $R^2$ is that it is a
number in the range 0 to 1 and $100 \, R^2$ is a measure of the percentage of variation in the $y$ values that is accounted for by the regression model.

**t-TESTS**

In many cases, the regression model contains terms whose estimated coefficients are "small." This may be an indication that the term does not have a real effect on the dependent variable and that the estimate is nonzero due to random sampling variation. If this is true, it is desirable to delete the term from the regression model. A test statistic for deciding this is

$$t = \frac{\hat{b}_i}{\sqrt{\hat{\sigma}^2 (X'X)^{-1}_{ii}}}$$

where $(X'X)^{-1}_{ii}$ denotes the $i$th diagonal element of the $(X'X)^{-1}$ matrix. The statistic $t \sim t_{N-J-D}$. An equivalent test statistic is

$$F = t^2 = \frac{\hat{b}_i^2}{\hat{\sigma}^2 (X'X)^{-1}_{ii}}$$

where $F \sim F_{1, N-J-D}$. This is often referred to (ref. 5) as the partial F-test. The quantity $\hat{b}_i^2/[((X'X)^{-1}_{ii})]$ is called the additional sum of squares due to $b_i$, if $x_i$ were last to enter the equation. NEWRAP computes and prints the $t$-statistics, the probability associated with the interval $(-t, t)$, and the additional sums of squares for each term.

This particular test is the basis for the rejection option of NEWRAP. The analyst initially chooses which $\hat{\sigma}^2$ estimator to use by the choice of strategy. Then the analyst may choose a confidence level which all coefficients must meet. For example, suppose a confidence level of 0.900 is chosen. The $t$-statistic is then computed for each coefficient, and the coefficient with minimum $|t|$ is identified. If $\min |t| > t_{N-J-D, 0.950}$, all terms are concluded to be significant at the 0.1 level (or 90.0 percent level of confidence). If $\min |t| < t_{N-J-D, 0.950}$, the term corresponding to the minimum $|t|$ is dropped from the hypothetical model, and the regression is recomputed. This process is repeated until all remaining coefficients are significant at the specified level of probability. This procedure can be overridden by an option which allows certain specified terms of the model to be retained regardless of the significance of the coefficient.
nedy and Bancroft (ref. 8) present a study indicating the backward deletion method is slightly more efficient than forward selection in special situations.

**PREDICTING VALUES FROM ESTIMATED REGRESSION EQUATION**

Regression equations are often used to predict an estimated response at some condition of the independent variables. Useful estimates of parameters to know are the variance of the regression equation and the variance of a single further observation at the desired combination of the independent variables.

Let \( x' = (x_1, \ldots, x_J) \) denote the vector of independent variables at which a prediction is desired. Let \( x^* = x - \bar{x} \). Let \( \hat{\sigma}_{\mu \cdot x}^2 \) denote the estimated variance of the regression equation at \( x \). Let \( \hat{\sigma}_{y \cdot x}^2 \) denote the estimated variance of a single further observation at \( x \). Then,

\[
\hat{\sigma}_{\mu \cdot x}^2 = \hat{\sigma}^2 \left[ \frac{D}{N} + x^*(X'X)^{-1} x^* \right]
\]

\[
\hat{\sigma}_{y \cdot x}^2 = \hat{\sigma}^2 \left[ 1.0 + \frac{D}{N} + x^*(X'X)^{-1} x^* \right]
\]

where, as before, \( D = 1 \) if a \( b_0 \) coefficient is estimated and \( D = 0 \) if a \( b_0 \) coefficient is not estimated. The quantity \( s = \hat{\sigma}_{\text{RES(J)}} \) is called the standard error of estimate and often is used as a simple approximation to \( \hat{\sigma}_{y \cdot x} \). This approximation is close if \( N \) is very large and \( x = \bar{x} \), in which case,

\[
\hat{\sigma}_{y \cdot \bar{x}}^2 = s^2 \left( 1.0 + \frac{D}{N} \right) \approx s^2
\]

When \( x \neq \bar{x} \), this may be a poor approximation. NEWRAP accepts input vectors \( x \) and computes \( \hat{y} = \hat{b}_0 + \hat{b}_1 x_1 + \ldots + \hat{b}_J x_J \), as well as \( \hat{\sigma}_{\mu \cdot x}^2, \hat{\sigma}_{\mu \cdot x}, \hat{\sigma}_{y \cdot x}, \hat{\sigma}_{y \cdot x}, \hat{\sigma}_{y \cdot x} \), and the standard error of estimate.
NEWRAP PROGRAM

USERS GUIDE TO NEWRAP INPUT

Illustrative Regression Problem Requiring No Transformations

The illustrative example is described in chapter 7 of reference 5. The data is reproduced in table I. Figure 1 presents this data in a sample input form.

The basic model to be fitted is

$$y = b_0 + b_1 x_1 + b_2 x_2 + b_3 x_3 + b_4 x_4$$

</table>

The model equation is defined by set 4 of table II. An example illustrating the use of one blank card for input set 4 which can be used for simple linear regressions is presented by figure 1 and table I. A second example illustrating the use of the set of MODEL cards in the presence of prior constants and transformations will be given at the end of this section of the report. A pictorial representation of an input deck is given by figure 2.
Figure 2. - Sample input deck. (Asterisk denotes the card is optional and its use depends upon data input on previous cards.)
Figure 2. - Concluded.
Details of the input cards are as follows:

1. **IDENTIFICATION** (I, IDENT)(I2, 13A6): IDENT is Hollerith data used to identify the problem. I indicates the number of additional cards to read for further identification or description (columns 1 to 78).

2. **PROBLEM SIZE** (NOVAR, NODEP, NOTERM, NOOB, NTKEEP)(3I4, I5, I4)

   - **NOVAR**: Number of input independent variables (number of z's in eq. (2))
   - **NODEP**: Number of input dependent variables
   - **NOTERM**: Number of terms in model equation (number of x's in eq. (3)). Note that b_0 is not counted as a term.
   - **NOOB**: Number of observations
   - **NTKEEP**: First NTKEEP independent terms of model equation will be retained in model regardless of significance level

3. **LOGIC**: One card with nine one-column fields

   - **BZERO**: b_0 term appears in model equation (T or F)
   - **IFTT**: t-statistics and their descriptive confidence levels are to be computed (T or F)
   - **IFWT**: Weight of 1.0 is applied to all observations (T or F). If this is F, see input sets 7 and 8 for further information.
   - **IFCHI**: Compute and plot residuals (T or F)
   - **STORYX**: Calculate eigenvalues and eigenvectors of X'X (T or F)
   - **IFSSR**: Model shall be increased by one term at a time using bordering method for matrix inversion (T or F)
   - **ECONMY**: Use economy version of output (T or F). NEWRAP does not print X'y, (X'X)^{-1}, or C when set to F.
   - **ISTRAT**: Pooling strategy is 1, 2, or 3:
     1. Never pool. Use replication error as estimate of error. If 1 is selected and no replication is found, strategy 3 is used.
     2. Pool initial residual only.
     3. Pool all residuals.
Punch residuals and predicted values (T or F). If T, observation number is punched and then residuals and predicted values are punched in \((16, 4E16.8/(6X, 4E16.8))\) format in pairs (observation number, \(e_1, \hat{y}_1, e_2, \hat{y}_2\), etc.).

(4) MODEL: The MODEL cards are used to manipulate the observed input data, supplied by input set 8, into the form of the desired model equation. There are four subsets of this input set 4, namely, MODEL SIZE, TERMS, TRANSFORMATIONS, and CONSTANTS, of which the latter three are used only in the development of complex models.

If a simple linear model is being analyzed, the MODEL SIZE card is left blank, indicating that the number of transformations is zero and the number of constants to be read in is zero. In this case, the TERMS, TRANSFORMATIONS, and CONSTANTS cards of this input set are not expected by the program, and the program assumes the independent and dependent variables are arranged on the input cards of input set 8 as

\[x_1, x_2, \ldots, x_J, y_1, \ldots, y_{\text{NODEP}}\]

where NODEP is the number of dependent variables.

If a weighting factor other than 1.0 is to be used (i.e., if item 3 of the LOGIC card contains an F), the value of the weighting factor for each observation must appear as the last item in the list, so that in this case the data for each observation is entered on the cards as

\[x_1, x_2, \ldots, x_J, y_1, \ldots, y_{\text{NODEP}}, WT\]

If the weighting factor is identically 1.0, NEWRAP reads a total of \(M\) numerical values for each observation, where \(M\) is the sum of the number of independent and dependent variables. The variables are stored consecutively in an array called \(X\), beginning with location 01 and ending with location \(M\). If the weighting factor is not identically 1.0, then \(M + 1\) numerical values are read for each observation, but the last value, being the weighting factor, is treated and stored separately. The data in \(X\) are used with their appropriate weighting factors to cumulatively create \(X'X\) and \(X'y\) as shown in equations (12a).

The remaining discussion of this set explains the use of transformations and/or constants to build more complex models. Therefore, the reader who does not immediately need a complex model may skip this material and proceed directly to the description of input set 5.

As mentioned previously, there are up to four subsets of the MODEL cards. Their purpose is to give the structure of the model equation and thereby specify the initial
operations to be performed on the input data. As used here, CONSTANTS means any numerical value specified to be in the model equation in advance of parameter estimation. These numerical values are read from the CONSTANTS cards.

Also, the word TRANSFORMATIONS is to be interpreted as the operations performed on the input data (read from data cards) to compute the \( f_j \) values (eq. (2)) of the model equation. The structure of these functions (and of any transformations of the dependent variables) is read from the TRANSFORMATION cards. Finally, the word TERMS is to be interpreted as the computed results of the operations specified by the transformation (including any operations that leave the input data unchanged). The results of the TRANSFORMATIONS are stored in an array \( \text{CON} \), and the TERMS cards designate the order of the relative locations in \( \text{CON} \) where the final values for the terms of the model equations are to be found.

The four subsets, MODEL SIZE, TERMS, TRANSFORMATIONS, and CONSTANTS, will be described in detail now. Also, at the end of the description of this input set, a summary of these cards, with the formats used, is given for convenience.

The MODEL SIZE card specifies \( \text{NTRANS} \) and \( \text{KONNO(214)} \) where

\[
\text{NTRANS} \quad \text{Number of transformations that will be performed}
\]

\[
\text{KONNO} \quad \text{Number of constants that will be read in which are required to specify model equation}
\]

If the number of transformations is zero, and therefore, the number of constants is zero, the TERMS, TRANSFORMATIONS, and CONSTANTS cards are not expected by the program. This being a simple linear model case, only the MODEL SIZE card, which can be blank, is necessary in this subset, but the values for the observations which are provided in input set 8 must conform to the order as specified in the first three paragraphs describing this input set.

When, however, a more complex model is desired, information must be supplied instructing the program as to (1) where to find the values for the TERMS of the equation, (2) how to create the terms from the variables and the constants, and (3) what the values of the constants are. This information is supplied on the TERMS, TRANSFORMATIONS, and CONSTANTS cards.

The numerical values to be used in the transformations are stored in two arrays called \( \text{X} \) and \( \text{CON} \). The transformations always require that an operator (some value from \( \text{CON} \)) performs an operation (see table III) on an operand (some specified value from \( \text{X} \)) to produce a result which will be stored in \( \text{CON} \). Thus \( \text{CON} \) serves two purposes. First, if the number of constants (\( \text{KONNO} \)) specified on the MODEL SIZE card is nonzero, that many constants will be read from the CONSTANTS cards and stored in \( \text{CON} \) beginning with location 01. If the number of constants is zero, a CONSTANTS card is not expected by the program. Second, all intermediate and final results of

*aAll function names and operations are consistent with FORTRAN IV mathematical subroutines.

Transformations are also stored in CON as specified on the TRANSFORMATION cards. The TERMS card then specifies which of the locations in CON finally contain the values needed to construct the X'X and X'y matrices. After all the transformations have been performed on an observation, the contents of the relative locations of the CON array specified on the TERMS card are moved back to X in consecutive locations beginning with location 01.

Note especially that CONSTANTS data are stored in CON from location 01 through KONNO. Thus, if a transformation specifies that a result is to be placed in any of these locations, the result will replace the constant, so that further operations on subsequent transformations would use the new value stored instead of the constant value to which it was initialized. Care should be taken, therefore, that the results of the transformations be stored in relative locations greater than KONNO.

Each transformation code is made up of four subfields of two card columns each, with the following interpretation:
Thus, subfield 1 always references the X array, and subfields 3 and 4 reference the CON array. The result of every transformation is a term which is stored in the designated location of the CON array, with the added feature that, if the term is stored in relative location 61 or beyond, it is also stored in the parallel location in the X array. This is illustrated by the arrows in figure 3. This feature allows successive transformations to be performed more easily.

The OP (operation codes) are tabulated in table III. The transformation with OP = 00 is simply an identity transformation. This transfers data from X to CON so that when terms are selected there is a value available in CON that can be moved back to X.

When there are no transformations, NEWRAP assumes the first NOTERM values on a data card are the independent variables and the last NODEP values are the depend-

Figure 3. Map of X and CON arrays. Data transferred into any location of CON array beyond location 60 are immediately duplicated in same relative location in X array.
ent variables. When transformations are used, this convention need not hold for the raw input data but instead holds for the terms on the TERMS card. Thus, the first NOTERM values input on the TERMS card indicate the locations of the CON array which correspond to the independent variables and the last NODEP values indicate the locations of the CON array which correspond to the dependent variables. If the analyst desires to force certain terms to remain in the model regardless of their significance, these terms must be the first terms of the model. Then if the input for NTKEEP of the PROBLEM SIZE card is not zero, the first NTKEEP terms of the model will be retained.

The complete sequence of MODEL cards and the formats used are summarized as follows:

(a) MODEL SIZE (NTRANS, KONNO)(214): NTRANS specifies the number of transformations required and KONNO the number of CONSTANTS involved. NTRANS may not be greater than 100 and KONNO not greater than 60. If NTRANS = 0, the following three sets are skipped and the program goes directly to input set 5.

(b) TERMS (4012): One or more cards as necessary, using two-column fields to denote the relative locations of the CON array containing the final values for the terms to be used and the order in which they enter into the model equation. The number of terms used is specified on the PROBLEM SIZE card.

(c) TRANSFORMATIONS (4012): As many cards as necessary containing up to 10 transformation instructions per card. Each transformation instruction is composed of four two-column fields. See table III for the list of available transformations.

(d) CONSTANTS (5E15.7): As many cards as necessary containing the number of CONSTANTS as specified by KONNO. Up to 60 CONSTANTS may be specified. If KONNO = 0, these cards are not expected by the program.

(5) REJECTION (DELETE, P)(L1, F3.3): If DELETE is set to T, the backward rejection option is used and the desired level of confidence is given by P. The P value is written without a decimal point so that a 95 percent confidence level is indicated by a 950, a 99.9 percent level as 999, and so forth.

(6) REPLICATION (REPS)(L1): If REPS is F, the program skips to set 7 and assumes there is no replicated data. If REPS is set to T, then more cards are read in 2014 format specifying:

IREP in the first field of the first card indicates the number of replicate sets.

NARAY in the second field of the first card and the remaining fields of this and succeeding cards consists of an array containing the number of observations in each of the replicate sets.

Note that it is not safe for the program to assume that all the data points for an experiment with the same levels of the independent variables are true replicates. Thus the user must explicitly specify the truly replicated sets. NEWRAP does check that all
independent terms within a replicate set are the same. If not, the program stops. A nonreplicated data point is considered to be a group of size 1. Note that the data in table I are grouped to clearly indicate the replicated data points.

(7) FORMAT (INPUT, FMT)(I2, 13A6): INPUT specifies the unit number on which the input data is stored; and FMT supplies the format for reading it.

Note that, if a weighting factor other than 1.0 is to be used, its value will be read with each data point, and the format must allow for this.

The example from Draper and Smith (ref. 5) uses a weighting value of 1.0 for all data. The format is (12X, 5F6.0) since there are four independent and one dependent variable to be read. If a weighting value other than 1.0 is used, it must appear with every data point as the last value on the card. In such a case, the format could, for example, be (12X, 5F6.0, F10.3).

(8) DATA: Each observation consisting of the given z's and y's read by the execution of one READ statement. Thus, there will be at least one card for each observation. As mentioned previously, if the transformation option is not used, the program expects the first variables to be the independent variables, in the order in which they enter the model, followed by the dependent variables and then the weighting value if IFWT = .F. Otherwise, if transformations are used, the independent and dependent variables may be entered in any convenient order, because the TERMS card(s) will be needed to specify the order in which the values will enter the model equation. However, if IFWT = .F., the weighting value is still the last value supplied with each observation.

(9) PREDICTIONS (PREDCT)(L1):

(Data) If, with the program LOGIC (input set 3) card, a computation of residuals is requested by a T in card column 4, then predicted values of the dependent variables are computed for all the input values of the independent variables. In addition to these predicted values, predictions at other values of the independent variables might be desired. In PREDICTIONS input, one card with one column is used to indicate if these other predictions are desired (T or F). If this is F, a new case is started and the new case should start with input set 1 cards. If it is T, the following cards are read: One card with one four-column field specifying the number of predictions desired. This is followed by cards with the values of the independent variables at which predictions are desired. Only the final regression model is used, but the number of independent and dependent variables originally supplied on the PROBLEM SIZE data cards are read. All transformations indicated on the MODEL cards are performed. Then the proper terms are chosen by the program to correspond to the final model. Since the dependent variables are not needed in this part of the program, the numerical values for the dependent variables are dummy values and should be in the appropriate range so that when subroutines required for the transformations (e.g., ALOG, SQRT) use these values, abnormal exits will not occur.
Illustrative Problem Requiring Transformations

As an example of the MODEL cards usage consider the following. Suppose the model we are required to construct is

\[ \log_{10}(y + 273.15) = b_0 + b_1z_1 + b_2z_2 + b_3z_3 + b_4z_1z_2 + b_5z_1z_3 + b_6z_2z_3 + b_7z_1^2 + b_8z_2^2 + b_9z_3^2 \]

Thus, in terms of equation (2) we have

\[ x_1 = z_1 \]
\[ x_2 = z_2 \]
\[ x_3 = z_3 \]
\[ x_4 = z_1^2 \]
\[ x_5 = z_1^2 \]
\[ x_6 = z_2^2 \]
\[ x_7 = z_1^2 \]
\[ x_8 = z_2^2 \]
\[ x_9 = z_3^2 \]

\[ y = \log_{10}(y + 273.15) \]

Table IV shows a sequence of transformations which could be used to construct this model equation. Figure 4 shows how the MODEL cards describing this equation would appear on a FORTRAN data sheet. Figure 5 shows the X and CON array contents both before and after the transformations are performed upon one observation and the X array after the appropriate terms have been selected according to the TERMS card data.

NEWRAP DOCUMENTATION AND LISTINGS

The contents of this section include a flow chart of the program, a listing of the routines used in NEWRAP and their major functions, the call structure of the program, a dictionary of the program, and the listing.

General Mathematical and Logical Flow of Program

The flow of operation in NEWRAP is illustrated in figure 6.
I Perform transformations
Replications?
Yes
Calculate replication error
Calculate $X'X$, $X'y$, C
Add one term at a time?
No
Yes
j = 0
j = j + 1
3
Calculate $(X'X)^{-1}$
Compute coefficients
Compute ANOVA data $R^2$, $R$, $\theta$

START
Given data
Perform transformations

Want to delete terms?
Yes
Choose term, among those not being forced to remain in model, with minimum significance
No
Below critical level?
Yes
Delete proper row and column from $X'X$

START
Given $X_0$
Compute $x_0'X_0(X'X)^{-1}x_0$
Compute $\theta_0^2$, $s_0^2$, $s^2$
More points to predict?
No
Yes
START

Choose term, among those not being forced to remain in model, with minimum significance
No
Below critical level?
Yes
Compute residuals, chi-squared statistic

START
Want to predict variables?
Given $X_0$
Compute $x_0'X_0(X'X)^{-1}x_0$
Compute $\theta_0^2$, $s_0^2$, $s^2$
More points to predict?
No

Figure 6. - Flow chart for NEWRAP.
## Routines and Their Major Functions

<table>
<thead>
<tr>
<th>FORTRAN name</th>
<th>Function of routine</th>
</tr>
</thead>
<tbody>
<tr>
<td>BORD</td>
<td>Inverts symmetric matrix of order $n$ by adding bordering column to already inverted matrix of order $n - 1$</td>
</tr>
<tr>
<td>EIGEN</td>
<td>Computes eigenvalues and eigenvectors of input symmetric matrix</td>
</tr>
<tr>
<td>HIST</td>
<td>Prints histogram of residuals</td>
</tr>
<tr>
<td>INVXTX</td>
<td>Inverts symmetric matrix</td>
</tr>
<tr>
<td>LOC</td>
<td>When given row and column indices of symmetric matrix element, it computes location this element would have if only lower triangular part were stored as vector.</td>
</tr>
<tr>
<td>MATINV</td>
<td>Controls inversion process; computes regression coefficients; computes eigenvalues and eigenvectors of $X'X$ if requested</td>
</tr>
<tr>
<td>MFIX</td>
<td>Prints $X'X$ and computes and prints $C$</td>
</tr>
<tr>
<td>NEWRAP</td>
<td>Executes overall problem control; computes replication error; controls deletion of variables when given results of t-test</td>
</tr>
<tr>
<td>OUTPLT</td>
<td>Computes residuals at observed points and plots them. Compute chi-squared statistic</td>
</tr>
<tr>
<td>PREDCT</td>
<td>Computes predicted values, variances, and standard deviations of regression line and further observations at specified points</td>
</tr>
<tr>
<td>RECT</td>
<td>Writes rectangular matrix</td>
</tr>
<tr>
<td>RSTATS</td>
<td>Computes regression statistics and writes regression and lack-of-fit analysis of variance tables</td>
</tr>
<tr>
<td>SUMUPS</td>
<td>Constructs $X'X$ and $X'y$ matrices one observation at a time, in double precision</td>
</tr>
<tr>
<td>TRAN</td>
<td>Performs transformations</td>
</tr>
<tr>
<td>TRIANG</td>
<td>Writes lower triangular part of symmetric matrix</td>
</tr>
<tr>
<td>TTEST</td>
<td>Computes t-statistics and their significance levels; determines which variable should be deleted</td>
</tr>
</tbody>
</table>

### Call Structure of Program

The call structure of the program is illustrated in figure 7.
Dictionary of Program

<table>

SUBROUTINE MATINV

目的
1) 计算矩阵 (X-转置 X) 的特征值和特征向量。
2) 计算 (X 乘以 X 的转置) 的逆。
3) 计算回归系数。
4) 计算其他回归统计量。

所需子程序
BORD, LOC, EIGEN, INVXTX, RECT, RSTATS, TRIANG

注释
特征值的计算作为确定系统方程组条件的辅助手段。
特征值及其相关特征向量的检查可能会显示一组独立变量是高度相关的
并且不容易独立地研究。

SUBROUTINE KSTATS

PURPOSE

1) Compute and print the analysis of variance tables on regression and lack-of-fit if appropriate.
2) Compute and print R-squared and standard error of estimate.
3) Compute and print sums of squares due to each variable if it were last to enter regression.
4) Compute and print the standard deviations of each regression coefficient.

135 FORMAT(51H FOR EACH DEPENDENT TERM AND OBSERVATION IS PRINTED
X /31H OBSERVED RESPONSE (Y OBSERVED)
   /29H CALCULATED RESPONSE (Y CALC)
CRSPLT accepts a subset of the data used for a NEWRAP problem. It can be used as a preregression analysis program to help formulate model equations to be analyzed with NEWRAP or it may be used as a postregression program by using punched output from NEWRAP to obtain more complex residual plots than direct use of NEWRAP allows.

When used as a preregression program, it will compute an $X'X$ and $C$ matrix including all the terms (independent and dependent) if requested. It can also compute eigenvalues and eigenvectors of the submatrix of $X'X$ corresponding to the independent variables.

When used as a postregression program, the punched output of residuals and predicted values from NEWRAP can be plotted against new functions of the independent variables.

The input is much the same as for NEWRAP. The seven sets of input are as follows:

1. **IDENTIFICATION** (I, IDENT)(I2, 13A6): IDENT is Hollerith data used to identify the problem. I indicates the number of additional cards to be read for identification (columns 1 to 78).

2. **PROBLEM SIZE** (NOVAR, NODEP, NOTERM, NOOB)(314, I5)
   
   NOVAR: Number of input independent variables
   NODEP: Number of input dependent variables
   NOTERM: Number of terms in model equation
   NOOB: Number of observations

3. **TRANSFORMATIONS**: This input is the same as the transformations of NEWRAP except for the upper limit of 150 transformations.

4. **FORMAT** (INPUT, FMT)(I2, 13A6): INPUT specifies the unit number the input data is stored on and FMT indicates the format for reading it.
(5) PLOTTING REQUESTS

NOPLTS (I4)

One card supplies NOPLTS, the number of plots desired. The following cards supply pairs of integers indicating which pairs of terms to plot. The format is 40I2 (i.e., 20 plots per card). The first number of the pair (IXPLT) specifies the sequence number of the term to be used as the abscissa. The second number (IYPLT) specifies the sequence number of the term to be used as the ordinate. As an example, the following sequence of transformations and subsequent plotting requests would cause \( X_1^2 \) to be plotted against \( x_1 \) as well as against \( x_3^3 \):

\[
\begin{align*}
\text{MODEL SIZE} & \quad 0003 \\
\text{TERMS} & \quad 616263 \\
\text{TRANSFORMATIONS} & \quad 01000061 \ 01026162 \ 01026263 \\
\text{CONSTANTS} & \quad \text{blank card} \\
\text{NOPLTS} & \quad 0002 \\
(\text{IXPLT, IYPLT}) & \quad 0102 \ 0302
\end{align*}
\]

(6) MATRIX REQUESTS (XTXC, EIGENC)(2L1): If XTXC is F, no matrix calculations are executed. If it is T, then an \( X'X, X'X \) deviation and a correlation matrix of all the NOTERM + NODEP terms appearing on the TERMS card are computed. If EIGENC is T, then the eigenvalues and eigenvectors of the submatrix corresponding to the independent terms (the first NOTERM terms) are calculated.

(7) DATA: Same usage as in NEWRAP.

An illustrative set of input is given, followed by the corresponding sample of output and a main program listing. The subprograms TRIANG, RECT, and EIGEN are required and are the same as in NEWRAP.

CREDUC PROGRAM

In optimum-seeking experimentation involving many independent variables, quadratic response surfaces are often used. A development of the most important aspect of the design and analysis of response surface experiments can be found in Davies (ref. 9) and Box and Hunter (ref. 10). A discussion of the interpretation of a quadratic surface fitted to a large experiment is given in reference 11.

The general form of a quadratic surface is given by

\[ y = b_0 + b'X + X'BX + \epsilon \]

\[
= b_0 + (b_1, b_2, \ldots, b_p) \begin{pmatrix} x_1 \\ \vdots \\ x_p \end{pmatrix}
\]

\[
= b_0 + \left( \begin{array}{cccc}
    b_{11} & \frac{1}{2} b_{12} & \cdots & \frac{1}{2} b_{1p} \\
    \frac{1}{2} b_{12} & b_{22} & \cdots & \frac{1}{2} b_{2p} \\
    \cdots & \cdots & \cdots & \cdots \\
    \cdots & \cdots & \cdots & b_{pp} \\
\end{array} \right)
\begin{pmatrix}
    x_1 \\
    \vdots \\
    x_p
\end{pmatrix} + \epsilon
\]  

The analysis of such an equation is simplified by two calculations: (1) the calculation of the stationary point of the surface and (2) a transformation of axes to new independent variables which changes the \( B \) matrix to a diagonal matrix.

The stationary point of the surface is the solution \( X_s \) to

\[
\frac{\partial y}{\partial x_i} = 0 \quad i = 1, p
\]

The transformation of the axes is given by the computation of the orthogonal matrix \( P \) which reduces \( B \) to a diagonal matrix; that is,
The $\lambda_i$ are the eigenvalues of $B$. The new variables are given by

$$Z = P'X$$

where $P$ is the matrix whose columns are the eigenvectors of $B$. If two successive transformations of the variables are made as follows:

$$W = X - X_s$$

$$Z = P'W$$

then equation (26) becomes

$$y - y_s = \lambda_1 Z_1^2 + \lambda_2 Z_2^2 + \ldots + \lambda_p Z_p^2$$ (27)

where

$$y_s = b_0 + b'X_s + X_s'BX_s$$ (28)

From examination of equation (27), some general conclusions can be drawn concerning the attainment of a maximized response. For example, consider just two of the possible results.

(1) Suppose all the $\lambda_i \leq 0$ and $X_s$ is near or in the region of $X$ at which the experiments were performed. Then clearly any deviation of $Z$ from $Z = 0$ will decrease the response. Thus $Z = 0$ (or equivalently $X = X_s$) is a maximum and is the combination of independent variables the experimenter seeks.

(2) Some $\lambda_i < 0$ and some $\lambda_i > 0$, and $X_s$ is close to the region of experimentation. Thus $X_s$ represents what is sometimes called a saddlepoint. Moving in some directions will cause a decrease in $y$ and moving in other directions will cause an increase in $y$. Thus the experimenter could move from $X_s$ in the direction that corresponds to the direction of the $Z$ which has the largest positive coefficient in equation (27). This will increase $y$ most rapidly from the value of $y_s$. 

86
The INPUT (Sample input is shown in fig. 8) is as follows:

1. Identification: One card, all 80 columns.

2. The number of independent variations JFAC. (14) (JFAC must be less than or equal to 15)

3. Variable Format. One card, all 80 columns.

4. \( b_0 \) (according to FORMAT in item (3)).

5. \( b_1, \ldots, b_{JFAC} \) (according to format in item (3)).

6. \( b_1, b_2, \ldots, b_{JFAC} \)

\[
\begin{array}{cccc}
  b_1,1 & b_1,2 & b_2,2 & \\
  b_1,3 & b_2,3 & b_3,3 & \\
  \cdots & \cdots & \cdots & \\
  b_1, JFAC & b_2, JFAC & \ldots & b_{JFAC}, JFAC
\end{array}
\]
One READ statement for each line, according to the format in item (3). As an example, consider the following estimated equation:

\[ y = b_0 + b_1 x_1 + b_2 x_2 + b_3 x_3 + b_4 x_4 \]
\[ + b_{11} x_1^2 \]
\[ + b_{12} x_1 x_2 + b_{22} x_2^2 \]
\[ + b_{13} x_1 x_3 + b_{23} x_2 x_3 + b_{33} x_3^2 \]
\[ + b_{14} x_1 x_4 + b_{24} x_2 x_4 + b_{34} x_3 x_4 + b_{44} x_4^2 \]
\[ + b_{15} x_1 x_5 + b_{25} x_2 x_5 + b_{35} x_3 x_5 + b_{45} x_4 x_5 + b_{55} x_5^2 \]

\[ y = 147.2686 - 8.989120 x_1 - 6.817975 x_2 - 14.60964 x_3 + 9.248688 x_4 + 14.19698 x_5 \]
\[ + 1.805520 x_1^2 \]
\[ - 2.126719 x_1 x_2 - 1.475730 x_2^2 \]
\[ - 7.314218 x_1 x_3 - 16.10219 x_2 x_3 + 2.274270 x_3^2 \]
\[ + 1.310780 x_1 x_4 - 2.477188 x_2 x_4 - 1.289688 x_3 x_4 + 2.236770 x_4^2 \]
\[ + 2.664464 x_1 x_5 + 1.827434 x_2 x_5 + 2.389934 x_3 x_5 + 6.014934 x_4 x_5 - 12.58198 x_5^2 \]

A canonical reduction of this is given in the sample output. The listing of the main program is supplied. The subprograms TRIANG, DGELG, EIGEN, and RECT are required. TRIANG and RECT are as in NEWRAP. DGELG and EIGEN are the double precision general linear equation and eigenvalue routines from reference 12.

APPENDIX - BORROWED ROUTINES

Some of the routines used in the programs were taken from the literature. Both
INVXTX and TRIANG are by Webb and Galley (ref. 13), and EIGEN and HIST are from
the IBM programmer's manual (ref. 12), as are DGELG and the double precision version
of EIGEN.

Listing of INVXTX and TRIANG are given here, as follows:

$1BFTC TRIA

SUBROUTINE TRIANG(A,B,NN,NKOL,FORMAT,II)
DIMENSION FORMAT(1)
DIMENSION A(1), B(1)
DOUBLE PRECISION B
1 FORMAT (1H1)
3 FORMAT(1H /1H /1H )
COMMON/SMA L/DUM(15),LIST

REFERENCES

"The aeronautical and space activities of the United States shall be conducted so as to contribute ... to the expansion of human knowledge of phenomena in the atmosphere and space. The Administration shall provide for the widest practicable and appropriate dissemination of information concerning its activities and the results thereof."

—National Aeronautics and Space Act of 1958

NASA SCIENTIFIC AND TECHNICAL PUBLICATIONS

TECHNICAL REPORTS: Scientific and technical information considered important, complete, and a lasting contribution to existing knowledge.

TECHNICAL NOTES: Information less broad in scope but nevertheless of importance as a contribution to existing knowledge.

TECHNICAL MEMORANDUMS: Information receiving limited distribution because of preliminary data, security classification, or other reasons.

CONTRACTOR REPORTS: Scientific and technical information generated under a NASA contract or grant and considered an important contribution to existing knowledge.

TECHNICAL TRANSLATIONS: Information published in a foreign language considered to merit NASA distribution in English.

SPECIAL PUBLICATIONS: Information derived from or of value to NASA activities. Publications include conference proceedings, monographs, data compilations, handbooks, sourcebooks, and special bibliographies.

TECHNOLOGY UTILIZATION PUBLICATIONS: Information on technology used by NASA that may be of particular interest in commercial and other non-aerospace applications. Publications include Tech Briefs, Technology Utilization Reports and Technology Surveys.

Details on the availability of these publications may be obtained from:
