PPG-113
Mode Coupling and Wave Particle Interactions
for Unstable Ion Acoustic Waves

Pablo Martin and Burton D. Fried

Department of Physics, University of California, Los Angeles, California 90024

A theory for the spatial development of linearly unstable, coupled waves is presented in which both quasi-linear and mode coupling effects are treated in a self-consistent manner. Steady state excitation of two waves (with frequencies $\omega_1$, $\omega_2$) is assumed at the boundary $x = 0$, the plasma being homogeneous in the $y$ and $z$ directions. Coupled equations are derived for the $x$ dependence of the amplitudes of the primary waves ($\omega_1$, $\omega_2$) and the secondary waves, $n\omega_1 + m\omega_2$ ($n$ and $m$ being integers), correct through terms of second order in the wave amplitude, $\epsilon\phi/T_e$, but without the usual approximation of small growth rates. This general formalism is then applied to the case of coupled ion acoustic waves driven unstable by an ion beam streaming in the direction of the $x$ axis. If the modifications of the ion beam by the waves ("quasi-linear" effects) are ignored, "explosive" instabilities (singularities in all of the amplitudes at finite $x$) are found, even when all of the waves have positive energy. If these wave-particle interactions are included, the solutions are no longer singular, and all of the amplitudes have finite maxima, at locations in reasonable agreement with experimental results of Taylor and Ikezi.

This work was partially supported by the Office of Naval Research, Grant N00014-69-A-0200-4023; the National Science Foundation, Grant #GP-22817; the Atomic Energy Commission, Contract AT(04-3), Project #157; and the National Aeronautics and Space Administration, Contract NGR-05-007-190 and NGR-05-007-116.
I. INTRODUCTION

This calculation was motivated by observations of Taylor and Ikezi\(^{(1)}\) on the propagation of ion acoustic waves in presence of ion streaming. In these experiments, a Double Plasma (DP) machine\(^{(2)}\) was used to produce a broad beam of ions streaming through a plasma with a velocity, \(V\), somewhat larger than the ion acoustic speed \(c_s = \left(\frac{T_e}{M}\right)^{1/2}\). Signals applied to the grid separating the driver plasma (the source of the ions) from the target plasma excite ion acoustic waves which propagate into the target plasma. Over a range of frequencies which depends on \(V\), the ion beam makes the ion acoustic waves unstable,\(^{(10)}\) and spatial growth is observed.

If two sinusoidal signals, with frequencies \(\omega_1, \omega_2\), both lying within the unstable range, are simultaneously applied to the grid, it is observed that these waves grow; saturate at distances of 50 to 100 Debye lengths from the grid; and then decay. In addition, a number of waves with frequencies \(n\omega_1 + m\omega_2\), where \(n\) and \(m\) are integers, also grow; saturate, further downstream; and then likewise decay. The observed variation of the primary waves and the largest of the secondary waves are shown in Fig. 1.

At first sight, these results seem eminently reasonable. Since all of the ion acoustic waves have approximately the same velocity, strong mode coupling should be expected, with a consequent coupling of energy from the primary waves (which are driven by the free energy of the ion beam) to the collection of secondary (beat) waves. Thus, mode coupling should explain the observed saturation and decay of the waves.

In fact, however, a straightforward mode coupling calculation leads to a somewhat surprising result. All of the waves, both primary and secondary, become infinite at finite distances from the grid, as shown in Fig. 2.
This apparent violation of energy conservation is, of course, a consequence of neglecting the wave particle interactions, i.e., the perturbation of the beam by the growing waves. If the beam distribution function is taken to be the same at all $x$, an infinite energy reservoir is available, and there is no a priori limit on the wave amplitudes. While "explosive" instabilities are well known in the theory of mode coupling when some of the waves have a "negative" energy, the present case does not fall into that category. Apparently, linear instability of the individual waves combines with the amplification resulting from the mode coupling to produce the singular behavior at finite distance.

When the "quasi-linear" modification in the beam distribution function (or, more precisely, in the plasma dielectric function) is taken into account, the amplitudes remain finite and show a spatial variation consistent with the experimental results. Although the agreement is not completely quantitative at present, additional experimental observations are planned.

We note the following features of our analysis, some of which have also been considered in earlier papers on mode coupling:

1. We consider waves which are linearly unstable.

2. We study the "boundary value" problem (real $\omega$, complex $k$, in the vernacular) rather than the more traditional, but experimentally less accessible, initial value problem (real $k$, complex $\omega$).

3. We eschew the usual restrictions to very small growth rate ($\gamma \ll \omega$ or $\text{Im} \, k \ll \text{Re} \, k$) or a very weak beam ($n_{\text{beam}} \ll n_{\text{plasma}}$). (Neither is satisfied in the Taylor-Ikezi experiments.)

4. We analyze the problem in configuration space rather than wave-number space.

5. We solve, self-consistently, the coupled mode coupling (wave-wave
interaction) and quasi-linear (wave-particle interaction) problems.

Since the beam in the DP machine is very broad (of order 100 times Debye length) and the primary waves have $k$ parallel to the drift velocity, with $\omega_1, \omega_2$ below the ion plasma frequency, a one dimensional formulation in terms of electrostatic waves is justified. The kinetic theory analysis required in order to treat adequately the wave particle interaction is given in Section II and coupled equations for the wave amplitudes are derived, assuming no external electric or magnetic fields. These equations involve, in an essential way, both the self-consistent (quasi-linear) d.c. electric field, $E_0$, generated by the waves and the change, $\Delta \varepsilon$, in the plasma dielectric constant due to the wave-induced modification of the beam distribution function. Equations for $E_0$ and $\Delta \varepsilon$ are derived in Section III. The results are specialized to the case of ion acoustic waves in Section IV, and in Section V numerical solutions for the wave amplitudes are given, first for the case where $\Delta \varepsilon$ is neglected, leading to the explosive instabilities, and then for the complete problem, with $\Delta \varepsilon$ included. As already noted, the latter results are in qualitative agreement with the experimental data.
We start with the Vlasov and Poisson equations, assuming no external electric or magnetic fields. For each species we have

$$\frac{\partial f}{\partial t} + v \frac{\partial f}{\partial x} + \frac{q}{m}E \frac{\partial f}{\partial v} = 0$$  \hspace{1cm} (1)

(To minimize clutter in the notation, we omit species subscripts whenever this will not cause ambiguity.) Poisson's equation is written

$$\frac{\partial E}{\partial x} - 4\pi \int dv nqf = 0$$  \hspace{1cm} (2)

where the symbol \(\int\) denotes sum over species as well as integration over velocity, and \(n\) is the average density of a species. Since we assume a steady state system, with excitation at frequencies \(\omega_1\) and \(\omega_2\), the time dependence of \(f\) and \(E\) can be written as a generalized Fourier sum over all frequencies of the form

$$\omega_{nm} = n\omega_1 + m\omega_2$$  \hspace{1cm} (3)

The \(x\) dependence remains to be found, but it is convenient to separate out that part which follows from linear theory. Accordingly, we set

$$f(x,v,t) = f_0(x,v) + \sum_\omega f_\omega(x,v) \exp[i(k_\omega x - \omega t)]$$  \hspace{1cm} (4)

$$E(x,t) = E_0(x) + \sum_\omega E_\omega(x) \exp[i(k_\omega x - \omega t)]$$  \hspace{1cm} (5)

where the sum over \(\omega\) stands for a sum over all values, positive and negative, of the integers \(n\) and \(m\) in (3), excluding those which would make \(\omega = 0\), since the time independent terms are treated separately. We assume that, for given \(\omega\), the linear dispersion relation

$$\epsilon(k_\omega, \omega) = 0$$  \hspace{1cm} (6)
has at most one unstable root,

\[ k_\omega = \kappa_\omega - i\beta_\omega \]

with \( \beta_\omega > 0 \). Here

\[ \epsilon(k,\omega) = 1 - \int \frac{dv}{(\omega/k)^2} F'_o(v) (v-u)^{-1} \quad u = \omega/k \]  

is the dielectric function corresponding to \( x = 0 \), with \( f_0(0,v) = F_o(v) \).

At other values of \( x \) we write the dielectric function as \( \epsilon + \Delta\epsilon \) where

\[ \Delta\epsilon(k,\omega;x) = -\int \frac{dv}{(\omega/k)^2} \left[ \frac{\partial f_0(x,v)}{\partial v} \right] (v-u)^{-1} \]

\[ \Delta f_0 = f_0(x,v) - f_0(0,v) = f_0(x,v) - F_0(v) \]  

[Choosing \( k_\omega \) to be the root of \( \epsilon + \Delta\epsilon \) rather than \( \epsilon \) simplifies the formalism somewhat but greatly complicates the subsequent (numerical) solution of the mode coupling equations due to the consequence \( x \)-dependence of \( k_\omega \) and hence of the matrix elements.] The contour of integration in (7) and (8) is, as usual, the real axis, when \( \text{Im} \ k \) is negative, the function being analytically continued into the upper half \( k \) plane. At \( x = 0 \), the boundary values

\[ f_0(0,v) = F_0(v) \], \quad \int dv F_0(v) = 1 \]

and

\[ E_{\omega_1}(0) = E_{\omega_1}, \quad E_{\omega_2}(0) = E_{\omega_2} \]  

are given, all other amplitudes being 0 there. In particular, we note that the d.c. electric field, \( E_0(x) \), is a self-consistent field, generated from nonlinear effects, and not the consequence of any external fields. Although the amplitudes \( E_\omega \) are most convenient for purposes of analysis, we note that the experimentally measured amplitudes are in fact the quantities
\[ E_\omega(x) = 2E_\omega \exp(\beta_\omega x) \quad , \]

so we shall give our final equations and numerical results in terms of these.

To solve the coupled, nonlinear equations which result from substituting the Fourier series (4) and (5) into (1) and (2), we make an expansion in the field amplitudes, treating all of the \( E_\omega \) and \( f_\omega \) as proportional to a small parameter, \( \eta \). (The dimensionless small quantity is actually \(|eE/k_e T_e|\).) In addition, our ordering ansatz assumes that the amplitudes \( f_\omega \) and \( E_\omega \) are slowly varying, in the sense that \( (\delta f_\omega/\delta x) \) and \( (\delta E_\omega/\delta x) \) are of order \( \eta^2 \).

We shall see that \( \Delta f_\omega \), defined in (8), is at most of order \( \eta \) compared to \( f_\omega \) and that \( E_\omega \) is of order \( \eta^2 \).

Substituting (4) and (5) into (1) and (2), we obtain equations for the amplitudes \( f_\omega \) and \( E_\omega \) by equating to zero the individual Fourier coefficients:

\[
\begin{aligned}
 f_\omega &= (i/k)(\nu-u)^{-1} \left\{ (qE_\omega/m) \partial f_\omega/\partial \nu + v\partial f_\omega/\partial x + \right. \\
 &+ (q/m) \sum'_{\omega'} (\delta f_{\omega'}/\delta \nu) E_{\omega'} \exp(i\Delta k x) + (qE_0/m) \partial f_\omega/\partial \nu \right\} \\
 ikE_\omega + dE_\omega/dx &= 4\pi \int dv nq f_\omega
\end{aligned}
\]

where

\[
\begin{aligned}
k &= k_\omega \ , \quad k' = k_{\omega'} \ , \quad k'' = k_{\omega''} \ , \quad \omega'' = \omega - \omega' \ , \quad \Delta k = k' + k'' - k
\end{aligned}
\]

The prime on the summation symbol means that \( \omega' = 0 \) and \( \omega'' = 0 \) are excluded.

From the time independent terms of (1) and (2) we obtain

\[
\begin{aligned}
\nu \partial (\Delta f_\omega)/\partial x + (qE_\omega/m) \partial f_\omega/\partial \nu &= (-q/m) \sum'_{\omega'} (\delta f_{\omega'}/\delta \nu) E_{\omega'} \exp(2\beta x) \\
dE_\omega/dx &= 4\pi \int dv nq \Delta f_\omega
\end{aligned}
\]

So far, of course, our equations are exact. To obtain an approximate formulation, correct through terms of order \( \eta^2 \), we take advantage of the
fact that the first term in the bracket on the right hand side of (11) is of
order \( \eta \); the second and third are of order \( \eta^2 \); and the last is of order
\( \eta^3 \) (assuming, as will be established later, that \( E_0 \) is of order \( \eta^2 \)). Consequently, in (11) we can drop the last term and substitute in the second
and third terms

\[ f_\omega = (i/k)(v-u)^{-1} (qE_\omega/m)(\partial E_\omega/\partial v) \quad , \]  

thus obtaining an expression for \( f_\omega \) correct to order \( \eta^2 \):

\[ f_\omega (x,v) = (i/k)(v-u)^{-1} (q/m) \left\{ E_\omega (\partial F_\omega/\partial v) + i(v/k)(v-u)^{-1} (\partial E_\omega/\partial v)(dE_\omega/dx) + \right. \]

\[ \left. + (iq/m) \sum_{\omega'} \left[ (E_{\omega',E_{\omega''}}/k') \exp(i\Delta kx)(\partial/\partial v)[F_{\omega'}(v)/(v-u')] \right] \right\} . \quad (17) \]

In the second and third terms of (17) we have replaced \( f_\omega (x,v) \) by \( F_\omega (v) \);
since these terms are already of order \( \eta^2 \), this introduces errors of order
\( \eta^3 \), which we are dropping here. We now integrate this expression for \( f_\omega \)
over \( v \) and substitute it on the right hand side of (12), obtaining a typical
set of mode coupling equations,

\[ D(\omega) dE_\omega /dx = ik\Delta \epsilon E_\omega + \sum_{\omega'} G(\omega',\omega'') E_{\omega'}E_{\omega''} \exp(i\Delta kx) \quad . \quad (18) \]

Here \( \Delta \epsilon \) is given by (8);

\[ D(\omega) = -k \partial \epsilon(k,\omega)/\partial k = -2 - u \int dv (\omega_p/k)^2 F_0'(v)(v-u)^{-2} \quad ; \quad (19) \]

and the mode coupling matrix elements, \( G \) (cf. the \( \epsilon^{(2)} \) of Sagdeev and
Galeev(7)), are given by

\[ G(\omega',\omega'') = \int dv (\omega_p^2/kk')(q/m) F_0'(v-u)^2(v-u') \quad . \quad (20) \]

While (18) is similar in form to the usual (temporal) mode coupling equations
with \( x \) in place of \( t \) as independent variable, we note two important differences:
i) The wave-particle effects (modification of $f_\omega$ by the waves) appear in the linear term involving $\Delta \varepsilon$.

ii) The quantities $u$ and $k$ are complex, i.e., we have made no assumption of small growth rates.

Before we can attempt to solve (18), we must adjoin to it an equation for $\Delta \varepsilon$, which is derived in the next section. For later reference, we note that $G(\omega',\omega'')$ can be replaced by an expression which is symmetric in the $\omega'$ and $\omega''$ modes by taking half the sum of $G(\omega',\omega'')$ and $G(\omega'',\omega')$:

$$\tilde{G}(\omega',\omega'') = \frac{1}{2} \left[ G(\omega'',\omega') + G(\omega',\omega'') \right]$$

$$= (2k'k'')^{-1} \int \frac{dv}{q/m} \left[ F'_o(v)/(v-u),(v-u')(v-u'') \right] \cdot \left[ 1 + v\Delta k/k(v-u) \right]$$

(21)

If we also go over from the $E_\omega$ to the physically measured amplitudes $\tilde{E}_\omega$, defined in (10), we have as our basic mode coupling equations

$$D(\omega) \frac{d\tilde{E}_\omega}{dx} = [i\Delta \varepsilon + \beta_\omega D(\omega)] \tilde{E}_\omega + \frac{1}{2} \sum' \omega, \tilde{G}(\omega',\omega'') \tilde{E}_\omega \tilde{E}_\omega', \exp(i\Delta k x)$$

(22)

The coefficients $D$ and $\tilde{G}$, defined by (19) and (21), are independent of $x$ and, for a given set of frequencies, involve simply some integrals related to the plasma dispersion function (8); explicit evaluations of these are discussed in Appendix I. On the other hand, the coefficient $\Delta \varepsilon$, defined by (8), is a function of $x$, to whose determination we now turn.
III. DETERMINATION OF $E_o$ AND $\Delta \varepsilon$

If we drop the $\Delta \varepsilon$ term in (22), then the coupled differential equations for the wave amplitudes, $E_\omega$, constitute a closed set, which does not involve the time-independent variables $f_o$ and $E_0$ of (14) and (15). However, as already noted, the resulting amplitudes, $E_\omega$, diverge at finite $x$ so the quasi-linear effects, represented in (22) by $\Delta \varepsilon$, must be included. This requires, in essence, the simultaneous solution of the quasi-linear problem, represented by (14) and (15), together with the mode coupling problem, represented by (22). Moreover, the quasi-linear problem is more difficult than the usual one in two respects:

i) We are dealing with a discrete spectrum of coherent waves and hence cannot take advantage of the formal simplifications associated with averages over the phases of a continuous spectrum of random waves.

ii) We are interested in the eventual application to ion acoustic waves and must therefore take proper account of both ions and electrons. Our analysis of the effect of the waves on $f_o$ is complementary to the approach of Dupree and Weinstock,\(^{(7)}\) who consider the actual particle orbit modifications. We first discuss this quasi-linear sub-problem.

On the right side of (14) we can, to lowest order in $\eta$, replace $f_\omega$ by its leading term, (16), which gives an equation for $\Delta f_o$:

$$
\nu \frac{\partial (\Delta f_o)}{\partial x} = -(q/m) (\partial/\partial v) \{ f_o E_o + (iq/2m) \sum \tilde{E}_\omega |E_\omega|^2 f'_o / k(v-u) \} \tag{23}
$$

where, as before,

$$
f_o(x,v) = F_o(v) + \Delta f(x,v); \quad F_o(v) = f_o(0,v)
$$

If we regard the wave intensity,
as a known function of \( x \), then we can use (15) to express \( E_0 \) as an integral, over \( x \) and \( v \), of \( \Delta f_0 \); substituting this into (23) leads to a differential-integral equation for \( f_0 \), which can be solved by iteration on \( \Delta f_0 \). To lowest order, this is equivalent to simply replacing \( f_0 \) by \( F_0 \) on the right-hand side of (23), thus obtaining an explicit expression for \( \Delta f_0 \), and then substituting this into (15), thereby obtaining an ordinary differential equation for \( E_0(x) \). Actually, it is more convenient to work with the derivative of this equation,

\[
\frac{d^2 E_0}{dx^2} = 4\pi \int dv \, nq \frac{\partial (\Delta f_0)}{\partial x} = \int dv (\omega_p^2/v) \{ E_0 F'_o + (iq/2m) \sum I_\omega \left( \frac{\partial}{\partial v} \right) [F'_o/k(v-u)] \}. \tag{24}
\]

Note that, notwithstanding the \( v^{-1} \) factor in the integrand of (24), this integral is non-singular: since \( \Delta f_0 \) must be finite at \( v = 0 \), the right side of (23) must vanish at \( v = 0 \), and so the integrand of (24) has no singularity at \( v = 0 \). Of course, when we subsequently break up the right hand side of (24), individual pieces may be singular, but there will be no difficulty provided we use the same definition of the \( v = 0 \) singularity in all terms. We shall choose the Cauchy principal value definition.

Our final approximation within this quasi-linear sub-problem is to neglect the left side of (24). This charge neutrality approximation is justified if the scale for \( E_0 \) is large compared to the Debye length; it is clear from our numerical results that this is in fact the case for the ion acoustic wave application. We then have from (24)

\[
E_0(x) = -i \int dv (\omega_p^2 q/2mv) \sum I_\omega \left( \frac{\partial}{\partial v} \right) [F'_o/k(v-u)] \cdot \left\{ \int dv \, \omega_p^2 F'_o/v \right\}^{-1} \tag{25}
\]
which shows that the scale of $E_o$ is essentially that of the $I_\omega$ and that, like $I_\omega$, $E_o$ is of order $\eta^2$. [It then follows from (23) that $\partial(\Delta f_o)/\partial x$ is of order $\eta^2$ and hence that $\Delta f_o$ is of order $\eta$; this justifies, a posteriori, our procedure of iterating (23) with respect to $\Delta f_o$.]

The sum over $\omega$ in (25) is one we shall encounter often. It proves convenient to combine the terms $\omega$ and $-\omega$, reducing the sum to one over $\omega > 0$, and to define

$$P(\omega,v) = (i/2)(\partial/\partial v) \left\{ [(kv-\omega)^{-1} - (k^*-v-\omega)^{-1}] F'_o \right\}$$

$$= -\text{Im} \left( \partial/\partial v \right) \left[ F'_o/(k(v-u)) \right], \tag{26}$$

where we have used the property (5) $k_{-\omega} = -k^*_\omega$. Then

$$E_o(x) = \{ \int dv \left( \omega^2 q/mv \right) \sum_{\omega' > 0} I_{\omega', P(\omega',v)} \} \cdot \{ \int dv \left( \omega^2 F'_o/v \right)^{-1} \}. \tag{27}$$

Having found $E_o$, we can return to (23) and find $\Delta f_o$ (replacing $f_o$ by $F'_o$ on the right side). However, for the mode coupling problem, (22), we need only $\Delta \varepsilon$, computed from $\Delta f_o$ according to (8). From (23) we have then

$$\partial(\Delta \varepsilon)/\partial x = \int dv(\omega^2 k/mv) \left\{ (\partial(\Delta f_o)/\partial x)(v-u)^{-2} \right\}$$

$$= \int dv[k(v-u)] \left( q/mv \right) \left\{ E_o F'_o + (q/m) \sum_{\omega' > 0} I_{\omega', P(\omega',v)} \right\}. \tag{28}$$

Since $E_o$ is, itself, a sum over $I_\omega$, as we see from (27), we have, finally,

$$\left( \partial/\partial x \right) \Delta \varepsilon(\omega,x) = -(1/k^2) \sum_{\omega' > 0} H(\omega,\omega') I(\omega') \tag{28}$$

where

$$H(\omega,\omega') = \left\{ \int dv(\omega^2 q/m) F'_o/(v-u)^2 \right\} \left\{ \int dv(\omega^2 q/m) P(\omega',v)/v \right\} \left\{ \int dv \left( \omega^2 F'_o/v \right)^{-1} \right\}$$

$$- \left\{ \int dv(\omega^2 q/m) P(\omega',v)/v(v-u)^2 \right\}. \tag{29}$$
gives a set of coefficients which are independent of $x$, like the coefficients $D$ and $G$ in (22).

In fact, we may consider $\Delta \varepsilon(\omega, x)$ as an additional amplitude, to be treated on the same basis as the $\tilde{E}_\omega(x)$. Like the amplitudes $\tilde{E}_\omega$, $\Delta \varepsilon$ is of order $\eta$, not $\eta^2$, as one might suppose. In fact, from (28) we see that $\partial(\Delta \varepsilon)/\partial x$ is of order $\eta^2$, which implies that $\Delta \varepsilon$ itself is of order $\eta$. Adjoining (29) to (22) gives us the desired formulation in which mode coupling and quasi-linear effects are included in a self-consistent, albeit approximate, fashion. Our basic equations are thus the set (22) plus (28),

$$
\frac{d\tilde{E}_\omega}{dx} = \left[ \beta_\omega + ikA_\varepsilon/D \right] \tilde{E}_\omega + \sum_{\omega', \omega''} \left[ G(\omega', \omega'')/D \right] \tilde{E}_{\omega'} \tilde{E}_{\omega''} \exp(iA x)
$$

$$
\frac{d(\Delta \varepsilon)}{dx} = - \left( \frac{1}{k^2} \right) \sum_{\omega' > 0} H(\omega, \omega') I(\omega')
$$

with

$$
I(\omega) = \left| \tilde{E}_\omega \right|^2
$$

and the constant coefficients, $D$, $G$, $H$ defined by (19), (21), and (29). We discuss in the next section the specialization of the formalism to the case of ion acoustic waves.
IV. UNSTABLE ION ACOUSTIC WAVES

We consider an infinite, homogeneous "beam" of ions, with density \( n_b \), streaming with velocity \( V > c_s \) through an infinite, homogeneous plasma consisting of stationary "plasma" ions (density \( n_p \)) and electrons (density \( n = n_b + n_p \)). At \( x = 0 \) (the location of the exciting grid in the plasma) we assume the ion distribution functions to be streaming Maxwellians,

\[
F_{oi}(v) = \sum_j \left( \frac{\mu_j}{\pi^{1/2} a_j} \right) \exp\left[\frac{- (v-V_j)^2}{a_j^2}\right]
\]

(31)

where \( j \) ranges over the two ion "species", beam and plasma, with

\[
V_b = V, \quad V_p = 0 \\
\mu_b = n_b/n = 1 - \mu_p
\]

and

\[
a_j = (2T_j/M)^{1/2}.
\]

For the electrons, we simply assume a single Maxwellian,

\[
F_{oe}(v) = (\pi^{1/2} a_e^{-1}) \exp\left[\frac{- (v-V_e)^2}{a_e^2}\right]
\]

\[
a_e = (2T_e/m_e)^{1/2}.
\]

(32)

It is to be expected that for ion acoustic waves driven unstable by an ion beam with \( V > c_s \), the details of the electron distribution function do not matter much when \( T_e/T_i >> 1 \), which is the case we want to consider here. Thus, using for the electrons a double humped Maxwellian, with streaming velocities 0 and \( V \), should not give different results. Since we assume a steady state current, the electron current must balance the ion current, i.e., with the single Maxwellian (32) we should choose \( V_e = \mu_b V_b \). However, the error due to choosing, instead, \( V_e = 0 \) is of order \( (m/M)^{1/2} \). This is most
easily seen for the dielectric function $\varepsilon(k,\omega)$. From (7), (31), and (32) we have

$$\varepsilon = 1 - k^{-2} \left\{ \sum_{\text{pe}} \frac{\omega^2}{2} Z'[\frac{(u-V_e)/a_e}{2}] + \sum_{\text{ion}} \frac{\mu_j \omega^2}{a_j^2} Z'[\frac{(u-V_j)/a_j}{2}] \right\} \tag{33}$$

where $Z$ is the plasma dispersion function$^{(8)}$ and $\sum_{\text{ion}}$ denotes summation over the ions (plasma and beam). At this point, it is convenient to choose our units of $x$ and $t$ so that the quantities

$$k_b = \frac{4\pi n e^2}{T_e}, \quad c_s = \left( \frac{T_e}{M} \right)^{1/2}, \quad \omega_{pi} = k_b c_s$$

and $\omega_{pi}$ are all equal to 1. Then

$$a_j^2 = 2T_j, \quad a_e^2 = 2/\delta$$

where

$$\tau_j = T_j/T_e \ll 1, \quad \delta = m_e/M_i,$$

and we have

$$\varepsilon = 1 - k^{-2} \left\{ (1/2) Z'[\frac{(u-V_e)(\delta/2)^{1/2}}{2}] + \sum (u_j/2T_j) Z'(U_j) \right\}$$

where

$$U_j = \frac{(u-V_j)}{2T_j}^{1/2}.$$ \tag{35}

Since

$$Z'[\frac{(u-V_e)(\delta/2)^{1/2}}{2}] = -2 + \theta(\delta^{1/2})$$

it does not matter whether we set $V_e$ equal to $\mu_b V_b$ or 0. Thus, our final expression is

$$\varepsilon = 1 + k^{-2} \left[ 1 - \sum (u_j/2T_j) Z'(U_j) \right] \tag{36}$$

and $\varepsilon = 0$ defines $k_\omega$ for $\omega > 0$, with$^{(5)}$ $k_\omega = -k^*$. For the coefficient $D(\omega)$, defined by (19), the electronic contribution is smaller than the ionic ones by a factor of $\delta^{1/2}$, as shown in Appendix I,
so we may drop it altogether. Then

\[ D(\omega) = -2 - (u/k^2) \sum \mu_j (2\tau_j)^{-3/2} Z''(U_j) \]  

(37)

[which also follows from differentiating (36)]. In the remaining coefficients, \( G \) and \( H \), the contribution of a given species contains factors of \( \omega_p^2 q/m \) or \( (\omega_p q/m)^2 \) from which it might appear that the electron contributions dominate those of the ions, making the results sensitive to the choice of electronic distribution function. We show in Appendix I that this is not the case: the electron and ion terms are of equal order so far as \( \delta \) is concerned, although the electron terms tend to be smaller by some power of \( (T_i/T_e) \). In any case, the changes in the electron terms consequent upon choosing \( v_e = 0 \) rather than \( \mu_b v_b \) are of order \( \delta^{1/2} \). Explicit expressions for \( G \) and \( H \) can most easily be given in terms of a multi-variable generalization of the \( Z' \) function,

\[ Y_n(s_1, s_2, \ldots s_n) = \pi^{-1/2} \int dt [(t-s_1)(t-s_2)\ldots(t-s_n)]^{-1} (d/dt) e^{-t^2} . \]  

(38)

Such expressions are presented in equations (A10) through (A15) in Appendix I.

Specifically, we obtain a dimensionless form of the basic equations (30) if we introduce a dimensionless potential, \( \phi_\omega \):

\[ \tilde{E}_\omega = -i k \phi_\omega = -i(kT/e) \phi_\omega . \]  

(39)

Then (30) becomes, in our dimensionless units \( (\omega_{pi} = k_D = c_s = 1) \)

\[ d\phi_\omega/dx = (\beta_\omega + i k \Delta \varepsilon/D)\phi_\omega + \frac{1}{2} \sum_{\omega' > \omega''} M(\omega, \omega', \omega'') \phi_{\omega'}, \phi_{\omega''}, \exp[i\Delta \varepsilon x] , \]  

(40)

\[ d\Delta \varepsilon(\omega, x)/dx = -\sum_{\omega' > 0} h(\omega, \omega') |\phi_{\omega'}|^2 , \]  

(41)

where \( D(\omega) \) is given by (37); and

\[ M(\omega, \omega', \omega'') = i L(\omega, \omega', \omega'')/kD(\omega) , \]  

(42)
L and \( h \) being given in terms of \( Y \) in Appendix I.

In the following section we give the results of the numerical solution of the coupled equations (40) and (41) for the case of ion acoustic waves, with parameters chosen to approximate the conditions of the Taylor-Ikezi experiments. We shall see that if the quasi-linear effects, represented by (40), are neglected - i.e., if we set \( \Delta c = 0 \) in (40) - then an explosive instability results; including \( \Delta c \) gives results in qualitative agreement with the experiments. (1)

Regarding the character of the explosive instability, we cannot, as noted earlier, properly speak of the "energy", positive or negative, of the individual waves when the imaginary part of the phase velocity is not infinitesimally small. However, our contention that the explosive instability is not the familiar one associated with negative energy waves\(^{(7)}\) can be properly stated in the following way. Having computed the matrix elements \( M(\omega, \omega', \omega'') \) using (42), (37), and (A10), we may consider the equations (40) with linear terms \( \beta \omega \) and \( \Delta c \) set equal to zero. We find the amplitudes to be well-behaved, oscillatory functions, with no singularities, i.e., they behave like coupled waves whose energies all have the same sign. If, now, we introduce the unstable linear terms, \( \beta \phi \) with \( \beta > 0 \), we immediately find an explosive instability, the value of \( x \) at the singularity being smaller the larger the value of \( \beta \). Finally, we include the \( i\Delta c \phi \) term, which has a negative real part which grows like \( \int dx |\phi_\omega|^2 \) and hence prevents a singularity at finite \( x \).
V. NUMERICAL RESULTS

We consider the case of ion acoustic waves with excitation frequencies
\( \omega_1 = 0.4, \quad \omega_2 = 0.25. \) (As in Section IV, we use units in which \( \omega_{pi}, k_D, \) and \( c_s \) are equal to 1.) The beam strength is
\[
\nu_b = n_b/(n_p+n_b) = 0.23\;;
\]
the streaming velocity is
\[
V_b = 1.67\;;
\]
and the temperature ratios are
\[
\tau_b = T_b/T_e = 0.1; \quad \tau_p = T_p/T_e = 0.066\;.
\]
(These correspond to the Taylor-Ikezi experiments which had \( T_e = 3 \text{ eV} \), \( n = 10^9 \text{ cm}^{-3} \).) The values of \( u, k, D, L, M, \) and \( h \) for this choice of parameters are given in Appendix I.

The results are best given in terms of the dimensionless potentials, \( \phi_\omega \), defined in (39). If we drop the \( \Delta \varepsilon \) term in (40), then for three waves (\( \omega_1, \omega_2, \) and \( \omega_3 = \omega_1 - \omega_2 \)) we obtain the results shown in Fig. 2. (The initial amplitudes of the \( \phi_\omega \), as given in the figure caption, correspond approximately to those of the Taylor-Ikezi experiment.) The explosive instability is apparent and this feature persists if we include more waves, with frequencies \( \omega_{nm} \) given by (3). Including the \( \Delta \varepsilon \) term in (40) and solving the coupled set (40) and (41) for \( \Delta \varepsilon \) and the wave amplitudes gives the results shown in Fig. 3 for three waves. The inclusion of more waves does not greatly change the behavior of the first three. Comparison with Fig. 1 indicates a qualitative agreement with the Taylor-Ikezi experiments. Pending further experiments, we cannot say whether the discrepancies are to be attributed to third order effects, neglected here, or to experimental errors.
VI. CONCLUSIONS AND DISCUSSION OF RESULTS

We find that a straightforward extension of mode-coupling theory to waves of well-defined phase which are linearly unstable leads to explosive instabilities (infinite amplitudes at finite distance). This phenomenon appears to be different from the superficially similar one associated with the coupling of positive and negative energy waves, in that here the energy required to feed the explosive instability comes directly from the free energy (in our case, the ion streaming) responsible for linear instability. Of course, in the case of negative energy waves, the ultimate source of energy is similar, so the distinction may be more formal than physical. When the "quasi-linear" modification in free energy due to the wave growth is taken into account, the amplitudes remain bounded and show a qualitative agreement with experiments on ion acoustic waves. Although we deal here only with the boundary-value problem (real \( \omega \), complex \( k \)) entirely similar results hold for the complementary initial value problem (real \( k \), complex \( \omega \)).

We conclude that, in general, both mode coupling and quasi-linear effects must be included in even the lowest order non-linear theoretical treatment of linearly unstable waves. We have considered here only the case of coherent waves (meaning well-defined phase), but similar conclusions should obtain in the case of a continuous spectrum of waves with random phases.

We are indebted to James Drake for assistance with the calculations.
FOOTNOTES AND REFERENCES

4. The usual definition of wave energy as \[ \frac{\partial^2 \epsilon}{\partial \omega^2} E^2 \frac{\partial \mu}{\partial \omega} \] [Landau and Lifshitz, Electrodynamics of Continuous Media (Pergamon Press, Oxford, 1960), p. 253] is valid only when the imaginary part of \( \epsilon \) and its roots can be neglected, an approximation we do not make. A more detailed discussion of why the explosive instability encountered here is not simply that associated with the interaction of positive and negative energy waves is given below, following Eq. (41).

5. For \( \omega > 0 \), a root, \( u_\omega \), of the dispersion equation (7) with \( \text{Im} u_\omega > 0 \) corresponds to \( \text{Im} k_\omega < 0 \) (since \( k_\omega = \omega / u_\omega \)). There the representation (7), with real integration path, is correct. If \( u_\omega \) is a root with \( \text{Im} u_\omega > 0 \), then \( u^* \omega \) will also, formally, be a root, but it cannot be associated with \( \omega > 0 \) since it leads to \( \text{Im} k > 0 \) and the representation (7) is not correct in the upper half \( k \) plane. (As noted, the proper analytic continuation must be used there.) However, \( u^* \omega \) is an acceptable root for \( \omega < 0 \), since it again gives \( \text{Im} k < 0 \). Thus, \( u_{-\omega} = u^* \omega \) which
leads to the usual result [required by the reality of \( E(x,t) \) and \( f(x,v,t) \)] that \( k_{-\omega} = -k^*_{\omega} \). In the subsequent analysis, we shall encounter many integrals with one or more factors of \( (v-u)^{-1} \). In each of these, the contour in the velocity plane is taken to be the real axis, with \( u \) above the real axis for \( \omega > 0 \), below it for \( \omega < 0 \). For real \( u \) we will choose the Cauchy principal value, as explained in more detail following Eq. (24).

6. Statements regarding the "order" of any functions of \( v \) are really to be understood as referring to the various integrals over \( v \) which occur in the subsequent analysis.

APPENDIX I

CALCULATION OF INTEGRALS AND COEFFICIENTS

We summarize here the algebraic considerations involved in computing the coefficients $D$, $G$, and $H$ which appear in (30), as well as the dielectric function $\epsilon$, Eq. (7), which determines $k_\omega$, when the distribution functions are those specified in (31) and (32).

The first point to be considered is that some of the integrals involve $\omega_p^2$, some $\omega_p^2 q/m$, and some $(\omega_p q/m)^2$. This might make it appear that the electron contributions dominate the ion terms in some of the coefficients. While specific calculations show that this is not the case, it is useful to establish this in a general way, as follows.

Consider first the coefficient $D(\omega)$, given by (19). We see that the contribution of a given species, of mass $m$, temperature $T$, is proportional to

$$m^{-1} \int dv \frac{F'_o(v)}{(v-u)^2} = m^{-1} \int dv \frac{F''_o(v)}{(v-u)} \quad (A1)$$

We introduce a dimensionless variable, $t = v/a$, where $a$ denotes the thermal velocity for that species, and make use of the fact that $F_o(v)$ can be written as

$$F'_o(v) = g(t)/a$$

and hence

$$F''_o(v) = g''(t)/a^3$$

where $g$ is independent of $T$ or $m$. The expression $(A1)$ has then the form

$$(ma^3)^{-1} \int dt \frac{g''(t)(t-u/a)^{-1}}{a} \quad (A2)$$

where the integral is bounded and generally of order 1. Since $ma^2 = 2T$, the contribution of a given species to $D$ is proportional to $m^{1/2}/T^{3/2}$ and the
electron contribution is negligible.

We next examine $\tilde{G}$, given by (21). Here, the contribution of a given species to the term independent of $\Delta k$ is proportional to

$$m^{-2} \int dv \frac{F'(v-u)(v-u')(v-u'')}{v(v-u)^2} \sim (ma^2)^{-2} \int dt \frac{g'/(t-u/a)(t-u'/a)(t-u''/a)}{dt g'/(t-u/a)}$$

(A3)

and hence varies as $T^{-2}$, independent of $m$. The same result holds for the term proportional to $\Delta k$, since

$$v/(v-u) = t/(t-u/a)$$

(A4)

is, again, independent of $m$. Thus, we expect the electron contributions to $\tilde{G}$ to be smaller than the ion ones by $(T_i/T_e)^2$; in any case, they do not dominate.

Finally, we consider $H$, defined by (29), which we write as

$$H = \left( H_1 H_2 - H_3 H_4 \right)/H_3$$

(A5)

where

$$H_1 = \int dv \frac{(\omega p^2 q/m) F'/v(v-u)^2}{F'/v(v-u)^2}$$

$$H_2 = \int dv \frac{(\omega p^2 q/m) P(w',v)/v}{P(w',v)/v}$$

$$H_3 = \int dv \frac{\omega p^2 F'/v}{F'/v}$$

$$H_4 = \int dv \frac{(\omega p q/m)^2 P(w',v)/v(v-u)^2}{P(w',v)/v(v-u)^2}$$

(A6)

Using the same method of analysis as above, and noting that

$$P(w',v) \equiv - \text{Im} \left( \partial / \partial \nu \right) [F'/k'(v-u')] = a^{-4} \hat{P}$$

with

$$\hat{P} = \text{Im} \left( \partial / \partial t \right) [g'/k'(t-u'/a)]$$

we have for the contribution of one species to $H_1$ through $H_4$ the following:
As with $G$, the electron terms are, if anything, smaller than the ion terms, by powers of $(T_i/T_e)$.

In all of these integrals, of course, denominators like $(t-u/a)$ really cause no trouble, since the contour of integration is along the real $t$ axis and $\text{Im } u$ is non-zero. In the electron terms where we will make the approximation $u/a_e \to 0$, we let

$$
(t-u/a)^{-1} \to P(t-u/a)^{-1} \pm i\pi \delta(t-u/a)
$$

where the sign agrees with that of $\text{Im } u$. The $1/t$ factors are to be taken in the Cauchy principal value sense [cf. the discussion following (24)]. For denominators of higher order, like $(t-u/a)^{-2}$, integration by parts (together with a separation into partial fractions, if necessary) reduces the problem to (A7). Alternatively, one can use

$$(t-z)^{-2} = (d/dz)(t-z)^{-1}$$

For the electronic terms in these various integrals, we have $u/a_e \sim c_s/a_e \sim (m_e/M_1)^{1/2}$ so they can, to good approximation, be evaluated at $u = 0$, the corrections being of order $(m_e/M_1)^{1/2}$. The same consideration shows that we can also take the electron streaming velocity, $V_e$, in (32) as equal to zero, rather than $u_b V_b$, since with $V_b$ of order $c_s$ this, too, represents a correction of order $(m_e/M_1)^{1/2}$.
We now give explicit expressions for the coefficients $G$ and $H$ in terms of dimensionless integrals. First, we define a multi-argument generalization of the plasma dispersion (6) (or, more precisely, of its derivative):

$$G(t) = e^{-t^2/\pi^{1/2}}.$$  \hfill (A8)

The contour of integration is understood to be the real axis when $s$ is complex, whether Im $s$ is positive or negative. For real $s$, the Cauchy principal value is to be taken. If all of the arguments coincide, we have

$$Y_n(s, s, \ldots s) = (d/ds)^n Z(s).$$

In particular

$$Y_1(s) = Z'(s).$$

[Here $Z$ is to be interpreted as the $Z_+$ function (defined by

$$Z_+(s) = \pi^{-1/2} \int dt \, e^{-t^2} (t-s)^{-1}$$

for Im $s > 0$ and analytically continued into the lower half $s$ plane) for Im $s > 0$; as the $Z_-$ function ($Z_-(s) = Z_+(s^*)^*$) for Im $s < 0$; and as Re $Z$ for $s$ real.] If two of the arguments coincide, we have

$$Y_n(s_1, s_1, s_2, \ldots s_{n-1}) = (\partial/\partial s_1) Y_{n-1}(s_1, s_2, \ldots s_n).$$ \hfill (A9)

We also introduce a symbol for the Gaussian,

$$g(s) = e^{-s^2/\pi^{1/2}}.$$

Then the distribution functions (31) and (32) are all of the form

$$F_0 = \mu g(t)/a; \quad dF_0/dv = \mu g'/a^2.$$
with
\[ s = \frac{(v-V)}{a} \]

For denominators like \((v-u), v\) we have
\[
\begin{align*}
    v-u &= a(s-U); \quad U = \frac{(u-V)}{a} \\
    v &= a(s+W); \quad W = \frac{V}{a}
\end{align*}
\]

Thus
\[
P(\omega', v) = \left(\frac{\mu}{a^4}\right) \text{Im} \left(\frac{\partial}{\partial s}\right)[g'/k'(s-U')]
\]

We then have from (21)
\[
\begin{align*}
    2k'k'' G(\omega', \omega'') &= (\omega^2_{\pi} e/M) \int ds \left(\frac{q}{e}\right) \left(\frac{M}{m}\right)^2 \left(\frac{\mu}{a^4}\right) \\
    \times [g'(s)/(s-U)(s-U')(s-U'')][(1+\Delta k/k) + (\Delta k/k)(\mu/a)/(s-U)]
\end{align*}
\]

where \(M\) denotes ion mass and \(m, \mu, a, g\) carry an implicit species index.

We have also
\[
ma^2/M = 2T/M = 2c_s^2(T/T_e)
\]

Going over to the dimensionless units \((\omega_{\pi}, c_s, T/T_e)\) we then have
\[
L(\omega, \omega', \omega'') = -2k'k'' G M/e = -\left(\frac{1}{4}\right) \left\{ \sum_j \left(\frac{\mu_j}{\tau_j}\right)^2 \left[(1+\Delta k/k) Y_3(U_{j', U'_{j'}, U''})ight.ight.
\]
\[
+ (\Delta k/k)[u/(2\tau_j)^{1/2}] Y_4(U_{j', U_{j'}, U''_{j}, U''}) - 8(1+\Delta k/k) \right\} \quad (A10)
\]

where we have used the fact that \(Z''''(0) = 8\).

For the coefficient \(H\) we have from (A5) and (A6)
\[
H = \left(\frac{e/M}{2}\right)^2 h = \left(\frac{e/M}{2}\right)^2 (h_1 h_2/h_3 h_4)
\]

with
\[
h_1 = \omega^2_{\pi} \int ds \left(\frac{\mu/a^4}{q/e}\right) \left(\frac{M}{m}\right)^2 g'/(s+W)(s-U)^2
\]

where the \((s+W)\) denominator is to be taken as a Cauchy principal value, so
that, in dimensionless units.

\[ h_1 = \frac{1}{4} \left\{ \sum \left( \mu_j / \tau_j \right)^2 U_3(U_j, U_j; -W) - 8 \right\} \]

\[ h_2 = -\omega^2 \pi^2 \int ds \left( \mu/a^4 \right) \frac{(q/e)(M/m)^2(s+W)^{-1}(\partial/\partial s)[g'/k'(s-U')] \right]

\[ =-\frac{1}{4} \text{Im} \int ds \mu(T_e/T)^2 (q/e) g'/k'(s+W)^2 (s-U') \]

or

\[ h_2 = -\frac{1}{4} \text{Im} \left\{ \sum_j \left( \mu_j / \tau_j \right)^2 Y_3(U'_j, -W'_j, -W_j) - 8 \right\} \]

\[ h_3 = \omega^2 \pi^2 \int ds \left( \mu/a^2 \right)(M/m) g'/(s+W) \]

or

\[ h_3 = \frac{1}{2} \left\{ \sum \left( \mu_j / \tau_j \right) R_e Z' (-W_j) - 2 \right\} \]

and

\[ h_4 = -\omega^2 \pi^2 \int ds \left( \mu/a^6 \right)(M/m)^3(s+W)^{-1}(s-U)^{-2} \text{Im} (\partial/\partial s) g'/k'(s-U) \]

\[ = -(\omega^2 \pi^2 / 8) \int ds \mu(T_e/T)^3 \left[ (s+W)^{-2}(s-U)^{-2} + 2(s+W)^{-1}(s-U)^{-3} \right] \text{Im} g'/k'(s-U') \]

or

\[ h_4 = -(1/16i) \sum \left( \mu_j / \tau_j \right)^3 \left[ Y_5(-W_j, -W_j, U_j, U_j, U'_j) / k' \right. \]

\[ + 2 Y_5(-W_j, U_j, U_j, U_j, U'_j) / k' - (U'_j \rightarrow U'_j, k' \rightarrow k'^*)] \]

With the choice of parameters given in the caption of Fig. 1, the values of \( u, k, \) and \( D \) obtained from (36) and (37) for the three wave approximation are given in Table I. Note that \( \text{Im} u \) is typically 20% of \( \text{Re} u \), which is the reason we have eschewed the usual approximation of infinitesimal \( \text{Im} u \).

The other coefficients needed for the system (40) and (41) are the \( h(\omega, \omega') \) defined by (A11) through (A15). In the case of three waves, there are only three mode coupling coefficients: \( M(\omega_1) \equiv M(\omega_1, \omega_2, \omega_3) \); \( M(\omega_2) = M(\omega_2, \omega_1, -\omega_3) \); and \( M(\omega_3) = M(\omega_3, \omega_1 - \omega_2) \). These, together with the associated \( L \) values, are also listed in Table I. Since (40) requires \( ik\Delta \epsilon/D \) it is convenient to
tabulate the quantity

$$\xi(\omega, \omega') = -ik h(\omega, \omega')/D(\omega) \quad ,$$

which is given in Table II for the case of three waves. As is to be expected from our earlier discussion in this appendix, $\xi$ is dominated by the ion terms because of the $T_e/T$ and $(T_e/T)^2$ factors in $h_1$ through $h_4$ as well as the $(m_e/M_i)^{1/2}$ weighting of the respective contributions to $D$.

R-18 "Cyclotron Echoes from Doppler Effects", A.Y. Wong (March 1968)
R-21 "Test Particle Theory for Quantum Plasmas", M.E. Rensink (October 1967)*
R-23 "Landau Damping of Ion Acoustic Waves in a Cesium Plasma with Variable Electron-Ion Temperature Ratio", K.B. Rajangam (October 1967)
R-24 "The Inhomogeneous Two-Stream Instability", G. Knorr (September 1967)
R-26 "Small Amplitude Waves in High Beta Plasmas", V. Formisano and C. Kennel (February 1968)*
R-27 "Low Beta Plasma Penetration Across a Magnetic Field", B.D. Fried and S. Ossakow (March 1968)†
R-29 "The Theorist's Magnetosphere", C. Kennel (April 1968)
R-31 "Electromagnetic Echoes in Collisionless Plasmas", A.Y. Wong (April 1968)*
R-32 "Parametric Excitation of Drift Waves in a Resistive Plasma", G. Weyl and M. Goldman (June 1968)†
R-33 "Parametric Excitation from Thermal Fluctuations at Plasma Drift Wave Frequencies", A.Y. Wong, M.V. Goldman, F. Hai, R. Rowberg (May 1968)*
R-34 "Current Decay in a Streaming Plasma Due to Weak Turbulence", S.L. Ossakow and B.D. Fried (June 1968)†
R-35 "Temperature Gradient Instabilities in Axisymmetric Systems", C.S. Liu (August 1968)†
R-37 "Transverse Plasma Wave Echoes", B.D. Fried and Craig Olson (October 1968)†
R-38 "Low Frequency Interchange Instabilities of the Ring Current Belt", C.S. Liu (January 1969)†
R-39 "Drift Waves in the Linear Regime", R.E. Rowberg and A.Y. Wong (February 1969)*
R-41 "Nonlinear Oscillatory Phenomena with Drift Waves in Plasmas", F. Hai and A.Y. Wong (September 1970)
R-42 "Ion-Burst Excited by a Grid in a Plasma", H. Ikezi and R.J. Taylor (February 1969)
R-43 "Measurements of Diffusion in Velocity Space from Ion-Ion Collisions", A. Wong and D. Baker (March 1969)*
R-44 "Nonlinear Excitation in the Ionosphere", A.Y. Wong (March 1969)
R-46 "A New Representative for the Conductivity Tensor of a Collisionless Plasma in a Magnetic Field", B.D. Fried and C. Hedrick (March 1969)†
R-47 "Direct Measurements of Linear Growth Rates and Nonlinear Saturation Coefficients", A.Y. Wong and F. Hai (April 1969)*
R-49 "Auroral Micropulsation Instability", F. Coroniti and C.F. Kennel (May 1969)†
R-50 "Effect of Fokker-Planck Collisions on Plasma Wave Echoes", G. Johnston (June 1969)†
R-52 "Theory of Stability of Large Amplitude Periodic (BGK) Waves in Collisionless Plasmas", M.V. Goldman (June 1969)†
R-55 "Optical Mixing in a Magnetoactive Plasma", G. Weyl (August 1969)†
R-56 "Trapped Particles and Echoes", A.Y. Wong and R. Taylor (October 1969)†
R-84  "Observations of Parametrically Excited Ion Acoustic Waves", R. Stenzel (March 1971)
R-85  "Remote Double Resonance Coupling of Radar Energy to Ionospheric Irregularities", C.F. Kennel (January 1971)
R-86  "Ion Acoustic Waves in a Multi-Ion Plasma", B.D. Fried, R. White, T. Samec (January 1971)
R-87  "Current-Driven Electrostatic and Electromagnetic Ion Cyclotron Instabilities", D.W. Forslund, C.F. Kennel, J. Kindel (February 1971)
R-88  "Locating the Magnetospheric Ring Current", C.F. Kennel and Richard Thorne (March 1971)
R-89  "Ion Acoustic Instabilities Due to Ions Streaming Across Magnetic Field", P.J. Barrett, R.J. Taylor (March 1971)
R-90  "Evolution of Turbulent Electronic Shocks", A.Y. Wong and R. Means (July 1971)*
R-91  "Density Step Production of Large Amplitude Collisionless Electrostatic Shocks and Solitons", David B. Cohen (June 1971)
R-95  "3-D Velocity Space Diffusion in Beam-Plasma Interaction without Magnetic Field", P.J. Barrett, D. Gresillon and A.Y. Wong (September 1971)
PPG-96  "Dayside Auroral Oval Plasma Density and Conductivity Enhancements due to Magnetosheath Electron Precipitation", C.F. Kennel and M.H. Rees (September 1971)
PPG-97  "Collisionless Wave-Particle Interactions Perpendicular to the Magnetic Field", A.Y. Wong, D.L. Jassby (September 1971)
PPG-98  "Magnetospheric Substorms", F.V. Coroniti and C.F. Kennel (September 1971)
PPG-100  "Structure of Ion Acoustic Solitons and Shock Waves in a Two-Component Plasma", R.B. White, B.D. Fried and F.V. Coroniti (September 1971)
PPG-101  "Solar Wind Interaction with Lunar Magnetic Field", G. Siscoe (Meteorology Dept.) and Bruce Goldstein (JPL) (November 1971)
PPG-102  "Changes in Magnetospheric Configuration During During Substorm Growth Phase", F.V. Coroniti and C.F. Kennel (November 1971)
