ABSTRACT

THIS REPORT DESCRIBES THE FORTRAN VERSION FGRAAL OF THE GRAPH ALGORITHMIC LANGUAGE GRAAL (TECHN, REPORT TR-158) AS IT HAS BEEN IMPLEMENTED FOR THE UNIVAC 1108. FGRAAL IS AN EXTENSION OF FORTRAN V. AND IS INTENDED FOR DESCRIBING AND IMPLEMENTING GRAPH ALGORITHMS OF THE TYPE PRIMARILY ARISING IN APPLICATIONS. THE FORMAL DESCRIPTION CONTAINED IN THIS REPORT REPRESENTS A SUPPLEMENT TO THE FORTRAN V. MANUAL FOR THE UNIVAC 1108 (UP-4060), THAT IS, ONLY THE NEW FEATURES OF THE LANGUAGE ARE DESCRIBED. SEVERAL TYPICAL GRAPH ALGORITHMS, WRITTEN IN FGRAAL, ARE INCLUDED TO ILLUSTRATE VARIOUS FEATURES OF THE LANGUAGE AND TO SHOW ITS APPLICABILITY.
# TABLE OF CONTENTS

1. **INTRODUCTION** 1-1
2. **SET THEORETIC FOUNDATIONS OF GRAAL** 2-1
3. **VARIABLES, DECLARATION STATEMENTS** 3-1

A GRAPH ALGORITHMIC LANGUAGE, FGRAAL, IS DESCRIBED AS IT IS IMPLEMENTED FOR THE UNIVAC 1108. THE LANGUAGE IS AN EXTENSION OF FORTRAN V, AND IT IS INTENDED FOR IMPLEMENTING GRAPH ALGORITHMS OF THE TYPE PRIMARILY ARISING IN APPLICATIONS. THIS REPORT CONTAINS THE DESCRIPTION OF THE LANGUAGE EXTENSION FOR A POTENTIAL USER, AND IT SHOULD BE USED TOGETHER WITH THE FORTRAN V. MANUAL FOR THE UNIVAC 1108 (UP-4060). FGRAAL HAS BEEN IMPLEMENTED BY MODIFYING THE RALPH COMPILER. IT CAN BE CALLED BY

`FGRAAL, <OPTIONS> <SPECIFICATIONS>`

WHERE `<OPTIONS>` AND `<SPECIFICATIONS>` ARE AS DEFINED FOR FORTRAN PROGRAMS.

CHAPTER 2 GIVES A SUMMARY OF THE SET THEORETIC FOUNDATION OF FGRAAL. CHAPTERS 3-14 CONTAIN THE DESCRIPTION OF THE SPECIAL FEATURES OF THE LANGUAGE. CHAPTER 15 SUMMARIZES THE SPECIAL OPERATIONS AND STATEMENTS IN A TABLE. CHAPTER 16 CONTAINS SEVERAL EXAMPLES PROGRAMMED IN FGRAAL.
2. SET THEORETIC FOUNDATIONS OF GRAAL

In this chapter, capital letters $X, S, T,$ etc., stand for finite sets, and the basic set operations are indicated by the usual symbols: $\cup$ (union), $\cap$ (intersection), $\sim$ (difference), and $\Delta$ (symmetric sum). For any set $X$, the cardinality is denoted by $|X|$. $P(X)$ is the power set, and we define

\[(2.1) \quad P_k(X) = \{S \in P(X) \mid |S| = k\}, \quad k = 0, 1, \ldots, |X|
\]

In GRAAL, the set operations are denoted by $\cup$, $\cap$, $\setminus$, and $\Delta$, respectively. The cardinality of a set $X$ is given by the built-in function Size($X$).

It is well-known that under union, intersection, and complementation (in $X$), $P(X)$ is a Boolean algebra with the members of $P_1(X)$ as generators. To obtain another algebraic structure, let $GF(2)$ be the binary Galois field with the integers $0, 1$ as elements. Then $P(X)$ becomes a vector space over $GF(2)$ if the symmetric sum is used as addition and the scalar product is defined by

\[
\lambda S = \emptyset \text{ for } \lambda = 0 \quad \text{and} \quad \lambda S = S \text{ for } \lambda = 1
\]

The elements of $P_1(X)$ now form a basis.

For any sets $X, Y$ we denote by $B(X, Y)$ the class of all morphisms $\psi : P(X) \rightarrow P(Y)$ between the Boolean algebras $P(X)$, $P(Y)$. Any $\psi \in B(X, Y)$ is uniquely characterized by the image sets $\psi\{x\} \subseteq P(Y)$ of the generators $\{x\} \subseteq P_1(X)$ and

\[(2.2) \quad \psi S = \bigcup_{x \in S} \psi\{x\}, \quad \forall S \in P(X)
\]

Correspondingly, we define $L(X, Y)$ as the class of all linear mappings $\varphi : P(X) \rightarrow P(Y)$ between the vector spaces $P(X)$, $P(Y)$. Then, instead of (2.2), we have for any $\varphi \in L(X, Y)$ the representation

\[(2.3) \quad \varphi S = \Delta \varphi\{x\}, \quad \forall S \in P(X)
\]
Let $G$ be a graph with node set $V$ and arc set $A$. The elements of $P(V)$ and $P(A)$ constitute the basic data objects for all operations on $G$ under GRAAL and the structure of the graph is defined by certain boolean or linear mappings between the two power sets. In the remainder of this chapter we define the basic graph operators presently included in GRAAL.

In FGRAAL, the node set $V$ and the arc set $A$ of a graph $G$ are referred to by the built-in functions $NODES(G)$ and $ARCS(G)$, respectively.

An undirected pseudograph is a triple $G = (V,A,\phi)$ consisting of a node set $V$, an arc set $A$, and an incidence operator

$$\phi \in \mathcal{B}(A,V)$$

$$\forall a \in A, \phi\{a\} \in P_1(V) \cup P_2(V),$$

thus for any arc $a$, $\phi\{a\}$ is either the two-element subset of $V$ consisting of the two distinct endpoints of $a$, or an atomic subset of $V$, in which case $a$ is a self loop. We speak of a multigraph if in (2.4) the condition (i) is replaced by

$$\forall a \in A, \phi\{a\} \in P_2(V),$$

the unqualified term graph is used if, in addition to (ii), the restricted mapping $\phi : P(A) \rightarrow P(V)$ is one-to-one.

In FGRAAL, the incidence operator is implemented by a built-in function, $INC(G,S)$, with two arguments, the first being the graph identifier, and the second a set of arcs in $G$, the value of the function is a set (of nodes of $G$) as defined by (2.2) and (2.4).

For any undirected pseudograph $G = (V,A,\phi)$ the star operator is the boolean mapping

$$\sigma \in \mathcal{B}(V,A)$$

$$\sigma\{v\} = \{a \in A | v \in \phi\{a\}\}, \forall v \in V$$

while the standard boundary operator $\partial$ and coboundary operator $\delta$ are defined as the linear mappings

$$\partial \in \mathcal{L}(A,V)$$

$$\forall a \in A, \partial\{a\} = (|\phi\{a\}| - 1) \phi\{a\},$$

and

$$\delta \in \mathcal{L}(V,A)$$

$$\forall v \in V, \delta\{v\} = \{a \in V | |\phi\{a\}| = 2\}. \forall v \in V.$$
Hence, for any node $\sigma$, $\delta[\sigma]$ is the set of all arcs of $G$ which are incident with $\sigma$. The boundary operator $\partial$ maps each arc into the set of its two endpoints, provided they are distinct, and otherwise into the empty set. Finally, $\delta[\alpha]$ consists of all arcs incident with $\alpha$ excluding any self-loops.

In FGRAAL, the above operators are implemented as built-in functions, $\text{star}(G, T)$, $\text{bd}(G, S)$ and $\text{cob}(G, T)$, each with two arguments. The first is the graph identifier, and the second is a set, $T$ or $S$, where $T$ is a subset of nodes of $G$, and $S$ is a subset of arcs of $G$. The values of the functions are sets of nodes or arcs of $G$ according to the definitions (2.2) and (2.5) for $\text{star}$, (2.3) and (2.6) for $\text{bd}$, (2.3) and (2.7) for $\text{cob}$.

In a graph $G$, each arc is uniquely determined by the two element set of its endpoints, and hence the arcs are losing some of their own identity. Accordingly, it is often expedient to work exclusively with the nodes. For this we introduce for a graph $G = (V, A, \phi)$ the adjacency operator

\[(2.8) \quad \alpha \in B(V, V) \quad \alpha \{\nu\} = \{u \in V \mid \exists \alpha \in \delta[\nu], \phi{\alpha} = \{u, \nu\}\}, \forall \nu \in V\]

Thus, $\alpha$ produces for each node $\nu$ the set of all nodes $u$ which form with $\nu$ the (distinct) endpoints of some arc of $G$.

In FGRAAL, the adjacency operator is implemented as a built-in function, $\text{adj}(G, S)$, with the graph identifier $G$ again as first argument and the set of nodes of $G$ as the second. The value of the function is a set of nodes as defined by (2.2) and (2.8).

Other operators are possible and may be included later. Each one of these operators can be used in place of $\phi$ to characterize graphs of specific type. For example, note that $\alpha$ has the properties

\[
(2.9) \quad \begin{align*}
(i) & \quad \alpha \in B(V, V) \\
(ii) & \quad \nu \notin \alpha \{\nu\}, \forall \nu \in V \\
(iii) & \quad u \in \alpha \{\nu\} \quad \text{if and only if} \quad \nu \in \alpha \{u\}, \forall \nu \in V
\end{align*}
\]

If $V$ is any set and the mapping $\alpha$ satisfies (2.9) then $G = (V, A, \phi)$ with

\[
\begin{align*}
A &= \{(u, \nu) \in E_2(V) \mid u \in \alpha \{\nu\}\}
\phi \in B(A, V), \phi{\alpha} = \{u, \nu\} \quad \text{if} \quad \alpha = \{u, \nu\}, \forall \alpha \in A
\end{align*}
\]
IS A WELL-DEFINED GRAPH WITH $\alpha$ AS ITS ADJACENCY OPERATOR. WE CALL $(V, \alpha)$ THE NODE FORM REPRESENTATION OF $G$.

THE DEFINITION OF THE VARIOUS OPERATORS ARE EASILY CARRIED OVER TO DIRECTED GRAPHS. A DIRECTED PSEUDOGRAPH SHALL BE A QUADRUPLE $G = (V, A, \phi_+, \phi_-)$ CONSISTING OF A NODE SET $V$, AN ARC SET $A$, AS WELL AS A POSITIVE AND A NEGATIVE INCIDENCE OPERATOR

\[(2.10) \quad \phi_+, \phi_- \in B(A, V)\]

\[\phi_+ \{a\}, \phi_- \{a\} \in P(V), \quad \forall a \in A\]

IN OTHER WORDS, $\phi_+ \{a\}$ AND $\phi_- \{a\}$ ARE ATOMIC SUBSETS OF $P(V)$ CONSISTING OF THE INITIAL AND TERMINAL NODES OF $a$, RESPECTIVELY. IN MANY CASES, IT IS CONVENIENT TO USE THE COMBINED INCIDENCE OPERATOR

\[(2.11) \quad \phi \in B(A, V)\]

\[\phi \{a\} = \phi_+ \{a\} \cup \phi_- \{a\}, \quad \forall a \in A\]

AS IN THE UNDIRECTED CASE WE SPEAK OF A DIRECTED MULTIGRAPH IF $\phi \{a\} \in P(V)$, FOR ALL $a \in A$, AND OF A DIRECTED GRAPH (DIGRAPH) IF, IN ADDITION, $\phi : P(A) \rightarrow P(V)$ IS ONE-TO-ONE.

THE POSITIVE AND NEGATIVE STAR OPERATORS OF THE DIRECTED PSEUDOGRAPH $G$ ARE DEFINED BY

\[(2.12) \quad \sigma_+ \in B(V, A)\]

\[\sigma_+ \{\nu\} = \{a \in A \mid \nu = \phi_+ \{a\}\}, \quad \forall \nu \in V\]

\[\sigma_- \in B(V, A)\]

\[\sigma_- \{\nu\} = \{a \in A \mid \nu = \phi_- \{a\}\}, \quad \forall \nu \in V\]

AND WE INTRODUCE ALSO THE COMBINED STAR OPERATOR

\[(2.13) \quad \sigma \in B(V, A)\]

\[\sigma \{\nu\} = \sigma_+ \{\nu\} \cup \sigma_- \{\nu\}, \quad \forall \nu \in V\]

THUS, $\sigma_+ \{\nu\}$ CONSISTS OF ALL THE ARCS BEGINNING AT $\nu$ AND $\sigma_- \{\nu\}$ OF THOSE TERMINATING AT THAT NODE.

THE POSITIVE AND NEGATIVE BOUNDARY AND COBOUNDARY OPERATORS OF A DIRECTED PSEUDOGRAPH ARE NOW THOSE LINEAR MAPPINGS WHICH COINCIDE WITH THE INCIDENCE AND STAR OPERATORS ON THE APPROPRIATE FAMILY OF ATOMIC SETS:

\[(2.14) \quad \partial_+, \partial_- \in L(A, V)\]

\[\partial_+ \{a\} = \phi_+ \{a\}, \quad \partial_- \{a\} = \phi_- \{a\}, \quad \forall a \in A\]
It is natural to define also the combined mappings

\[ \forall v \in V, A \]

\[ \delta^+(v) = \delta^+_A(v), \quad \delta^-(v) = \delta^-_A(v) \]

Thus, \( \delta^+\) is again the set of the endpoints of \( A \) if these endpoints are distinct, and the empty set, if they are not. Similarly, \( \delta^-\) is once more the set of all arcs incident with \( v \) excluding all self loops.

Finally, we define for a digraph \( G = (V, A, \phi^+, \phi^-) \) the positive and negative adjacency operators by the relations

\[ \forall v \in V, \ A \]

\[ \alpha^+ \{v\} = \{u \in V \mid \exists a \in \delta^+_A(v), \ u = \phi^+(a)\}, \quad \forall v \in V \]

\[ \alpha^- \{v\} = \{u \in V \mid \exists a \in \delta^-_A(v), \ u = \phi^-(a)\}, \quad \forall v \in V \]

Then the combined adjacency operator

\[ \forall v \in V, \ A \]

\[ \alpha \{v\} = \alpha^+ \{v\} \cup \alpha^- \{v\} \]

Has again exactly the same meaning as in the undirected case. Moreover, \( \alpha^+ \) and \( \alpha^- \) may be used to characterize the incidence structure of a digraph. Here conditions (\( \sim \)) and (\( \ll \)) of (2.9) have to hold for both \( \alpha^+ \) and \( \alpha^- \), and (\( \ll \)) is replaced by

\[ \ll \quad u \in \alpha^+ \{v\} \text{ if and only if } \forall u, v \in V \]

This defines the node representation \((V, \alpha^+, \alpha^-)\) of a digraph.

In FGRAAL, the positive (negative) operators are implemented by having the letter 'P' ('N') in front of the corresponding built-in function name. For example, the positive incidence operator corresponds to the built-in function \( \text{PINC}(G, S) \), the negative incidence operator to \( \text{NINC}(G, S) \).
3. VARIABLES, DECLARATION STATEMENTS

There are four new types of variables introduced in FGRAAL; namely SET-, LIST-, PROPERTY- and GRAPH-VARIABLES. All of these variables must appear in the proper declaration statement. Sets constitute a new basic data type. Lists are doubly-opened linked list structure which may be used as stacks or queues. Property variables resemble subscripted variables with set variables corresponding to subscripts. Graphs represent specific data structures. All of these variables may appear in the argument list of a subroutine call.

3.1. Sets

In FGRAAL, sets constitute a new basic data type. An atomic set is a set consisting of one item, and any set is either empty or a union of atomic sets. The only constant set is the empty set. An atomic set carries a sequence number which is assigned to it at the time of its creation, and the members of a set are ordered in ascending order of their sequence number. All sequence numbers are retained in an element sequence; it is an ordered internal structure serving the dual purpose of cataloging the atomic sets which have been created so far and of providing the linkage between an atomic set and the properties which are assigned to it.

Set variables are declared by a set declaration, which consists of the word set followed by the list of variables, e.g.

\[
\text{set S, T}
\]

Sets can also be declared implicitly, as any other variables in Fortran. The statement

\[
\text{implicit set (s-w)}
\]

causes all variables whose leading character is in the range from \(s\) to \(w\) to be considered as set variables.

The creation of atomic sets is accomplished by the create function which is described in the section 4.1.

The empty set is denoted by the character \(\text{&}\) or by the keyword \(\text{.empty}\), enclosed in periods. A declared set can be made empty by the following set assignment statement:

\[
\text{S = & or S = .empty}
\]

And can be tested if it is empty or not by the logical expression
SET VARIABLES MAY BE DIMENSIONED AS OTHER TYPE OF VARIABLES
(REAL, INTEGER, ETC.), EITHER IN A SEPARATE DIMENSION STATEMENT OR
IN THE DECLARATION STATEMENT ITSELF, E.G.

SET R(10)

DEFINES AN ARRAY CONSISTING OF 10 SETS, R(1), ..., R(10).

3.2. LISTS

A LIST IS A DOUBLY-OPEN, LINKED LIST STRUCTURE WHICH MAY BE
USED AS A STACK OR A QUEUE, IT OFFERS A DYNAMIC ALTERNATIVE TO
THE ARRAY FOR THE STORING VALUES OF VARIABLES IN THE ORDER DEFINED
BY THE USER. EACH LIST MUST BE DECLARED BY ITS TYPE (INTEGER,
REAL, BOOLEAN OR SET) REFERING TO THE TYPE OF VALUES THE LIST MAY
CONTAIN. THE LIST DECLARATION STATEMENT CONSISTS OF THE TYPE,
FOLLOWED BY THE WORD STAUQE, FOLLOWED BY A LIST OF NAMES, E.G.

INTEGER STAUQE I,J

OPTIONALLY, THE TYPE MAY BE DELETED, IN WHICH CASE, THE TYPE OF
THE LIST IS DEFINED BY THE 'NAME RULE'.

3.3. PROPERTIES

A PROPERTY MAY BE ASSOCIATED WITH ANY ATOMIC SET. THE PROPERTY
DECLARATION ESTABLISHES THE TYPE ASSOCIATED WITH EACH PROPERTY
NAME. THE DECLARATION CONSISTS OF THE TYPE, FOLLOWED BY THE WORD
PROPERTY, FOLLOWED BY THE LIST OF PROPERTY NAMES, E.G.

SET PROPERTY S,TREF
REAL PROPERTY CAP,F1,F2

WHENEVER THE TYPE IS NOT EXPLICITLY GIVEN IN THE DECLARATION, THE
TYPES OF THE PROPERTIES IN THE LIST ARE DEFINED BY THE 'NAME
RULE'.

ASSIGNING OR REASSIGNING OF A PROPERTY VALUE TO AN ATOMIC SET,
AND RETRIEVING IT, IS DESCRIBED IN CHAPTER 7.
3.4. Graphs

Graphs represent specific data structures together with certain operations for manipulating them. The graph declaration identifies the data structures used and the family of operators available with it. The language is modular in the sense that, in general, only some of the possible graph operations are usable with any specific graph. Four modules are presently defined in the language:

0. Directed pseudograph
1. Undirected pseudograph
2. Directed node graph
3. Undirected node graph

The pseudograph is the most general module and allows self-loops (arc with the same node as end-points) and multiple arcs (more than one are connecting two different nodes). The node graph does not allow self-loops or multiple arcs, furthermore arcs do not have an identity.

The identity of a node or arc is established by assigning atomic sets to the graph. These operations are described in Chapter 9.

Graphs with different modules must be declared in separate statements. The graph declaration statement consists of the word GRAPH, followed by the graph module number in parentheses, and by a list of graph variables, e.g.

```
GRAPH(0) G, H
GRAPH(3) T
```

Statements declare G and H as directed pseudographs, T as an undirected node graph.

3.5. Variables as function or subroutine arguments

Any of the above described variables may be submitted to functions or subroutines in the argument list, e.g.

```
SET S, T(10)
GRAPH(1) G
REAL PROPERTY LENGTH
*******
CALL SUB(S, T, G, LENGTH)
*******
```
WHEN A SUBROUTINE OR FUNCTION HAS THE ABOVE VARIABLES IN ITS ARGUMENT LIST, IT MUST DECLARE THEM, E.G.

SUBROUTINE SUB(S,T,G,LENGTH)
   SET S, T(10)
   GRAPH G
   REAL PROPERTY LENGTH
   .........

THE MODULE NUMBER OF THE GRAPH DECLARATION MAY BE OMITTED IN THE SUBROUTINE.

3.6. EXTERNAL SET FUNCTIONS

EXTERNAL FUNCTION SUBPROGRAMS OF SET TYPE CAN BE USED THE SAME WAY AS OTHER TYPE OF EXTERNAL FUNCTION SUBPROGRAMS, I.E. THE TYPE OF THE FUNCTION MUST BE DECLARED UNLESS ITS NAME IN CONTAINED IN AN IMPLICIT SET DECLARATION, E.G.

C CALLING PROGRAM
   ......
   SET SFCT
   ......
   X = .. SFCT(Z,R) ...
   ......
END

C FUNCTION PROGRAM
   SET FUNCTION SFCT(S,T)
   ......
   SFCT = ..
   RETURN
END
4. SET EXPRESSION

A SET EXPRESSION IS A RULE FOR CREATING, REFERENCING, AND MANIPULATING SETS. EACH ATOMIC SET CARRIES A SEQUENCE NUMBER WHICH IS ASSIGNED TO IT AT THE TIME OF ITS CREATION. A SET IS A UNION OF ATOMIC SETS ORDERED IN ASCENDING ORDER BY THEIR SEQUENCE NUMBER. ALL SEQUENCE NUMBERS ASSIGNED TO ATOMIC SETS ARE RETAINED IN AN ELEMENT SEQUENCE. THIS IS AN ORDERED INTERNAL STRUCTURE SERVING THE DUAL PURPOSE OF CATALOGING THE ATOMIC SETS WHICH HAVE BEEN CREATED THUS FAR AND PROVIDING THE LINKAGE BETWEEN AN ATOMIC SET AND THE PROPERTIES WHICH ARE ASSIGNED TO IT.

4.1. CREATION AND REMOVAL OF ATOMIC SETS

THE SPECIAL FUNCTION,

CREATE (0)

WITH ARGUMENT ZERO CREATES A NEW ELEMENT WITH THE NEXT SEQUENCE NUMBER IN THE ELEMENT SEQUENCE AND RETURNS THE ATOMIC SET CONTAINING THAT ELEMENT. THE SAME FUNCTION MAY BE USED WITH A LIST OF ARGUMENT PAIRS:

CREATE (P1, V1, P2, V2, ..., PN, VN) (N>0)

WHERE THE PI'S ARE DECLARED PROPERTY NAMES, AND THE VI'S ARE VARIABLES OR CONSTANTS OF THE SAME TYPES AS THE CORRESPONDING PROPERTIES. THIS VERSION OF THE FUNCTION CAUSES A SEARCH OF THE ELEMENT SEQUENCE FOR AN ATOMIC SET FOR WHICH ALL THE NAMED PROPERTIES EXIST AND ARE PRESENTLY ASSIGNED THE SPECIFIED VALUES. IF A (COMPLETE) MATCH IS FOUND THE FUNCTION RETURNS THE CORRESPONDING ATOMIC SET. IF NO MATCH (OR ONLY A PARTIAL MATCH) OCCURS, A NEW ELEMENT WITH THE NEXT SEQUENCE NUMBER IS ADDED TO THE ELEMENT SEQUENCE WITH THE GIVEN PROPERTIES AND CORRESPONDING VALUES. THE ATOMIC SET CONTAINING THIS NEW ELEMENT IS RETURNED.

THE REMOVE STATEMENT REMOVES ALL ATOMIC SETS WHICH ARE ELEMENTS OF THE ARGUMENT SET FROM THE ELEMENT SEQUENCE, TOGETHER WITH THEIR ASSOCIATED PROPERTIES, E.G.

REMOVE S

REMOVES THE ATOMIC SETS WHICH ARE ELEMENTS OF THE SET S. IF A REMOVED ATOMIC SET IS REFERENCED AN ERROR CONDITION OCCURS.

THE SPECIAL FUNCTION,
ATOM (1)

WHERE I IS AN INTEGER, CAN BE USED TO OBTAIN THE ATOMIC SET WHOSE ELEMENT HAS THE GIVEN SEQUENCE NUMBER I. IF THERE IS NO SUCH AN ELEMENT, IT RETURNS AN EMPTY SET.

4.2. SET OPERATORS

THE FOLLOWING FOUR SET OPERATORS ARE DEFINED IN FGRAAL:

- DF: DIFFERENCE (~)
- UN: UNION (∪)
- IT: INTERSECTION (∩)
- SM: SYMMETRIC SUM

4.3. SET FUNCTIONS

SET FUNCTIONS ARE BUILT-IN FUNCTIONS WHICH PRODUCE SETS. TWO OF THESE FUNCTIONS ARE THE CREATE AND ATOM FUNCTIONS DESCRIBED IN SECTION 4.1. OTHER SET PRODUCING FUNCTIONS ARE THE FUNCTIONS SUBSET AND LLT (CHAPTER 8), THE GRAPH OPERATORS (CHAPTER 9), THE SET-PROPERTIES (CHAPTER 7) AND THE ELEMENTS OF A LIST OF TYPE SET (CHAPTER 6).

4.4. SET-EXPRESSIONS

SET EXPRESSIONS ARE FORMED BY THE PROPER SEQUENCE OF SETS, SET-OPERATORS, SET-FUNCTIONS AND PARENTHESES. THE PRECEDENCE OF THE SET OPERATORS AND FUNCTIONS ARE AS FOLLOWS (IN INCREASING ORDER):

- DF
- UN
- IT
- SM
- SET-FUNCTIONS
The expression

\[ \text{CREATE(0) \text{.UN.} S \text{.SM.} T \text{.DF.} R} \]

would be evaluated as though it were parenthesized as follows

\[ ( \text{CREATE(0) \text{.UN.} ( S \text{.SM.} T )} ) \text{.DF.} R \]

When two operators are of the same precedence, the one of the left has precedence over the one on the right, e.g.

\[ S \text{.DF.} T \text{.DF.} R \]

is evaluated as

\[ ( S \text{.DF.} T ) \text{.DF.} R \]

Parentheses can be used to alter the precedence relation.

If a variable is used more than once in the context of an expression or argument list, and at least one such a use is as an argument of a function or operator which modifies it then certain problems arise. See Appendix for more information.
b. Set-Relations: Logical Expressions

The following 3 set-relation operators may be used to obtain logical value true or false:

- `EQ`: Sets equal
- `NE`: Sets not equal
- `IN`: Set is contained in

The logical expression

\[ S \text{EQ} T \]

Gives the value true whenever the two sets, \( S \) and \( T \), are equal, and the value false otherwise. The logical expression

\[ S \text{NE} T \]

Gives the value true when the two sets are not equal, and the value false when they are equal. The logical expression

\[ S \text{IN} T \]

Gives the value true when the set \( S \) is contained in the set \( T \) \( (S \subseteq T) \), and the value false otherwise.

The above expressions may form a subexpression in any Fortran type of logical expression, e.g.

\[(I \text{LE} 2) \text{AND} (S \text{IN} T)\]

If a variable is used more than once in the context of an expression or argument list, and at least one such use is as an argument of a function or operator which modifies it then certain problems arise. See appendix for more information.
LIST OPERATIONS

AS STATED IN SECTION 3.2, A LIST IS BASICALLY A STACK OR A QUEUE. TO BUILD THE LIST, ITEMS ARE CONCATENATED TOGETHER. A LIST STATEMENT CONSISTS OF A LIST IDENTIFIER, THE EQUAL SIGN AND A LIST OF ITEMS SEPARATED BY COLONS. THE ITEMS MUST BE CONSTANTS, VARIABLES, LISTS BE USED FOR COLON, E.G.

\[ \text{REAL STACK: } Q.R \]
\[ Q = X :: Q : R :: 2.5 \]

OR

\[ Q = X . \text{ET} \cdot Q . \text{ET} \cdot R . \text{ET} \cdot 2.5 \]

LISTS APPEARING IN THE CONCATENATION ARE COPIED, E.G.

\[ L = 1 : 2 \]
\[ LL = L : 3 \]

IS EQUIVALENT TO

\[ LL = 1 : 2 : 3 \]

AN EMPTY LIST IS REFERENCED BY THE CHARACTER 'nil' OR BY 'NIL'. A LIST CAN BE EMPTIED BY THE ASSIGNMENT STATEMENT

\[ L = \text{nil} \]

AND CAN BE TESTED BY

\[ L . \text{EQ} . \text{nil} \]

TO OBTAIN AND POSSIBLY REMOVE AN ITEM FROM A LIST, THERE ARE FOUR OPERATORS:

FIRST (L)

RETURNS THE FIRST ITEM OF THE LIST L.

DFIRST (L)

RETURNS THE FIRST ITEM AND DELETES IT FROM THE LIST L.

LAST (L)

RETURNS THE LAST ITEM OF THE LIST L, AND

DLAST (L)
RETURNS THE LAST ITEM AND DELETES IT FROM THE LIST L.

THE ITEM RETURNED IS OF THE TYPE OF THE DECLARED LIST L, THUS IT MAY BE USED IN ANY PROPER CONTEXT (EXPRESSIONS).

IF A VARIABLE IS USED MORE THAN ONCE IN THE CONTEXT OF AN EXPRESSION OR ARGUMENT LIST, AND AT LEAST ONE SUCH USE IS AS AN ARGUMENT OF A FUNCTION OR OPERATOR WHICH MODIFIES IT THEN CERTAIN PROBLEMS ARISE. SEE APPENDIX FOR MORE INFORMATION.
PROPERTY ASSIGNMENT AND RETRIEVAL

As stated in Section 3.3, properties can be associated with atomic sets. In Section 4.1, property assignment by the create function was already described.

A simple property assignment is done for the atomic set $X$ as

$$ P(X) = E $$

where $P$ is a declared property and $E$ is an expression of the same type as $P$ (integer, real, double precision, boolean or set). If the atomic set $X$ had property $P$ already, then the previous value is reset to the value of $E$. Otherwise, the property $P$ is established with the value of $E$.

When $P(X)$ is referenced, e.g., as part of an expression, its current value is retrieved. Whenever the argument set $X$ is not an atomic set, but a set with more than one element, then the operations are performed in respect to the first element of the set.

The special built-in logical function,

$$ \text{CHECK}(P, X) $$

returns the value true when the property $P$ has been defined for the atomic set $X$, and returns the value false otherwise.

The remove statement with argument of a property name,

$$ \text{REMOVE} P $$

removes the property $P$ from all atomic sets for which it had been defined. The statement with argument $P$ followed by a set in parentheses,

$$ \text{REMOVE} P(X) $$

removes the property $P$ only from the atomic sets which were elements of the set $X$. 

8. BUILT-IN FUNCTIONS

8.1. ELT AND INDEX FUNCTIONS

THE FUNCTION,

ELT (I, S)

WITH INTEGER I AND SET S, RETURNS THE I-TH ELEMENT OF S AS AN
ATOMIC SET. IF THERE IS NO I-TH ELEMENT OF S THEN IT RETURNS THE
EMPTY SET.

THE FUNCTION,

INDEX (X, S)

WITH ATOMIC SET X AND SET S, RETURNS INTEGER I IF X IS THE I-TH
ELEMENT OF S, RETURNS ZERO OTHERWISE.

8.2. SUBSET FUNCTION

THE FUNCTION,

SUBSET (X, R)

RETURNS A SET OF ELEMENTS WHICH SATISFY THE LOGICAL EXPRESSION B.
X IS A DUMMY VARIABLE WHICH CAN BE USED IN THE LOGICAL EXPRESSION
B.
E.g.

SUBSET(X : (X.IN.S).AND.(DIST(X).GT.0))

8.3. SIZE, PARITY, COUNT FUNCTIONS

THE FUNCTION,

SIZE (S)

RETURNS THE NUMBER OF ELEMENTS IN THE SET S.

THE FUNCTION,
PARITY (S)

RETURNS ZERO IF THE SIZE(S) IS EVEN, RETURNS ONE OTHERWISE.

THE FUNCTION:

COUNT (X)

OR

COUNT (0)

RETURNS THE SEQUENCE NUMBER OF THE GIVEN ATOMIC SET X OR RETURNS
THE SEQUENCE NUMBER OF THE LAST ATOMIC SET CREATED WHEN THE ARGU-
MENT IS ZERO.

8.4. DOMAIN FUNCTION

THE FUNCTION:

DOMAIN (P)

WHERE P IS A PROPERTY IDENTIFIER, GENERATES THE SET WHOSE ELEMENTS
HAVE PROPERTY P DEFINED. THIS FUNCTION PROVIDES A FASTER OBJECT
TIME EXECUTION THAN THE EQUIVALENT FUNCTIONAL EXPRESSION

SUBSET (X, CHECK(P,X))
9. GRAPH OPERATIONS

GRAPH OPERATIONS ALLOW FOR THE ASSIGNMENT OF ATOMIC SETS AS NODES OR ARCS TO A GRAPH, THE REMOVAL OF NODES AND ARCS FROM A GRAPH, AND THE OBTAINING OF SUBSETS OF NODES OR ARCS OF A GRAPH.

9.1. GRAPH ASSIGNMENT STATEMENTS

THE STATEMENT, ASSIGN, IS USED TO ASSIGN ATOMIC SETS AS NODES OR ARCS TO A GRAPH. THREE FORMS OF ASSIGNMENT IS POSSIBLE:

(I) ASSIGNMENT OF AN ISOLATED NODE:

ASSIGN G, X

THE ATOMIC SET X IS ASSIGNED AS A NODE TO THE GRAPH G.

(II) ASSIGNMENT OF AN ARC IN A NODE-GRAPH:

ASSIGN G, X-Y

THE ATOMIC SETS X AND Y ARE ASSIGNED AS NODES TO THE GRAPH G, AND THE CONNECTION OF THE TWO NODES IS KEPT INTERNALLY.

(III) ASSIGNMENT OF AN ARC IN A GRAPH:

ASSIGN G, X-Y, Z

THE ATOMIC SETS X AND Y ARE ASSIGNED AS NODES TO THE GRAPH G, THE ATOMIC SET Z IS ASSIGNED AS AN ARC TO G.

WHEN THE GRAPH HAD BEEN DECLARED AS A DIRECTED GRAPH, THE ARC ASSIGNMENT X-Y IS UNDERSTOOD AS FROM X TO Y.

IF EITHER OR BOTH OF THE NODES HAVE BEEN PREVIOUSLY ASSIGNED TO G, THEN JUST THE UNASSIGNED NODE (IF ANY) AND THE ARC WILL BE ASSIGNED TO G.

9.2. REMOVAL OF ARCS AND NODES

THE DETACH STATEMENT IS USED TO REMOVE ARCS AND NODES FROM A GRAPH. THE DETACH STATEMENT HAS 3 FORMS:

(1) EMPTYING A GRAPH
DETACH G

REMOVES ALL ELEMENTS, NODES AND ARCS, FROM GRAPH G.

(II) REMOVAL OF ELEMENTS OF A GRAPH

DETACH G, S

REMOVES THE ELEMENT OF SET S FROM THE GRAPH G IF THEY HAD BEEN ASSIGNED AS NODES OR ARCS TO G PREVIOUSLY. WHEN A NODE OF G IS REMOVED THEN ALL THE INCIDENT ARCS OF THE NODE ARE ALSO REMOVED.

(III) REMOVAL OF ARCS

DETACH G, S-T

REMOVES ALL ARCS FROM G WHICH CONNECT THE TWO SETS OF NODES, S AND T, IN THE GRAPH G. IF THE GRAPH IS DIRECTED, THIS WILL MEAN ARCS FROM NODES IN S TO NODES IN T.

9.3. NODES AND ARCS OF A GRAPH

THE FUNCTIONS:

NODES (G)

ARCS (G)

RETURN SETS CONSISTING THE ELEMENTS WHICH WERE ASSIGNED TO G AS NODES AND ARCS, RESPECTIVELY.

9.4. INCIDENCE OPERATORS

THE INCIDENCE OPERATORS ARE BUILT-IN FUNCTIONS WITH ARGUMENTS CONSISTING OF A GRAPH AND A SET WHOSE ELEMENTS WERE ASSIGNED TO THE GRAPH AS NODES OR ARCS. THE VALUE OF THE FUNCTION IS A SET WHICH IS A SUBSET OF THE NODES OR ARCS OF THE GRAPH. THE FORM OF THE FUNCTIONS ARE AS FOLLOWS:

\[ \text{OP}(G, S) \]

WHERE G IS THE GRAPH NAME, S IS A SET OF NODES OR ARCS OF G (S MAY BE A SET EXPRESSION). THE VARIOUS OPERATORS (OP) ARE AS FOLLOWS:

\[ \text{INC}(G, A) \]

A MUST BE AN ARC-SET OF G. THE FUNCTION RETURNS A SET WHICH IS THE UNION OF ALL NODES WHICH ARE
BOUNDARY NODES OF THE ARCS IN A.

**STAR** (G,V)  
V MUST BE A NODE-SET OF G. THE FUNCTION RETURNS A SET WHICH IS THE UNION OF ALL ARCS WHICH ARE INCIDENT TO THE NODES IN V.

**BD** (G,A)  
A MUST BE AN ARC-SET OF G. THE FUNCTION RETURNS A SET WHICH IS THE SYMMETRIC SUM OF ALL NODES WHICH ARE BOUNDARY NODES OF THE ARCS IN A.

**COB** (G,B)  
V MUST BE A NODE-SET OF G. THE FUNCTION RETURNS A SET WHICH IS THE SYMMETRIC SUM OF ALL ARCS WHICH ARE INCIDENT TO THE NODES IN V.

**ADJ** (G,V)  
V MUST BE A NODE-SET OF G. THE FUNCTION RETURNS A SET WHICH IS THE UNION OF ALL NODES WHICH ARE ADJACENT TO THE NODES IN V.

In case of a node graph G, only the **ADJ** operator is defined.

If G is a directed graph, all the above operators have extended operators by placing P or N in front of their names:

- **INC**  
- **PINC**  
- **NINC**
- **STAR**  
- **PSTAR**  
- **NSTAR**
- **BD**  
- **PBD**  
- **NRD**
- **COB**  
- **PCOB**  
- **NCOB**
- **ADJ**  
- **PADJ**  
- **NADJ**

The **P** (positive) operators are defined such that for arcs they give the starting nodes, for nodes they give the arcs which are directed outward from the nodes.

The **N** (negative) operators are defined such that for arcs they give the ending nodes, for nodes they give the incoming arcs.
THE SET ASSIGNMENT STATEMENT IS SIMILAR TO THE FORTRAN ASSIGNMENT STATEMENT:

\[ V = E \]

WHERE \( V \) MUST BE A SET VARIABLE, \( E \) MUST BE A SET EXPRESSION. SPECIAL CONVERSION TAKES PLACE IF \( V \) OR \( E \) IS INTEGER TYPE:

\[ i = E \]

WHERE \( i \) IS AN INTEGER VARIABLE AND \( E \) IS A SET EXPRESSION, IS EQUIVALENT TO

\[ i = \text{INDEX}(1,E) \]

THE ASSIGNMENT:

\[ V = i \]

WHERE \( V \) IS A SET VARIABLE, IS EQUIVALENT TO

\[ V = \text{ATOM}(I) \]
11. ITERATIVE STATEMENT

THERE ARE TWO NEW ITERATIVE STATEMENTS IN FGRAAL WHICH ARE SIMILAR TO THE DO STATEMENT IN FORTRAN.

11.1. WHILE STATEMENT

THE FORM OF THE WHILE STATEMENT IS AS FOLLOWS:

\[
\text{DO ST. NO. WHILE LOG. EXPR.}
\]

E.G.

\[
\text{DO 10 WHILE S . NE. 8}
\]

11.2. FORALL STATEMENT

THE FORM OF THE FORALL STATEMENT IS AS FOLLOWS:

\[
\text{DO ST. NO. FORALL V. IN. E}
\]

WHERE V MUST BE A SET VARIABLE, E IS A SET EXPRESSION. THE SET E SHOULD NOT BE ALTERED IN THE RANGE OF THE DO STATEMENT. THE STATEMENT IS EQUIVALENT TO

\[
N = \text{SIZE (E)}
\]

\[
\text{DO ST. NO. I = 1, N}
\]

\[
V = \text{ELT (I, E)}
\]

EXCEPT THAT THE LOOP MAY BE SKIPPED COMPLETELY WHEN THE SET E IS EMPTY.

E.G.

\[
\text{DO 15 FORALL X. IN. T}
\]
The REMOVE statement removes atomic sets from the universal sequence, or removes defined properties of atomic sets. The statement consists of the word 'REMOVE' followed by a list of arguments separated by commas:

```
REMOVE S,T,...,P,Q,...,PP(X),PQ(Y),...
```

The arguments may be:

1. Sets - then all atomic sets which are elements of the set are removed from the universal sequence;
2. Property names - the property is removed from all atomic sets where it had been assigned;
3. Property names followed by set in parentheses - the property is removed from those atomic sets which are elements of the given set.
13. SAVE, RESET STATEMENTS

THE SAVE STATEMENT IS USED TO TRANSFER INFORMATION FROM CORE TO AN AUXILIARY STORAGE FILE. RESET STATEMENT IS USED TO RETRIEVE INFORMATION FROM THE AUXILIARY STORAGE. THE INFORMATION CAN BE EITHER PROPERTY VALUES, OR A FULL GRAPH.

AT THE PRESENT, THESE STATEMENTS ARE NOT IMPLEMENTED.
The following three closely related subroutines are available:

\[ \text{CONTR}(G, S, X) \]
\[ \text{NODSET}(G, X, S) \]
\[ \text{EXPAND}(G, X) \]

which can be called by standard FORTRAN call statements.

SUBROUTINE CONTR contracts a given subset \( S \) of nodes of graph \( G \) into a new node which is returned in the atomic set \( X \). On subsequent usage of the graph, \( X \) is to be considered as a node of \( G \), but the elements of \( S \) will not be nodes of \( G \). The subroutine may be called subsequently, i.e., one may further contract an already contracted graph. Modification of a contracted graph by assign and detach statements should be avoided.

SUBROUTINE NODSET returns a set \( S \) consisting of the previous nodes of \( G \) which were contacted to the node \( X \).

SUBROUTINE EXPAND expands the previously contracted nodes of graph \( G \) corresponding to the node in atomic set \( X \). \( X \) will not be a node of graph \( G \) upon return.

Care should be taken by the proper usage of these subroutines, i.e., expansions of a graph should be in the reverse order of its contractions.
15. SUMMARY OF OPERATORS AND STATEMENTS

16. EXAMPLES

IN THE FOLLOWING PAGES, SOME EXAMPLES ARE PRESENTED. ALL THE PROGRAMS ARE WRITTEN AS SUBROUTINES, THUS DECLARATIONS FOR THE VARIABLES APPEARING IN THE CALLING SEQUENCES ARE ASSUMED TO BE DONE IN A CALLING MAIN PROGRAM.

THE EXAMPLES ARE AS follows:

1. READ I. READ DATA FOR GRAPH G
2. READ II. READ DATA FOR GRAPH G
4. SUBGRAPH. ESTABLISHING A GRAPH WHICH IS A SUBGRAPH OF G
5. LINE GRAPH. ESTABLISHING THE LINE GRAPH OF G
6. CONDENSE. ESTABLISHING A CONDENSE GRAPH OF G
7. COCYCLES. COCYCLES OF GRAPH G
8. SPANNING TREE. SPANNING TREE OF GRAPH G
9. CYCLES. CYCLES OF GRAPH G
10. CUTS. FUNDAMENTAL CUTS OF GRAPH G
11. SHORTEST PATH. 2-DIRECTIONAL SEARCH FOR SHORTEST PATH IN GRAPH G
**Title**

**Read 1, Read Data for Graph G**

**Specification**

The subroutine assumes that the first record from unit IU contains the sizes, N and M, of the node and arc set, and that then K records are supplied each containing three integers. Any such triple (K, I, J) satisfies

\[ 1 \leq K \leq M \]
\[ 1 \leq I \leq N \]
\[ 1 \leq J \leq N \]

and signifies that the K'th arc has the I'th node as initial, and the J'th node as terminal vertex.

**Sequence Chart**

**Read Sizes**

Create an element for each node and arc.

Loop to read triplets and

* 10 Assign them to G

RETURN
END
**CONNDENSE GRAPH**

*SPECIFICATION*

The list $L$ is assumed to contain a family of sets representing a partition of the node set of $G$. The procedure sets up a condensed graph which has the members of $L$ as nodes and in which two nodes are adjacent if there is at least one arc between the corresponding sets of nodes in $G$. The property $R$ of the nodes of $CONG$ remembers the sets of $L$.

**SEQUENCE CHART**

**TITLE**

**SHORTEST PATH.**

**SPECIFICATION**

G is a directed graph in which each arc has a given nonnegative length. The subroutine finds a shortest path from node START to node TERM, and returns it in the list PATH. If no such path exists, the list will be empty. The real number INF represents infinity, it is assumed to be larger than the sum of the length of all arcs of G. The length of the final path will be in M, and this number will be equal to INF, if no path exists.

**METHOD**

The method used is the bidirectional search by I. Pohl: Bi-directional and Heuristic Search in Path Problems, Techn. Report CS-136, Stanford University, 1969.

**DATA-STRUCTURE**

NODES REACHED FROM START AND TERM, RESPECTIVELY:

NODES NOT REACHED BUT REACHABLE ALONG ONE ARC FROM THE NODES REACHED FROM START AND TERM, RESPECTIVELY:

CURRENT DISTANCE OF A REACHED NODE FROM START OR TERM, RESPECTIVELY:

CURRENT ARC LEADING FROM A NODE OR TO A NODE WHICH WAS REACHED:

MINIMAL DISTANCE TO THE NODES REACHABLE ALONG ONE ARC FROM START AND TERM, RESPECTIVELY:

FLAG TO SET WHEN THE TWO DIRECTIONAL SEARCH MEET:

17. APPENDIX. EVALUATION OF EXPRESSIONS

The FGRAAL compiler was constructed by augmenting the existing RALPH compiler for the UNIVAC 1108.

The RALPH compiler assumes that no function can modify itself and thus takes certain liberties with the evaluation of expressions and elements in an argument list. An expression or argument list is scanned right to left and each time a function is encountered, it is evaluated. Each time an operand is encountered which has strictly greater precedence than the operator to its left, it is evaluated, and processing continues by examining the precedence relation between the operator to the right of the newly evaluated result and looking for a strictly greater precedence than the operator to its left, thus the expression

\[ F(A) + B \ast C \ast D + F(E) \]

will be evaluated as though it were parenthesized as follows

\[ ((F(A))_4 + ((B \ast C)_2 \ast D)_3)_5 + (F(E))_6 \]

where the number at the base of the right parenthesis gives the order in which the evaluations are made. This parsing algorithm yields perfectly valid results as long as functions are not permitted to modify their arguments or some global variables, i.e., so long there are no side effects.

However side effects do exist in GRAAL. For example, there are operators (functions) that are allowed to modify their arguments, e.g., DFIRST(L). Because of this, if a variable is used more than once in the context of an expression or argument list, and at least one such use is as an argument of a function or operator which modifies it, the unusual order of evaluation used by the RALPH compiler must take into consideration in order to simulate the actual results.

Example 1. Let

\[ L = 1 : 2 : 3 : 4 : 5 \]

then the statement

\[ X = \text{DFIRST}(L) - \text{DFIRST}(L) \]

is equivalent to

\[ X = 2 - 1 \]

and not \( X = 1 - 2 \), since the rightmost DFIRST operator is evaluated first.

Example 2. The function call

\[ \text{FUNC(DFIRST(L),L,DFIRST(L))} \]

with the previously defined L, is equivalent to

\[ \text{FUNC(2,3;4;5;1)} \]
SINCE THE RIGHTMOST DFIRST IS EVALUATED FIRST, THE SECOND ARGUMENT IS NOT EVALUATED SINCE THERE IS NO OPERATOR OR FUNCTION IN IT, AND THE LEFTMOST DFIRST IS EVALUATED SECOND, WHICH LEAVES L WITHOUT ITS ORIGINAL FIRST TWO ELEMENTS.

**Example 3.** Even parentheses do not help

\[ x = (\text{DFIRST}(L) - \text{DFIRST}(L)) \times \text{DFIRST}(L) \]

IS EQUIVALENT TO

\[ x = (3-2) \times 1 \]

One way to avoid this problem would be to break the expression down into separate statements. Thus we can rewrite Example 1, as

\[
\begin{align*}
x_1 &= \text{DFIRST}(L) \\
x &= x_1 - \text{DFIRST}(L) & (1-2) \\
\text{or} & \quad x &= \text{DFIRST}(L) - x_1 & (2-1)
\end{align*}
\]

Depending upon which expression we actually want, we can rewrite Example 2 as

\[
\begin{align*}
m &= L \\
x &= \text{DFIRST}(L) \\
& \quad \text{FUNC}(x, m, \text{DFIRST}(L))
\end{align*}
\]

To yield

\[
\text{FUNC}(1, 1:2:3:4:5, 2)
\]

GRAAL - A GRAPH ALGORITHMIC LANGUAGE,
PROCEEDINGS OF THE SECOND IBM RESEARCH SYMPOSIUM
ON SPARSE MATRICES AND THEIR APPLICATIONS,
SEP. 9-10, 1971. PLENUM PRESS, N.Y.
This report describes the Fortran version FGRAAL of the graph algorithmic language GRAAL (Technical Report TR-158) as it has been implemented for the Univac 1108. FGRAAL is an extension of FORTRAN V and is intended for describing and implementing graph algorithms of the type primarily arising in applications. The formal description contained in this report represents a supplement to the FORTRAN V manual for the Univac 1108 (UP-4060), that is, only the new features of the language are described. Several typical graph algorithms, written in FGRAAL, are included to illustrate various features of the language and to show its applicability.
