NATIONAL AERONAUTICS AND SPACE ADMINISTRATION • WASHINGTON, D. C. • SEPTEMBER 1972
This report describes the numerical calculation of the steady-state flow of electrons in an axisymmetric, spherical, electrostatic collector for a range of boundary conditions. The trajectory equations of motion are solved alternately with Poisson's equation for the potential field until convergence is achieved. A direct (noniterative) numerical technique is used to obtain the solution to Poisson's equation. Space charge effects are included for initial current densities as large as $100 \text{ A/cm}^2$. Ways of dealing successfully with the difficulties associated with these high densities are discussed. The report includes a description of the mathematical model, a discussion of numerical techniques, results from two typical runs, and the FORTRAN computer program.

NUMERICAL METHOD AND FORTRAN PROGRAM FOR THE SOLUTION OF AN AXISYMMETRIC ELECTROSTATIC COLLECTOR DESIGN PROBLEM

by Oliver W. Reese
Lewis Research Center

SUMMARY

This report describes the determination of the steady-state flow of electrons in an axisymmetric spherical collector under a variety of boundary conditions. The electron trajectory equations of motion are solved alternately with Poisson's equation for the potential field until convergence is achieved.

The bounding surfaces are a sphere below, a spherical cone above, and, optionally, a thin axial spike suspended from the apex of the cone. Negative decelerating potentials are prescribed on the cone-spike surface and on segmented zones of the spherical surface. Polar angles of the cone may vary from $0^\circ$ to $160^\circ$.

The principal value of this report is that it pushes design research into the high-current-density range, where space charge effects are strong. Initial attempts met with convergence difficulties for current densities above 50 A/cm$^2$.

This report describes the method used to surmount these difficulties and handle values as high as 100 A/cm$^2$. This was achieved in two ways: first, by using variable mesh spacing to ensure accuracy in regions where the solution was changing rapidly; and second, by using a fast, accurate subprogram for obtaining the potential field. This subprogram uses a direct, noniterative numerical solution to Poisson's equation, the details of which are given in NASA TN D-6438.

The present report includes a description of the mathematical model, a discussion of numerical techniques, results from two typical runs, and the FORTRAN computer programs.

INTRODUCTION

Satellite communication systems have been proposed in which the satellite can receive, amplify, and rebroadcast microwave signals. The high efficiency of the micro-
wave amplifiers to be used is of prime importance to the lifetime and reliability of such a system.

Microwave amplifiers, as a class, convert the energy of bunched electron beams into radiofrequency (rf) energy. Since this process is only partially efficient, the remaining beam energy is dissipated as heat in the electron collector. However, collectors can be designed and maintained at proper potentials to slow the electrons. The electron energy is then spent doing work against the collector potential and is recoverable as useful electrical power.

Reference 1 discusses how the results of the program described in this report are used in collector design. Reference 2 describes a computer program which solves Poisson's equation for a given space charge and which is required as a subroutine in the iterative solution of the current problem.

It is important to realize that there are two characteristics of electron beam trajectory patterns that facilitate efficient collector design:

1. Good, uniform, vertical and horizontal spreading (i.e., a sufficient rise away from the entry hole, and a pushing away from the collector axis)
2. Good, uniform separation permitting insertion of electrodes to collect electrons near the peak of their trajectories, where their energy is close to minimum

Both these characteristics imply no backstreaming, crossing, or impingement of beams on the underside of the electrodes.

The original computer program dealt with negative decelerating potentials prescribed only on segmented zones of the sphere. But this approach was ineffective because of the great distance between these surface potentials and the incoming stream of electrons.

A second stage of the design was to prescribe a decelerating potential on a cone of varying polar angle. This slowed down the incoming stream considerably, and in most cases the beam spread was sufficient.

In other instances where even more beam spread was desirable, a third and final design modification was made. Here a negative potential was prescribed on a thin spike suspended from the cone. This had the effect of spreading the flow even more as it entered, and allowing the other decelerating potentials to come into play more effectively.

The final FORTRAN program reported herein allows for the presence or absence of an axial spike of varying length, as well as for the choice of decelerating surface potentials on zonal segments of the sphere and on the cone-spike surface. The cone angle varies from $0^\circ$ to $160^\circ$. Initial conditions also include variable velocity and injection positions of entering electron groups.

It was assumed that, prior to entry into the collector, the electron beam had been sorted into graded velocity groups, with the outermost being the slowest. This is physically more realistic than assuming a constant velocity only. The beam was then
injected through a small entry hole in the collector where the negative polar axis pierces the spherical surface. The potential distribution on the surface of the sphere was assumed to be a function of the polar angle only. This report describes the numerical solution to a problem used in the design of such a collector under varying conditions of surface potential, current density, and collector geometry.

A typical configuration is shown in figure 1. Notice that the electron groups reach minimum velocity at their peaks and start falling back. If electrodes of the proper potential are inserted to collect the electrons at these minimum velocity points, the efficiency of the collector will then be maximized.

The numerical technique and computer program described in reference 2 were used to determine the potential field inside the collector as required. The results were then used as part of the design criteria of the collector as described in reference 1.

In situations where current density is low, less than 10 A/cm², space charge effects were found to be negligible. But with higher current densities and associated higher space charge, certain problems arise near the entry hole that require special techniques to ensure numerical stability. This report describes these techniques. Current densities as high as 100 A/cm² were dealt with successfully. Initially, calculations were successful only with current densities half as large, before numerical difficulties precluded further computation.

A complete description of the mathematical model is given, along with a discussion of the assumptions made. The technique used in determining the space charge distribution is then described. Appendixes A to G contain the results of two typical computer
runs, a complete listing of the FORTRAN computer program, flow charts, magnetic
field calculations, the derivation of the equations of motion, and the mathematical
symbols.

STATEMENT OF THE PROBLEM

The problem is to determine the steady-state potential field and the associated
steady-state electron beam trajectory patterns within a spherical collector (1) for any
specified collector geometry (cone angle; collector radius; entry hole radius; and length
of axial spike, if any), (2) for negative potential distribution on the surfaces of the col-
lector, and (3) for magnetic field distribution and electron beam initial entry conditions
(current, current density, perveance, injection angles, positioning, and velocity).

This involves the determination at every mesh point in the sphere of the potential $V$
that satisfies Poisson's equation

$$\nabla^2 V = f(V)$$  \hfill (1a)

where

$$\nabla^2 V = \frac{\partial^2 V}{\partial \rho^2} + \frac{2}{\rho} \frac{\partial V}{\partial \rho} + \frac{1}{\rho^2} \frac{\partial^2 V}{\partial \theta^2} + \cot \theta \frac{\partial V}{\partial \theta} + \frac{1}{\rho^2 \sin^2 \theta} \frac{\partial^2 V}{\partial \phi^2}$$  \hfill (1b)

The bars refer to dimensioned values. All mathematical symbols are defined in appen-
dix G. For convenience, these expressions and all others following are normalized by
the substitution

$$\rho = \frac{\bar{p}}{R}$$  \hfill (1c)

We may now write

$$f(V) = \frac{\rho_e(V)}{\epsilon_0}$$  \hfill (1d)

The right-hand term in equation (1d) is related to space charge resulting from the
beam trajectories. These trajectories are obtained from the solution to the differential
equation of motion (eq. (3)). Note that the determination of $V$ is an iterative process,
in that the right-hand side (or source term), which depends on the space charge, changes when the internal potential $V$ changes.

The source term consists of the dielectric constant $\epsilon_0$ and $\rho_e(V)$ where

$$\rho_e(V) = \frac{|\vec{J}|}{|u|}$$

The velocity term $u$ is easily calculated since it is simply a function of certain initial conditions and the potentials $V$ and $V_m$.

The current density term $J$ is somewhat more complicated. In general, it is calculated from the current flow through annuli formed by adjacent trajectories of the various electron energy groups. This flow is shown later in figure 4. These trajectories are calculated from the differential equation of motion

$$\frac{\partial^2 \rho}{\partial \theta^2} = \rho'' + \rho \sin^2 \theta \dot{\phi}^2 + \eta \left( \frac{1}{R} \frac{\partial V}{\partial \rho} - \sin \theta \dot{\phi} \frac{\partial V_m}{\partial \theta} \right) - \rho' \sin \theta \cos \theta \dot{\phi}^2$$

$$+ \frac{2\rho'^2}{\rho} - \frac{\rho' \eta}{\rho^2} \left( \frac{\partial V}{\partial \theta} + \rho^2 R \sin \theta \dot{\phi} \frac{\partial V_m}{\partial \rho} \right)$$

(3)

where

- $\rho$ normalized radius vector
- $\theta$ polar angle
- $\phi$ azimuthal angle
- $R$ radius of sphere
- $V_m$ magnetic field

Details of this iterative process are described in the next section.

**METHOD OF SOLUTION**

First, the steady-state flow of electrons with a given velocity distribution was determined within the collector. This was accomplished by taking the following four steps:

1. With the given collector geometry and a specified set of initial conditions, a first approximation to the potential field inside the collector was found by assuming zero space charge and solving Laplace's equation.
\[ \nabla^2 V = 0 \quad (4) \]

or

\[ \frac{\partial^2 V}{\partial \rho^2} + \frac{2}{\rho} \frac{\partial V}{\partial \rho} + \frac{1}{\rho^2} \frac{\partial^2 V}{\partial \theta^2} + \frac{\cot \theta}{\rho^2} \frac{\partial V}{\partial \theta} = 0 \quad (5) \]

(2) An arbitrary number of equally spaced electron trajectories were then calculated from the equation of motion (eq. (3)). This equation is derived in appendix F. In general, nine electron groups were solved for in this problem.

(3) From these trajectory patterns, the space charge was then calculated at each mesh point, and the results were used as source terms in Poisson's equation which was solved next,

\[ \nabla^2 V = \frac{\rho e}{\epsilon_0} \quad (6) \]

Details of how the space charge was calculated are given in a later section.

(4) Equation (3) was solved again to obtain new trajectories based on the new potential field obtained from equation (6). This iterative process was then continued until convergence was achieved. The entire process is shown in flow chart form in figure 2.

Prior to solving the problem, the following four sets of normalized initial conditions must be specified. (The quantities listed in the first three sets are shown in figure 3 for the case of three electron classes.)

1. Collector geometry: radius of collector R, initial polar angle \( \theta_0 \), and radius of entry hole \( a \).

2. Collector boundary values of electric potential: on a spherical surface \( (V_1, V_2, \ldots, V_f) \) (In general, the potential on the spherical surface decreases linearly to zero \( (V_f = 0) \) as the polar angle increases from \( \theta_0 \) to some prescribed \( \theta_f \); on a conical surface if \( \theta_0 \neq 0(V_1) \); and along the negative polar axial spike if \( \theta_0 \neq 0(V_1) \) (optional).

3. Electron beam entry conditions: type of flow (Brillouin or confined; confined flow means there is no initial rotational velocity of the beam, or \( \phi = 0 \)), values of beam energy classes \( v_i \), entry positions of electron classes in hole at injection \( \delta_i \) (\( \delta_i \) is the supplement of the polar angle \( \theta \)), and entry angles \( \alpha_i \). In general, \( i = 1, 2, \ldots, 9 \).
Figure 2. - Flow of operations in solution of complete problem.

Figure 3. - $\rho-\theta$ plane of a typical axisymmetric collector, showing various initial conditions.
(4) Electron beam parameters: magnetic flux density $B_0$, magnetic field potential $V_m$, electric potential $V_0$, current $I_0$, and current density $J_0$

**Auxiliary Equations**

We now discuss the auxiliary equations which are required in the solution of equation (3).

The first two are the magnetic field terms expressed in cylindrical coordinates.

\[
\frac{\partial V_m}{\partial \rho} = R \left( \frac{\partial V_m}{\partial r} \sin \theta + \frac{\partial V_m}{\partial z} \cos \theta \right) \quad (7a)
\]

\[
\frac{\partial V_m}{\partial \theta} = \rho R \left( \frac{\partial V_m}{\partial r} \cos \theta - \frac{\partial V_m}{\partial z} \sin \theta \right) \quad (7b)
\]

or letting $B_r = \frac{\partial V_m}{\partial r}$ and $B_z = \frac{\partial V_m}{\partial z}$, then

\[
\frac{\partial V_m}{\partial \rho} = R(B_r \sin \theta + B_z \cos \theta) \quad (8a)
\]

\[
\frac{\partial V_m}{\partial \theta} = \rho R(B_r \cos \theta - B_z \sin \theta) \quad (8b)
\]

Prior to entering the collector, the electron beam passes through a magnetic field which is used to confine the beam. Part of this field leaks into the collector through the entry hole and influences the flow of the electrons. It must be considered in the equations of motion.

Also used are the velocity terms, $\dot{\theta}^2$ and $\dot{\varphi}$, and the magnetic flux $\psi$. These are expressed as

\[
\dot{\theta}^2 = \frac{1}{1 + (\rho'/\rho)^2} \left[ \frac{2\eta_e V_0 (V_1 + V)}{\rho^2 R^2} - \dot{\varphi}^2 \sin^2 \theta \right] \quad (9)
\]

\[
\dot{\varphi} = \frac{\eta_e (\psi - \psi_0)}{2\pi \rho^2 R^2 \sin^2 \theta} \quad (10)
\]
which are equations (B16), (B8), and (B9) of reference 1, respectively.

Finally, the components \( B_r \) and \( B_z \) of the magnetic field \( V_m \) (eqs. (D9) and (D10) of ref. 1) are expressed as

\[
B_r(r, z) = \sum_{n=0}^{\infty} \frac{(-1)^n}{n!(n+1)!} \cdot \frac{\partial^{2n+1} B(0, z)}{\partial z^{2n+1}} \cdot \left( \frac{r}{2} \right)^{2n+1}
\]

and

\[
B_z(r, z) = \sum_{n=1}^{\infty} \frac{(-1)^{n+1}}{[(n-1)!]^2} \cdot \frac{\partial^{2n-2} B(0, z)}{\partial z^{2n-2}} \cdot \left( \frac{r}{2} \right)^{2n-2}
\]

where

\[
B(0, z) = B_0 \left[ 1 - \frac{1}{\pi} \tan^{-1} \left( \frac{a}{z} \right) - \frac{1}{\pi} \frac{z/a}{1 + (z^2/a^2)} \right]
\]

The approximations of \( B_r(r, z) \) and \( B_z(r, z) \) that were used are given in appendix E.

The Equation of Motion

The second-order differential equation of motion (eq. (3)) was transformed into two first-order equations and solved by using a fourth-order Runge-Kutta method. As is typical in integration techniques of this type, the choice of step size is based largely on experience. In this problem, the most critical region is near the entry hole. For a large collector radius (\( R = 16 \) cm) and a small entry hole (\( a = 0.05 \) cm), an initial step size \( \Delta \theta \) of 0.01° was required. For a small collector radius (\( R = 8 \) cm) and a large entry hole (\( a = 0.10 \) cm), an initial \( \Delta \theta \) of 0.05° was sufficient. As the trajectory moved away from this critical region, the \( \Delta \theta \) step was increased to minimize computer execution time.

Initially, the solution was obtained in the \( \rho-\theta \) spherical plane. Then when any par-
ticular trajectory started to arc over \( (p^* = 0) \), a change was made to the \( r-z \) cylindrical coordinate system to avoid any possible discontinuities in the integration process.

### Poisson's Equation

For any space charge field, the set of right-hand sides for Poisson's equation written at all interior grid points may be computed, and the subroutine of reference 2 may be applied to solve Poisson's equation for the internal potential field. The method of calculating the space charge field from the trajectory field is now presented.

### Calculation of Space Charge

The source term, or space charge term, in equation (6) is

\[
\frac{\rho_e}{\epsilon_0}
\]

where

- \( \epsilon_0 \) dielectric constant, \( 8.86 \times 10^{-14} \text{ F/cm} \) (farads per centimeter)
- \( \rho_e \) volume charge density, \( \text{C/cm}^3 \) (coulombs per cubic centimeter)

Furthermore,

\[
\rho_e = \frac{J}{u}
\]

where

- \( J \) current density, \( \text{A/cm}^2 \) (amperes per square centimeter)
- \( u \) velocity, \( \text{cm/sec} \)

Figure 4 shows where a typical \( \rho_e \) is computed; namely, at a point midway between two trajectories. To ensure accuracy, space charge is calculated at selected points along center lines midway between adjacent trajectories where the \( \rho \)-mesh lines are crossed.

Since \( u \) is known at various points along a trajectory, one may interpolate to compute \( u \) at any point, say at a position midway between two trajectories. Therefore, the
space charge at each mesh point may be determined once $J$ is known. We now show how this is accomplished.

In general,

$$J = \frac{I}{A}$$  \hspace{1cm} (17a)

where

- $I$ current, A
- $A$ any particular element of area through which current flows

Referring again to equation (6), we may now write

$$J_i = \frac{I_{0,i}}{A_i}$$  \hspace{1cm} (17b)
where

\[ I_0 \] initial current at injection
\[ i \] \( i^{th} \) electron energy group

Referring again to figure 4, it is seen that the equally spaced electron energy groups form eight annuli at the entrance hole. The areas \( dA \) of these annuli may be expressed

\[
\begin{align*}
\frac{dA_1}{dA_2} &= \pi r_2^2 \\
\frac{dA_2}{dA_3} &= \pi (2r_2)^2 - \pi (r_2)^2 = 3 \ dA_1 \\
\frac{dA_3}{dA_4} &= \pi (3r_2)^2 - \pi (2r_2)^2 = 5 \ dA_1 \\
&\vdots \\
\frac{dA_8}{dA_1} &= \pi (8r_2)^2 - \pi (7r_2)^2 = 15 \ dA_1
\end{align*}
\]

Since \( I = JA \), the current at injection through each annulus may be expressed

\[
\begin{align*}
\frac{I_0, 1}{I_0, 2} &= J_0 \ dA_1 \\
\frac{I_0, 2}{I_0, 3} &= J_0 \ dA_2 = 3J_0 \ dA_1 \\
&\vdots \\
\frac{I_0, 7}{I_0, 8} &= J_0 \ dA_7 = 15J_0 \ dA_1 \\
\frac{I_0, i}{I_0, i-1} &= (2i - 1)J_0 \ dA_1
\end{align*}
\]
In the example of figure 4, the point shown represents a typical space coordinate midway between two adjacent trajectories, in this case, trajectories 5 and 6. The normal distance between the trajectories at this point is \( d \). The area of the annulus is then

\[
A = 2\pi rd = 2\pi \rho_5,j \sin \vartheta_5,j d
\]  

(20)

The general expression for the current density, \( J = I/A \) (eq. (17a)), may now be written as

\[
J_{i,j} = \frac{(2i - 1) J_0 dA_{i}}{2\pi (\rho_{i,j} \sin \vartheta_{i,j}) d_{i,j}}
\]  

(21a)

or

\[
J_{i,j} = \frac{(2i - 1) J_0}{2d_{i,j} (\rho_{i,j} \sin \vartheta_{i,j})}
\]  

(21b)

Notice that current is preserved in each annular region, namely

\[
I_{0,i} = (2i - 1)J_0 dA_i = J_{i,j} A_{i,j}
\]

(22)

Since \( A_{i,j} \) can be computed at \( (\rho_i,j, \vartheta_i,j) \) by

\[
A_{i,j} = 2\pi \rho_{i,j} \sin \vartheta_{i,j} d_{i,j}
\]

(23)

where \( d_{i,j} \) is the normal thickness of an annulus at this point.

**Use of Irregular Mesh Spacing**

The successful solution to this problem, especially those phases dealing with high current densities, was largely due to the use of irregular mesh spacing in both the \( \rho \) and \( \theta \) directions. From figure 5 it is clearly apparent that the region in which the solution varies most rapidly is immediately along and adjacent to the negative polar axis, where the entering electron beam is most dense and of greatest velocity. Consequently, a closely spaced mesh was used in this region. Conversely, a coarse spacing was used where the solution was varying very slowly and quite predictably.
Convergence Acceleration

Experience has shown that in solving this problem, the iterants are well behaved and ultimately converge to an acceptable approximation to the solution. But because of the steadily decaying oscillatory nature of the iterants, a considerable savings in computer execution time was achieved by halving the newly calculated changes in the variables at each step. Normally, a maximum of five iterations would provide an acceptable solution.

FORTRAN PROGRAM

General Description

The program consists of the following 16 subroutines:

(1) MAIN is the executive routine for processing multiple cases and has primary control of logical flow throughout the complete program.

(2) INPUT reads and prints initial conditions, parameters, and other data required for internal use by the program (printout frequency, looping indices, convergence criteria, etc.).
(3) INTGRN controls integration looping of equations of motion, step size, change-over of coordinate systems, and the number of iterations required for convergence.

(4) DE is the spherical coordinate version of a routine for computing trajectories by integrating the equations of motion.

(5) DERIV calculates \( \partial V / \partial \rho \) and \( \partial V / \partial \theta \) for any specified interior point.

(6) RK is the spherical coordinate version of a Runge-Kutta integration subroutine used to compute trajectories.

(7) MESH generates graduated mesh point arrays in both the \( r \) and \( \theta \) directions for any specified collector geometry.

(8) RZTRAJ is the cylindrical coordinate version of a routine for computing trajectories by integrating equations of motion.

(9) RZRK is the cylindrical coordinate version of a Runge-Kutta integration subroutine used to compute trajectories.

(10) RZDE contains the equations of motion in the cylindrical coordinate system. It is similar to subroutine DE.

(11) OUT controls the printing of results at specified intervals along the trajectories.

(12) VFIELD provides for the calculation of the potential field for any particular set of boundary values and source terms. It uses the program described in reference 2.

(13) EQLINE calculates the spherical coordinates of any specified number of equipotential lines. It is used only after convergence is achieved in the main portion of the program.

(14) RHSCAL generates space charge values along center lines of the various annuli formed by the trajectories. It interpolates for these values at each mesh point, as required in the solution of Poisson's equation.

(15) PSICAL calculates the magnetic flux \( \psi \) of the magnetic field at each mesh point.

(16) BRBZ calculates \( B_r \) and \( B_z \), the \( r \) and \( z \) components of the magnetic field, at each mesh point.

All calculations were done on the IBM 7094 II/7044 Direct Couple System computer. The program will perform about 210 integration steps per minute. This figure is based on trajectory calculations for eight electron energy groups.

About 15 000 storages are required for the program. This does not include that required for the solution of Poisson's equation. An additional 10 000 storage locations are needed for a solution to Poisson's equation similar to that described in reference 2.

The FORTRAN program is listed in appendix B, FORTRAN symbols are defined in appendix C, and flow charts are presented in appendix D.
Using the Program

The program always starts by reading in a nine-card input data deck. The contents of each of these cards is now described.

Card 1 (Format 55H. . .)
Contains any desired information to identify the particular case being run (card columns 1 to 55 only). This will be printed out at the top of a listing.

Card 2 (Format 4E10.3)
- \text{R} \quad \text{radius of collector, } R, \text{ cm}
- \text{B0} \quad \text{magnetic flux density, } B_0, \text{ G}
- \text{DTHTD} \quad \theta \quad \text{step size used in Runge-Kutta integration (spherical coordinate)}, \Delta \theta, \text{ deg}
- \text{TH1} \quad \text{cone angle, } \theta_1, \text{ deg}

Card 3 (Format 8E10.3)
- \text{ZI0} \quad \text{initial current}^1, \text{ } I_0, \text{ A}
- \text{ZJO} \quad \text{current density}^1, \text{ } J_0, \text{ A/cm}^2
- \text{V0} \quad \text{initial electric potential, } V_0, \text{ V}
- \text{DELR} \quad \text{r step size used in Runge-Kutta integration (cylindrical coordinates), } \Delta r
- \text{CONFLO} \quad \text{indicates confined flow when equal to 1 and Brillouin flow when equal to 0}
- \text{RAD} \quad \text{radius of collector entry hole, } a, \text{ cm}
- \text{FLOOP} \quad \text{number of iterations for space charge calculations (If no space charge calculation is desired, this value should be set to 1.)}

Card 4 (Format 4012)
- \text{NT} \quad \text{number of trajectories to be calculated}
- \text{KPOI} \quad \text{printout frequency control, (e.g., 4 means to print results at every fourth integration step of a trajectory)}
- \text{N1}\}
- \text{N2}\}
- \text{N3}\}
\begin{align*}
\text{integrate trajectories N1 to N2 in steps of N3}
\end{align*}

\footnote{These two values are used only in the calculation of the source term in Poisson's equation when space charge iteration is necessary.}
IBAR when nonzero, indicates boundary values will be supplied along the negative polar axis
LOOP counter for number of space charge loops
KPOSC print control for interim space charge calculations

Card 5 (Format 4F5.1)
These values are used by the integration subroutine in the spherical coordinate system, which is the system used in the beginning portion of the program.

\[
\begin{align*}
\text{THSFAC} & \quad \text{step-size controls; increase step size } DTH \text{ by a factor of } \text{THSFAC} \\
\text{THSDEL} & \quad \text{every } \text{THSDEL} \text{ (deg) in the } \theta_5 \text{ range from } \text{THSWHI} \text{ (deg) to } \\
\text{THSWHI} & \quad \text{THSWLO} \text{ (deg)}
\end{align*}
\]

Card 6 (Format 16F5.3)
VSMI(I), electron energy classes for each of NT trajectories to be solved
\[
I = 1, \quad \text{NT for}
\]

Card 7 (Format 12, 10F5.3)
This calculation is done only once, after convergence has been achieved in the main part of the program.
NEQL number of equipotential lines to be calculated
EQL(I), array of potential values for each equipotential line
\[
I = 1, \quad \text{NEQL}
\]

Card 8 (Format 16F5.3)
XT(J, 16), boundary values on surface of spherical collector from initial
\[
J = 1, \quad 16 \quad \text{cone angle } \theta_1 \text{ to } 180^\circ, \quad V
\]

Two sample test runs are given in appendix A. These runs were chosen to more clearly illustrate the makeup of the input data deck and to show the various options in output format available to the user.

CONCLUDING REMARKS

We have described the numerical technique used to obtain a solution to a problem
associated with the design of an axisymmetric, spherical, depressed collector. Varying initial conditions include current density of electrons, surface potential on the collector, collector geometry, and the velocity and position of entering electron groups.

Of particular importance to the successful solution is the scheme used near the entry hole in the collector. Here the entering electron stream is of highest velocity and greatest density, giving rise to computational problems, especially in cases of high initial current densities.

Calculations by others in the past were successful in handling current densities to 50 A/cm² before numerical difficulties precluded further computation. The numerical approach described in this report is used to solve systems with current densities to 100 A/cm².

Computational stability was achieved primarily by using a graduated mesh in both the $r$ and $\theta$ directions, with greatest mesh point density in the hole region. In addition, computational efficiency was improved by taking advantage of the fact that all entering electron groups were distributed uniformly both in positioning and velocity grouping. That is, the fastest group entered closest to the axis, and the slowest group entered nearest the edge of the entry hole.

Space charge effects were found to be negligible for initial current densities less than 10 A/cm². Consequently, the problem was reduced to requiring only one iteration and essentially solving Laplace's equation to obtain the potential distribution inside the collector.

APPENDIX A

SAMPLE PROBLEMS

Short, partial, representative computer output listings of two sample runs are presented. Run 1, depicted graphically in figure 6, is for a 0.2 spike, no space charge iterations, confined flow, and a cone angle of 60°. Run 2, figure 7, is for no spike, space charge effects calculated, Brillouin flow, and a cone angle of 45°.

Figure 7 shows a poor pattern. Beam spread and separation is rather nonuniform and erratic. In contrast, figure 6 shows well-shaped and well-behaved beams with good spread and uniform spacing.

Figure 6. - Sample run 1. No iterations necessary (current density, 8 A/cm²); 0.2 spoke; cone angle, 60°.

Figure 7. - Sample run 2. Five iterations for space charge effect; no spike; cone angle, 60°.

FLOW CHARTS

Flow charts are presented only for those five subroutines, INTGRN, DE, RZTRAJ, VFIELD, RHSCAL, which might not otherwise be easily understood. Diamond-shaped blocks indicate decision-making points in the subroutines. Numbers appearing on blocks refer to the corresponding FORTRAN statement numbers in the subroutines.

Subroutine INTGRN

1.2 Integrate one step to obtain $p_i$, $\eta_j$ (i = 1, NT) for NT electron velocity classes

1.2 Integrate one step to obtain $p_s$, $\eta_s$ for mid-electron velocity class

DTH = DTH + THSFAC

JT = JT + 1

Call RZTRAJ

Change to r,z coordinates?

SPCH = 0?

Call OUT

Yes

Yes

Yes

Yes

No

No

No

Yes

Call RHSCAL

Return

Return

$p_s \leq 0.633$?
**Subroutine DE**

1. Enter
2. Call subroutine DERIV to obtain \( \delta V/\delta \phi \) and \( \delta V/\delta \theta \)
3. Call subroutine PSICAL to obtain \( \psi \)
4. Call subroutine BRBZ to obtain \( B_r \) and \( B_z \)
5. Call \( \phi, \theta \), \( \delta V_m/\delta p \), \( \delta V_m/\delta \phi \), \( \delta V_m/\delta \theta \)
6. Calculate \( \rho^{*} \)

**Return**

**Subroutine RZTRAJ**

1. Entry
2. Write trajectory number and \( \Delta r \)
3. \( z^* \), \( p^*z^*z^*p^*r \), \( \rho z - \rho^*r \)
4. Call subroutine RZGE
5. \( r = \rho \sin \theta \), \( z = \rho \cos \theta \)
6. Write \( p, \theta, r, z, z^*, \delta V_r/\delta r, \delta V_r/\delta \phi \)
7. Call subroutine RZRK
8. \( \Delta r \)
9. Yes: \( p < 1 ? \), No: Last trajectory?
10. Yes: Exit to MAIN, No: Return
where \( x = \frac{z}{a} \). Then,

\[
B_z^0(0, z) = \frac{B_0}{\pi} \left[ \pi - \tan^{-1} \left( \frac{a}{-z} \right) - \frac{x}{1 + x^2} \right]
\]  

\[ (E1) \]

\[
B_z^I(0, z) = -\frac{2B_0}{\pi a} \times \frac{1}{(1 + x^2)^2}
\]

\[
B_z^II(0, z) = \frac{8B_0 x}{\pi a^2} \times \frac{1}{(1 + x^2)^3}
\]

\[
B_z^III(0, z) = \frac{8B_0 x}{\pi a^2} \times \frac{1 - 5x^2}{(1 + x^2)^4}
\]

\[
B_z^IV(0, z) = -\frac{48B_0 x}{\pi a^3} \times \frac{3 - 5x^2}{(1 + x^2)^5}
\]

\[
B_z^V(0, z) = \frac{48B_0 x}{\pi a^4} \times \frac{3 - 42x^2 + 35x^4}{(1 + x^2)^6}
\]

\[
B_z^VI(0, z) = \frac{12 \times 480B_0}{\pi a^7} \times \frac{3 - 14x^2 + 7x^4}{(1 + x^2)^7}
\]

\[
B_z^VII(0, z) = \frac{12 \times 14 \times 480B_0}{\pi a^9} \times \frac{3 - 14x^2 + 7x^4}{(1 + x^2)^9}
\]

\[
B_z^VIII(0, z) = \frac{12 \times 14 \times 480B_0}{\pi a^{10}} \times \frac{3 - 14x^2 + 7x^4}{(1 + x^2)^{11}}
\]

\[
B_z^IX(0, z) = \frac{14 \times 48 \times 480B_0}{\pi a^{10}} \times \frac{3 - 14x^2 + 7x^4}{(1 + x^2)^{12}}
\]

\[
B_z^{XI}(0, z) = \frac{14 \times 48 \times 480B_0}{\pi a^{10}} \times \frac{3 - 14x^2 + 7x^4}{(1 + x^2)^{13}}
\]
To simplify these expressions, let

\[ T_3 = 1 - 5x^2 \]

\[ T_4 = 3 - 5x^2 \]

\[ T_5 = 3 - 42x^2 + 35x^4 = 3 - 7x^2(6 - 5x^2) \]

\[ T_6 = 3 - 14x^2 + 7x^4 = 3 - 7x^2(2 - x^2) \]

\[ T_7 = 1 - 27x^2 + 63x^4 - 21x^6 = 1 - 3x^2\left[9 - 7x^2(3 - x^2)\right] \]

\[ T_8 = 5 - 45x^2 + 63x^4 - 15x^6 = 5 - 3x^2\left[15 - x^2(21 - 5x^2)\right] \]

\[ T_9 = 5 - 220x^2 + 990x^4 - 924x^6 + 165x^8 = 5 - 11x^2\left[20 - 3x^2\left[30 - x^2(28 - 5x^2)\right]\right] \]

\[ T_{10} = 135 - 1980x^2 + 5346x^4 - 3564x^6 + 495x^8 = 9\left(15 - 11x^2\left[20 - x^2\left[54 - x^2(36 - 5x^2)\right]\right]\right) \]

\[ T_{11} = 3 - 195x^2 + 1430x^4 - 2574x^6 + 1287x^8 - 143x^{10} = 3 - 13x^2\left(15 - 11x^2\left[10 - x^2\left[18 - x^2(9 - x^2)\right]\right]\right) \]

\[ T_{12} = 231 - 5005x^2 + 22022x^4 - 28314x^6 + 11011x^8 - 1001x^{10} = 11\left[21 - 13x^2\left(35 - x^2\left[154 - x^2\left[198 - 7x^2(11 - x^2)\right]\right]\right]\right] \]

Then, substituting these expressions for those in (E2), we now have
\[B_z^I(0, z) = -\frac{2B_0}{\pi a (1 + x^2)^2}\]

\[B_z^II(0, z) = \frac{8B_0^2}{\pi a^2 (1 + x^2)^3}\]

\[B_z^III(0, z) = \frac{8B_0 T_3}{\pi a^3 (1 + x^2)^4}\]

\[B_z^IV(0, z) = -\frac{48B_0^4 T_4}{\pi a^4 (1 + x^2)^5}\]

\[B_z^V(0, z) = -\frac{48B_0^2 T_5}{\pi a^5 (1 + x^2)^6}\]

\[B_z^VI(0, z) = \frac{4 \times 480B_0^3 T_6}{\pi a^6 (1 + x^2)^7}\]

\[B_z^VII(0, z) = \frac{12 \times 480B_0^4 T_7}{\pi a^7 (1 + x^2)^8}\]

\[B_z^VIII(0, z) = -\frac{12 \times 14 \times 480B_0^5 T_8}{\pi a^8 (1 + x^2)^9}\]

\[B_z^IX(0, z) = \frac{12 \times 14 \times 480B_0^6 T_9}{\pi a^9 (1 + x^2)^10}\]

\[B_z^{X}(0, z) = \frac{14 \times 45 \times 48 \times 480B_0^7 T_{10}}{\pi a^{10} (1 + x^2)^11}\]

\[B_z^{XI}(0, z) = \frac{14 \times 45 \times 48 \times 480B_0^8 T_{11}}{\pi a^{11} (1 + x^2)^12}\]

\[B_z^{XII}(0, z) = -\frac{28 \times 45 \times 48 \times 480B_0^9 T_{12}}{\pi a^{12} (1 + x^2)^13}\]
Since

\[ B_r(r, z) = -B^I(0, z) \frac{r}{2} + \frac{1}{1! 2!} B^{III}(0, z) \left(\frac{r}{2}\right)^3 - \frac{1}{2! 3!} B^V(0, z) \left(\frac{r}{2}\right)^5 + \frac{1}{3! 4!} B^{VII}(0, z) \left(\frac{r}{2}\right)^7 - \ldots \]  

\hfill (E5)

We make the substitution \( r_2 = r/2 \), and nest as follows,

\[ B_r(r, z) = -r_2 \left[ B^I - \frac{r_2^2}{1 \times 2} \left( B^{III} - \frac{r_2^2}{2 \times 3} \left( B^V - \frac{r_2^2}{3 \times 4} \left[ B^{VII} - \frac{r_2^2}{4 \times 5} \left( B^IX - \frac{B^{XI} r_2^2}{5 \times 6} \ldots \right) \right] \right) \right] \]  

\hfill (E6)

and similarly,

\[ B_z(r, z) = B^0 - r_2^2 \left[ B^{II} - \frac{r_2^2}{2^2} \left( B^IV - \frac{r_2^2}{3^2} \left( B^VI - \frac{r_2^2}{4^2} \left[ B^VIII - \frac{r_2^2}{5^2} \left( B^IX - \frac{r_2^2}{6^2} B^{XII} - \ldots \right) \right] \right) \right] \]  

\hfill (E7)
APPENDIX F

DERIVATION OF EQUATIONS OF MOTION

The equations of motion as derived in reference 1, equations (B17) and (B18), are

\[
\rho'' \dot{\theta} = \rho \dot{\theta}^2 + \rho \sin^2 \theta \dot{\phi}^2 - \rho'' \dot{\theta}^2 + \frac{n}{R^2} \frac{\partial V}{\partial \rho} - \frac{n}{R} \sin \theta \dot{\phi} A_\phi - \frac{n}{\rho R} \rho \sin \theta \dot{\phi} \frac{\partial A_\phi}{\partial \rho}
\]  

(\text{F1})

\[
\ddot{\theta} = - \frac{2\rho' \dot{\theta}^2}{\rho} + \sin \theta \cos \theta \dot{\phi}^2 + \frac{n}{\rho R^2} \frac{\partial V}{\partial \theta} + \frac{n}{\rho R} \cos \theta \dot{\phi} A_\phi - \frac{n}{\rho R} \sin \theta \dot{\phi} \frac{\partial A_\phi}{\partial \theta}
\]

(\text{F2})

Solving these two equations simultaneously for \( \rho'' \) yields

\[
\rho'' = \rho + \rho \sin^2 \theta \dot{\phi}^2 + \frac{n}{R \dot{\theta}^2} f_1 + \frac{2\rho' \dot{\theta}^2}{\rho} - \rho' \sin \theta \cos \theta \dot{\phi}^2 - \frac{\rho''}{\rho^2 R^2 \dot{\theta}^2} f_2
\]

(F3)

where

\[
f_1 = \frac{1}{R} \frac{\partial V}{\partial \rho} - \sin \theta A_\phi \dot{\phi} - \rho \sin \theta \dot{\phi} \frac{\partial A_\phi}{\partial \rho}
\]

(F4a)

\[
f_2 = \frac{\partial V}{\partial \theta} - \rho R \cos \theta A_\phi \dot{\phi} - \rho R \sin \theta \dot{\phi} \frac{\partial A_\phi}{\partial \theta}
\]

(F4b)

or, using the relations described in appendix D of reference 1, these expressions may be rewritten

\[
f_1 = \frac{1}{R} \frac{\partial V}{\partial \rho} - \sin \theta \dot{\phi} \frac{\partial V_m}{\partial \theta}
\]

(F4b)

Away from the entry hole, the magnetic field terms \( \dot{\phi}, A_\phi, \) and \( V_m \) are negligible. Therefore, in this region equation (F3) may be expressed
using equation (B16) of reference 1 as

\[
\dot{\theta}^2 = \frac{2\eta V_0 (\epsilon_i + V)}{R^2 \rho^2 [1 + (\rho')^2]}
\]  

and, with the appropriate substitutions, we may express this equation in cylindrical coordinates

\[
z'' = \frac{\frac{\partial V}{\partial z} - z' \frac{\partial V}{\partial r}}{2 \left[ \frac{\epsilon_i + V}{1 + (z')^2} \right]}
\]
APPENDIX G

MATHEMATICAL SYMBOLS

A  area of annulus, cm²

a  radius of collector entry hole, cm

B_r  r-component of potential field, ∂\(V_m/∂r\), G/cm

B_z  z-component of potential field, ∂\(V_m/∂z\), G/cm

B_0  magnetic flux density, G

b  radius of electron beam at injection, cm

E  \(v_1 + V\)

I  current, A

J  current density, A/cm²

K_p  perveance, A/\(V^{3/2}\)

R  unreduced radius of spherical collector, cm

r, z  cylindrical coordinates

u  electron energy

V  normalized electric potential

\(V_m\)  magnetic field potential

\(V_r\)  ∂\(V/∂r\)

\(V_z\)  ∂\(V/∂z\)

\(V_\rho\)  ∂\(V/∂\rho\)

\(V_\theta\)  ∂\(V/∂\theta\)

\(v_i\)  \(i^{th}\) normalized injection energy class

\(\epsilon_0\)  permittivity of free space, 8.86×10^{-14} F/cm

\(\eta_e\)  electron charge-mass ratio, charge/kg×10^{11}

\(\rho\)  normalized radius vector

\(\overline{\rho}\)  unnormalized radius vector, cm

\(\rho_e\)  space charge density, C/cm³

\(\tau_0\)  \(R/(2\eta V_0)^{1/2}\)

\(\theta, \phi\)  polar and azimuthal spherical coordinate angles
