Lunar Laser Ranging Data Deposited in the National Space Science Data Center:
Filtered Observations for 1971 January through 1971 June and
Unfiltered Photon Detections for 1971 July through 1971 December

Research Memorandum in Astronomy
No. 73-013

1973 January
I. Introduction

One of the most striking new techniques in modern astrometry is that of laser ranging to a reflector fixed on a celestial object, partly because the attainable precision is so high that the data can tell us as much about Earth as about the observed object. The Apollo astronauts have now placed three widely separated reflector arrays on the Moon as a part of the Lunar Laser Ranging Experiment (LURE), the participants in which are listed in the Acknowledgements.

Although the groundwork in the experiment began much earlier, the data-taking process did not begin, of course, until 1969 July, when the Apollo 11 mission was flown. Success in recognizing returns from the reflector was not achieved until the following month. For many months there-after, various causes contributed to a very low data rate. It was not until 1970 April that regular successes became common.

From the experiment's inception, the LURE Team has recognized the obligation to make these data available in a reasonably usable form, and we have agreed upon a time-schedule that strives for a fair compromise between timely release and priority of the members of the LURE Team. This report is the documentation to be used in conjunction with the deposition in the National Space Science Data Center (NSSDC) of the filtered data obtained during laser ranging operations between the McDonald Observatory and the Apollo 11 and 14 reflectors for the six months ending 1971 June 30 and the unfiltered photon detections for the succeeding six months. These two blocks will be discussed in more detail in subsequent sections of this memorandum.
II. Observatory and Reflectors

The laser ranging equipment is mounted on the 272 cm reflector at the McDonald Observatory, Fort Davis, Texas. The physical installation has been so thoroughly described in the literature (e.g. Silverberg and Currie 1972) that it seems unnecessary to dwell on it here. The nominal coordinates presently recommended for this instrument, based on high-order land survey ties to the SAO Organ Pass Tracking Station, are

- geocentric radius $p=6374.665$ km
- east longitude $\lambda=+255.97779$ degrees
- geocentric latitude $\varphi'=+30.50320$ degrees

These refer to the intersection of the polar and transverse axes of the telescope. The center of the primary mirror, as the telescope tracks across the sky, describes a circle of radius 305 cm whose plane is normal to the polar axis.

The present data refer to the reflectors at Tranquility Base, Fra Mauro and Hadley, whose nominal coordinates are

</tbody>
</table>

based on data supplied by NASA/MSC during tracking operations during the Apollo 11 mission.

III. Filtered Data

The photon detections have been submitted to a data filtering procedure developed at the University of Texas. This process is based on the assumption of the linearity of $\varnothing-C$ residuals over a relatively short time interval and relies on Poisson statistics for
establishing a level of confidence in a collection identified by the filter. Application of the process resulted in the identification of the observations during the subject interval.

The potential user should be aware that the laser cannot be relied upon to produce a simple pulse shape. There sometimes is a complex and/or biased structure within the pulse. Therefore, residuals derived from signal photons are not necessarily expected to show a Gaussian distribution. The uncertainties assigned are based on the sum of the pulse half-width and the measured uncertainty in calibrating the electronic system. The calibrations were performed by E. C. Silverberg. The data format is as defined by Mulholland (1971).

IV. Unfiltered Photon Detections

It is most important that the potential user observe the designation "unfiltered". By this, we mean that the real data are heavily interspersed with noise photons from any of the various sources of stray light. Any attempt to use these data in a simple Gaussian application would probably result in a solution closely adhering to the prediction ephemeris used to control the detector range gating. Some filtering process needs to be applied to these data before effective use can be made of them. Such filtering is now underway at the University of Texas at Austin, and all filtered data will also be deposited with NSSDC, but the unfiltered data may be of direct utility or interest to those potential users who may wish to replace our filter criteria with their own. These data also
conform to the data format standard referenced above, except that
the clock epoch error carries the opposite sign, as is the case with
all previous NSSDC depositions.

V. Data Description

The data are contained on two files of a binary magnetic tape
written in card image format, using a CDC 6600 computer. It is
written with odd parity at 800 bpi. Two types of cards are present,
distinguished by an alphabet character in column 1: The letter Z
designates a "run" card, giving environmental and operational
parameters for a series of shots. Except for clock epoch error,
these will not customarily be required for application of the range
data, but serve to provide information on the observing conditions
and the state of the equipment. Most users will find them helpful
only as separators between observing sessions. The letter P in
column 1 represents a "shot" card, containing the result of a single
laser firing.

A word of warning is in order to the unwary users. Some of
the specified data items may not be available. In the card images,
a blank field is a "no information" indicator. Actual null values
will be represented by zero punches.

IV. Acknowledgements

The data described herein were generated at the McDonald
Observatory through the collective efforts of the LURE Team and
numerous supporting personnel at their several institutions.
The Team is composed of C. O. Alley and D. G. Currie (Univ. of Maryland), P. L. Bender (JILA), R. H. Dicke and D. T. Wilkinson (Princeton Univ.), J. E. Faller (JILA), W. M. Kaula (UCLA), G. J. F. MacDonald (Dartmouth Univ.), J. D. Mulholland and E. C. Silverberg (McDonald Observatory, Univ. of Texas), H. H. Plotkin (NASA/GSFC), J. G. Williams (JPL). Preliminary processing of some of the data described here was done at the University of Maryland and provided by D. G. Currie to the authors for this purpose. This report and the data tapes described herein were prepared under NASA Grant NGR 44-012-219.
