DESIGN AND PERFORMANCE ANALYSIS OF SOLID-PROPELLANT ROCKET MOTORS USING A SIMPLIFIED COMPUTER PROGRAM

By Richard H. Sforzini

Auburn University
Auburn, Alabama

October 1972

Final Report

Prepared for

NASA-GEORGE C. MARSHALL SPACE FLIGHT CENTER
Marshall Space Flight Center, Alabama 35812
This report presents an analysis and a computer program which represents a compromise between the more sophisticated programs using precise burning geometric relations and the textbook-type of solutions. The program requires approximately 900 computer cards including a set of 20 input data cards required for a typical problem. The computer operating time for a single configuration is approximately 1 minute and 30 seconds on the IBM 360 computer. About 1 minute and 15 seconds of the time is compilation time so that additional configurations input at the same time require approximately 15 seconds each. The program uses approximately 11,000 words on the IBM 360. The program is written in FORTRAN IV and is readily adaptable for use on a number of different computers; e.g., IBM 7044, IBM 7094 and Univac 1108.
ERRATUM

All of the computations in the main report and in the appendix were performed with the following error in the programming of the Newton-Raphson solution of the burning rate equation: PONOZ was used in place of PNOZ in Table IV-2, p. 43, line 16 of the report. The program statement is correct in the report, but because of the error numerical results obtained from the program will differ slightly from those presented in the report especially during the initial portion of the traces. The variations are not large enough to change the conclusions of the report or to invalidate the use of the design charts presented in the appendix.

ACKNOWLEDGEMENTS

The author expresses grateful appreciation to Mr. J. M. Lyon, Graduate Research Assistant in Aerospace Engineering, Auburn University, who skillfully and enthusiastically programmed the analysis given in this report for the digital computer and rendered other valuable assistance.

The advice and helpful suggestions given by personnel at the George C. Marshall Space Flight Center who used the computer program during its development and provided data for analysis are also acknowledged. The aid thus received from Messrs. B. W. Shackelford, Jr. (NASA Project Coordinator) and K. W. Jones is especially appreciated.

I. INTRODUCTION AND SUMMARY

This report presents the results of research performed at Auburn University during the period from June 16 to October 12, 1972, under Modification No. 6 to the Cooperative Agreement, dated October 6, 1969, between the NASA Marshall Space Flight Center and Auburn University. The principal objective of the research was to develop a simplified computer program which would serve as an aid in preliminary design of solid-propellant rocket motors (SRMs). The program would also permit generation of SRM parametric and performance data which were to be compiled as a part of the task.

A number of computer programs are already available to government and industry for use in SRM design which will give results based on quite precise mathematical formulation of burning surface geometry. The general tendency has been toward developing more and more sophistication in these programs. This creates substantial difficulty for the user in understanding the program and preparing inputs; lengthy orientation times are frequently required. Also, use of such programs involves long operating and turn-around times on the computer and attendant high costs. Elementary textbook-type approaches are of course possible, but the accuracy requirements must be considered. Indeed, in view of the high cost associated with SRM development, a propulsion contractor would be ill-advised in not making use of a tried and proven sophisticated program available to him. On the other hand, it is questionable whether the accuracy obtained with the sophisticated programs is sufficient to justify their adoption for the bulk of preliminary design work. Unknowns such as the erosive burning characteristics of a new propellant, or even a new SRM design with a well characterized propellant, cast doubt on the accuracy of performance predictions. In view of this, a less precise approach is often acceptable in preliminary design; for example, in determining the effects to anticipate from a given design change.

This report presents an analysis and a computer program which represents a compromise between the more sophisticated programs using precise burning geometric relations and the textbook-type of solutions. The program requires approximately 900 computer cards including a set of 20 input data cards required for a typical problem. The computer operating time for a single configuration is approximately 1 minute and 30 seconds on the IBM 360 computer. About 1 minute and 15 seconds of the time is compilation time so that additional configurations input at the same time require approximately 15 seconds each. The program uses approximately 11,000 words on the IBM 360. The program is written in FORTRAN IV and is readily adaptable for use on a number of different computers; e.g., IBM 7044, IBM 7094 and Univac 1108.

Based on input of solid-propellant rocket initial geometric properties, data on the characteristics of the propellant and inert materials, and design criteria constants, the program computes the weights of major components and
performance characteristics of the SRM including specific impulse, thrust, chamber pressures, and other significant time varying parameters. The program may be used for rocket motors of all sizes; however, primary consideration was given in this study to very large SRMs (120 in. dia. and above). Therefore, some of the empirical expressions for component weights developed, such as the one for nozzle weights, may be more accurate for larger motors than for smaller ones as discussed further in the body of the report.

With large motors again in mind, particularly those under consideration for application to the Space Shuttle Booster (References 1-4), the program was designed to treat segmented configurations with both star and circular perforated grains present in various arrangements in the same SRM. In addition, monolithic grains and either standard star or truncated star (slotted tube) shapes may be analyzed. While there is considerable flexibility provided in specifying the geometry of the ends of circular perforated grains, there are severe constraints on the specification of the geometry of star grains and on passageways in the grain for thrust termination ports. To offset this, as a program option, the user may specify tabular data to correct precisely or approximately for variation in burning surface geometry with distance burned. Alternately, the entire burning area geometry may be specified by tabular input.

The key to the relative simplicity of the program, aside from the use of end constraints on burning surface geometry, is the way in which the variation in surface regression along the length of the grain is treated. The more sophisticated programs result from mathematically dividing the grain axially into a large number of segments. For each segment, in turn, the governing fluid dynamic equations are solved. The difficulty here is that the flow velocity at each segment is unknown until the burning rate is determined, but the burning rate depends on the velocity. Therefore, an iterative technique must be used which requires assumption of the conditions at the head end of the grain, solution of the governing equations for each segment in turn and finally a comparison of the total amount of mass generated with that theoretically discharged through the nozzle. If the check fails, a new assumption and repetition is required to obtain a solution for one instant of time. The advantage of this method is that it permits the surface regression to be determined at each segment for each instant of time, but it is clear that these results in both long computation time and large computer storage capacity. The present analysis avoids the above mentioned difficulties through the assumption that the surface regresses in a linear fashion along the length of grain consistent with the difference in surface regression at the head and aft ends for which regression (burning) rates are separately calculated. Support for this assumption as an approximation may be found in the results of interrupted burning tests (See for example Reference 5, p. 118). As already noted, the nature of erosive burning characteristics is at best poorly known which casts some doubt on a need for a more rigorous model of the burning surface geometry. Separate determination of head and
nozzle end burning rates taking into account erosive burning effects provides a means of accounting for one of the principal effects of a surface regression which varies along the length of the grain. This is the effect on tailoff characteristics which, in somewhat simplified terms, is treated in the present analysis by reducing the burning surface at tailoff in proportion to the length of propellant that has experienced burnout according to the linear model of the regressing surface.

A discussion of the program input and output variables is presented in Section II of this report. This will serve as a guide to the user in proper specification of his problem and interpretation of the output. The discussion should also be read by those desiring to understand the mathematical analysis which is outlined as a step-by-step procedure in Section III. However, Section III may be omitted without loss of continuity by the user interested only in understanding how to specify his problem. Section IV presents the information required to operate the program and computer format and flowcharts. Once the input variables discussed in Section II have been specified, the information given in Section IV should suffice for anyone familiar with use of a computer having FORTRAN IV capability to obtain the program output. Also, the program listing and flowcharts in Section IV will be useful for determining how to modify the program and for a detailed understanding of the program logic. However, for those desiring to understand only the basic logic of the program, study of Section III is recommended, as it was written as a step-by-step procedure with the purpose in mind of conveying the basic program logic. Section V presents test cases and comparison with results of others, both theoretical and experimental. Again those seeking only to know how to use the program may omit this section, although the user will find the example listings of input and output data, which are presented only here, helpful. Finally, the Appendix is a design data compilation resulting from use of the program which may be of aid to the designer in predicting effects of various design parameters on SRM characteristics and performance.
II. DISCUSSION OF INPUT AND OUTPUT

The computer program described in this report is capable of calculating performance for a large variety of different grains and combinations. On the other hand, to attain the goal of a simplified program, it is necessary to impose substantial restrictions on the geometric end constraints of the burning grain surfaces. Thus the accuracy of results will depend to a large degree on judicious selection of the geometric input variables. The difficulties encountered in approximating the geometric burning characteristics may be lessened, of course, by making use of the program options which permit specification of the burning geometry of part or all of the grain by using tabular inputs with the distance burned being the single argument. In any event, it is necessary that the program user have a clear understanding of the definition of each input variable so that he can appropriately specify each configuration to be analyzed. In addition, the user must understand how to specify proper design criteria and the physical characteristics of propellant and inert materials.

In this section each input variable is defined in the order in which it is encountered in the program. The English or Greek symbol is given first followed by the computer symbol in parenthesis. Sketches of geometric characteristics are given for clarification. Where appropriate, additional discussion of the variable and recommended or typical numerical values are given. In addition, the present outputs of the program are defined. It is the aim of this section to provide a guide to the user in the specification of his problem and interpretation of the outputs.

Propellant Characteristics

\( \rho \) (RHO) Density of the solid propellant (slugs/in.\(^3\)).

\( a \) (A) Propellant burning rate coefficient in the equation \( r = aP^n \) (in/sec-p sia\(^n\)).

\( n \) (N) Burning rate exponent (1).

\( a_{eb} \) (ALPHA) Erosive burning coefficient in the Robillard-Lenoir burning rate rule (Equation III-11)(in\(^2\).8-ft\(^0.8\)/sec\(^1.8\)lbf\(^0.8\)).

\( \beta \) (BETA) Erosive burning pressure coefficient in the Robillard-Lenoir rule (1).

\( \mu \) (MU) Absolute viscosity of the chamber gases (lbf-sec/in.-ft).

\( C^* \) (CSTAR) Characteristic exhaust velocity (ft/sec). This is the gas dynamic characteristic velocity which can be obtained from the expression \( C^* = \sqrt{RT_c/T} \) where \( R \) is the gas constant and \( T_c \) the adiabatic flame temperature of the propellant.
Primary Basic Motor Dimensions

L (L)  Total initial perforated grain length including gaps at slots (in.). This is used only for calculation of the initial length Reynolds number and in the erosive burning rate equation.

\( T_w \) (TAU)  Web thickness of the controlling propellant length (in.). (See ZO below for definition of controlling length). If the grain is tapered, the length average value should be specified excluding lengths having additional taper not represented by ZO and segments located anywhere having a step decrease in thickness. Such step decreases must be handled by the additive tabular input option if they introduce two significantly different web thicknesses for the same grain type; e.g., two circular perforated grains. If a circular perforated grain is used, it is assumed that it will have the approximate average web thickness of the controlling propellant length.

\( V_{ci} \) (VCI)  Initial volume of chamber gases \((\text{in}^3)\). This is the volume of the empty case less the volume of the propellant. A reasonable estimate based on the case volume and the estimated volumetric loading density will suffice.

\( V_{cf} \) (VCF)  Final volume of chamber gases \((\text{in}^3)\). This is the volume of the empty case. A reasonable estimate will suffice.

\( D_i \) (DI)  Initial diameter of the nozzle throat (in.).

\( \alpha_n \) (ALFAN)  Exit half angle of the nozzle (radians).

\( \theta_n \) (THETA)  Cant angle of the nozzle with respect to the motor axis (radians).

\( L_{Ta} \) (LTAP)  Estimated length of grain at the aft end at start of first tailoff having an additional taper not represented by ZO or THETAG (in.). See Figure II-1. This variable permits the designer to specify an additional taper at the nozzle end of a circular perforated or star grain to produce regressivity shortly before tailoff.

\( x_{Ta} \) (XT)  Difference in web thickness at ends of LTAP (in.). See Figure II-1.

\( z_o \) (ZO)  Initial difference between web thickness at the head and aft ends of controlling grain length, not including any initial length associated with LTAP or THETAG (in.). The controlling length of the grain is the axial length between the head end of the grain and the position of expected maximum Mach number in the port. It may be assumed, in most cases, that this length terminates whenever there is an abrupt decrease in web thickness near the aft end of the chamber or when \( \theta_g \) is greater than 5°.
Figure II-1. Basic motor dimensions. $L_{Gci}$, $L_{Gni}$, and $\theta_G$ are used only for circular perforated grains. The controlling grain length may be $L_{Gci}$ or some lesser value depending on the position of maximum port Mach number. $\tau_W$ is the length average web thickness over the grain length excluding the lengths associated with $L_{Ta}$, $\theta_G$ and the head end dome.
### Basic Performance Constants

<table>
<thead>
<tr>
<th>Symbol</th>
<th>Description</th>
<th>Details</th>
</tr>
</thead>
<tbody>
<tr>
<td>$\Delta y_1$ (DELTAY)</td>
<td>Initial desired burn increment (in.).</td>
<td>This increment will be used by the program for the initial 5% of the web thickness burned, for the period shortly preceding and following tailoff and at such other times as the rate of pressure change is large. Larger increments will automatically be used at other times. An initial increment size of approximately 0.005TW is recommended but larger increments may be used for relatively flat burning surface versus distance burned traces.</td>
</tr>
<tr>
<td>$x_{out}$ (XOUT)</td>
<td>Distance burned at which the propellant breaks up (in.).</td>
<td>This permits the option of specifying termination of burning resulting from possible structural breakup of the propellant. If this option is not desired, XOUT should be set to some large value; e.g., 1000 in.</td>
</tr>
<tr>
<td>$(\Delta p/\Delta y)_{out}$ (DPOUT)</td>
<td>Rate of change of pressure with respect to distance burned at which the propellant is extinguished (lb/in$^2$).</td>
<td>This permits the option of specifying termination of burning resulting from rapid depressurization. If this option is not desired, DPOUT should be set to some large value; e.g., 10,000 psia/in. However, if an abrupt tailoff is expected, a smaller value of DPOUT must be specified as the computer will not otherwise be able to handle the discontinuity. For large motors (120 in. dia. and up) a value of 500 psia/in is recommended and proportionately larger values for smaller motors.</td>
</tr>
<tr>
<td>$\zeta_F$ (ZETAF)</td>
<td>Thrust loss coefficient (1).</td>
<td>In the absence of data to the contrary a value of 0.98 is recommended.</td>
</tr>
<tr>
<td>$t_{bl}$ (TB)</td>
<td>Estimated burning time (sec).</td>
<td>This and the variable that follows permits the program to calculate delivered specific impulse and thrust based on an assumed trajectory which was determined from analysis of typical large SRM applications.</td>
</tr>
<tr>
<td>$h_b$ (HB)</td>
<td>Estimated burnout altitude (ft).</td>
<td>To obtain sea level performance characteristics, HB should be set equal to zero.</td>
</tr>
<tr>
<td>$\lambda$ (GAM)</td>
<td>Ratio of specific heats for propellant gases (1).</td>
<td></td>
</tr>
<tr>
<td>$E_r$ (RADER)</td>
<td>Radial erosion rate of the nozzle (in/sec).</td>
<td>A value of 0.0135 ips has been used by one propulsion company to predict the performance of 156 in. dia. motor with a graphite tape-phenolic impregnated throat.</td>
</tr>
</tbody>
</table>
Basic Properties for Weight Calculation

\( (\pi)_p \) \( (\text{PIPK}) \)  
Temperature sensitivity coefficient of pressure at constant 
\( K = A_p/A^* (1/\circ F) \).

\( \Delta T_i \) \( (\text{DTEMP}) \)  
Maximum expected increase in initial grain temperature above 
design point conditions (\(^\circ\)F).

\( (\sigma_p/p)(\text{SIGMAP}) \)  
Statistical variation in the maximum calculated pressure(1); 
i.e., one standard deviation in maximum pressure divided by 
the calculated value of maximum pressure. The value used is 
typically 0.03 for an untried design. Lower values may be 
used if supported by data on a proven design.

\( \sigma_y/y_c \) \( (\text{SIGMAS}) \)  
Statistical variation in yield strength of the case material 
(1). A value of 0.02 is recommended. Alternately \( y_c \) may be 
taken as the minimum yield strength in which case SIGMAS is 0.

\( n_1, n_2 \) \( (\text{N1,N2}) \)  
Number of standard deviations in maximum chamber pressure and 
case yield strength, respectively, to be used as bases for 
design (1). A value of 3 gives statistical assurance that 
99.5% of the time the calculated limits of the variable will 
not be exceeded in tests.

\( S_{ycnom} \) \( (\text{SYCNOM}) \)  
Nominal yield strength of the case material (lbs/in\(^2\)). See 
also SIGMAS.

\( D_{cc} \) \( (\text{DCC}) \)  
Estimated mean diameter of the motor case (in.). A rough 
estimation of the case and insulation thicknesses may be 
added to the grain diameter to obtain DCC.

\( \psi_c \) \( (\text{PSIC}) \)  
Safety factor on case thickness (1). This factor is super-
imposed on the safety provided by use of the statistical 
limits on pressure and case strength.

\( \delta_c \) \( (\text{DELC}) \)  
Specific weight of the case material (lbs/in\(^3\)). For steel 
the approximate value is 0.283 lbm/in\(^3\).

\( L_{cc} \) \( (\text{LCC}) \)  
Length of the cylindrical portion of the case including forward 
and aft segments (in.).

\( n_{seg} \) \( (\text{NSEG}) \)  
The number of case segments (1). NSEG is 1 for a mono-
lithic case.

\( h_{cn} \) \( (\text{HCN}) \)  
Axial length of the nozzle closure (in.). See Figure II-1.
Nominal yield strength of the nozzle structural material (lb/in²).

Safety factor on the nozzle structural and ablative materials, respectively (1). No additional allowances are made in the computation for statistical variation, so PSIS and PSIA provide the only safety factors. Values of 1.4 and 2.0 are recommended for PSIS and PSIA, respectively.

Empirical constants in the nozzle weight estimation equation (Eq. 63b). (lbm/in³, in/sec). For single, submerged conical nozzles using ablative exit cones with the steel body extending over about one-third of the exit cone, the values recommended based on empirical analysis of large (120 to 156 in. dia.) SRMs are K₁ = 0.208 lbm/in³ and K₂ = 0.0925 in/sec. These values should also yield approximations of the weights for smaller and larger nozzles of the same type. For better results with larger or small motors or nozzles of different types, the K's should be redetermined.

Safety factor on the nozzle insulation (1). No additional allowance is made in the computations for statistical variation. A value of 2.0 has been used extensively in man-rated applications.

Specific weight of the case insulation (lbm/in³). DELINS is typically 0.0462 lbm/in³.

Erosion rate of the exposed insulation taken everywhere the same except at the nozzle closure (in/sec). KEH is typically 0.003 in/sec.

Erosion rate of the exposed insulation in the nozzle closure. KEN is typically 0.012 in/sec.

Specific weight of the liner (lbm/in³). DLINER is typically 0.033 lbm/in³.

Thickness of the liner (in.). TAUL is typically 0.065 in.

Any additional weight not considered elsewhere in weight calculations (lbm). This includes weights associated with thrust termination and thrust reversal, thrust vectoring devices, thrust skirts (except for "y" joints), ignitors, instrumentation and final thermal protection of the motor case after burnout (see Eq. 64, Section III).
Input to Establish the Program and Basic Grain Configuration and Arrangement

\( I_{op} \) (INPUT)  
1 for only tabular input.
2 for only equation input.
3 for a combination of 1 and 2.

\( G_{op} \) (GRAIN)  
1 for an entirely circular perforated grain.
2 for star grain only.
3 for combination of 1 and 2.

\( S_{op} \) (STAR)  
0 for an entirely circular perforated grain.
1 for standard star (See Fig. II-2).
2 for truncated star (See Fig. II-3).

A standard star may not be combined with a truncated star.

\( n_{T} \) (NT)  
Number of thrust termination passageways in grain (1)
NT is zero if there are no thrust termination passageways.

\( Q_{op} \) (ORDER)  
1 if a star grain is at head end and a circular perforated grain at aft controlling end.
2 if a circular perforated grain is at both ends. A star grain segment may still be present.
3 if a circular perforated grain is at head end and a star at the aft controlling end.
4 if a star grain is at both ends.

If grain = 1, value of order must be 2
If grain = 2, value of order must be 4.

It is important to realize that ORDER establishes the controlling port area equations to be used. Thus if the nozzle end segment is not indeed the controlling one (the one that establishes the maximum Mach number in the port), ORDER should be specified to designate the actual controlling segment as the nozzle end segment. GRAIN, STAR, N1 and ORDER are not used for INPUT = 1, but values must be assigned for continuity of computer operations.
Figure II-2. Standard star grain cross-section. The evolution of the burning perimeter is shown. Calculated variables are circled. Second and third (final) zones of burning are cross-hatched.
Figure II-3. Truncated (slotted tube) star grain cross-section. The evolution of the burning perimeter is shown. Calculated variables are circled. First and third (final) burning zones are cross-hatched.
Tabular Burning Surface and Port Areas (Not required for INPUT = 2)

- $A_{bpT}$ (ABPK) Burning area in the port ($\text{in}^2$).
- $A_{bsT}$ (ABSK) Burning area in the slots ($\text{in}^2$).
- $A_{bnT}$ (ABNK) Burning area at the nozzle end ($\text{in}^2$).
- $A_{phT}$ (APHK) Port area at the nozzle end of the controlling grain length ($\text{in}^2$).
- $A_{pnT}$ (APNK) Port area at the head end of the grain ($\text{in}^2$).

$A_{phT}$ and $A_{pnT}$ are not required when INPUT is 2 or 3; the equation inputs must be used to provide the information in these cases. Values of all A's used must be specified to completely describe the burning surface and port areas versus distance burned. The program computes intermediate values by linear interpolation. The number of values required is arbitrary and limited only by the storage capacity of the computer, but values must be specified for $y = 0$. Also, as an example of the procedure for specifying terminal values which must be followed, burning surfaces must be specified as zero at burnout of the tabular surfaces and at a $y$ exceeding the highest anticipated calculated performance value. Separate input cards must be prepared for each value of $y$ and arranged as described in Section IV of this report. The use of these tabular values in conjunction with the equation inputs (INPUT = 3) increases the flexibility of the program considerably. Frequently it is easy to estimate burning surface effects which end constraints on the equation inputs neglect. In this case a table of input values can be readily prepared from estimates of the effects. Also, the program can be run first without the tabular values and outputs used as an aid in obtaining the estimate. For example, the burning perimeters of a star grain can be determined in this way and the values used to estimate the effects of a head end closure on the star grain.

Geometry for Circular Perforated Grain – Not required for completely star-shaped grain (GRAIN = 2) or for only tabular inputs (INPUT = 1)

- $D_0$ (DO) Length average outside diameter of circular perforated grain, excluding lengths extending into the closures (in.).
- $D_i$ (DI) Length average inside initial diameter of circular perforated grain (in.). Only the controlling length excluding LTAP should be considered in the averaging.
- $\Delta D_i$ (DELDI) Difference between the initial circular perforated grain diameter at the nozzle end of the controlling length and DI (in.).
S (S)  Number of burning flat ends of a circular perforated grain not including an extreme aft grain end (1).

θₐ (THETAG)  Angle burning surface element of circular perforated grain located at the extreme nozzle end of chamber makes with the motor axis (radians). See Figure II-1. THETAG must be set to zero if a star grain is located at the nozzle end (GRAIN = 3, ORDER = 3) or if aft end burning surfaces are represented by tabular values. THETAG is π/2 if the circular perforated grain represented by equations has a flat burning surface located at the extreme nozzle end of the chamber. If THETAG is less than or equal to 5°, a value must be assigned (zero is satisfactory), but the effect of THETAG on burning surface area is not computed (See also LGNI and LTAP). THETAG is zero if the end surface is flat and inhibited.

Lₐci (LGCI)  Initial total axial length of circular perforated grain represented by equation inputs not including gaps (in.). LGCI excludes lengths associated with THETAG.

Lₐni (LGNI)  Initial slant length of a burning conical circular perforated grain at the nozzle end (in.). LGNI is set equal to zero if THETAG is less than or equal to 5°. In this case the length otherwise associated with LGNI should be added to LGCI. If the error in burning surface area thus introduced is deemed significant, a correction may be introduced by making use of tabular inputs in combination with the equation inputs. Basic effect of small THETAG on tailoff may be accounted for by specification of LTAP. If a nozzle end burning surface is flat (THETAG = π/2), LGNI equals one half the difference between inside and outside local grain diameters.

θₐn (THETCN)  The contraction angle of a circular perforated grain bonded to the nozzle closure. See Figure II-1. Use an estimated value which yields approximately the correct volume of propellant burned. If a star shaped grain is located at the extreme nozzle end of the chamber or if tabular values are used to represent downstream burning surfaces, THETCN is π/2. THETCN is also π/2 if the extreme aft end of the grain is inhibited, but only a flat ended, inhibited grain (THETAG = 0) which does not extend into the nozzle closure may be accurately represented. THETCN is zero for a burning flat end (THETAG = π/2) which does not extend into the closure.

θₐh (THETCH)  The contraction angle of a circular perforated grain bonded to the head end. See Figure II-1. Use an estimated value which yields approximately the correct volume of propellant burned. THETCH is π/2 if the extreme forward end of the circular perforated grain (bonded or not) represented by equations is flat. A head end flat burning surface is treated by proper specification of S.
Basic Geometry for Star Grains - Not required for entirely circular perforated grains (GRAIN = 1) or for only tabular inputs (INPUT = 1)

$n_s$ (NS) Number of burning flat end surfaces of a star grain not located at extreme nozzle end of the chamber (1).

$L_{GSI}$ (LGSI) Initial total axial length of star-shaped perforated grain represented by equations (in.). No provision comparable to the use of $LGNI$ for circular perforated grains is made here to treat effects resulting from THETAG greater than 5°. Adjustments may be made, however, by use of tabular input values in conjunction with the equation inputs. Also, effects of taper, including additional small taper at the nozzle end, on tailoff may be treated by use of the variables ZO, XT and LTAP.

$n_p$ (NP) The number of star points (1).

$R_c$ (RC) The star grain outside radius (in.).

$f$ (FILL) The fillet radius at star valleys (in.). See Figure II-2,3.

$n_n$ (NN) Number of burning flat end surfaces (0 or 1) of a star grain located at the extreme nozzle end of the chamber (1).

Special Geometry for Truncated Star - Not required for standard star grains (STAR = 1)

$R_p$ (RP) The length average initial radius of the truncation (in.). See Figure II-3.

$\tau_s$ (TAUS) The length average initial thickness of the propellant web at the bottom of the slots (in.).

Special Geometry for Standard Star Grain - Not required for truncated star grains (STAR = 2)

$\tau_{ws}$ (TAUWS) The web thickness of a standard star grain (in.). See Figure II-2. If the grain is tapered, the length average value should be used. TAUWS will be the same as TAU if the entire controlling length of grain is a star grain. Otherwise TAUWS may or may not be different from TAU.

$\theta_f$ (THETAP) Angular location of the fillet center of standard star from line of symmetry (radians).

$\theta_p$ (THETAP) The apex angle of the star point (radians).
Geometry of Thrust Termination Passageways - Not required if NT = 0.

$L_{TP}$ (LTP) Initial length of the termination passageway between the centers of gravity of perimeters of the bases (in.). See Figure II-1.

$D_{TP}$ (DTP) Initial diameter of the termination passage (in.).

$\theta_{TP}$ (THETTP) The acute angle between the axis of the passage and the motor axis (radians).

$\tau_{Teff}$ (TAUEFF) Estimated effective web thickness at the termination port (in.). The user must judge the distance burned at which the effect of the termination passage on modification of the burning surface geometry ceases to be significant. In general, this should be between two-thirds and full web thickness. The equation used to account for the burning surface is based on a passageway in a circular perforated grain terminated at the case by a flat inclined plane. Thus only a rough estimate of the effect of the termination passage is provided.

Special Equation Inputs - Required only at the option of the user. May be used when INPUT = 1, 2, or 3.

$B_{bp}$ (BBP) Additive burning surface input as function of Y for port burning surface (in²).

$B_{bs}$ (BBS) Additive burning surface input as function of Y for slot burning surface (in²).

$B_{bn}$ (BBN) Additive burning surface input as function of Y for nozzle end burning surface (in²). In order to make use of the option of specifying the B's, a minor program modification is required. The B's are all set equal to zero in the present program. If this option is to be used the program statements assigning values to the B's are easily replaced with the desired equation inputs.

Program Outputs

The variables whose values are printed by the present program are defined below. Additional variables may also be printed with minor program modification.
Outputs as functions of time

\( t \) (\( T \)) Operating time (sec.). This is calculated from the time initial equilibrium operating pressure is attained.

\( y \) (\( Y \)) Average distance burned (in.).

\( r_n \) (\( RNOZ \)) Nozzle end controlling burning rate (in/sec).

\( r \) (\( RHEAD \)) Head end burning rate (in/sec).

\( P_{on} \) (\( PONOZ \)) Stagnation pressure at the nozzle end of the chamber (lb/in\(^2\)).

\( P_h \) (\( PHEAD \)) Pressure at the head end of the chamber (lb/in\(^2\)).

\( 1/J \) (\( PTAR \)) Port-to-throat cross-sectional area ratio (1).

\( M_n \) (\( MNOZ \)) Mach number at the nozzle end of the controlling grain length (1).

\( S_G \) (\( SG \)) Average perimeter of a star-shaped grain (in.). This will be printed as zero if there is no star grain or if tabular input values are used alone.

\( P_a \) (\( PATM \)) The atmospheric pressure at altitude (lb/in\(^2\)). This is based on the assumed trajectory and specification of HE.

\( A_{bp} + A_{bs} + A_{on} \) (\( SUMAB \)) The total burning surface of the propellant (in\(^2\)).

\( C_{Fvac} \) (\( CFVAC \)) The vacuum thrust coefficient (1). No adjustments are made in the calculations for nozzle divergence, cant, or other losses.

\( F_{vac} \) (\( FVAC \)) The vacuum thrust (lbf). Adjustments are made in \( F_{vac} \) and \( F \) for nozzle divergence and cant, and other losses.

\( F \) (\( F \)) The delivered thrust based on the assumed trajectory (lbf). Losses are included.

Weight and related values

\( W_{pl} \) (\( WP1 \)) Propellant weight calculated from mass discharge rates (lbm).

\( W_{p2} \) (\( WP2 \)) Propellant weight calculated from the products of burning surfaces and incremental distances burned (lbm).
Maximum head end chamber pressure calculated by the program (lb/in²).

Arithmetic average of WP1 and WP2 (lbm). A check on the calculation accuracy is provided by comparison of this with WP1 or WP2.

Average delivered specific impulse (lbf-sec/lbm). Losses are included as for FVAC and F.

Total delivered specific impulse (lbf-sec). Losses are included.

Average vacuum specific impulse (lbf-sec/lbm). Losses are included.

Maximum expected operating pressure (lb/in²). This includes allowances for statistical variations and initial grain temperature.

Thickness of the cylindrical section of the case.

Total weight of the empty case (lbm).

Total weight of the nozzle (lbm).

Total weight of the case insulation (lbm).

Total weight of the loaded case including added weight, WA (lbm).

Motor mass fraction; i.e., the ratio WP/WM (1).

Total delivered impulse-to-motor weight ratio (lbf-sec/lbm)
III. ANALYSIS

This section of the report presents the mathematical analysis of the SRM design problem in a step-by-step procedure. The aim is twofold: 1) to identify the fundamental physical relationships used and 2) to establish the basic mathematical logic of the computer program.

No attempt has been made to justify completely the relationships used. The theory applied involves, in the main, basic internal ballistics and trigonometry applied in a more or less conventional way. The internal ballistics analysis follows one-dimensional frictionless compressible flow theory with the flow taken as reversible in the nozzle. Equilibrium pressure is established by iteration to find the chamber pressure which balances the mass flow rate relationship

\[ \dot{m}_p = \dot{m}_c - d(p_c V_c)/dt \]

A number of excellent references are available which explain the fundamental relations in some detail; e.g., Reference 6, Chapters 5 and 6. Although in the present analysis fewer simplifying assumptions are made in the application of the physical principles than in the example and in similar references, the reader familiar with the basic internal ballistics of SRMs should have no difficulty in following the procedure and recognizing generalizations of the elementary approaches. In the development of the weight relationships, explanation of the assumptions made are given as changes in basic design criteria, new design approaches, or advances in the state-of-the-art may dictate changes to the equations used.

**Internal Ballistics**

At this point it is assumed that the port areas at the head and nozzle ends and burning surfaces areas are known as functions of the distance burned. The procedure for calculating these quantities is given later in this section. The computer program uses a subroutine in calculating the areas which is called as required.

0. Set \( y = 0 \) and \( t = 0 \)

1. Compute \( A^* \) and \( M_n \) in turn from:

   a. \( A^* = (\pi/4)(D_i^* + 2E_n t)^2 \)

   b. \( M_n = (X A^*/A_{bp}) \{2[1 + (y-1)M_n^2/2]/(y+1)\}^{(y+1)/2(y-1)} \)

where \( X = (A_{bp} + A_{bs})/(A_{bp} + A_{bs} + A_{bn}) \)
2. Compute
\[ u_n = \gamma C^* M_n \left\{ \frac{2}{(\gamma+1)} \right\} (\gamma+1)/((\gamma-1)1+ (\gamma-1) M_n^2/2) \right\}^{1/2} \]

3. \[ P_n/P_{on} = [1 + (\gamma-1) M_n^2/2]^{-\gamma/(\gamma-1)} \]

4. \[ \Gamma = \gamma \left\{ \frac{2}{(\gamma+1)} \right\} (\gamma+1)/(2(\gamma-1)) \]

5. \[ J = A^*/A_{pn} \]

6. Compute first estimate of \( P_{on} \),
\[ P_{on} = \left[ aP C^* (A_{bp} + A_{bs} + A_{bn}) / A^* \right]^{1/(1-n)} (1+\Gamma^2 J^2/2)^{n/(1-n)} \]

7. Compute mass flow discharge rate through nozzle
\[ \dot{m}_D = A^* P_{on}/C^* \]

8. \[ P_n = (P_n/P_{on}) P_{on} \]

9. \[ P_h = P_n + 2\dot{m}_D u_n / (A_{pn} + A_{pn}) \]

10. Compute head end burning rate
\[ r_h = aP^h \]

11. Compute nozzle (aft) end burning rate
\[ r_n = aP^h + \alpha_{eb} \left( \frac{\dot{m}_D X/A_{pn}}{A_{pn}} \right)^{0.8/L^{0.2}} \exp(\beta r_{pn} A_{pn}/\dot{m}_D X) \]

The Robillard-Lenoir erosive burning rate rule is used. Reference 7 provides support for this selection, but the relationship may be changed if desired to express \( r_n \) in terms of any of the variables available at this point.

12. Compute the mass flow generation rate
\[ \dot{m}_G = (\rho_p/2) [r_h + r_n] (A_{bp} + A_{bs}) + 2aP^h A_{bn} \]

13. If \( \dot{m}_D > \dot{m}_G > 0.999 \dot{m}_D \), the solution is complete for \( y=0 \).

Go to step 16

14. If not, set \( \dot{m}_D = \dot{m}_G \), and
15. \( P_{on} = C^* \frac{m_d}{A^*} \)

16. Compute the initial length Reynolds number
\[ R_{eL} = \frac{m_d XL}{A_{pn} u} \]

17. Set \( t = 0 \).

18. Solve for \( M_e \) in
\[ M_e = A^*/A_e \left\{ \frac{2[1 + (\gamma - 1)M_e^2/2]/(\gamma+1)^{(\gamma+1)}/2(\gamma-1)}{2[1 + (\gamma - 1)M_e^2/2]/(\gamma+1)^{(\gamma+1)}/2(\gamma-1)} \right\} \]

19. Compute
   a. \( \frac{\rho_e}{P_e} = [1 + (\gamma - 1)M_e^2/2]^{-\gamma}/(\gamma-1) \)
   b. \( A_e = \pi D_e^2/4 \)

20. Compute estimated altitude (Reference 8, pp. 7-13)
\[ h = h_b(t/t_b)^{\frac{2}{3}} \]

21. Compute atmospheric pressure (Reference 8)
\[ P_a = 14.696 \exp(-0.43103 \times 10^{-4}h) \]

22. Compute the thrust coefficients
   a. \( C_F = \Gamma \left\{ 2\gamma[1-(P_e/P_{on})(\gamma-1)/\gamma]/(\gamma-1) \right\}^{\frac{1}{2}} \)
   \[ + (A_e/A^*)[(P_e/P_{on}) - P_a/P_{on}] \]
   b. \( C_{Fvac} = C_F + (A_e/A^*)(P_a/P_{on}) \)

23. Compute thrust
   a. \( F = \zeta_F \cos \theta_n P_{on} A^* C_F(1 + \cos \alpha_n)/2 \)
   \[ + (1-\cos \alpha_n)(A_e/A^*)[(P_e/P_{on}) - P_a/P_{on}]/2 \]
   b. \( F_{vac} = \zeta_F \cos \theta_n P_{on} A^* C_{Fvac}(1+\cos \alpha_n)/2 \)
   \[ + (1-\cos \alpha_n)(A_e/A^*)(P_e/P_{on})/2 \]

The above thrust equations have been arranged so that the nozzle divergence loss factor \((1 + \cos \alpha_n)/2\) modifies only the momentum term of the thrust equation.
24. Compute the instantaneous specific impulses and total delivered impulses

24. a. \[ I_{sp} = \frac{F}{m_{D}g} \]

24. b. \[ I_{sp\text{vac}} = \frac{F_{\text{vac}}}{m_{D}g} \]

24. c. \[ I_{T} = \sum_{j} \frac{F_{j}}{\Delta t_{j}} \]

24. d. \[ I_{T\text{vac}} = \sum_{j} \frac{F_{\text{vac}j}}{\Delta t_{j}} \]

where the bars indicate here and below the arithmetic average value over \( \Delta y \) except at \( y = 0 \) where the initial value is used.

25. Set \( y = \Delta y_{j} \) and \( j = 1 \)

Repeat steps 1 through 3 and 5

26. Compute a first estimate of new mass flow discharge rate using the value of \( P_{on} \) at the beginning of the previous increment.

\[ \dot{m}_{D} = \dot{A}^{*} P_{on}/C^{*} \]

Repeat steps 8 through 12

27. a. Compute an estimate of \( \frac{dP_{c}}{dy} \), the rate of change of chamber pressure

\[ \frac{\Delta P_{c}}{\Delta y} = \left( \frac{P_{av}}{P_{av}} \right) \frac{\Delta T_{av}}{\Delta y} \]

\[ + \left[ \frac{P_{av}}{A_{bp} + A_{bs} + A_{bn}} \right] \Delta (A_{bp} + A_{bs} + A_{bn})/\Delta y \]

where the subscript av indicates the arithmetic averages of nozzle and head end values.

27. b. Compute the gaseous volume of the case

\[ V_{c} = V_{ci} + \sum_{j} \Delta y_{j} \left( A_{bp} + A_{bs} + A_{bn} \right) \]

28. If \( 1.002 \dot{m}_{D} \geq \dot{m}_{G} \frac{A^{*}}{12T^{2}C^{2}} \left[ V_{c} \frac{\Delta P_{c}}{\Delta y} + \frac{P_{av}}{A_{bp} + A_{bs} + A_{bn}} \right] \geq 0.998 \dot{m}_{D} \),

the solution is complete for \( y = \sum_{j} \Delta y_{j} \)

Go to step 31

29. If not, set

\[ \dot{m}_{D} = \dot{m}_{G} - \left( V_{c} \frac{T_{av}}{12T^{2}C^{2}} \right) \frac{\Delta P_{c}}{\Delta y}, \]

and

30. \[ P_{onj} = \dot{m}_{D}C^{*}/\dot{A}^{*} \]

Repeat steps 8 through 12 and then 27 through 28

31. a. Compute the time increment

\[ \Delta t_{j} = 2\Delta y_{j}/(\bar{T}_{h} + \bar{T}_{n}) \]
31. b. Compute the time 

\[ t = \sum_{j} \Delta t_j \]

32. Compute the difference between web thicknesses at the head and aft ends of the controlling grain length exclusive of any length near the nozzle end having an additional taper for the purpose of controlling tailoff characteristics (See discussion of \( r_w, z_w, l_{Ta} \) and \( x_{Ta} \), Section III).

\[ z = \sum_{j} \Delta t_j (\bar{r}_{n_j} - \bar{r}_{h_j}) + z_0 \]

33. Repeat steps 18 through 24c.

34. Set \( j = 2 \)

35. If \( y > 0.05 \) \( r_w \) and

\[ y + \Delta y_1 < (r_w - |z/2| - x_{Ta})_{j-1} \]

\[ \left| v_c \bar{r}_{av}/r^2 \right| \cdot \Delta P_c/\Delta y \mid_{j-1} = \frac{\dot{m}_P}{100} \]

set \( \Delta y_j = 10 \Delta y_1 \)

36. If not, set \( \Delta y_j = \Delta y_1 \)

37. Not used

38. \( y = \sum \Delta y_j \)

39. a. Repeat steps 1 through 3 and then 26 through 33 and 35 through 38 using \( \bar{A}_{pn} \) and \( \bar{A}^* \) in 1

39. b. Set \( j = 3, 4, \ldots \) Recreation steps 35 through 39b for each \( j \) until \( y > r_w - |z/2| \)

39. c. Set \( z = z_w \) and \( \Delta y = \Delta y_w (j \text{ is now } w) \)
39. d. Compute the loss in length of burning propellant $T_{z}$ associated with additional tailoff controlling taper near the nozzle end of the grain.

(1) If $x_{Ta} = 0$, set $T_{z} = 0$

(2) If $x_{Ta} > 0$, set

$$T_{z} = (y - \tau_{w} + x_{Ta} + z/2)L_{Ta}/x_{Ta}$$

If $T_{z} < 0$, set $T_{z} = 0$

If $T_{z} > L_{Ta}$, set $T_{z} = L_{Ta}$

40. If $z_{w} \leq 0$ and

40. a. If $|z_{w}| > \Delta y_{1}$ and $y < \tau_{w} + |z_{w}/2|$, set

$$A_{bp} + A_{bs} + A_{bn} = A_{bto} \left[ 1 + \sum_{j=w}^{j} \Delta y_{j}/z_{w} - \Delta y_{w}/2z_{w} \right]$$

$$- A_{bm} \left[ \sum_{j=w}^{j} \Delta y_{j}/z_{w} - \Delta y_{w}/2z_{w} \right]$$

40. b. If $|z_{w}| < \Delta y$, or if $y \geq \tau_{w} + |z_{w}/2|$, set

$$A_{bp} + A_{bs} + A_{bn} = A_{bm}$$

41. If $z_{w} > 0$ and

41. a. If $z_{w} > \Delta y_{1}$ and $y < \tau_{w} + z_{w}/2$, set

$$A_{bp} + A_{bs} + A_{bn} = A_{bto} \left[ 1 - \sum_{j=w}^{j} \Delta y_{j}/z_{w} + \Delta y_{w}/2z_{w} \right]$$

$$+ A_{bto} \left[ \sum_{j=w}^{j} \Delta y_{j}/z_{w} - \Delta y_{w}/2z_{w} \right]$$

41. b. If $z_{w} \leq \Delta y_{1}$ or $y \geq \tau_{w} + z_{w}/2$, set

$$A_{bp} + A_{bs} + A_{bn} = A_{bto}$$
42. a. Compute a first estimate of $P_{on}$ during tailoff

$$P_{on} = [a_p C*(A_{bp} + A_{bs} + A_{bn})/A^*]^{1/(1-n)}$$

42. b. Set $P_h = P_{on}$

43. a. Compute $m_D = A^*P_{on}/C^*$

43. b. $\Delta P_c/\Delta y = [P_{on}/(1-n)(\bar{A}_{bp} + \bar{A}_{bs} + \bar{A}_{bn})] \Delta(A_{bp} + A_{bs} + A_{bn})/\Delta y$

43. c. $r_h = aP_{on}^n$

43. d. $r_n = r_h$

44. $m_G = \rho_p r_{av} (A_{bp} + A_{bs} + A_{bn})$

45. Not used

46. Repeat steps 27b through 29, then 47a, b, and c below as required until 28 is satisfied

47. a. $P_{on}^j = P_{on}^{(j-1)} + (\Delta P_c/\Delta y)\Delta y_j$

47. b. $P_h = P_{on}$

47. c. Repeat steps 43b through 46

48. a. Repeat steps 31a through 33, 36 and 38

48. b. Repeat steps 40 through 47c for other values of $j > w$ until $P_{on} < 30$ psia, or

$$|\Delta P_c/\Delta y| > \left|\Delta P/\Delta y\right|_{out}$$, or

$$y = x_{out}$$, or

$$(A_{bp} + A_{bs} + A_{bn}) = 0$$

If any of the conditions in step 48b are met, begin "half-second trace."

49. a. Set $P_{ht} = P_h$

49. b. Set $t_t = t$
49. \( c. \quad P_n = P_{ht} \exp\left[-r^2C*^2\frac{t - t_l}{V_c}\right] \)

49. \( d. \quad \text{Set } P_{on} = P_n \)

49. \( e. \quad \text{Compute } \dot{m}_D = P_{on} \frac{A^*/C^*}{\dot{m}_D} \)

49. \( f. \quad \text{Compute } t = \sum \Delta t_j \)

49. \( g. \quad \text{Set } \Delta t_j = 0.5 \text{ sec.} \)

49. \( h. \quad \text{Repeat steps 49c through 49g ten times or until } P_h \leq 30 \text{ psia} \)

50. \( \text{Not used} \)

51. \( a. \quad \text{Calculate weight of propellant burned} \)

\[ W_{pl} = \rho_c \sum \dot{m}_D \Delta t_j \]

51. \( b. \quad W_{p2} = \rho_p \rho_c \sum (\bar{A}_{bp} + \bar{A}_{bs} + \bar{A}_{bn}) J \Delta y_j \)

51. \( c. \quad W_p = (W_{pl} + W_{p2})/2 \)

52. \( a. \quad \text{Compute} \)

\[ I_{spav} = I_T / W_p \]

52. \( b. \quad I_{spav \ vac} = I_T \ vac / W_p \)

53. \( \text{Determine the maximum head end pressure } P_h \max \)

\textbf{Inert Weight Calculations}

54. \( \text{Calculate the maximum expected instantaneous pressure at the upper limit of initial grain temperature} \)

\[ P_{meop} = P_h \max \left[1 + n_1 (\sigma / P)\right] \exp\left[\left(n_1 P / K T_i\right)\Delta T_i\right] \]
55. Calculate the minimum expected case material yield strength

\[ S_{yc} = S_{yc}^{nom} \left[ 1 - n_2 \left( \frac{\sigma_c}{S_{yc}} \right) \right] \]

56. Compute the nominal thickness of the cylindrical portion of the case

\[ \tau_{cc} = \psi_c P_{meop} D_{cc} / 2S_{yc} \]

57. Compute the weight of the case material in the cylindrical length including forward and aft segment joints

\[ W_{cc} = \pi \tau_{cc} D_{cc} \delta_{cc} L_{cc} \left[ 1 + \left( n_{seg} - 1 \right) \frac{h_0}{L_{cc}} \right] \]

Note: A joint is considered \( \frac{1}{4} \) nominal case thicknesses thick and 10 nominal case thicknesses long.

58. Compute the hoop-stress thickness requirement for the head end and aft end closures.

\[ \tau_{cd} = \psi_c P_{meop} D_{cc} / 4S_{yc} \]

59. Compute the weight of the head end dome

\[ W_{ch} = 2.5 \pi D_{cc}^2 \delta c \tau_{cd} / 2 \]

Note: The 2.5 multiplying factor is an allowance for the igniter boss and forward thrust skirt attachment joint ("Y" joint). A similar but larger (4.5) allowance is made in the aft closure weight calculation for the nozzle and aft thrust skirt attachment joint. In case only one skirt is used, the dual allowance should still roughly approximate the net weight requirement because of the greater load carrying requirement placed on the single thrust reacting element.

60. Compute the estimated weight of the nozzle closure

\[ W_{cn} = 4.5 \pi D_{cc} h_{cn} \tau_{cd} \delta c / 2 \]

61. Compute the total estimated weight of the motor case

\[ W_c = W_{cc} + W_{ch} + W_{cn} \]
62. Compute the nozzle expansion ratio
\[ \varepsilon = \frac{A_c}{A^*} \]

63. Compute the estimated weight of the nozzle
\[ W_n = K_1 D^{*2} \left[ K_2 t_f \psi_a + (\varepsilon - \varepsilon^*) \frac{D^{*2}}{S_y} \right] / \left[ 1 + (\sin a_n)/2 \right] \]

64. Compute the estimated weight of the case insulation
\[ W_{ins} = t_f \psi_{ins} \delta_{ins} \frac{\pi D_{cc}}{2} \left\{ K_{en} \left[ 0.80 D_{cc}/2 + (s + n_e) (s/2) \right] + 0.15 (L_{cc} - \tau_w s - \tau_w n_s)/\psi_{ins} \right\} + K_{en} 0.80 h_{cn} \]

Note: Head and nozzle end domes are assumed exposed for 80 percent of \( t_b \). The cylindrical length, exclusive of the areas exposed by circumferential slot burning, is assumed exposed for 15 percent of \( t_b \) with no safety factor. No allowance is made for final thermal protection of exposed areas for which an allowance may be included in \( W_a \).

65. Compute the estimated weight of the liner
\[ W_L = \tau_L \delta_L \frac{\pi D_{cc}}{2} \left[ D_{cc}/2 + L_{cc} + h_{cn} \right] \]

66. Compute the estimated total motor weight
\[ W_m = W_c + W_n + W_{ins} + W_L + W_a + W_p \]

67. Compute the motor mass fraction
\[ \varepsilon_M = \frac{W_p}{W_m} \]

68. Compute the total impulse to motor weight ratio \( I_T/W_M \).
The geometric relations described below are treated in the computer program as a major subroutine. It should be noted that end effects are treated by approximations both in the specification of input variables and in several instances in the mathematical relationships used.

AO.a. Select an option for the type of input.
   If only tabular input, set $I_{op} = 1$
   If only equation input, set $I_{op} = 2$
   If a combination input, set $I_{op} = 3$

AO.b. Select an option for the grain configuration.
   If only a circular perforated grain, set $G_{op} = 1$
   If only a star grain, set $G_{op} = 2$
   If a combination grain, set $G_{op} = 3$

AO.c. Select an option for the type of star.
   If a standard star, set $S_{op} = 1$
   If a truncated star, set $S_{op} = 2$

AO.d. Select an option for the grain arrangement.
   If a star grain is at head end of the chamber and a circular perforated grain at nozzle end, set $Q_{op} = 1$
   If circular perforated grains are at both ends of the chamber, set $Q_{op} = 2$
   If a circular perforated grain is at the head end of the chamber and a star grain is at the nozzle end, set $Q_{op} = 3$
   If star grains are at both ends of the chamber, set $Q_{op} = 4$

AO.e. Specify the number ($n_m$) of thrust termination passageways in the grain.

AO.f. Specify tabular input values of burning surface areas $A_{bpT}$, $A_{bsT}$, and $A_{bnT}$ versus $y$. Set each equal to zero if $I_{op} = 2$. 
AO.g. If $I_{op} = 1$, specify the head end and nozzle end controlling port areas $A_{phT}$ versus $y$.

A1. If $I_{op} = 1$, set $\Delta A_{bT} = A_{bpc} = A_{bps} = A_{bsc} = A_{bsb} = A_{bnc} = A_{bns} = 0$

Go to step A51

A2. If $I_{op} = 2$ or 3

Go to step A3a

A3.a. If $G_{op} = 1$ or 3

Go to step A4

A3.b. If $G_{op} = 2$, set $A_{bpc} = A_{bsc} = A_{bnc} = 0$

Go to step A7

A4. Compute the burning surface areas of tubular grain segments:

A4.a. For slots

$$A_{bsc} = \pi S/[D_{o}^{2}-(D_{i} + 2y)^{2}] /4 \text{ for } A_{bsc} > 0$$

$$A_{bsc} = 0 \text{ for } A_{bsc} \leq 0$$

A4.b. For perforations

If $2y + D_{i} > D_{o}$, set $A_{bnc} = A_{bpc} = 0$

Go to step A5

If not and if $\theta_{G} \leq 5^\circ$ (See Figure II-1) compute

$$L_{Gc} = L_{Gci} - y(\cot \theta_{cn} + \cot \theta_{ch}) \text{ and}$$

$$A_{bpc} = \pi(D_{i} + 2y)[L_{Gc} - T_{L} - Sy] \text{ for } A_{bpc} > 0$$

$$A_{bpc} = 0 \text{ for } A_{bpc} \leq 0, \text{ or}$$

If $\theta_{G} > 5^\circ$, compute

$$A_{bpc} = \pi(D_{i} + 2y)[L_{Gci} - y \cot \theta_{ch} - T_{L} - [S + \tan (\theta_{G}/2)]y] \text{ for } A_{bpc} > 0$$

$$A_{bpc} = 0 \text{ for } A_{bpc} \leq 0$$

A4.c. For the nozzle end surface

If $\theta_{G} \leq 5^\circ$, set $A_{bnc} = 0$
If $\theta_G > 5^\circ$, compute

$$A_{bnc} = \pi \left[ L_{Gni} - y \cot (\theta_G + \theta_{cn}) 
- y \tan (\theta_G/2) \right] [D_i + AD_i + y 
+ L_{Gni} \sin \theta_G + y \csc (\theta_G + \theta_{cn}) \sin \theta_{cn}]$$

for $A_{bnc} > 0$

Note: the above equation represents the entire surface as conical although a non-conical surface area evolves if $\theta_G + \theta_{cn} > \pi/2$.

$$A_{bnc} = 0$$

for $A_{bnc} < 0$

A5. Compute the controlling port areas

A5.a. If $Q_{op} = 1$ or 4

If $Q_{op} = 2$ or 3, compute

$$A_{ph} = \pi \left[ D_i + 2 \sum_j \frac{R_j}{h_j} \Delta t_j \right]/4$$

for $A_{ph} < \pi D_o^2/4$

$$A_{ph} = \pi D_o^2/4$$

for $A_{ph} > \pi D_o^2/4$

A5.b. If $Q_{op} = 3$ or 4

If $Q_{op} = 1$ or 2, compute

$$A_{pn} = \pi \left[ D_i + AD_i + 2 \sum_j \frac{R_j}{n_j} \Delta t_j \right]/4$$

for $A_{pn} < \pi D_o^2/4$

$$A_{pn} = \pi D_o^2/4$$

for $A_{pn} > \pi D_o^2/4$

A6. If $G_{op} = 1$,

A7.a. If $G_{op} = 2$ or 3 and $S_{op} = 1$

A7.b. If $G_{op} = 2$ or 3 and $S_{op} = 2$

A8. Compute the star point half angle (See Figure II-3)

$$\theta_s = \pi/n_p$$

A9. Compute the approximate length of star sides

$$l_s = R_c - r_s - f - R_p$$
A10. Compute the angular location of the burning slot sides

\[ \theta_{sl} = \theta_s - \arcsin \left( \frac{f+y}{R_p+y} \right) \]

A11. Compute the perimeter of the grain. (If \( \theta_{sl} < 0 \), Go to step A22)

A11.a. If \( y \leq \tau_s \), compute

\[ S_G = 2n_p \left\{ (R_p + y) \theta_{sl} + \ell_s - [(R_p + y) \cos (\theta_s - \theta_{sl}) - R_p] + \pi(f+y)/2 \right\} \]

Go to step A14

A11.b. If not, compute

\[ \theta_c = \arcsin \left\{ \left[ R_c^2 - (\ell_s + R_p)^2 - (f+y)^2 \right] / 2(f+y)(\ell_s + R_p) \right\} \]

A12. If \( \theta_c \geq 0 \), compute

\[ S_G = 2n_p \left\{ (R_p + y) \theta_{sl} + \ell_s - [(R_p + y) \cos (\theta_s - \theta_{sl}) - R_p] + (f+y) \theta_c \right\} \]

Go to step A14

A13.a. If \( \theta_c < 0 \) and \( y < R_c - R_p \), compute

\[ S_G = 2n_p \left\{ (R_p + y) \theta_{sl} + [R_c^2 - (f+y)^2]^1/2 - [(R_p + y)^2 - (f+y)^2]^1/2 \right\} \]

Go to step A14

A13.b. If \( \theta_c < 0 \) and \( y \geq R_c - R_p \), set \( S_G = 0 \)

A14. Compute the initial burning area of flat ends of grain.

\[ A_{Gs} = \pi(R_c^2 - R_p^2) - n_p \left( \pi f^2/2 + 2\ell_s f \right) \]

A15. Compute burning slot end surface areas

\[ A_{bss} = n_s \left[ A_{Gs} - \sum_j S_{Gj} \bar{r}_{avj} \Delta t_j \right] \]

Set \( A_{bss} = 0 \) if \( A_{bss} < 0 \) or \( S_G = 0 \)

A16. Compute burning flat nozzle end surface area

\[ A_{bns} = n_n \left[ A_{Gs} - \sum_j S_{Gj} \bar{r}_{nj} \Delta t_j \right] \]

Set \( A_{bns} = 0 \) if \( A_{bns} < 0 \) or \( S_G = 0 \)

Go to step A31

A17,18,19 Not used.
A20. Compute the half angle of the standard star grain (See Fig. II-2).

$$\theta_s = \pi / n_p$$

A21. Compute the radial position of the fillet center

$$r_f = R_c - \tau_w - f$$

A22. Compute the grain perimeter (Equation A22a and A22b are taken from Reference 6, p. 303)

A22.a. If \((y+f)/r_f < (\sin \theta_f)/\cos (\theta_p/2)\) and \(y < \tau_w\),

$$S_G = 2n_p r_f \{[(\sin \theta_f)/\sin (\theta_p/2) + [(y+f)/r_f][\pi/2 + \theta_s - \theta_f]/\cos (\theta_p/2)] + \theta_s - \theta_f\}$$

Go to step A23

A22.b. If \((y+f)/r_f < (\sin \theta_f)/\cos (\theta_p/2)\) and \(y \geq \tau_w\),

$$S_G = 2n_p \{2\pi [y+f] \arcsin \left[ \frac{R_c - r_f^2 - (y+f)^2}{2r_f(y+f)} \right] - \left(\theta_s - \theta_p/2\right) \}

+ \left(\frac{r_f \sin \theta_f}{\sin (\theta_p/2)} - (y+f) \cot (\theta_p/2)\right)$$

A22.c. If \((y+f)/r_f > (\sin \theta_f)/\cos (\theta_p/2)\) and \(y < \tau_w\),

$$S_G = 2n_p r_f \{[(y+f)/r_f][\theta_s + \arcsin (\frac{r_f}{y+f} \sin \theta_f)] + \theta_s - \theta_f\}$$

Go to step A23

A22.d. If \((y+f)/r_f > (\sin \theta_f)/\cos (\theta_p/2)\) and \(y \geq \tau_w\),

$$S_G = 2n_p (y+f) \left\{ \theta_f + \arcsin \left( \frac{r_f}{y+f} \sin \theta_f \right) \right\}

- \arccos \left( \frac{R_c - r_f^2 - (y+f)^2}{2r_f(y+f)} \right) \text{ for } S_G > 0$$

If \(S_G < 0\), Go to step A23

A23. Compute the initial burning areas of slots and flat nozzle end.

$$A_{Gs} = \pi R_c^2 - n_p \pi r_f \{\sin \theta_f [\cos \theta_f - (\sin \theta_f) \cot (\theta_p/2)] + \theta_s - \theta_f + \left(2f/r_f\right) [(\sin \theta_f)/\sin (\theta_p/2)

\theta_s - \theta_f + (f/2r_f)[\pi/2 + \theta_s - \theta_p/2 - \cot (\theta_p/2)]}$$

...
A24. Compute the burning slot surfaces

\[ A_{bss} = n_s [A_{Gs} - \sum J S_{Gj} \bar{r}_{nj} \Delta t_j] \text{ for } A_{bss} > 0 \]

\[ A_{bss} = 0 \text{ for } A_{bss} \leq 0 \]

A25. Compute the burning flat nozzle end surface

\[ A_{bns} = n_n [A_{Gs} - \sum J S_{Gj} \bar{r}_{nj} \Delta t_j] \text{ for } A_{bns} > 0 \]

\[ A_{bns} = 0 \text{ for } A_{bns} \leq 0 \]

A26-30 Not used

A31. Compute the port burning surface areas

\[ A_{bps} = [L_{Gsi} - T - y (n_s + n_n)] S_G \text{ for } A_{bps} > 0 \]

\[ A_{bps} = 0 \text{ for } A_{bps} \leq 0 \]

A32-35 Not used

A36. Compute the controlling port areas of the grain segments

A36.a. If \( Q_{op} = 2 \) or 3

If \( Q_{op} = 1 \) or 4, compute

\[ A_{ph} = \pi R_c^2 - A_{Gs} + \sum J S_{Gj} \bar{r}_{nj} \Delta t_j \text{ for } A_{ph} < \pi R_c^2 \]

\[ A_{ph} = \pi R_c^2 \text{ for } A_{ph} > \pi R_c^2 \text{ or } S_G \leq 0 \]

Go to step A36b

A36.b. If \( Q_{op} = 1 \) or 2

If \( Q_{op} = 3 \) or 4, compute

\[ A_{pn} = \pi R_c^2 - A_{Gs} + \sum J S_{Gj} \bar{r}_{nj} \Delta t_j \text{ for } A_{pn} < \pi R_c^2 \]

\[ A_{pn} = \pi R_c^2 \text{ for } A_{pn} > \pi R_c^2 \text{ or } S_G \leq 0 \]

Go to step A50
A37-49 Not used

A50.a. If there are no thrust termination passageways in the grain \((N_T=0)\),

Go to step A51

A50.b. If \(n_T \neq 0\), compute change in \(A_p\)

\[
\Delta A_{bT} = n_T \pi [(D_{Tp} + 2y)(l_{Tp} - y/\sin \theta_{Tp})
- (D_{Tp} + 2y)^2/4 + (y + D_{Tp}/2)(D_{Tp}/2)(1 - 1/\sin \theta_{Tp})]
\text{for } y \leq r_{Teff}
\]

\[
\Delta A_{bT} = 0 \text{ for } y > r_{Teff}
\]

A51. Compute special equation surface area inputs \(B_{bp}, B_{bs}, \text{ and } B_{bn}\)

Note: the B's are all set equal to zero in the present program but the zeros may be replaced by any functions of \(y\) desired simply by changing three program statements giving the B's

A52. Compute the total surface areas

A52.a. \(A_{bp} = A_{bpT} + A_{bpc} + A_{bps} + \Delta A_{bT} + R_{bp}\)

\(A_{bs} = A_{bsT} + A_{bsc} + A_{bs} + R_{bs}\)

\(A_{bn} = A_{bnT} + A_{bnc} + A_{bns} + R_{bn}\)

Note: the present analysis treats \(A_{bp}\) and \(A_{bs}\) identically. They are kept separate, however, to permit possible alternate treatment.

A53. Compute the burning surface areas applicable to tailoff surface area calculations

If \(z_w \geq 0\), set

\[
A_{bm} = (A_{bp} + A_{bs} + A_{bn})\bigg|_y - \sum_{j=w}^{j} \Delta y_j/2
\]

\[
A_{bto} = (A_{bp} + A_{bs} + A_{bn})\bigg|_y + (z_w/2) - \sum_{j=w}^{j} \Delta y_j/2
\]

If \(z_w < 0\), set

\[
A_{bm} = (A_{bp} + A_{bs} + A_{bn})\bigg|_y - (z_w/2) - \sum_{j=w}^{j} \Delta y_j/2
\]

\[
A_{bto} = (A_{bp} + A_{bs} + A_{bn})\bigg|_y - \sum_{j=w}^{j} \Delta y_j/2
\]
IV. THE COMPUTER PROGRAM

This section contains the instructions for preparation and arrangement of the data cards. Also a complete listing of the program statement is given followed by flowcharts showing the sequence of computer operations.

Data Card Usage

The data formats have been established to allow the operator to look at the card and know which variables are represented on it. The format should be followed to insure correct reading of the inputs. The various data cards are as follows: (See Table IV-1 for the complete format)

I. Number of configurations
II. Initial zero values
III. Propellant data
IV a&b. Motor geometry (2 cards)
V a&b. Performance data (2 cards)
VI. Input, grain, etc.
VII a&b. Data for tabular input (2 cards)
VIII a&b. Tubular grain input (2 cards)
IX. General star data
X. Truncated star data
XI. Standard star data
XII. Termination port data
XIII a-e. Data for weight calculations (5 cards)

Cards II-VI must accompany each and every configuration even if only one parameter changes. If INPUT = 1 or 3, a number of sets of data cards VII a&b are used. Consider a test run on three different configurations:

a. A combination grain with only tabular inputs.
b. A combination circular perforated and standard star grain with only equation inputs (no termination ports).
c. A truncated star grain with two termination ports using both tabular and equation inputs.
The correct order for the data cards is:

<table>
<thead>
<tr>
<th>Configuration a</th>
<th>Configuration b</th>
<th>Configuration c</th>
</tr>
</thead>
<tbody>
<tr>
<td>1. I</td>
<td>12. II</td>
<td>21. II</td>
</tr>
<tr>
<td>2. II</td>
<td>13. III</td>
<td>22. III</td>
</tr>
<tr>
<td>3. III</td>
<td>14. IV a&amp;b</td>
<td>23. IV a&amp;b</td>
</tr>
<tr>
<td>4. IV a&amp;b</td>
<td>15. V a&amp;b</td>
<td>24. V a&amp;b</td>
</tr>
<tr>
<td>5. V a&amp;b</td>
<td>16. VI</td>
<td>25. VI</td>
</tr>
<tr>
<td>6. VI</td>
<td>17. VIII a&amp;b</td>
<td>26. VII a&amp;b (y=0)</td>
</tr>
<tr>
<td>7. VII a&amp;b (y=0)</td>
<td>18. IX</td>
<td>27. IX</td>
</tr>
<tr>
<td>8. VII a&amp;b (y=y1)</td>
<td>19. XI</td>
<td>28. X</td>
</tr>
<tr>
<td>9. VII a&amp;b (y=y2)</td>
<td>20. XIII a-e</td>
<td>29. XII</td>
</tr>
<tr>
<td>10. VII a&amp;b (y=y3)</td>
<td></td>
<td>30. VII a&amp;b (y=y1)</td>
</tr>
<tr>
<td>11. XIII a-e</td>
<td></td>
<td>31. VII a&amp;b (y=y2)</td>
</tr>
<tr>
<td></td>
<td></td>
<td>32. VII a&amp;b (y=y3)</td>
</tr>
<tr>
<td></td>
<td></td>
<td>33. XIII a-e</td>
</tr>
</tbody>
</table>

Note that when tabular inputs are used alone, as in Configuration a., the sets of cards VII a&b (4 sets for Configuration a) giving the tabular inputs follow each other sequentially. When combination tabular and equation inputs are used, as in Configuration c., the sets of cards VII a&b for y=0 follows card VI and the remaining sets of cards VII a&b follow card XII or the next lower applicable number if XII does not apply. Note also that if a particular data card does not apply, no card is used. For example, X is omitted for Configuration b. and XI for Configuration c.

Program Listing

A complete program listing is presented in Table IV-2

Flowcharts

Flowcharts of the computer program are presented in Figures IV-1 through IV-3.

READ IN BASIC PROPERTIES REQUIRED FOR WEIGHT CALCULATIONS

PIPK IS THE TEMPERATURE SENSITIVITY COEFFICIENT OF PRESSURE AT CONSTANT K

DTEMP IS THE MAX EXPECTED INCREASE IN TEMPERATURE ABOVE CONDITIONS UNDER WHICH PARTIAL TRACE WAS CALCULATED IN DEGREES FAHRENHEIT

SIGMAP IS THE VARIATION IN PHMAX

SIGMAS IS THE VARIATION IN CASE MATERIAL YIELD STRENGTH

N1 IS THE NUMBER OF STANDARD DEVIATIONS IN PHMAX TO BE USED AS A BASIS FOR DESIGN

N2 IS THE NUMBER OF STANDARD DEVIATIONS IN SY TO BE USED AS A BASIS FOR DESIGN

SYCNOM IS THE NOMINAL YIELD STRENGTH OF THE CASE MATERIAL IN LBS/INCH

CCC IS THE ESTIMATED MEAN DIAMETER OR THE CASE IN INCHES

PSIC IS THE SAFETY FACTOR ON THE CASE THICKNESS

DELCC IS THE SPECIFIC WEIGHT OF THE CASE MATERIAL IN LBS/INCH

LCC IS THE LENGTH OF THE CYLINDRICAL PortIoN OF THE CASE INCLUDING FORWARD AND AFT SEGMENTS IN INCHES

NSEG IS THE NUMBER OF CASE SEGMENTS

HCN IS THE AXIAL LENGTH OF THE NOZZLE CLOSURE IN INCHES

SYNNOM IS THE NOMINAL YIELD STRENGTH OF THE NOZZLE MATERIAL IN LBS/INCH

PSIS IS THE SAFETY FACTOR ON THE NOZZLE STRUCTURAL MATERIAL

PSIA IS THE SAFETY FACTOR ON THE NOZZLE ABLATIVE MATERIAL

K1 AND K2 ARE EMPRICAL CONSTANTS IN THE NOZZLE WT. EQUATION

PSINS IS THE SAFETY FACTOR ON NOZZLE INSULATION

DELINS IS THE SPECIFIC WEIGHT OF THE INSULATION IN LBS/INCH

KEH IS THE EROSION RATE OF INSULATION TAKEN CONSTANT EVERYWHERE EXCEPT AT THE NOZZLE CLOSURE IN IN/SEC

KEN IS THE EROSION RATE OF INSULATION AT THE NOZZLE CLOSURE IN IN/SEC

CLINER IS THE SPECIFIC WEIGHT OF THE LINER IN LBS/INCH

TAUL IS THE THICKNESS OF THE LINER IN INCHES

WA IS ANY ADDITIONAL WEIGHT NOT CONSIDERED ELSEWHERE IN LBS

V. TEST CASES

In this section two test cases of the simplified computer program are presented. The complete input data and samples of the printout are tabulated. Plots of chamber pressure and thrust versus time are presented and compared with the results of others. Similar comparisons are made for weight calculations and related calculated values.

The first test case is for a 156 inch diameter SRM and the second for a 31 inch diameter SRM. For the latter, actual static test results are available for comparison. For the former, the comparison must be based on other theoretical results because the SRM has not been constructed.

Test Case 1 - SRM Number 1

SRM 1 is based on a design presented in Reference 4. The basic design is depicted on Figure V-1 and input data is tabulated in Table V-1. This design is of the general type under consideration for use by NASA as the Space Shuttle Booster. This particular SRM was selected because a relatively complete set of the required input data is presented in the reference as well as prediction results which are needed for comparison with the results of the simplified computer program. Also, the design is one which will test the use of the program for a combination circular perforated and star grain.

The SRM has three center segments consisting of circular perforated grains, an aft segment with a circular perforated grain and a forward segment with a truncated (slotted tube) star grain. Representation of the grain design is a straightforward process in this case. The aft dome must, however, be represented by a conical closure which is specified by selection of the angle $\theta_{cn}$. Also, since a star grain is located in the forward dome an effective grain length must be specified and the star grain treated as being flat at both ends. Since this can introduce substantial error an adjustment is made by introduction of tabular input values. In this case the tabular inputs were based on a simple linear approximation to the effect of the curvature using as a guide the values of star grain perimeter obtained from a previous run in which the effect was neglected. The effect of the cutback in the grain inside diameter to accommodate the submerged nozzle was neglected in this case but the taper in the remaining portion of the grain, which substantially affects tailoff characteristics, was taken into account by specification of $X_{Ta}$ and $I_{Ta}$.

The value of nozzle throat diameter used was 47.00 inches which differs from the 45.01 inches given in Reference 4. This substitution was made based on information received from NASA which indicated that the higher value had been used in predicting the performance data given in Reference 4. The program was tested with the erosion constants equal to zero because it is apparent that the predictions of Reference 4 were based on little or no propellant erosion.
A simple printout of the transients values for the initial portion of the trace computed by the program is given in Table V-2, and on Figure V-2 the chamber pressures and thrust versus time results are plotted and compared with results taken from Reference 4. The reference gives only one chamber pressure which is presumably the nozzle end stagnation pressure. It will be noted that the results for nozzle end stagnation pressure and thrust are in agreement within 5% except for the period between 110 to 125 seconds where the variation is somewhat greater. A large portion of the larger variation can be attributed to the approximations made in representing the effects of the closures. The remaining portion of the variation here as well as the small difference throughout the traces are more difficult to explain but are probably attributable to differences in analytical technique although a possibility exists that there could be some differences in the input data used.

It is notable that there is good agreement in the web time calculated by the several approaches. Weight and related calculated values are tabulated as Table V-3. Comparison with corresponding data from Reference 4 are made later in this section.

Test Case 2 - SRM Number 2

SRM 2 is based on design of the TX354-5 rocket motor as presented in Reference 9. The basic design is depicted on Figure V-3 and input data is tabulated in Table V-4. This SRM was selected because of the availability of a relatively complete set of input data as well as specific test results.

The grain has, in general, a cylindrical port with two radial slots. The main propellant grain geometry was represented by the circular perforated grain equations. The effect of the forward closure was represented by selection of $O_{ch}$. Radii at the slots were neglected except at the aft face of the aft slot. Here the geometry of the entire portion of the propellant aft of the aft slot was represented by tabular input values because the step change in port area does not permit accurate representation through the equation inputs. In specification of $x_{Ta}$ the effect of the tapered insulation thickness at the bottom of the aft slot was taken into account so that $x_{Ta}$ was taken somewhat larger than it would have been based on the inside taper alone.

As data on the erosive burning constants of the propellant was not available, arbitrary values were devised to give a moderate erosion rate. These values are listed under ALPHA and BETA in Table V-4. The tests were also run with ALPHA and BETA both assigned zero values; i.e., no erosive burning. A sample printout of the transients values calculated for the final portion of the trace is given in Table V-5. These are for finite values of ALPHA and BETA. On Figure V-4 the head end pressure and thrust versus time results are plotted and compared with static test results reported in Reference 9. The chamber pressure results of the typical test given in the reference are in this case presumably head end pressure since this is the pressure routinely recorded in standard test firings.
Comparison of the program output with the test data of Reference 9 shows that both sets of assumed values for erosive burning constants give only fair representation of test data for the initial portion of the trace. (It should be noted that the initial peaks in the test results may be at least partially attributable to the ignitor, effects of which are not considered in the program). The agreement for the remaining portion of the trace is again within 5% except for a small portion of the trace shortly before tail-off. The larger variation near tailoff may be traced directly to the approximation of the effect of the forward closure made by the specification of $\delta_{ch}$. Here an adjustment could be easily introduced to correct precisely or approximately for the effect through use of the tabular input values. This was not done in the test case so that the result of the approximation could be evaluated by the reader.

Again there is good agreement in the web time calculated by the program and that given by the reference. The agreement is poorer in case of action time probably due principally to neglect of the effect of chamber wall heating on chamber depressurization in the simplified program.

**Comparisons of Weights and Related Values**

Weights and related values for both test cases are tabulated in Table V-3. The values for SRM 2 are based on the finite erosion rates.

Generally excellent agreement is found between the program and the reference results for propellant weights and impulse values for both SRMs. For SRM 1, a substantial difference in the value of $P_{mep}^0$ exists which results in rather large differences in the case thicknesses, case weights and nozzle weights. It is believed that this may be principally the results of differences in the ballistic variability factors used in the two predictions. The rather large difference in insulation weights for SRM 1 is attributed to neglect of requirements for final thermal protection in the present program. (See step 64, Section III and $W_a$, Section II).

For SRM 2 substantial differences exist in the case and nozzle weights resulting in a similar difference in total motor weight. The difference in case weight is attributable to two factors: 1) the use of approximately 10 percent additional basic chamber thickness in the actual motor to allow for manufacturing variations, and 2) the use of a thick wall case segment (0.25 inches in thickness) to accommodate a thrust ball bracket and related hardware. The difference in nozzle weight is principally the result of the assumption for the present program of a nozzle design radically different from that used in the TX354-5. (See $K_1$ and $K_2$, Section II).

Additional testing of the program was accomplished in the process of compiling the design performance data given in the Appendix.

VI. CONCLUDING REMARKS

The SRM design and analysis program presented in this report is based in part on approximate equations and methods but gives a reasonable description of SRM performance. Computational times are reasonably short. The designer should be able to acquire quickly the skills necessary to prepare input data.

Additional comparisons should be made between program and actual test results to establish clearly the accuracy of the program.

Obvious improvements possible in the program fall into two categories: 1) several modifications may be made to reduce the number of input variables without compromising accuracy, and 2) the method of handling the end conditions can be made more accurate. Most, but not necessarily all, changes in the latter category are toward more sophisticated programs which it was the objective of this analysis to avoid.

APPENDIX

DESIGN DATA COMPILATION

Here the effects of changes in various design parameters are examined and the results compiled in the form of traces of nozzle end stagnation pressure versus time. The baseline SRM used in the analysis is the same as SRM 1 of Section V. Except as noted below, the effect of each design parameter is determined separately; that is, all other input parameters given in Table V-1 are kept the same while computations are made for different values of the parameter under consideration. Also, the parameters selected for variation have in general only minor influence on the propellant volume so that the designs analyzed all load approximately the same amounts of propellant. The stagnation pressure at the nozzle end of the grain was selected for plotting versus the burning time because this characteristic is most descriptive of SRM performance. For example, the vacuum thrust may be obtained by multiplying the stagnation pressure by the product of the vacuum thrust coefficient and throat cross-sectional area. This product is a constant at a given time for all the variations considered except in the case of changes in the radial erosion rate of the nozzle throat. Study of the resulting plots should provide a guide to the designer in predicting at least the qualitative effects of changes in the various design characteristics on the performance of SRMs of the general type considered.

Radial Erosion Rate

Figure A-1 shows the effect of the radial erosion rate \( E_n = \text{RADA} \) on the stagnation pressure at the nozzle end of the grain at various times.

As can be seen, the effect is substantial during the latter portion of the trace, the higher erosion rates producing significant lower stagnation pressure as the burning progresses. The effect on thrust, however, will be much less throughout the trace because of the larger throat areas which accompany higher erosion rates. Of somewhat more significance is the influence of radial erosion rate on the burning time of the SRM. As seen from the plot, the burning time variation is approximately four percent over the range of erosion rates considered.

Initial Grain Temperature

This parameter was investigated by adjusting the burning rate coefficient \( \alpha = \lambda \) according to the relationship

\[
\alpha = \alpha_o \exp \left[ \left( \frac{\pi}{\rho} \right)_k (1-n)\Delta T_i \right]
\]
where \( a \) is the burning rate of the baseline design, which is based on an initial temperature of 70°F, and \( \Delta T \) is the variation from this temperature. The results are shown on Figure A-2 for various initial grain temperatures. The generally higher pressures and reduced burning times at the higher initial grain temperatures are evident from the plot.

**Number of Burning Slot Faces**

The results are shown on Figure A-3. An increase in the number of burning slot faces \( (S=S) \) in the circular perforated grain section of the baseline design produces initially higher chamber pressures because of the added burning surface area, but the trace is more regressive because of the additional decrease in propellant length with distance burned. It is of interest that the net effect is an essentially constant burning time over the range of this parameter considered.

**Number of Star Points**

Influences of the number of truncated star points \( (n_p = N_P) \) on the trace of nozzle end stagnation pressure versus time for a fixed length of the star grain in the baseline design is shown on Figure A-4. The results are qualitatively similar to those of the variations in the number of burning slot faces \( (S=S) \) in the circular perforated grain section.

**Length of Star Grain**

Influences of changes in the initial length of the star grain \( (L_{Gsi}=L_{GSI}) \) were evaluated for a fixed overall grain length \( (L_{Gsi} + L_{Gci} = 1196.50 \text{ inches}) \). The results plotted in Figure A-5 confirmed the expected higher initial pressures and greater regressivities accompanying the greater lengths of star grain.

**Taper**

Effects of taper were investigated by independently varying the aft end taper and the taper of the main portion of the grain. The former variation involved changes in the difference in web thickness \( (X_{Ta} = XT) \) over the aft end tapered length and the latter involved changes in the differences in web thickness \( (z_0 = ZO) \) over the remaining portion of the grain. The results are shown in Figures A-6 and A-7 for the final portion of the traces which is the only part where a substantial effect is produced. The pressure changes for the initial portion of the traces were less than 1.7 percent over the range of variations considered, these changes being produced by changes in the parameter \( \Delta D_i = \Delta EL_Di \) corresponding to and equal to the changes in the parameter \( z_0 = ZO \). It should be noted that the effects of \( z_0 \) variations are
coupled with the effects of an $X_Ta$ value of 5.0 inches which is the value for the baseline design. Influences of the two types of changes are similar except that $z_0$ increases produce much greater regressivities and burning times. The longer burning times result from the burning rate reductions which accompany the reduced pressures. It is noteworthy that if each center grain segment were tapered identically with a $z_0$ over each segment equal to the $z_0$ corresponding to a continuous taper over the entire grain length (the present case) the results would be essentially the same, and therefore the alternate design could be treated by the simplified computer program.

**Thrust Termination Passageways**

Figure A-8 illustrates the effects produced by use of two thrust terminations in conjunction with SRM 1. The passageways were assigned the same diameter ($D_{TP} = D_{TP}$) as the nozzle throat. The angle between the axis of the passage and the motor axis ($\theta_{TP} = \theta_{TP}$) was taken as $45^\circ$. The effective web thickness ($\tau_{Teff} = \tau_{Teff}$) was assigned various values. The discontinuities in the resultant traces occurring at $y = \tau_{Teff}$ are the result of the method used to approximate the effects of the passage geometry in the simplified analysis and will not occur in actual firings. To obtain a better approximation, the traces should be smoothed out for some distance ahead of the discontinuity depending on the precise geometrical situation, i.e., the location of the axis of the passage with respect to the head end of the motor.

**Erosive Burning**

Erosive burning was investigated by arbitrary variation of the constants ($a_{eb} = \text{ALPHA}$ and $\beta = \text{BETA}$) in the Robillard-Lenoir burning rate equation. The values $a = 7.7$ and $\beta = 68.7$ are the approximate values given by Peretz (Reference 7) for a composite unmetallized 78% ammonium perchlorate - 22% polyester propellant. Computations were made for these values and for changes of 50% in each variable. The results are shown in Figure A-9 along with the baseline results.
