Foreword

JPL Bibliography 39-16 describes and indexes the formalized technical reporting, released January through December 1974, that resulted from scientific and engineering work performed, or managed, by the Jet Propulsion Laboratory. Five classes of publications are included:

(1) Technical Reports (32-series), in which the information is complete for a specific accomplishment and is intended for a wide audience.

(2) Technical Memorandums (33-series), in which the information is complete for a specific accomplishment but is intended for a limited audience to satisfy unique requirements.

(3) Articles from the bimonthly Deep Space Network (DSN) Progress Report (42-series). Each collection of articles in this new class of publication beginning with 42-20 presents a periodical survey of current accomplishments by the Deep Space Network. Formerly, each collection of articles was published as a separate volume of Technical Report 32-1526. The last of the 32-1526 volumes (Volume XIX) is indexed in this bibliography.

(4) Special Publications (43-series), a new class of publication, in which the information is complete for a specific accomplishment and is presented in a special format to emphasize its unique character and direction.

(5) Articles published in the open literature.

The publications are indexed by: (1) author, (2) subject, and (3) publication type and number. A descriptive entry appears under the name of each author of each publication; an abstract is included with the entry for the primary (first-listed) author. Unless designated otherwise, all publications listed are unclassified.

JPL personnel can obtain loan copies of formal documents cited from the JPL Library. Personnel of outside organizations can obtain information copies of documents cited by addressing a written request to the Technical Information and Documentation Division, Document Review Group, Attention: Mr. George Mitchell, Jet Propulsion Laboratory, 4800 Oak Grove Drive, Pasadena, California 91103. If documents are out of print, an alternate source for the material will be given to the requester.

ACTON, C. H., JR.

A001 Mariner Mars 1971 Optical Navigation Demonstration Final Report

Technical Memorandum 33-683, April 15, 1974

For abstract, see Born, G. H.

ADAMS, J. B.

A002 Visible and Near-Infra-Red Transmission and Reflectance Measurements of the Luna 20 Soil

J. B. Adams (Fairleigh Dickinson University, Virgin Islands), P. M. Bell (Carnegie Institution of Washington), J. E. Conel, H. K. Mao (Carnegie Institution of Washington), T. B. McCord (Massachusetts Institute of Technology), and D. B. Nash

Visible and near-infrared spectra of chemically analyzed grains of glass and minerals from the Luna 20 sample were compared with diffuse reflectance spectra of the bulk soil. As in the spectra of soil samples from other localities on the Moon, pyroxene contributes two broad absorption features near 1 μm. The soil has a high integral reflectance (or albedo) arising from plagioclase, which appears to be the dominant mineral in the lunar highlands. The Luna 20 soil curve is most similar to the reflectance curves of the non-rayed soils at Apollo 16, in agreement with the generally similar mineralogy of these samples.

The average pyroxene composition in the Luna 20 soil, as determined from the absorption bands in the diffuse reflectance spectra, and analyses of single crystals, is more calcic than in the lithic fragments. Thus, the soil appears to have a few percent of admixed material derived from mare basalts. Comparison of the soil spectrum with telescopic curves of nearby areas reveals a close similarity; however, the Luna 20 sample is slightly younger than expected. Luna 20 may have sampled subsurface material that is fresher than the regional surface soil, or alternatively, the Luna 20 area may contain an admixture of relatively recently exposed material from a ray center.

ADEYEMI, O. H.

A003 Forward Error Correction for the Ground Communications Facility?

O. H. Adeyemi and R. J. McEliece

The tradeoffs between block error correction efficiency and block overhead for several forward error correction schemes have been calculated using the recently developed five-state Markov model for the Ground Communications Facility (GCF). The results indicate that this particular kind of error control is not suitable for the GCF.

A004 Error Control in the GCF: An Information-Theoretic Model for Error Analysis and Coding

O. H. Adeyemi

Technical Memorandum 33-699, October 15, 1974

This memorandum covers one aspect of the total effort to understand the structure of data-transmission errors within the Ground Communications Facility (GCF) and provide error control (both forward error correction and feedback retransmission) for improved communication. The emphasis is on constructing a theoretical-model of errors and obtaining from it all the relevant statistics for error control. Thus, no specific coding strategy is analyzed, but references to the significance of certain error pattern distributions, as predicted by the model, to error correction are made.

AJELLO, J. M.

A005 Formation of HO₂⁺ by Reaction of Metastable O₂⁺ Ions With H₂

J. M. Ajello, W. T. Huntress, Jr., A. L. Lane, P. R. LeBreton (California Institute of Technology), and A. D. Williamson (California Institute of Technology)

The photoionization efficiency curves of H₂⁺, O₂⁺, and HO₂⁺, have been studied in a mixture of hydrogen and oxygen over the wavelength range 650-810 Å. The HO₂⁺ ion appears at 804 Å, the threshold for ionization of H₂, by the reaction H₂⁺ + O₂ → HO₂⁺ + H. The
relative photoionization efficiency curves of \( \text{H}_2^+ \) and \( \text{HO}_2^+ \), are the same from 804 to 764 Å. Below 764 Å, production of the \( \text{a}^4\text{II}_u \) metastable electronic state of \( \text{O}_2^+ \) leads to the formation of \( \text{HO}_2^+ \) by the reaction \( \text{O}_2^+ (\text{a}^4\text{II}_u) + \text{H}_2 \rightarrow \text{HO}_2^+ + \text{H} \).

**A006 Cross-Section for the Dissociative Photoionization of Hydrogen by 584 Å Radiation: The Formation of Protons in the Jovian Ionosphere**

K. M. Monahan (University of California, Santa Barbara), W. T. Huntress, Jr., A. L. Lane, J. M. Ajello, J. M. Burke, P. R. LeBreton (California Institute of Technology), and A. D. Williamson (California Institute of Technology)

For abstract, see Monahan, K. M.

**ALLEN, J. E.**

**A007 Support of the Mariner 10 Television Enhancement Experiment**

J. E. Allen

This article describes the support provided by DSN Operations for the Mariner Venus/Mercury 1973 Television Enhancement Experiment that was conducted during the second Mercury encounter. The experiment included antenna arraying at the Goldstone Deep Space Stations (DSSs 12, 13, and 14) and signal combining at DSS 14 of the spacecraft’s uncodded 117.6-kbps high-rate telemetry data. In addition, analog recordings of symbol-synchronizer assembly outputs were made at DSSs 14 and 43 during the encounter-pass view-period overlap for later processing and correlation at JPL to improve the video data beyond the quality that could be obtained from a single recording.

**ALLEN, W., III**

**A008 The Availability of Local Aerial Photography in Southern California**

W. Allen III, B. Sledge, C. K. Paul, and A. J. Landini (City of Los Angeles)

Special Publication 43-14, December 1, 1974

Aerial photography’s potential as a primary data source for planning projects is increasingly being realized by local agencies. This report attempts to delineate a few of the major photography and photogrammetric suppliers and users located in Southern California. Also noted are recent trends in aerial photographic coverage of the Los Angeles basin area as well as the uses made of that imagery.

**ALSBERG, H.**

**A009 TEM Data Retrieval for Computer Electron Micrograph Processing**

H. Alsberg, R. E. Hartman, and R. Nathan

As a part of the broad program in biological image processing being pursued at JPL, the development of an integrated electron microscope/computer system has been undertaken. The ultimate goal of this project is the recovery of useful information concerning the structure of biological systems. A major part of the effort in this program has been directed toward the development of a satisfactory electron microscope/computer interface system for the recovery and analysis of the information contained in the electron image. This article describes the current state of the development of this system.

**ANDERSON, J. D.**

**A010 Geodetic and Dynamical Properties of Planets**

J. D. Anderson

The purpose of this article is to discuss the sources of planetary data and to present a general review of the current knowledge of planetary dynamics and geodesy. The scope of the article is limited to Mercury, Venus, Mars, and the four major planets. Future expectations in some areas are discussed briefly.

**A011 Transformation Between Orbital Parameters in Different Coordinate Systems of the General Relativistic Schwarzschild Problem**

R. M. Georgevic and J. D. Anderson

*J. Franklin Inst.*, Vol. 296, No. 4, pp. 275-286, October 1973

For abstract, see Georgevic, R. M.

**A012 Gravity Results From Pioneer 10 Doppler Data**

J. D. Anderson, G. W. Null, and S. K. Wong
Two-way doppler data received from Pioneer 10 during its encounter with Jupiter have been analyzed, and preliminary results have been obtained on the mass and the gravity field of Jupiter and on the masses of the four Galilean satellites. The ratios of the masses of the satellites to the mass of Jupiter are \((4.696 \pm 0.06) \times 10^{-5}\) for Io, \((2.585 \pm 0.06) \times 10^{-5}\) for Europa, \((7.845 \pm 0.08) \times 10^{-5}\) for Ganymede, and \((5.603 \pm 0.17) \times 10^{-5}\) for Callisto (all error estimates presented in this paper are standard errors; those for Pioneer 10 represent our evaluation of the real errors as distinguished from formal errors). The ratio of the mass of the Sun to the mass of the Jupiter system is \(1047.342 \pm 0.02\), which is in good agreement with recent determinations from the motions of asteroids.

The second- and fourth-degree zonal harmonic coefficients in the gravity field of Jupiter are \(J_2 = (1.4720 \pm 0.0040) \times 10^{-2}\) and \(J_4 = (-0.85 \pm 1.5) \times 10^{-4}\), based on an equatorial planetary radius of 71,400 km, and the derived dynamical oblateness \(f\) is \(0.0047 \pm 0.0001\) at the same radius. Any differences in the equatorial principal moments of inertia are bounded by \((B - A)/MR^2 < 4 \times 10^{-6}\). A similar bound on the third-degree zonal harmonic coefficient \(J_3 < 1.5 \times 10^{-4}\) is less precise because of a strong correlation with the location of Jupiter's rotation axis. Data from Pioneer 11 should weaken this correlation considerably, and better resolution in the overall gravitational field should result. The Pioneer 10 data are consistent with the assumption that Jupiter is in hydrostatic equilibrium at all levels.

This paper presents the time specifications of the interface timing control signals for continuous data transfer as well as for asynchronous byte transfer. A set of control logic which complies with these timing specifications has been designed for and successfully checked out in connection with the star switch controller. This control logic, which includes synchronization and noise filter operations, is described in detail. Transfer rates for variable cable lengths are listed.

The Star Switch Controller Used in the Network Control System

T. O. Anderson

The Deep Space Network: March and April 1974, DSN Progress Report 42-21, pp. 82-86, June 15, 1974

This article describes the Star Switch Controller used in the Network Control System (NCS). The NCS requirements are first discussed as are different design philosophies for multi-computer hardware interface systems. The technique adopted is then presented and the functional characteristics discussed.

Quantitative Imagery in the Bio-Medical Sciences—II. Infrared Photography as a Diagnostic Tool for the Burn Wound

V. J. Anselmo and B. E. Zawacki (University of Southern California Medical Center)

About 30 years ago, burn physicians began to realize that the depth of a burn injury, not superficial appearance, was of prime importance. Thus, there evolved a two-category burn description, partial-thickness and full-thickness. Spontaneous skin repair occurs in partial-thickness burns but not in full-thickness burns. Developments over the past few years have indicated that early primary excision of the full-thickness burn reduces the risk of infection, fibrosis, and loss of function. However, in many cases it is very difficult or impossible to differentiate clinically between full- and partial-thickness burns until 3 to 4 weeks after injury. This paper presents evidence for the use of infrared photography, enhanced in some cases by image processing, in accelerating burn diagnosis by weeks to allow early primary excision of a full-thickness wound.
ANSPAUGH, B. E.

A017 Uncertainties in Predicting Solar Panel Power Output

B. E. Anspaugh

Technical Memorandum 33-673, April 15, 1974

This memorandum examines the problem of calculating solar-panel power output at launch and during a space mission. It also examines the major sources of uncertainty and error in predicting the postlaunch electrical performance of the panel. A general discussion of error analysis is given and examples of uncertainty calculations are included. A general method of calculating the effect on the panel of various degrading environments is presented, with references supplied for specific methods. A technique for sizing a solar panel for a required mission power profile is developed.

A018 Proton Irradiation of Conventional and Lithium Solar Cells: 11–37 MeV

B. E. Anspaugh and J. R. Carter (TRW Systems)

Conventional n/p and lithium solar cells were irradiated with 11–37 MeV protons. The energy dependence of the solar cell degradation, calculated from electrical parameters and lifetime measurements is shown to be very slight. Damage coefficients for the n/p cells are calculated. Annealing characteristics of both the lithium cells and the n/p cells are presented.

ARENZ, R. J.

A019 Effect of Crosslinking Density on Biaxial Relaxation of SBR by Using Reduced Variables

R. J. Arenz

Use of reduced variables to account for the effect of crosslinking density \( \nu_e \) in a styrene–butadiene rubber (SBR) system is demonstrated for general biaxial stress states. Recently published results from stress relaxation tests on five SBR vulcanizates crosslinked to different degrees by tetramethylthiuram disulfide were superposed by using \( \nu_e \) as a reduction variable. The equilibrium shear modulus \( G_e \) calculated from the master relaxation curve at long reduced times was in satisfactory agreement with other results for SBR. The time-axis shifts were related in a linear logarithmic manner to the crosslinking density but had a slope slightly less than values previously reported for elastomer systems.

ARNOLD, J. R.

A020 Some Correlations Between Measurements by the Apollo Gamma-Ray Spectrometer and Other Lunar Observations

J. I. Trombka (Goddard Spaceflight Center), J. R. Arnold (University of California, San Diego), R. C. Reedy (University of California, San Diego), L. E. Peterson (University of California, San Diego), and A. E. Metzger

For abstract, see Trombka, J. I.

A021 The Apollo Gamma-Ray Spectrometer

T. M. Harrington (MDH Industries, Inc.), J. H. Marshall (MDH Industries, Inc.), J. R. Arnold (University of California, San Diego), L. E. Peterson (University of California, San Diego), J. I. Trombka (Goddard Space Flight Center), and A. E. Metzger

For abstract, see Harrington, T. M.

ASBRIDGE, J. R.

A022 Observations at Mercury Encounter by the Plasma Science Experiment on Mariner 10

K. W. Ogilvie (Goddard Space Flight Center), J. D. Scudder (Goddard Space Flight Center), R. E. Hartle (Goddard Space Flight Center), G. L. Siscoe (University of California, Los Angeles), H. S. Bridge (Massachusetts Institute of Technology), A. J. Lazarus (Massachusetts Institute of Technology), J. R. Asbridge (Los Alamos Scientific Laboratory), S. J. Barne (Los Alamos Scientific Laboratory), and C. M. Yeates

Science, Vol. 185, No. 4146, pp. 145–151, July 12, 1974

For abstract, see Ogilvie, K. W.

ASSEFI, T.

A023 Two-Dimensional Signal Processing With Application to Image Restoration

T. Assefi

JPL BIBLIOGRAPHY 39-16
This report presents a recursive technique for modeling and estimating a two-dimensional signal contaminated by noise. A two-dimensional signal is assumed to be an undistorted picture, where the noise introduces the distortion. Both the signal and the noise are assumed to be wide-sense stationary processes with known statistics. Thus, to estimate the two-dimensional signal is to enhance the picture.

The picture representing the two-dimensional signal is converted to one dimension by scanning the image horizontally one line at a time. The scanner output becomes a nonstationary random process due to the periodic nature of the scanner operation. Procedures to obtain a dynamical model corresponding to the autocorrelation function of the scanner output are derived. Utilizing the model, a discrete Kalman estimator is designed to enhance the image.

AUMANN, H. H.

A024 Determination of Particle Sizes in Saturn’s Rings From Their Eclipse Cooling and Heating Curves
H. H. Aumann and H. H. Kieffer (University of California, Los Angeles)
A method is developed to estimate mean particle sizes in Saturn’s rings from eclipse cooling and heating curves, and applied to interpret recent ground-based observation of Saturn’s rings at 10 and 20 μ.

BACK, L. H.

B001 Explosive Propulsion Applications
Y. Nakamura, G. Varsi, and L. H. Back
Technical Memorandum 33-675, April 1, 1974
For abstract, see Nakamura, Y.

B002 Detonation Propulsion for High Pressure Environments
L. H. Back and G. Varsi
AIAA J., Vol. 12, No. 8, pp. 1123-1130, August 1974
One limitation encountered by chemical rocket propulsion in high-pressure planetary atmospheres is illustrated by the conflict between the dependence of specific impulse on the ratio of chamber pressure to ambient pressure and the dependence of the motor structural design on the difference between the pressures. This article proposes to resolve the difficulty by employing detonating propellant in which the high pressures necessary for efficient propulsion are developed over a short time and need not be contained statically. Experimental results are presented to substantiate this claim of relatively high performance, together with an analytical development that approximately describes the flow dynamics.

BAHADUR, A.

B003 DSN Progress Report for November–December 1973: Analysis of Staffing and Training Policies for a DSN Tracking Station
A. Bahadur and P. Gottlieb
This article presents a method for analyzing the effects of training and staffing policies, and for selecting optimum policies which minimize the expenditures for training and salaries while maximizing the performance of a deep space station. Two models have been developed which represent increasing levels of sophistication.

The first model characterizes steady-state behavior under the optimization of training, average capability, and crew size. The second, which is the dynamic model, optimizes the operating policy over a sequence of time segments. Each segment is characterized by a performance requirement (dependent on the phase of the mission), turnover, and training allocation with a corresponding change in average capability. With inputs such as required minimum station performance, training availability, current crew capability, and expected turnover, the output of the model will be the change in average crew capability, the percentage of time allocated for training, and the corresponding minimum cash expenditure for salaries and training.

BAME, S. J.

B004 Observations at Mercury Encounter by the Plasma Science Experiment on Mariner 10
K. W. Ogilvie (Goddard Space Flight Center), J. D. Scudder (Goddard Space Flight Center), R. E. Hartle (Goddard Space Flight Center), G. L. Siscoe (University of California, Los Angeles), H. S. Bridge (Massachusetts Institute of Technology), A. J. Lazarus (Massachusetts Institute of Technology), J. R. Asbridge (Los Alamos Scientific Laboratory), S. J. Bame (Los Alamos Scientific Laboratory), and C. M. Yeates
Science, Vol. 185, No. 4146, pp. 145-151, July 12, 1974
For abstract, see Ogilvie, K. W.
BAMFORD, R. M.

B005 A Shock Spectra and Impedance Method To Determine a Bound for Spacecraft Structural Loads

R. M. Bamford and M. R. Trubert

Technical Memorandum 33-694, September 1, 1974

This memorandum describes a method to determine a bound for structural loads of a spacecraft mounted on a launch vehicle. The method utilizes the interface shock spectra and the relative impedance of the spacecraft and launch vehicle. The method is developed for single-degree-of-freedom models and then generalized to multidegree-of-freedom models.

BARBOUR, B. H.

B006 Platelet Adhesion to Heparin-Bonded and Heparin-Free Surfaces

For abstract, see Rembaum, A.

BATELAAN, P. D.

B007 S/X-Band Experiment: Zero Delay Device Antenna Location

C. T. Stelzried, T. Y. Otoshi, and P. D. Batelaan

The Deep Space Network: January and February 1974, DSN Progress Report 42-20, pp. 64-68, April 15, 1974

For abstract, see Stelzried, C. T.

B008 S/X-Band Experiment: Zero Delay Device Z Correction

P. D. Batelaan

This article describes a new dual-frequency (S/X-band) zero-delay device (ZDD) which was required for the Mariner Venus/Mercury 1973 S/X-band experiment at the Mars Deep Space Station. To properly utilize the zero calibration provided by the ZDD, an evaluation of the Z term in the ranging equations must be made. An equation for this term is derived, and values are determined for several configurations.

B009 S/X Experiment: DSS 14 S/X Ground System Ranging Tests

T. Y. Otoshi and P. D. Batelaan

For abstract, see Otoshi, T. Y.

BATHKER, D. A.

B010 DSN Progress Report for November-December 1973: Dual Carrier Preparations for Viking

D. A. Bathker and D. W. Brown

While simultaneous transmission of two S-band carriers from a single deep space station is no longer a committed operating mode for Viking Mars 1975 Project support, the program of investigation and abatement of noise bursts and intermodulation interference has continued through the first three calendar quarters of 1973. At the Mars Deep Space Station, internal waveguide and external antenna work yielded major reductions in both types of interference. Supporting investigations were also conducted at JPL and at the Venus Deep Space Station during this period. This article presents conclusions and recommendations for future work.

B011 A Dual Hybrid Mode Feedhorn for DSN Antenna Performance Enhancement

R. F. Thomas and D. A. Bathker

For abstract, see Thomas, R. F.

B012 Low-Noise Microwave Receiving Systems in a Worldwide Network of Large Antennas

M. S. Reid, R. C. Clauss, D. A. Bathker, and C. T. Stelzried

Proc. IEEE, Vol. 61, No. 9, pp. 1330-1335, September 1973

For abstract, see Reid, M. S.
BAUMAN, A. J.

B013 Fluorometric Search for Porphyrins in Apollo 15 Exhaust-Contaminated Surface Fines and Deep Drill Cores and Apollo 16 Surface Fines

J. H. Rho, A. J. Bauman, and E. A. Cohen

For abstract, see Rho, J. H.

BECKENBACH, E. S.

B014 Picture Analysis Applied to Biomedicine

D. A. O’Handley, E. S. Beckenbach, K. R. Castieman, R. H. Selzer, and R. J. Wall

For abstract, see O’Handley, D. A.

BECKMAN, J. C.

B015 Exploring Jupiter and Its Satellites With an Orbiter

J. C. Beckman, J. R. Hyde, and S. I. Rasool (NASA Office of Space Sciences)

The long-standing and still growing interest in exploring Jupiter and its satellite system makes a wide-ranging orbiter the logical sequel to the initial Pioneer and Mariner flybys. This article discusses possible Mariner Jupiter Orbiter missions for 1981 or 1982 launch. It describes the mission design factors, a baseline spacecraft, major science objectives, and various orbit and trajectory strategies using satellite-gravity-assist techniques.

BEER, R.

B016 Abundance and Rotational Temperature of Telluric Methane as Determined From the 2v_3 Band

J. S. Margolis, J. V. Martonchik, R. Beer, and R. H. Norton

For abstract, see Margolis, J. S.

BEJCY, A. K.

B017 Robot Arm Dynamics and Control

A. K. Bejczy

Technical Memorandum 33-669, February 15, 1974

This memorandum treats two central topics related to the dynamical aspects of the control problem of the six-degrees-of-freedom JPL Robot Research Project manipulator: (1) variations in total inertia and gravity loads at the joint outputs, and (2) relative importance of gravity and acceleration-generated reaction torques or forces versus inertia torques or forces. The relation between the dynamical state equations in explicit terms and servoing the manipulator is briefly discussed in the framework of state-variable feedback control which also forms the basis of adaptive manipulator control.

The main result of this memorandum is the construction of a set of greatly simplified state equations which describe total inertia and gravity load variations at the output of the six joints with an average error of less than 5%. Included is a simplification of the general matrix algorithm for manipulator dynamics.

BELL, P. M.

B018 Visible and Near-Infra-Red Transmission and Reflectance Measurements of the Luna 20 Soil

J. B. Adams (Fairleigh Dickinson University, Virgin Islands), P. M. Bell (Carnegie Institution of Washington), J. E. Conel, H. K. Mao (Carnegie Institution of Washington), T. B. McCord (Massachusetts Institute of Technology), and D. B. Nash

For abstract, see Adams, J. B.

BELLMAN, R.

B019 Invariant Imbedding and Radiation Dosimetry: IX. Inverse Problem of Determining a Plane Source in a Finite Isotropically Scattering Target Slab

R. Bellman (University of Southern California), A. L. Fymat, S. Ueno (University of Southern California), and R. Vasudevan (University of Southern California)

Math. Biosci., Vol. 20, Nos. 3/4, pp. 315–325, April 1974

Considering a homogeneous, isotropically scattering target slab of optical thickness x, containing an internal, plane emitting source, the present paper aims to deter-
mine the distribution of the internal emitting source by measuring the angular distribution of the intensity of radiation emergent from the slab. First, a system of differential recurrence relations for the intensity of finite-order scattered radiation emergent from the top is deduced. In other words, a Cauchy system for determining the finite-order emergent intensity is expressed in terms of a source function in the diffuse radiation field and the Fredholm resolvent. Then, the quasilinearization technique is used to solve the inverse problem of determining characteristics of the internal source by measuring the radiation field emergent from the top. This method will be employed in future computations relating to realistic situations in the radiation diagnosis and therapy.

BELTON, M. J. S.

B020 Venus: Atmospheric Motion and Structure From Mariner 10 Pictures

B. C. Murray (California Institute of Technology), M. J. S. Belton (Kitt Peak National Observatory), G. E. Danielson, Jr., M. E. Davies (Rand Corporation), D. E. Gault (Ames Research Center), B. Hapke (University of Pittsburgh), B. O'Leary (Hampshire College), R. G. Strom (University of Arizona), V. Suomi (University of Wisconsin), and N. Trask (U.S. Geological Survey)

For abstract, see Murray, B. C.

B021 Mercury's Surface: Preliminary Description and Interpretation From Mariner 10 Pictures

B. C. Murray (California Institute of Technology), M. J. S. Belton (Kitt Peak National Observatory), G. E. Danielson, Jr., M. E. Davies (Rand Corporation), D. E. Gault (Ames Research Center), B. Hapke (University of Pittsburgh), B. O'Leary (Hampshire College), R. G. Strom (University of Arizona), V. Suomi (University of Wisconsin), and N. Trask (U.S. Geological Survey)

Science, Vol. 185, No. 4146, pp. 169-179, July 12, 1974

For abstract, see Murray, B. C.

BENDER, D. F.

B022 A Survey of Possible Missions to the Periodic Comets in the Interval 1974-2010

D. F. Bender

Technical Memorandum 33-684, April 15, 1974

In order to survey the mission possibilities for short-period comets, two catalogs are developed. The first presents physical and pertinent orbital characteristics for 65 short-period comets. Since missions for short-period comets are for the most part expected to utilize arrivals near perihelion at a time when the comet is comparatively active, the second catalog contains the predicted perihelia for each of the 65 comets between 1974 and 2010. Included is enough geometry to indicate feasibility of Earth-based observation and sighting within 100 days of perihelion.

Mission selection criteria and trajectory requirements are discussed with the aim of providing the background for categorizing the possibilities. The comets are then divided essentially on the basis of size and activity into three groups of interest from the data in the first catalog: primary, secondary, and low interest. The perihelia are separated into satisfactory and not satisfactory, essentially on the basis of Earth-comet distance. Three tables of targets for missions to the short-period comets are presented according to interest group. A fourth table lists chronologically the 51 perihelia for which a comet is predicted to pass within .75 AU of the Earth.

BERMAN, A. L.

B023 Tracking Operations During the Pioneer 10 Encounter

A. L. Berman

Tracking operations during critical mission phases have become increasingly complex due to more sophisticated mission objectives and expanded tracking capability within the DSN. This article describes tracking operations during the Pioneer 10 Jupiter encounter phase with special attention paid to the role of the newly installed digital-controlled oscillator.

B024 Tracking Operations During the Mariner 10 Venus Encounter

A. L. Berman and G. L. Spradlin

Tracking operations during the Mariner Venus/Mercury 1973 (Mariner 10) Venus encounter phase were strongly impacted by the first critical-phase usage of the Block IV S- and X-band receivers, the relatively new digitally controlled oscillators, and the large uncertainties associ-
ated with the Venustian atmosphere. This article describes the pre-encounter planning and subsequent analysis of tracking operations during the Mariner 10 Venus encounter phase.

B025 Tracking Operations During the Mariner 10 Mercury Encounter

A. L. Berman and G. L. Spradlin

Tracking operations during the Mariner Venus/Mercury 1973 Mercury encounter were quite smooth and highly successful. Contributing factors included a lack of any substantial Mercurian atmosphere and, hence, signal refraction, relatively small gravitational perturbations of the spacecraft by Mercury, and a great deal more experience with the Block IV S- and X-band receivers and the digitally controlled oscillators. This article describes the pre-encounter planning and subsequent analysis of tracking operations during the Mercury encounter phase.

B026 A New Angular Tropospheric Refraction Model

A. L. Berman and S. T. Rockwell

As part of an effort to obtain a new angular tropospheric refraction model for use within the DSN, an empirical model has been constructed which very accurately reflects precise optical refraction data. The model is a single analytic function, is finite over the entire domain of elevation angle, and is highly accurate over large ranges of pressure and temperature.

BERMAN, P. A.

B027 Lithium-Doped Solar Cell Pilot Line Fabrication and Test Programs

P. A. Berman and R. K. Yasui

Technical Memorandum 33-677, October 1, 1974

Results of a previous JPL lithium-doped solar cell program indicated that such cells can exhibit high efficiencies and radiation tolerance. This memorandum presents the results of an additional effort to determine the technology readiness of lithium-doped silicon solar cells with respect to use in space programs. This effort was comprised of a pilot line-fabrication program and an evaluation of the pilot line cells after exposure to environments representative of those presently imposed on state-of-the-art, nonlithium-doped silicon solar cells. A summary of the results is presented. It is concluded that further process improvements are required, particularly with respect to the P/N junction diffusion and the electrical contacting technique (including solder coating). It is also concluded that lithium-doped cells can be fabricated to exhibit high efficiencies, uniform cell-to-cell recovery characteristics after exposure to 1-MeV electrons, and good stability in most environments investigated (the only exception being the thermal shock environment).

BIERMAN, G. J.

B028 Sequential Square Root Filtering and Smoothing of Discrete Linear Systems

G. J. Bierman

Automatica, Vol. 10, No. 2, pp. 147-158, March 1974

Square-root information estimation algorithms are immensely important estimation analysis tools that are not sufficiently well understood nor adequately exploited. In an endeavor to rectify this state of affairs an expository derivation of the square-root information filter/smooth algorithm is given. It is based on the recursive least-squares method and is easier to grasp, interpret, and generalize than are the dynamic programming arguments previously used. Backward smoothing algorithms, both square-root and covariance recursions, are derived as direct consequences of the method. A comparison of smoothing algorithms indicates that those presented in this article are the most efficient. Partitioning the results to separate bias parameters provides further computational economies and reduction of storage requirements.

The principal objective of this article is to inspire greater utilization of square-root estimation algorithms. Arguments supporting this thesis are the new least-squares filter/smoker derivations, enhanced numerical accuracy, reduced computation, and lower storage requirements.

B029 A Square-Root Data Array Solution of the Continuous-Discrete Filtering Problem

G. J. Bierman

The Dyer-McReynolds discrete square-root filtering algorithm is extended to accommodate continuous dynamics. Differential equations are given to represent the time evolution of the filter data array. These equations are nonlinear, but it is shown that the nonlinearities act to enhance the stability of the solution.

B030 The Treatment of Bias in the Square-Root Information Filter/Smother
G. J. Bierman

The Dyer-McReynolds square root information filter is rederived, using recursive least-squares arguments. The result is applied to a system composed partly of biases. The filter "sensitivity" matrix, "computed" covariance, and "consider" covariance for this augmented system are reviewed. A new computationally attractive representation for the smoothed estimates, in terms of a smoothed "sensitivity" matrix and a smoothed "computed" covariance, is presented.

BIGGS, J. R.

B031 Mariner Venus/Mercury 1973: A Strategy of Cost Control

J. R. Biggs (NASA Office of Space Science) and W. J. Downhower

Astronaut. Aeronaut., Vol. 12, No. 6, pp. 48-53, June 1974

The Mariner Venus/Mercury 1973 (MVM'73) spacecraft proved a notable success both in space and on the ground as a development project. The MVM'73 Project kept within its originally established goals for schedule, performance, and cost. Underlying this development success was the availability of Mariner technology, but meeting the goals demanded management determination, planning, and discipline to make optimum use of state-of-the-art technology. This article on the development points out management approaches and techniques that kept schedules and controlled costs, the intent being to stimulate thought about how to do the same with future spacecraft and payloads.

BILLINGS, R.

B032 DSN Progress Report for November–December 1973: Computer Program Copy–Verify and Load Check System

R. Billings

This article presents the computer-program copy–verify and load–check system which consists of two programs, the Mag Tape Copy Routine and the Mag Tape Load–Check Loader Program. The system assures the integrity of a DSN program tape at two critical points—reproduction and loading. The Mag Tape Copy Routine verifies the tape as it is being copied, and the Mag Tape Load–Check Loader Program interacts with parts of the Mag Tape Copy Routine to check the validity of a load in progress.

BIRD, E. F.

B033 GCF Wideband Switch Subassembly—Application Techniques

E. F. Bird

This article discusses application techniques used in the development of the wideband switch subassembly (WBSS). The WBSS is a part of the Ground Communications Facility's wideband subsystem located in the Central Communications Terminal at JPL. It is used to support Mariner Venus/Mercury 1973 and Viking Mars 1975 operations. The WBSS is a complex switching unit that provides for simple control by the operator for effecting the many interconnect configurations of various data sets, coded multiplexers/demultiplexers, and JPL computer systems.

BLACKWELL, R. J.

B034 Automated Firearms Identification System (AFIDS): Phase I

R. J. Blackwell and E. P. Framan

Special Publication 43-8, July 1, 1974

This report, prepared for the NASA Applications Technology Office, examines items critical to the future development of an automated firearms identification system (AFIDS), with the following specific results: (1) Types of objective data, that can be utilized to help establish a more factual basis for determining identity and nonidentity between pairs of fired bullets, have been identified. (2) A simulation study has indicated that randomly produced lines, similar in nature to the individual striations on a fired bullet, can be modeled and that random sequences, when compared to each other, have predictable relationships. (3) A schematic diagram of the general concept for AFIDS has been developed and individual elements of this system have been briefly tested for feasibility. Future implementation of such a proposed system will depend on such factors as speed, utility, projected total cost, and user requirements for growth. The success of the proposed system, when operational, would depend heavily on existing firearms examiners.

BOOTH, R. W. D.

B036 Preliminary S-Band Noise Temperature Statistics at DSS 14 for 1971 and 1972

R. W. D. Booth, M. S. Reid, and T. J. Cullen

This article reports on the continuing effort to statistically characterize microwave weather-induced parameters as part of an overall effort to optimize the spacecraft-to-ground communications link. The article considers S-band 1971 and 1972 weather project data only. The statistics of interest are distribution tables for each year, distribution tables for each quarter, and tables of average excess noise temperature duration.

BORN, G. H.

B037 Mariner Mars 1971 Optical Navigation Demonstration Final Report

Technical Memorandum 33-683, April 15, 1974

The primary purpose of the Mariner Mars 1971 (MM'71) Optical Navigation Demonstration was to prove the feasibility of using a combination of spacecraft-based optical data and Earth-based doppler data to perform near-real-time approach navigation for the MM'71 mission. The optical data consisted of Mariner 9 television photographs of Mars' natural satellites Phobos and Deimos against a star background.

The objectives of the demonstration were successfully carried out, and this memorandum documents the important findings, conclusions, and recommendations resulting therefrom. The memorandum is divided into two parts: a formal summary section and a section of appended publications and papers giving additional details on the primary and secondary objectives of the demonstration. The appendices describe instrument calibration and performance as well as navigation and science results obtained by processing TV data of Mars' natural satellites, Mars' landmarks, and Mars' lit limb taken during both the approach phase and the orbital phase of the MM'71 mission.

B038 The Determination of the Satellite Orbit of Mariner 9

This article presents a comprehensive analysis of the Mars orbital phase of the Mariner Mars 1971 spacecraft trajectory as determined from Earth-based radio data. Both the method and accuracy of the orbit determination process are reviewed. Analysis is presented to show the effects of Mars-gravity-model and node-in-the-plane-of-the-sky errors on the accuracy of orbit determination. In addition, the long term evolution of the orbit from insertion through the first 500 revolutions is presented and decomposed into effects from the Mars gravity field, n-body perturbations, and solar radiation pressure. Since the orbit period is nearly commensurable with the Mars rotational period, the orbit experiences significant resonance perturbations. The primary perturbation is in-track with a maximum amplitude of 1000 km and a wavelength of 39 spacecraft revolutions.

B039 Mars Physical Parameters as Determined From Mariner 9 Observations of the Natural Satellites and Doppler Tracking

G. H. Born

Spherical harmonic coefficients of the Mars gravity field to degree 6, mass, spin-axis direction, and the orbits of Phobos and Deimos were determined from radio and optical data obtained by the Mariner Mars 1971 (Mariner 9) spacecraft. The optical data consist of 62 TV photographs of Phobos and Deimos. The radio data are in the form of apoapsis state vectors obtained from over 150 revolution fits of the doppler data. A first-order analytical theory was used to model the motion of both the satellites and the spacecraft. However, the resonance arising from the fact that the orbital period of Mariner 9 was very close to 1/2 day necessitated development of a partial second-order theory to model the long-period perturbations by even-order tesseral harmonics.
Results for the spherical harmonic coefficients are in good agreement with those previously published from Mariner 9 doppler data. The value obtained for the gravitational constant of Mars \(42,828.1 \pm 0.5 \, \text{km}^3/\text{s}^2\) is in excellent agreement with prior determinations from Mariner flyby trajectories. The direction of Mars' rotational pole relative to the Earth's mean equinox and equator of 1950 is given by \(\alpha = 317.3 \pm 0.1 \, \text{deg}, \delta = 52.7 \pm 0.1 \, \text{deg}\). The longitudes for Phobos and Deimos at the time of Mariner 9 Mars orbit insertion were found to be 0.2 deg less and 0.3 deg greater, respectively, than the longitudes predicted for this epoch on the basis of a recent processing of Earth-based data obtained for the satellites during 1877–1969.

**BRIGGS, G. A.**

**B044** Mariner 9 Observations of the Mars North Polar Hood

G. A. Briggs and C. B. Leovy (University of Washington)

Mariner Mars 1971 photographs showing variations in the behavior of the Mars atmosphere over 21 consecutive days during northern winter are displayed. The photographs show the north-polar cloud hood to be highly variable from day to day, with variations suggestive of the development, motion, and decay of baroclinic waves. Lee wave clouds apparently composed primarily of water ice, convective cloud lines inferred to consist of CO\(_2\) ice, and dust clouds all occur frequently in the active region between latitudes 40 and 60 deg N. The wave clouds show that persistent surface westerlies and strong westerly shear occur in this region.

**BROCKE, R. A.**

**B045** Ten Subroutines for the Manipulation of Chebyshev Series [C1]

R. A. Broucke

*Commun. ACM (Association for Computing Machinery, Inc.)*, Vol. 16, No. 4, pp. 254–256, April 1973

This article presents ten subroutines which deal with the manipulation of Chebyshev series. The operations performed are the construction of the Chebyshev approximation of functions, the evaluation of the series or its derivative, the integration or differentiation, and the construction of negative or fractional powers of such a series. The subroutines are written in ANSI Fortran, and have been extensively tested.
system design tests were initiated on the Engineering Model in early 1972 and the program culminated in verification of Helios Spacecraft/DSN compatibility on August 2, 1974. This article describes the tests and test results that provided the basis for establishment of telecommunications system design compatibility and verification.

A. I. Bryan

The Viking Flight Project/DSN Telecommunications Compatibility Test Program consists of three phases: subsystem design, system design, and system verification tests to be performed at JPL and at the Air Force Eastern Test Range/Kennedy Space Center complexes. Subsystem design tests were performed with the Viking Orbiter and the Viking Lander during 1973. System design compatibility tests were performed with the Viking Orbiter, Viking Lander, and a multiple Viking spacecraft configuration during the summer of 1974. This article describes the system design tests and test results that provided the basis for the establishment of telecommunications system design compatibility between the DSN and the Viking Lander, Viking Orbiter, and a simulated DSN/multiple spacecraft configuration for the Mars planetary orbital operations.

B051 DSN Progress Report for November–December 1973: Variable S-Band High-Power Tuner

H. R. Buchanan

This article reports progress in the development of a variable, high-power waveguide tuner that can be remotely controlled. Satisfactory operation at a 400-kW power level is the goal.

BUNCE, R. C.

B052 S-Band/X-Band Doppler Two-Way Nonlinear Jitter Analysis Using Simplified Series-Expansion Techniques

R. C. Bunce
Using a simplified, nonlinear approach by Yuen, together with simplified series expressions to obtain the nonlinear values for Alpha, Gamma, and Sigma, a full program was developed to output estimated two-way jitter in degrees as a function of ground and spacecraft signal-level margin above design point. Required modified (hyperbolic) Bessel functions were calculated individually with the defining series, rather than by recursion, to reduce the error. When the series was no longer feasible, results were replaced by linear approximation, well into the "linear range." As an experiment, and to establish feasibility of the entire model, programming was done entirely on a table calculator (four card-sides; about 1700 steps).

Comparative sequential decoding tests have also been performed for 128-bit/s data; no discrepancy was found between scaled and unscaled performance at any modulation index, either near-optimum or high (70 deg), where the carrier reference noise is dominant.

**B054** DSN Progress Report for November-December 1973: A Scaled-Time Telemetry Test Capability for Sequential Decoding

S. Butman, J. W. Layland, J. W. MacConnell, R. C. Chernoff, N. C. Ham, and J. Wilcher

This article describes the motivation for, and development and initial testing of, a scaled-time telemetry test capability. The immediate need for this capability is to establish the sequential decoding performance of the data decoder assembly for Helios and Pioneer, and the tests have been aimed at evaluating the suitability of the scaled phase-locked loop (PLL) for this task. The relevant parameters of limiter suppression, phase jitter variance, and phase jitter autocorrelation have been measured, and no discrepancy was found between the ×16-scaled PLL and the 12-Hz loop of the DSN receiver.

**B055** The Ultimate Limits of Binary Coding for a Wideband Gaussian Channel

S. Butman and R. J. McEliece

This article presents, in graphical form, the theoretical relationship between the bit signal-to-noise ratio, the bit error probability, and the bandwidth expansion factor for binary-coded telemetry on a wideband Gaussian channel.

**B056** Photoionization and Ion Cyclotron Resonance Studies of the Reaction of Vibrationally Excited C2H2+ Ions With H2

S. E. Buttrill, Jr., J. K. Kim, W. T. Huntress, Jr., P. R. LeBreton (California Institute of Technology), and A. D. Williamson (California Institute of Technology)

*J. Chem. Phys.*, Vol. 61, No. 5, pp. 2122-2128, September 1, 1974

The reaction C2H2+ + H2 → C2H3+ + H has been studied using ion cyclotron resonance and photoionization mass spectrometric techniques. At thermal kinetic energies, the cross section for the reaction is near zero for ground state reactants but increases rapidly with increasing vibrational energy in the C2H2+ ions. The ratio of the cross sections for ions in the v2 = 1 and v2 = 2 states is approximately 1:2, respectively. Some reaction is observed at photoionization energies below the threshold for formation of v2 = 1 ions owing to reaction of thermally excited ions and neutrals. For the distribution of vibrational energies in C2H2+ ions formed by electron impact at 15 eV, the rate constant for the reaction is 8.3 ± 1.6 × 10^-11 cm^3/s. Exchange of hydrogen atoms in nonreactive collisions between C2H2+ ions and D2 molecules has also been observed. An upper limit of ΔH/(C2H3+) = 267 kcal/mole is obtained.

**C001** Interpretation of Columnar Content Measurements of the Solar-Wind Turbulence

P. S. Callahan

*JPL BIBLIOGRAPHY 39-16*
The temporal spectrum of measurements of the integrated electron columnar content between the Earth and a distant source is considered. The relation between this spectrum and the three-dimensional wave-number spectrum of the solar-wind density is derived under the assumption that the correlation scale is the smallest scale of interest. The specific case of round-trip measurements to a spacecraft is investigated for a power-law solar-wind density spectrum. The resulting spectrum has a power-law envelope one power less steep than the solar-wind density spectrum with several deep minima superposed.

C009 NaK–Nitrogen Liquid Metal MHD Converter Tests at 30 kW
D. J. Cerini

A NaK–nitrogen liquid metal magnetohydrodynamic converter was operated over a range of nozzle inlet pressures of 100 to 165 N/cm², NaK flowrates of 48 to 72 kg/s, and nitrogen flowrates of 2.4 to 3.8 kg/s. The converter was operated as an eight-phase linear induction generator with two of the eight phases providing magnetic field compensation to minimize electrical end losses at the generator channel inlet and exit. Each of the eight phases was connected to a separately controlled capacitor bank for magnetization reactive power and a separately controlled load bank for dissipation of the output power. Generator operation was obtained with average winding currents and voltages up to 80 A and 500 V, respectively, with estimated channel magnetic fields up to 0.4 T over the range of frequencies of 270–470 Hz. The output power of the converter was varied from −6 to 31 kW. At maximum output, the winding losses, fluid friction losses, and fluid ohmic losses were estimated to be 18, 21, and 49 kW, respectively, for a sum of 119 kW extracted from the fluid corresponding to net and gross efficiencies of 31/119 = 0.26 and (31 + 18)/119 = 0.41, respectively.

CHAHINE, M. T.

C011 Remote Sounding of Cloudy Atmospheres. I. The Single Cloud Layer
M. T. Chahine

The relaxation method for the inverse solution of the radiative-transfer equation is applied in a dual-frequency scheme for the determination of complete vertical temperature profiles in cloudy atmospheres from radiance observations alone, without any additional information related to the expected solutions. The dual-frequency principle employs to advantage a property in the Planck function of the dependence of intensity on frequency. This property leads to the formulation of a new convergence criterion for the selection of cloud-sounding frequencies to be used for reconstructing the clear column radiance from observations made in the presence of a broken cloud layer in all fields of view.

The principle is applied to the case of observations in two adjacent or partially overlapping fields of view and to the case of observations in a single field of view. The solutions are illustrated by numerical examples in the dual-frequency ranges of the 4.3 and 15 µm CO₂ bands of the terrestrial atmosphere. The resulting profiles can possess the same degree of vertical resolution permitted under cloudless conditions.

CO16 Short Baseline QVLBI Doppler Demonstrations—Part II

C. C. Chao, R. A. Preston, and H. E. Nance

The Deep Space Network: January and February 1974, DSN Progress Report 42-20, pp. 20–26, April 15, 1974

This article describes the continuation of the short baseline quasi-very-long-baseline interferometry (QVLBI) demonstrations, which are designed to examine the stability of the current doppler frequency system. A total of six passes of simultaneous two-way and three-way doppler data from Pioneer 10 were obtained at the Pioneer Deep Space Station and the Mars Deep Space Station. Results indicate that the short-term (minute), medium-term (hour), and long-term (month) stabilities of the new rubidium frequency standard (HP 5065A) are 8 parts in $10^{13}$, 1.3 parts in $10^{13}$, and 1.9 parts in $10^{12}$, respectively. The relative drift rate between the two systems, the Pioneer Deep Space Station and the Mars Deep Space Station, is around 6 mHz/month. This indicates that the long-term stability of the current frequency system exceeds our limit level and makes the coming QVLBI Mariner Venus/Mercury 1973 Project demonstration very difficult.

CO19 Goldstone DSCC Energy Distribution Model

B. H. Chapman

In expectation of increases in cost and decreases in supply of currently available energy forms, the DSN is studying the installation of systems which will provide reliable energy for the Goldstone Deep Space Communications Complex in stable amounts and at stable cost. One of the main factors in improving the economic viability of such an installation is the efficiency with which the useful energy forms resulting from the conversion of the stable energy form to be provided can be distributed to the consumers.

The aim of the general distribution model presented in this article is to provide a method for the optimal design of a network for the distribution of several different types of energy to users and for the optimal operation of such a network when installed. When such a network is operational the consumers' demand for energy can be ascertained by real-time sampling, but during the design phase these energy demands are known only stochastically. The initial model describes the case of known constant demand and will form the basis of a subsequent model of the stochastic demand case. An algorithm to be used in the solution of this model problem is also outlined.

CHASE, S. C., JR.

CO20 Preliminary Infrared Radiometry of Venus From Mariner 10

S. C. Chase, Jr. (Santa Barbara Research Center), E. D. Miner, D. Morrison (University of Hawaii), G. Münch (California Institute of Technology), and G. Neugebauer (California Institute of Technology)

This paper presents the intensity of emission at 45 $\mu$m, measured with high spatial resolution along a single crossing of the Venus disk. On the average, the observed darkening toward the limb varies nearly linearly with the cosine of the emission angle. The brightness temperature, extrapolated to normal emission, is 255 K. The limb
darkening curve, interpreted in a linear approximation, implies that the atmosphere is quite opaque, with an absorption coefficient of 0.24/km. Changes in curvature present in the limb darkening curve suggest the existence of thermal inhomogeneities with scale comparable to that of the dark markings shown by ultraviolet images.

**C021 Preliminary Infrared Radiometry of the Night Side of Mercury From Mariner 10**

S. C. Chase, Jr. (Santa Barbara Research Center), E. D. Miner, D. Morrison (University of Hawaii), G. Münch (California Institute of Technology), G. Neugebauer (California Institute of Technology), and M. Schroeder (California Institute of Technology)  
Science, Vol. 185, No. 4146, pp. 142-145, July 12, 1974

The infrared radiometer on the Mariner Venus/Mercury 1973 spacecraft measured the thermal emission from Mercury with a spatial resolution element as small as 40 km in a broad wavelength band centered at 45 μm. The minimum brightness temperature (near local midnight) in these near-equatorial scans was 100 K. Along the track observed, the temperature declined steadily from local sunset to near midnight, behaving as would be expected for a homogeneous, porous material with a thermal inertia of 0.0017 cal cm⁻² s⁻¹/² K⁻¹, a value only slightly larger than that of the Moon. From near midnight to dawn, however, the temperature fluctuated over a range of about 10 K, implying the presence of regions having thermal inertia as high as 0.003 cal cm⁻² s⁻¹/² K⁻¹.

**C022 Manganese Laser Using Manganese Chloride as Lasant**

C. J. Chen  

A manganese vapor laser utilizing manganese chloride as a lasant has been observed and investigated. Lasing is attained by means of two consecutive electrical discharges. The maximum laser output is obtained at a vapor pressure of about 3 torr, a temperature of 860°C, and a time delay between electrical discharges of 150 μs. The maximum energy density is 1.3 μJ cm⁻³.

**C023 Lead Laser Using Lead Chloride as a Lasant**

C. J. Chen

A lead-vapor laser utilizing lead chloride as a lasant has been investigated. Lasing is attained by means of two consecutive electrical discharges. The maximum output is obtained at a vapor pressure of about 0.3 torr at a temperature of 500°C, a time delay between electrical discharges of 150 μs, and an output mirror transmittance of 80%. The maximum energy density and power density are 4 μJ cm⁻³ and 160 W cm⁻³, respectively.

C030 DSN Progress Report for November–December 1973: Low-Noise Receivers: Microwave Maser Development
R. C. Clauss and E. Wiebe
Two S-band maser systems with equivalent input noise temperatures of 2.1 K have been supplied to the DSN. These masers will be used on the 64-m-diameter antennas at the Mars Deep Space Station and the Ballina Deep Space Station to meet special requirements of the Mariner Venus/Mercury 1973 mission. The masers use a new shortened and cooled signal-input transmission line to reduce noise and are equipped with superconducting magnets to provide the best possible stability performance.

C031 Low-Noise Receivers: Microwave Maser Development
R. C. Clauss
A new multijunction, cryogenically coolable, X-band circulator has been developed and tested. Isolation exceeding 20 dB per junction and insertion loss less than 0.2 dB per junction between 8100 and 8800 MHz have been measured at 4.5 K. The new circulator will be used with a maser to provide low-noise amplification across a wide instantaneous bandwidth.

C036 Experimental and Theoretical Investigations in Two-Dimensional Transonic Flow

D. J. Collins and J. A. Krupp

AIAA J., Vol. 12, No. 6, pp. 771-778, June 1974

This paper presents experimental and theoretical results from a study of the flow over a family of transonically scaled circular-arc bodies mounted in a solid-wall wind tunnel. Data for Reynolds numbers between $1.2 \times 10^8$ and $3.6 \times 10^8$ based on chord, are compared with the results of computations based on inviscid theory in order to examine the scaling of inviscid transonic flows in a solid-wall wind tunnel, and to obtain a description of the flow near choking. For those cases for which extensive separation of the model and tunnel boundary layers does not occur, excellent agreement between theory and experiment is demonstrated for the flow in the vicinity of the model, and to a lesser degree for the flow near the opposite tunnel boundary. Some results are presented which illustrate the analogy between choked flow in a solid-wall wind tunnel and unbounded flow at $M_\infty = 1.0$.

C037 Laminar Viscous–Inviscid Interactions at Transonic Speeds

D. J. Collins

The interaction between the boundary layer which forms on an aerodynamic surface and the inviscid outer flowfield is most pronounced at transonic speeds where the nature of the mixed supersonic and subsonic inviscid flowfield is often determined by the viscous portions of the flow. In previous investigations, it has been clear that a strong interaction exists between the viscous and the inviscid flows, and as a consequence the boundary layer cannot be treated theoretically as a small perturbation to the outer flow, but must be closely coupled with the outer flow and must be solved simultaneously. This article discusses some aspects of the laminar viscous–inviscid interaction at transonic speeds by examining data obtained on a 6% thick biconvex circular-arc airfoil and comparing the results with theory.

C041 Power Processor Design Considerations for a Solar Electric Propulsion Spacecraft

E. N. Costogue and J. A. Gardner

Technical Memorandum 33-705, June 30, 1974

This memorandum describes the work performed during 1973 on the study of the propulsion power processor design options as part of the Solar Electric Propulsion System Integration Technology (SEPSIT) program. This propulsion power processor would generate the regulated de voltages and currents from a solar array source of a solar-electric propelled spacecraft. The power processor consists of 12 power supplies that provide the regulated voltages and currents necessary to power a 30-cm mercury ion thruster that is applied in this study to a 1980 Comet Encke rendezvous mission.
Included are: the study of the design options for processing the 200 to 400 V unregulated solar-array power; the design options for generating this regulated power required by each supply; the technical approaches utilized in the developed design; and the technological limitations of the identified design options. Alternate approaches for delivering power to a number of mercury ion thrusters (eight for the Comet Encke rendezvous mission) and methods of optimizing are also described.

The study identified a number of viable design options for processing and generating regulated power by each power supply and a proposed power processor configuration that has advantages over the current design approach. It was concluded that this proposed power processor design should be considered for application in solar–electric propulsion missions of the future.

pie solutions, and makes few demands on the supporting computational structure.

CUTTS, J. A.

C048 Mariner Mars 1971 Television Picture Catalog: Experiment Design and Picture Data

J. A. Cutts

This memorandum is a compilation of Mariner Mars 1971 television data which have been arranged and edited to help the serious scientific user in the study of the planet Mars and of its two satellites, Phobos and Deimos. Although only a part of the entire data base can be reproduced in a document of this size, an attempt has been made to indicate its size and availability. The concept of the basic mission, camera characteristics, and various processing techniques of the raw television data recovered from the spacecraft are discussed. In later sections, data are arranged into disciplines: mapping and geology, polar studies, geodesy, variable surface features, atmospheric phenomena, and satellites. Reproduction and arrangements of approximately 3000 individual pictures and photomosaics are presented.

DAVIS, W.

D010 Modifying an HA/Dec Coordinate Antenna Pointing System to Process Data From an X/Y-Mounted Antenna

W. Davis

About mid-1972, JPL assumed responsibility for the operation of NASA's Spaceflight Tracking and Data Network (STDN) station at Canberra. This action was prompted by the decommissioning of DSS 41 at Woomera and increased tracking commitments for the DSN. Although DSS 44 (previously STDN's Honeysuckle Apollo) is a unified S-band 26-m-diameter antenna, its coordinate system is X/Y. This article addresses the differences between the X/Y system and that of the DSN's HA/dec, and describes how a functional system was created using subsystem assemblies from both stations.

D. W. Kurtz and B. Dayman, Jr.

For abstract, see Kurtz, D. W.
DeMore, W. B. Technical Memorandum 33-672, February 1, 1974

This memorandum reviews the current state-of-the-art knowledge of the composition and structure of the atmosphere of Titan, based on theory and on spectroscopic and infrared data, for the development of numerical engineering models. Light, nominal, and heavy atmospheres are described and tabulated, and their profiles of radius, temperature, pressure, and density are illustrated. Corresponding descriptions of atmospheric dynamics, condensates, and surfaces are outlined.

Deuzé, J. L.

D013 Instrumentation Optimization in Fourier Spectroscopy. 1: Far Infrared Beam Splitters

J. L. Deuzé (Université des Sciences et Techniques de Lille, France) and A. L. Fymat

This article describes computations of the reflectivity, transmissivity, and efficiency properties for TE, TM, and T45° waves of far-infrared beam splitters (BS) and of the polarizations induced at both reflection and transmission. Effects of variations in the state of polarization, orientation, pointing accuracy, and wavelength of the incident light, as well as variations in refractive index and thickness of the BS, are discussed. These results apply directly to Fourier interferometer–spectrometers. They can be used for optimizing the performance of these instruments. They indicate, in particular, that some advantages may be gained by the use of incident polarized light (angle of polarization smaller than about 45 deg or negative elliptical polarization) or light of large incidence angle (larger than approximately 60 deg) or both. A novel method of inversion of experimental results to the end of determining the BS physical parameters is proposed. It makes use of the variations with incident light direction of the BS reflectivity, transmissivity, or efficiency curves.

Downs, G. S.

D018 Interplanetary Navigation Using Pulsating Radio Sources

G. S. Downs

Technical Report 32-1594, October 1, 1974

Radio beacons with distinguishing signatures exist in nature as pulsating radio sources (pulsars). These objects radiate well determined pulse trains over hundreds of megahertz of bandwidth at radio frequencies. Since they
are at known positions, they can also be used as navigation beacons in interplanetary space. Pulsar signals are weak and dispersive when viewed from Earth. If an omnidirectional antenna is connected to a wideband receiver (200 MHz bandwidth centered at 200 MHz) in which dispersion effects are removed, nominal spacecraft position errors of 1500 km can be obtained after 24 h of signal integration. An antenna gain of 10 dB would produce errors as low as 150 km. Since the spacecraft position is determined from the measurement of the phase of a periodic signal, ambiguities occur in the position measurement. Simultaneous use of current spacecraft navigation schemes eliminates these ambiguities.

DREYER, W. J.

D019 Automatic Mass-Spectrometric Analysis: Preliminary Report on Development of a Novel Mass-Spectrometric System for Biomedical Applications

Clinical Chem., Vol. 20, No. 8, pp. 998-1002, August 1974

A mass spectrograph, coupled to automatic sample preparation devices and an electro-optical ion detector/computer system, capable of detecting many ion species simultaneously, presents a promising new approach to biomedical analysis. It will permit simultaneous multi-component analysis of appropriately prepared samples and may detect as little as $10^{-15}$ g of a single component. This approach offers significant advantages over other methods, including conventional mass spectrometry.

DUMAS, L. N.

D020 Temperature Control of the Mariner-Class Spacecraft: A Seven-Mission Summary

L. N. Dumas

Mariner spacecraft have completed five missions of scientific investigation of the planets. Two additional missions are planned. A description of the thermal design of these seven spacecraft is given. The factors that have influenced the thermal design include the mission requirements and constraints, the flight environment, certain programmatic considerations, and the experience gained as each mission is completed. These factors are reviewed, and the impact of each on thermal design and developmental techniques is assessed. It is concluded that the flight success of these spacecraft indicates that adequate temperature control has been obtained, but that improvements in design data, hardware performance, and analytical techniques are needed.

DUNNE, J. A.

D021 Mariner 10 Venus Encounter

J. A. Dunne

The Mariner Venus/Mercury 1973 spacecraft encountered Venus at 1701 GMT on February 5, 1974. The preplanned encounter science sequence was executed satisfactorily, accomplishing all objectives despite a number of spacecraft problems that had occurred in the early phases of the flight. Seven experiments were conducted, including observations of the solar-wind interaction region, extreme ultraviolet and infrared emissions, radio occultation, and imaging.

D022 Mariner 10 Mercury Encounter

J. A. Dunne

Science, Vol. 185, No. 4146, pp. 141-142, July 12, 1974

The Mariner Venus/Mercury 1973 spacecraft's closest approach to Mercury on March 29, 1974 occurred on the dark side of the planet at a range of approximately 700 km. The spacecraft trajectory passed through the shadows of both the Sun and Earth. Experiments conducted included magnetic fields, plasma and charged-particle studies of the solar-wind interaction region, television photography, extreme ultraviolet spectroscopy of the atmosphere, the detection of infrared thermal radiation from the surface, and a dual-frequency radio occultation in search of an ionosphere.

DUXBURY, T. C.

D023 Mariner Mars 1971 Optical Navigation Demonstration Final Report

Technical Memorandum 33-683, April 15, 1974

For abstract, see Born, G. H.

D024 Viewing Phobos and Deimos for Navigating Mariner 9

T. C. Duxbury, G. H. Born, and N. Jerath
A new on-board optical-navigation data technique has been successfully demonstrated on the Mariner Mars 1971 spacecraft (Mariner 9). Science TV pictures of Phobos and Deimos against star fields were used in the real-time navigation process for inserting Mariner 9 into orbit about Mars. Real-time and postflight evaluation results have shown that the satellite/star data taken by Mariner 9 surpassed preflight accuracy predictions. Orbital insertion could have been achieved using only optical data to determine encounter parameters. The use of a science TV camera to obtain this data was successfully demonstrated. Stars as dim as 9th magnitude were detected and measurement accuracies of 3 arc sec (1 σ) were achieved.

D026 Trajectory Selection for the Mariner Jupiter/Saturn 1977 Project

J. S. Dyer and R. F. Miles, Jr.

Technical Memorandum 33-706, October 15, 1974

This memorandum describes the use of decision analysis to facilitate a group decision-making problem in the selection of trajectories for the two spacecraft of the Mariner Jupiter/Saturn 1977 Project. This NASA project includes the participation of some 80 scientists divided by specialization among 11 science teams. A set of 32 candidate trajectory pairs was developed by the Project in collaboration with the science teams. Each science team then independently ranked and assigned cardinal utility function values to the trajectory pairs. The data and statistics derived from collective choice rules were used by the scientists in selecting the science-preferred trajectory pair.

EISENBERGER, I.

E003 Cost Effective Spares Provisioning for the Deep Space Network

I. Eisenberger, F. R. Maiocco, and G. Lorden (California Institute of Technology)

The Deep Space Network: January and February 1974, DSN Progress Report 42-20, pp. 128-134, April 15, 1974

This article discusses a cost effective procedure for spares provisioning of the various components of an
assembly that is assumed to fail if any one of the components fails. The procedure not only provides a means for obtaining a given operational availability at minimum cost, but it is also applicable when a constraint is placed upon the total cost of the spares for the components making up the assembly.

E004 A Preliminary Deep Space Station Operational Availability Model

I. Eisenberger, F. R. Maiocco, and G. Lorden (California Institute of Technology)

This article describes a method for determining deep space station operational availability as a function of the reliability of replaceable subassemblies and the time required to replace them when they fail. It is shown that a reduction in replacement time can have a significant effect on station operational availability.

E005 Parametric Interactions Between Alfvén Waves and Sonic Waves

C. Elachi

This paper presents a study of parametric interactions between a sonic-pump wave and a weak Alfvén wave. It is shown that if the Alfvén-wave velocity $V_A$ is small relative to the sonic-wave velocity $V_s$ there is a time-growing instability leading to the increase of the Alfvén wave at the expense of the sonic wave. This phenomenon can be of importance in solar and stellar physics. For $V_A$ large relative to $V_s$, the interaction is of the stop-band type.

E006 Mode Conversion in Periodically Disturbed Thin-Film Waveguides

C. Elachi and C. Yeh (University of California, Los Angeles)

Mode conversion in a periodically perturbed thin-film optical waveguide is studied in detail. Three different types of perturbations are considered: periodic index of refraction of the film, periodic index of refraction of the substrate, and periodic boundary. The applications in filters, mode converters, and distributed feedback lasers are discussed.

E007 Aerodynamics of a Burning Turbulent Gas Jet in a Crossflow

M. P. Escudier (University of Southern California)

A theoretical treatment is presented of the motion of a turbulent gas jet burning in an oxidizing crossflow. The study represents a significant extension of the entrainment theory for weak plumes, through the incorporation into its framework of the influences of radiative-thermal energy transfer, large density variations, and thermalenergy generation through chemical reaction. Numerical calculations are presented for the variation of bulk temperature and species concentrations along the plume trajectory. The concentrations are shown to be strongly coupled with the temperature, suggesting a possible simplification of the problem of calculating the production rates of pollutants formed in secondary reactions. Thermal radiation is found to be of secondary importance to plume dynamics. Comparisons are made between exact (numerical) and approximate (asymptotic) calculations of plume trajectory, with and without thermal energy release. These calculations show that for conditions typical of those encountered in a gas-fired furnace, a plume’s motion is not significantly influenced by buoyancy forces until well downstream of the reaction zone.

E008 Bäcklund Transformation for Solutions of the Korteweg-de Vries Equation

H. D. Wahlquist and F. B. Estabrook

For abstract, see Wahlquist, H. D.

E009 Comments on Generalized Hamiltonian Dynamics

F. B. Estabrook

A reasonable generalization of Hamiltonian theory to 3m-dimensional phase space suggests a geometrical structure giving the proper characteristic vector field. This structure, however, has only a single integral invariant, and implies no sensible generalization of either Poisson-bracket formalism, or Hamilton-Jacobi theory. Associated statistical mechanics and quantization are unlikely. The algebraic source of the difficulty is the lack of understanding of canonical expressions and classes of closed 3-forms.
EVANS, D. D.

E010 Comment on: Computation of Angular Functions $\pi_n$ and $\tau_n$ Occurring in Mie Theory
D. D. Evans
This article compares two different definitions of the function $K_n$ used in the computation of the angular functions $\pi_n$ and $\tau_n$ occurring in Mie scattering theory. A number of test cases were run using both algorithms. It is concluded that the difference between the two in error propagation is insignificant for the purpose of summing Mie series, but that one method requires fewer computations and does not require new definitions for established notations.

E011 Mathematical Models for the Reflection Coefficients of Dielectric Half-Spaces
D. D. Evans
Radio Sci., Vol. 8, No. 12, pp. 1083-1092, December 1973
The reflection coefficients at normal incidence are found for a large class of one-dimensionally inhomogeneous or stratified half-spaces, which contain a homogeneous half-space. The formulation of the problem involves a combination of the classical boundary value technique, and the non-classical principle of invariant imbedding. Solutions are in closed form and expressible in terms of Bessel functions. All results are given in terms of the ratio of the distance between free space and the homogeneous half-space to the wavelength in vacuo.

One special case is that of an arbitrary number of layers lying on a homogeneous half-space where the dielectric constant of each layer has a constant gradient. A number of other special cases, limiting cases, and generalizations are developed including one in which the thickness of the top layer obeys a probability distribution, and another formulation that is computationally efficient in which there is an extremely small change in the dielectric constant such as with atmospheric inversion layers.

F003 Surface Properties of the Orgueil Meteorite: Implications for the Early History of Solar System Volatiles
F. P. Fanale and W. A. Cannon
Dehydration of the Orgueil meteorite by stepwise calculation produced more than a tenfold change in its Kr Brunauer-Emmett-Teller surface area, which increased to 120 m²/g, then fell to 40 m²/g. This phenomenon characterizes structures of the montmorillonite type, but not other plausible constituents of Orgueil. It results from the vacating of interlayer sites by H₂O molecules which are replaced by Kr until finally the sheets collapse, excluding Kr. Differential calorimetric scans of Orgueil also gave a better match for montmorillonite than for other minerals. However, a simple identification as montmorillonite conflicts with chemical analyses of Orgueil phyllosilicates.

Exchangeability of H₂O in Orgueil was shown by water regain from lab air between calcination cycles and the similarity of the cycles. Room temperature dehydration revealed up to 6% free-surface adsorbed water. High D/H ratios in CI meteorites may result from D enrichment in OH-groups during equilibration of dispersed phyllosilicate dust with nebula gas at temperatures <60°C. Adsorption on the very large free and interlayer surface areas of this dust was the major mechanism by which volatiles still uncondensed at the time of gas-dust separation (including planetary primordial Ar, Kr, and Xe) were incorporated into solid solar-system material.

F004 Optical Properties of Carbonaceous Chondrites and Their Relationship to Asteroids
T. V. Johnson and F. P. Fanale

FALIN, B.

B. Falin
This article describes Network Command System performance tests that were executed throughout the DSN in support of the Mariner Venus/Mercury 1973 (MVM'73) Project. The objectives of the performance tests and a description of the various sections of the test procedure are presented, and the status of each deep space station at MVM'73 launch is reported.

JPL BIBLIOGRAPHY 39-16
Estimates have been made of the capacity of the Martian regolith to exchange adsorbed $H_2O$ and $CO_2$ with the atmosphere-plus-cap system (APCS). These estimates are based upon measured isotherms for $H_2O$ and $CO_2$ adsorption on pulverized basalt at low temperatures and on theoretical considerations. Under favorable circumstances the top 3 cm can exchange much more adsorption on pulverized basalt at low temperatures and on constituents is presented. The question of the determination of adsorbents is presented. The question of the determination of the abundance of the lower stratosphere each day than is necessary to produce the diurnal brightening. The process appears to be seasonally reversible. The total regolith may contain, in the adsorbed phase alone, as much as 1% of the $H_2O$ and 5% of the $CO_2$ surface inventories expected for a hypothetical Mars that has experienced degassing as intensive as that of Earth.

Long-term ($\sim 10^5$ yr) variations in surface insolation caused by variations in the obliquity of Mars could cause efficient desorption of adsorbed $CO_2$ and $H_2O$ from a 100-m regolith; and variations in solar output with periods $> 1$ million years may well desorb $H_2O$ and $CO_2$ efficiently from all the unconsolidated material on Mars. Enough $CO_2$ could be desorbed to initiate major climatic change even if there is not enough in the APCS. The paradox presented by the fact that the APCS contains barely enough $CO_2$ molecules to form caps is mitigated by the observation that the APCS is itself in transient equilibrium with a much larger reservoir of adsorbed $CO_2$.

FARMER, C. B.

F007 Infrared Measurements of Stratospheric Composition

C. B. Farmer

This article reviews the observational techniques and results of infrared measurements of the minor and trace molecular composition of the lower stratosphere. Emphasis is given to those theoretical aspects of the formation of emission and absorption spectra which affect the quantitative interpretation of observational data in terms of the vertical distribution of observed molecular species.

A detailed summary of current knowledge of the abundances and spatial variability of the known minor constituents is presented. The question of the determination of the minimum detectable concentration of a constituent molecule and its relationship to the instrumental parameters, the molecular transition intensities, and observation geometry is discussed. Upper limit concentrations are given for some additional species of importance in current stratospheric studies.

F008 Detection of Nitric Oxide in the Lower Stratosphere

R. A. Toth, C. B. Farmer, R. A. Schindler, O. F. Raper, and P. W. Schaper

Nature Phys. Sci., Vol. 244, No. 131, pp. 7-8, July 2, 1973

For abstract, see Toth, R. A.

F009 Measurement of the Abundance of Several Natural Stratospheric Trace Constituents From High Altitude Aircraft

This article presents a summary of the initial results obtained from near-infrared observations of the stratosphere from the Anglo-French SST Concorde together with the most recent results from previous flights aboard an Air Force NC-135. The measurements were made with a fast Fourier interferometer spectrometer operating in the 1.2 to 7.5 $\mu$m range of the infrared with a spectral resolution of 0.35 cm$^{-1}$. For the Concorde experiments, flight times and trajectories were selected which allowed the Sun to be viewed near the horizon with the relative solar elevation angle held constant throughout the measurements. Mixing ratios as low as a few parts per ten billion for the trace constituents in the
absorption path were determined by spectroscopic analysis of the data. Results to be reported include the identification of features due to N₂O, NO, NO₂, CO, CO₂, CH₄, H₂O and indications of their latitudinal variations. New values for the upper limit of concentration levels for other trace gases of importance to pollution studies, such as HCl and H₂CO, have been determined and are discussed.

F011 A Relationship Between the Volume and Chemical Structure at the Glass Transition Temperature
R. F. Fedors

Since critical volumes have been measured for only a relatively few liquids, it is sometimes necessary to estimate the critical volumes of low-molecular-weight liquids as a function of molecular weight and chemical structure. This paper describes a system of additive group contributions from which the critical volumes of liquids can be estimated from a knowledge of the chemical structure alone, and presents a relationship between the volume and chemical structure at the glass transition temperature. A list of group and atomic contributions to molar volume is included.

F012 Effect of Degree of Crosslinking on the Tearing Energy
R. F. Fedors

Much recent work has been carried out on the tear behavior of elastomers, both filled and unfilled. The effects of variables such as test temperature, test rate, specimen geometry, and chemical nature of the elastomer have been investigated by use of a criterion for tearing involving the concept of the tearing energy. The one variable which has not yet been studied is the specific effect of changes in the degree of crosslinking on tear behavior. By use of data published in the literature on the smooth tear behavior of unfilled SBR (styrene-butadiene rubber) vulcanizates, it is shown that these data can all be superposed onto a common response curve when the proper normalizations are applied.

F013 A New Mechanism of Failure in Polymers
R. F. Fedors

In connection with other work, we had occasion to prepare and observe the swelling in distilled water of 1/2-inch-thick transparent laminates containing imbedded crystals of various ionic and nonionic substances. Briefly, we observed that under certain conditions it is possible for disk-shaped cracks to form around the swollen pockets containing a dissolving crystal. The role of water-soluble impurities in promoting the absorption of water by elastomers has been thoroughly discussed by Briggs, Edwards, and Storey. Briefly, they observed that the absorption of water, which in some cases can be appreciable, is directly relatable to osmotic pressure. Equilibrium water absorption occurs when the osmotic pressure of the solution formed within the rubber by the dissolution of the water-soluble material becomes equal to the hydrostatic pressure exerted by the rubber matrix on the boundary of the cavity. What we wish to describe here is that under certain conditions cracks associated with the cavities can form before equilibrium swelling is reached and that the occurrence of such cracks can severely damage the elastomer.

F014 A Method for Estimating Both the Solubility Parameters and Molar Volumes of Liquids
R. F. Fedors

The solubility parameters and molar volumes of substances can be used, in conjunction with suitable theory, to provide estimates of the thermodynamic properties of solutions; the solubility characteristics of polymer-solvent systems and the estimation of the equilibrium uptake of liquids by polymers are examples of the type of practical problems that are amenable to treatment.

For low molecular weight liquids, the solubility parameter δ is conveniently calculated using the expression δ = (ΔEₜ/VT)¹/², where ΔEₜ is the energy of vaporization at a given temperature and V is the corresponding molar volume which is calculated from the known values of molecular weight and density. For high molecular weight polymers, the volatility is much too low for ΔEₜ to be obtained directly and hence recourse must be made to indirect methods for estimating δ for these materials. One such widely used method is based on Small's additive group "molar-attraction constants" which when summed allow the estimation of δ from a knowledge of
the structural formula of the material; however, the density must still be determined experimentally.

The proposed method of estimating $\delta$, also based on group additive constants is believed to be superior to Small's method for two reasons: (1) the contributions of a much larger number of functional groups have been evaluated, and (2) the method requires only a knowledge of the structural formula of the compound.

F021 Attitude Dynamics Simulation Subroutines for Systems of Hinge-Connected Rigid Bodies
G. E. Fleischer and P. W. Likins
Technical Report 32-1592, May 1, 1974
This report describes several computer subroutines designed to provide the solution to minimum-dimension sets of discrete-coordinate equations of motion for systems consisting of an arbitrary number of hinge-connected rigid bodies assembled in a tree topology. In particular, these routines may be applied to (1) the case of completely unrestricted hinge rotations, (2) the totally linearized case (i.e., all system rotations are small), and (3) the mixed, or partially linearized, case. The use of the programs in each case is demonstrated using a five-body
spacecraft and attitude control system configuration. The ability of the subroutines to accommodate prescribed motions of system bodies is also demonstrated. Complete listings and user instructions are included for these routines (written in Fortran V) which are intended as multi- and general-purpose tools in the simulation of spacecraft and other complex electromechanical systems.

**F023 Viking Mars Lander 1975 Dynamic Test Model/Orbiter Developmental Test Model Forced Vibration Test: Summary Report**

J. Fortenberry and G. R. Brownlee

Technical Memorandum 33-689, November 15, 1974

The Viking Mars 1975 Lander dynamic test model and Orbiter developmental test model were subjected to forced-vibration tests during November–December 1973, at JPL’s dynamic test facility. Flight acceptance and type approval test levels were applied to the spacecraft structure in a longitudinal test configuration using a 133,440-N (30,000-lb) force shaker. Testing in the two lateral axes (X, Y) was performed at lower levels using four 667-N (150-lb) force shakers.

Forced vibration qualification test levels were successfully imposed on the spacecraft at frequencies down to 10 Hz. Measured responses showed the same character as analytical predictions, and correlation was reasonably good. Because of control system test tolerances, Orbiter primary structure generally did not reach the design load limits attained in earlier static testing. A post-test examination of critical Orbiter structure disclosed no apparent damage to the structure as a result of the test environment.

**FOSTER, C. F.**

**F024 Automated Pulsar Receiver**

C. F. Foster

This article describes a self-contained computer-controlled 30-MHz-to-baseband receiver. This receiver has three selectable predetection bandwidths, a diode power detector, an internal level set, and 15 postdetection bandwidths. It is designed to directly interface with an on-site data reduction system. Its primary utilization is the automatic monitoring of pulsar signals.

F032 Network Control System Block I and Block II Software

S. E. Friesema

The Network Control System (NCS) software implementation for Block I and Block II involves two distinct multicomputer systems. NCS Block I is a three-computer system; NCS Block II is a five-computer system. While completely separate, these two systems will operationally complement each other to provide required NCS operational support until NCS Block III is implemented. Both systems are presently designed and coded and are under NCS testing. NCS Block I will be available for operational testing July 1, 1974. This will not include the capabilities for sequence-of-events and tracking-predicts generation. Both programs are scheduled for operation at a later date. NCS Block II will be available for operational testing in early September 1974.

FREILEY, A. J.

F030 DSN Progress Report for November–December 1973: Radio Frequency Performance of DSS 14 64-m Antenna at 3.56- and 1.96-cm Wavelengths

A. J. Freiley

During February and March 1973, the Mars Deep Space Station 64-m-diameter antenna was fitted with major structural braces, and other structural modifications were made to improve low-angle-elevation system gain performance at centimeter wavelengths. The new system performance, as defined by the radio metric measurements of May 1973, is compared to the previous performance, with respect to system efficiency, subreflector focus, and equivalent radio frequency surface tolerance. The evaluation shows that the predicted effect of the structural braces has been achieved; however, either the main reflector or subreflector surface tolerance, or both, have been degraded. The degradation is well defined at X- and Ku-band frequencies; at S-band the effect is nearly negligible.

FRIEDMAN, L. D.

F031 A Design for a Venus Orbital Imaging Radar Mission

J. R. Rose and L. D. Friedman

For abstract, see Rose, J. R.
A. L. Fymat and R. E. Kalaba (University of Southern California)

The random grid search method and the minimization search method recently developed by Fymat for solving inverse multiple-scattering problems of planetary atmospheres are employed for a study of the extent and nature of true information yielded by theoretical partial fits of observed planetary curves. The study is conducted with the Venusian visual phase curve as a background example. It is shown that such fits cannot be used to infer the model scattering parameters of the planet’s atmosphere. They cannot provide any indication of the shape of the scattering diagram, even in the region of the fit. It is also shown that the measured Bond albedo can provide neither a criterion for sorting out different possible scattering model candidates nor a means for accurately determining the single scattering albedo. A high value of the latter albedo for Venus’ atmosphere at visible wavelengths is also found, and Euler’s scattering model is definitely discarded for this planet.

G005 Jupiter, Saturn, and Uranus Disk Temperature Measurements at 2.07 and 3.56 cm

B. L. Gary

Observations at 2.07 cm with the Goldstone 64-m (210-ft) antenna yield the following planetary disk temperatures: Jupiter, 173.4 ± 5.2 K; Saturn, 162.3 ± 3.8 K; and Uranus 178.7 ± 12.9 K. An observation of Saturn at 3.56 cm with the same antenna yields a disk temperature of 169.7 ± 2.3 K.

GATZ, E. C.

G006 DSN Data Record Generation

E. C. Gatz

The DSN is implementing a central Ground Communications Facility Log of all data received and/or generated in the DSN. Selected data from the log are sorted and placed in time order to form an Intermediate Data Record (IDR). This IDR is the principal nonreal-time interface with flight projects.
This memorandum presents methods of measuring moments of inertia with very high accuracy. The moment of inertia of the Helios Spacecraft about its spin axis was determined by use of a roll-fixture having two sets of crossed flexure pivots as elastic constraints. The test procedure entailed measurement of a system oscillation period with each of a set of added moment-of-inertia increments. The tare effect of the fixture was determined by a like process and was subtracted from the gross value to yield the spacecraft roll moment of inertia to an estimated accuracy of 0.2%.

Lateral moments of inertia (i.e., about each of three axes normal to the spin axis) were determined by a gravity pendulum method that makes use of the fact that any physical pendulum has a minimum period of oscillation determined by a particular distance from the axis of rotation to the system center of gravity. In situations where a knife-edge support is used, this distance is equal to the system centroidal radius of gyration. In the subject tests, the pivoting action was provided by hardened pins rolling on flat ways. The effect of the finite radius of the pins was considered in deriving the equations of motion, from which an error analysis revealed the criterion for maximum accuracy in determining the square of the centroidal radius of gyration. Though the centroidal moment of inertia of the swing fixture was over twice that of the spacecraft, an error analysis showed that accuracies of better than 1.0% were realized for the two lateral principal moments of inertia.

This paper develops the relationships between the osculating orbital elements for a family of solutions of the general relativistic Schwarzschild problems. These relationships provide a method for evaluating orbital elements in different Schwarzschild coordinate systems without the necessity of fitting the elements to real data every time the system of coordinates is changed. The objectivity of different coordinate systems is discussed. Considerations of orbital motions favor the standard Schwarzschild metric, but the propagation of light signals is more objective in the metric of Painlevé. Because the orbital motions usually dominate the representation of data, the standard Schwarzschild coordinates are the best objective choice for most applications.

GOLDSTEIN, B. E.

G015 Observations of Electrons at the Lunar Surface

B. E. Goldstein

Observations of electrons at the Apollo 12 and 15 sites by the Alsep Solar Wind Spectrometer experiments showed qualitative differences. In the geomagnetic tail the Apollo 15 instrument provided measurements of lunar photoelectron fluxes from 5 to 40 eV; at 20 eV the flux was $2 \times 10^6$ el/cm$^2$ sec eV ster. The estimated height-integrated conductivity of the photoelectron layer is $10^{-4}$ to $10^{-5}$ ohm$^{-1}$. A theoretical model, ignoring the magnetic field, indicates that most solar wind electrons should reach the lunar surface; a lunar surface potential at the subsolar point of $+5$ to $-3$ V is calculated. At the Apollo 15 site (6-y local magnetic field) electron densities and temperatures agree with this model. At the Apollo 12 site (38-y local field) energetic nonsymmetric electron fluxes are observed. The data support a local space charge separation and a magnetic field of 5 km scale size or less. Downward-moving solar wind electrons require a balancing current due to upward-moving lunar photoelectrons; this suggests that the less energetic lunar photoelectrons should decrease electron pressure on magnetic field lines connected to the Moon. When the magnetic field and solar wind velocity are approximately parallel, a solar wind density enhancement upstream of the Moon is required for pressure balance.

G018 Helios Mission Support

P. S. Goodwin

The Helios-A spacecraft is now less than 6 months from launch. DSN activity is shifting from implementation to operational preparations. There have been, however, three significant recent developments: (1) the final selection of the targeted perihelion distance for the Helios-A mission has been established as 0.31 AU; (2) the Helios-A launch trajectory has been changed from a direct-ascent mode to a parking-orbit mode; and (3) the prototype model spacecraft has successfully passed compatibility testing with the DSN. This article discusses the significance to the Tracking and Data System of each of these developments.

G019 Helios Mission Support

P. S. Goodwin

The Helios Prototype Model Spacecraft has been transported to Cape Canaveral where it will serve both as a forerunner to the first flight spacecraft and as back-up. This article treats the compatibility verification tests that were performed after the prototype's arrival at Cape Canaveral, with particular emphasis upon the first use of the former Spacecraft Compatibility Station equipment in the consolidated Spacecraft Tracking and Data Network facility at Merritt Island, Florida.

G023 Statistical Method for the Prediction of Matching Results in Spectral File Searching

S. L. Grotch

In file search techniques, the distribution of mismatches quantitatively measures the fit of a particular unknown against a given library. A simple theoretical method is developed to predict, a priori, this distribution. With this procedure, for any unknown code and library, the mean number of mismatches can be calculated exactly. For a given library and coding scheme, the mismatch distribution for most unknown codes closely follows a common curve which is easily calculated from statistical properties of the library. When this common curve is normalized to a constant mean, the observed matching behavior is well predicted. The theory should permit the user to more clearly assess the effects of errors on file search performance and suggest techniques by which recognition performance may be optimized.

GREENHALL, C. A.

G021 Minimum Cost Assignment of Crews to Meet Tracking Requirements

C. A. Greenhall

This article describes a model of the tracking constraints, maintenance constraints, labor constraints, and labor costs of a DSN complex. The problem of minimizing the labor costs while satisfying the constraints is solved. Minimum cost schedules for all cases of interest are given and modifications of the model are suggested.

GREGG, M. A.

G022 X-Band Radar Development

M. A. Gregg and R. B. Kolbly

This article describes the development progress of the Mars Deep Space Station X-band radar transmitter. Specific subassemblies discussed are the exciter, combiner-controller for the two 250-kW klystrons, and various high-power components associated with klystron-output combining and monitoring.

GUPTA, K. K.

G027 On a Combined Sturm Sequence and Inverse Iteration Technique for Eigenproblem Solution of Spinning Structures
K. K. Gupta
This paper describes an efficient numerical algorithm for the accurate computation of specific eigenvalues and related vectors of spinning structures. The Sturm sequence technique is first applied to isolate the required roots, which are then individually located by an inverse iteration technique adopting an efficient matrix formulation specially developed for this purpose. The associated digital computer procedure is numerically stable, which also fully exploits the banded form of relevant matrices. Furthermore, the algorithm proves to be much faster than other related existing procedures.

A computer program, based on the current algorithm, has been developed in FORTRAN V for the JPL UNIVAC 1108 computer. Numerical results for representative structures, computed by the program, are also presented in detail. Extensive applications of the program are envisaged in the attitude control of spacecraft and in the natural frequency analysis of spinning structures, discretized by the finite element method.

HAGLER, R., JR.

H001 Explosive-Actuated Valve Design Concept That Eliminates Blow-By
R. Hagler, Jr.
Technical Memorandum 33-682, May 1, 1974
This memorandum presents the JPL method of evaluating the normally open and normally closed, explosive-actuated valves that were selected for use in the trajectory correction propulsion subsystem of the Thermoelectric Outer Planet Spacecraft (TOPS) Program. The design philosophy which determined the requirements for highly reliable valves that could provide the performance capability during long-duration (10-year) missions to the outer planets is discussed. The techniques that were used to fabricate the valves and manifold, 10 valves in an assembly, with the capability of five propellant-flow initiation/isolation sequences are described. The test program, which was conducted to verify valve design requirements, is outlined and significant results are shown.

H002 Combined Effects of Hydrazine Exposure and Endurance Testing on Solenoid-Actuated Valve Performance
R. Hagler, Jr.
Technical Memorandum 33-691, July 1, 1974
This memorandum presents the results of a test program which was conducted to assess the capability of various solenoid-actuated valve design concepts to provide performance characteristics commensurate with long-duration (10-year) missions to explore the outer planets. The valves were installed in a hydrazine-flow test setup and periodically cycled during a nine-month test period under test conditions comparable to anticipated mission operating conditions. In situ valve performance was periodically determined, and leakage was continuously monitored.

HALL, R. C.

H003 Annual Chronology of International Astronautical Events: 1972
R. C. Hall
This article presents a chronology, compiled by the International Academy of Astronautics, of scientific and technological events and achievements during 1972 which attest to international cooperation in the exploration and use of outer space. Included is a bibliography of 1972 publications that pertain to the history of astronautics and a list of United Nations documents on the uses of outer space.

H004 Annual Chronology of International Astronautical Events: 1971
R. C. Hall
This article presents a chronology, compiled by the International Academy of Astronautics, of scientific and technological events and achievements during 1971 which attest to international cooperation in the exploration and use of outer space. Included is a bibliography of publications for the same year that pertain to the history of astronautics.
The Fifth International Symposium on the History of Rocketry and Astronautics (IAA) was held in Brussels, September 23, 1971. The symposium met in conjunction with the Twenty-second International Astronautical Federation (IAF) Congress. As in past IAA history symposia, the twelve memoir and research papers that were presented complied with the "twenty-year rule" incorporated into the 1971 program theme: "new contributions to the historical literature on rocket technology and astronautics before 1951." This article presents the title, author(s), and summary of each paper.

**HALL, R. I.**

**Electron Impact Excitation and Assignment of the Low-Lying Electronic States of N$_2$O**

R. I. Hall, A. Chutjian, and S. Trajmar

Electron-scattering spectra of nitrous oxide are reported in the 5–10 eV energy-loss range at scattering angles of 20, 30, 90, and 130 deg at a residual energy of 7.0 eV; and at residual energies of 10.0, 2.0, 1.0, 0.8, and 0.2 eV at a scattering angle of 90 deg. Several new distinct and overlapping continua are observed to lie in this energy-loss range. The experimental spectra are discussed in the light of semiempirical INDO calculations by Chutjian and Segal (1972) of the vertical transition energies of N$_2$O. An assignment of the symmetries of the observed excitations consistent with the experimental and theoretical data is suggested.

**HAMILTON, G. B.**

**Viking 1975 Analog Recording**

G. B. Hamilton

The requirements on the FR1400 analog magnetic tape recorders in the DSN have been increasing in recent years. Viking Mars 1975 requirements appeared particularly stringent. Problems of insufficient tape recording channels or bandwidth were solved by decreasing telemetry requirements and by providing no backup recording for occultation purposes on the standard telemetry recorders.

**HAPKE, B.**

**Venus: Atmospheric Motion and Structure From Mariner 10 Pictures**

N. C. Ham

Additional analysis and study have completed the mathematical model of the Helios spacecraft low-gain antenna and permitted the formulation of experimental tests for simulating the spin modulation effects at a typical deep space station communication system. This article discusses the details of the test technique, system test configuration, and results of the simulation tests.

**HARDY, J. P.**

**H013** 1-Butanol-Hydrogen Chloride: An Allegedly Anhydrous Esterification Reagent

J. P. Hardy, S. L. Kerrin, and S. L. Manatt

The stability of a common Fischer esterification reagent used extensively for preparation of amino acid and carboxylic acid esters, 2.1 M HCl-1-butanol, has been studied in detail. After 2 hr at 100 and 150°C, the concentrations of 1-chlorobutane, di-1-butyl ether, and water in this reagent are 0.71, 0.04, and 0.75, and 2.38, 0.22, and 2.58 M, respectively. Approximate rate constants for formation of these products at 100 and 150°C have been determined. It is concluded that esterifications with this reagent should be carried out below 100°C to achieve best yields. An equilibrium constant of 0.15 ± 0.03 has been measured in the esterification of a typical aliphatic amino acid, leucine. The significance of the production of water in this esterification reagent is discussed especially in light of its use in amino acid esterification procedures where the carboxylic acid concentrations may be at the millimolar or lower concentration level.

H021 DSN Progress Report for November-December 1973: X-Band Antenna Feed Cone Assembly

R. W. Hartop

In support of Viking Mars 1975 and future projects, the DSN must provide for X-band signal reception at its 64-m-diameter antenna stations. This article reports the progress to date in the construction of the new X-band feed cone assemblies, for which the feed subassemblies have been completed.

HATCH, J. T.

H022 Real-Time High-Rate Telemetry Support of Mariner 10 Operations

J. T. Hatch and J. W. Capps

Television pictures from the Mariner Venus/Mercury 1973 spacecraft were received and displayed in real-time at JPL during important phases of the mission. In order for the DSN to support this activity, the telemetry data processing equipment at the Mars Deep Space Station had to be modified and a special microwave super-group channel established between the station and JPL to handle transmission of the high rate (117.6 kbps) data. How this capability was implemented and operated by the DSN is described in this article.

HEYSER, R. C.

H023 Ultrasonic Transmission Measurements on Human Brain Sections

L. S. Fishman (Children's Hospital of Los Angeles), R. C. Heyser, and D. H. Le Croissette

For abstract, see Fishman, L. S.
R. C. Heyser and D. H. Le Croissette

This article describes a new method of forming a visual image by ultrasound. A shadowgraphic transmission image similar to an X-ray radiograph is produced by the application of a technique known as time delay spectrometry. The system uses a repetitive frequency sweep with a linear relationship between frequency and time, and the transmitting and receiving crystal are scanned in raster fashion about the subject. By electronic processing, an image may be built up which represents the energy transmitted through the specimen with a given time delay. An intensity modulated picture encompassing the full shades-of-gray capability of the recording system can be produced.

A second type of image showing transmission time through the specimen may also be formed. Brightness changes in the displayed image in this case correspond to changes in the ultrasonic transmission time through the specimen. There is no analog for this type of image in current X-ray or ultrasonic practice. Examples of both types of images of specimens both *in vitro* and *in vivo* are shown. The advantages and potentials of this method for biomedical ultrasonic imaging and analysis are discussed.

H026 Survey of Auxiliary-Propulsion Systems for Communications Satellites

L. B. Holcomb and D. H. Lee (TRW Systems Group)

This article surveys current auxiliary-propulsion systems to provide insight for the selection of attitude and station-keeping propulsion systems for future communications satellites. Thruster systems specifically considered are stored gas, vaporizing ammonia/electrothermal, catalytic monopropellant hydrazine, electrothermal monopropellant hydrazine, plenum monopropellant hy-

drazine, ion, colloid, and pulsed plasma. Details of each of the thruster types are divided into three sections: (1) description of thruster system and how it functions, (2) spaceflight experience, and (3) survey of state-of-the-art thrusters. In addition, a qualitative tabulation of thruster characteristics is included.

H027 The 1973 Mariner Mission to Venus and Mercury: Part One

A. J. Hooke

The Mariner Venus/Mercury 1973 spacecraft will perform history's first dual-planet flyby using gravitational assist and will return close-up pictures of the cloud cover of Venus and the first detailed glimpse of Mercury and its environment. This article is the first part of a two-part document that discusses in detail the Mariner Venus/Mercury 1973 mission. Specific areas covered are: project organization, mission objectives, science instruments and objectives, spacecraft trajectory and coordinate system, overall spacecraft configuration, specific spacecraft subsystems, and the proposed flight plan.

**HOUSEMAN, J.**

H029 On-Board Hydrogen Generator for a Partial Hydrogen Injection Internal Combustion Engine

J. Houseman and D. J. Cerini
A compact onboard hydrogen generator has been developed for use with a hydrogen-enriched gasoline internal combustion engine. The unit uses gasoline and air in a partial oxidation reactor to produce a gaseous product containing hydrogen, nitrogen, carbon monoxide, and minor amounts of methane, carbon dioxide, and water. A study of the theoretical equilibrium product composition has indicated an optimum operating point at an air/fuel ratio of 5.15, where a hydrogen/fuel mass ratio of 0.138 can be obtained under soot-free conditions. This is based on a gasoline with an atomic hydrogen to carbon ratio of 1.92.

Both thermal and catalytic reactors have been tested. The thermal unit requires a reaction temperature of 2400°F to obtain 80% of the theoretical hydrogen yield. Soot formation tends to be a problem. The catalytic reactor yields close to theoretical yields at an operating temperature of 1800°F without any soot formation. A commercial nickel catalyst is used. A 100 h test with the catalytic unit showed no signs of performance degradation, using fully leaded Indolene 30. The calculated effect of hydrogen generator operating conditions on the fuel efficiency of a generator/engine combination is presented.

H. T. Howard (Stanford University)

H030 Venus: Mass, Gravity Field, Atmosphere, and Ionosphere as Measured by the Mariner 10 Dual-Frequency Radio System

H. T. Howard (Stanford University) et al.

Analysis of the doppler tracking data from the Mariner Venus/Mercury 1973 spacecraft near Venus encounter yields a value for the ratio of the mass of the Sun to that of Venus of 408.5 ± 1.2, which is in good agreement with prior determinations based on data from Mariner 2 and Mariner 5. Preliminary analysis indicates that the magnitudes of the fractional differences in the principal moments of inertia of Venus are no larger than 10^-4, given that the effects of gravity-field harmonics higher than the second order are negligible. Additional analysis is needed to determine the influence of the higher order harmonics on this bound.

Four distinct temperature inversions were found at altitudes of 58, 58, 61, and 63 km. The X-band signal was much more rapidly attenuated than the S-band signal and disappeared completely at 52-km. The nightside ionosphere consists of two layers having a peak density of 10^4 electrons/cm^3 at altitudes of 140 and 120 km. The dayside ionosphere has a peak density of 3 × 10^5 electrons/cm^3 at an altitude of 145 km. The electron number density observed at higher altitudes was ten times less than that observed by Mariner 5, and no strong evidence for a well-defined plasmapause was found.

H031 Mercury: Results on Mass, Radius, Ionosphere, and Atmosphere From Mariner 10 Dual-Frequency Radio Signals

H. T. Howard (Stanford University) et al.

Science, Vol. 185, No. 4146, pp. 179-180, July 12, 1974

Analysis of the radio-tracking data from the Mariner Venus/Mercury 1973 spacecraft (Mariner 10) yields 6,023.600 ± 600 for the ratio of the mass of the Sun to that of Mercury, in very good agreement with values determined earlier from radar data alone. Occultation measurements yielded values for the radius of Mercury of 2440 ± 2 and 2438 ± 2 km at latitudes of 2°N and 66°N, respectively, again in close agreement with the average equatorial radius of 2439 ± 1 km determined from radar data. The mean density of 5.44 g cm^-3 deduced for Mercury from Mariner 10 data thus virtually coincides with the prior determination. No evidence of either an ionosphere or an atmosphere was found, with the data yielding upper bounds on the electron density of about 1500 and 4000 el cm^-3 on the dayside and nightside, respectively, and an inferred upper bound on the surface pressure of 10^-6 millibar.

H034 Reactions of Fragment Ions in Methane: Ion-Molecule Reactions in Methane and Helium-Methane Mixtures

The rate constants and product distributions for the reactions of CH$_2^+$ and CH$^+$ ions with methane have been measured over the range of ion kinetic energies from near thermal velocities to approximately 6 eV by using ion cyclotron resonance methods. The rate constant and product distribution for the reaction of He$^+$ ions with methane are also measured at near thermal velocities, and the possibility for the production of excited CH$_2^+$ and CH$^+$ ions by this latter reaction is examined.

H035 Product Distributions and Rate Constants for Ion-Molecule Reactions in Water, Hydrogen Sulfide, Ammonia, and Methane

W. T. Huntress, Jr. and R. F. Pinizzotto, Jr.

The thermal-energy, bimolecular ion–molecule reactions occurring in gaseous water, hydrogen sulfide, ammonia, and methane have been identified and their rate constants determined using ion cyclotron resonance methods. Absolute rate constants were determined for the disappearance of the primary ions by using the trapped ion method, and product distributions were determined for these reactions by using the cyclotron ejection method. Previous measurements are reviewed and compared with the results using the present methods. The relative rate constants for hydrogen-atom abstraction, proton transfer, and charge transfer are also determined for reactions of the parent ions.

H040 Efficient Generation of Statistically Good Pseudonoise by Linearly Interconnected Shift Registers

W. J. Hurd

This article presents some new algorithms for efficiently generating pseudorandom noise both in hardware and software. In software, a new word of pseudorandom bits can be generated about every 12 machine cycles, and hardware implementations can generate pseudo-Gaussian noise with bandwidth of 20 MHz or more. The algorithms generate binary maximal-length linear recursive sequences of high degree and with many nonzero terms. The ability to efficiently implement high-degree recursions is important because the number of consecutive bits which can be guaranteed to be both linearly and statistically independent is equal to the degree of the recursion. The implementations are by interconnection of several short shift registers in a linear manner in such a way that different widely spaced phase shifts of the same pseudonoise sequence appear in the stages of the several registers. Some specific algorithms have been subjected to extensive statistical evaluation, with no evidence found to distinguish the sequences from purely random binary sequences.

INGHAM, J. D.

1001 Microbial Abundance and Thermoluminescence of Antarctic Dry Valley Soils

J. D. Ingham, R. E. Cameron, and D. D. Lawson

The ecologies of Antarctica and other severe terrestrial environments are of fundamental interest in connection with the determination of the factors that most significantly affect the survivability and adaptability of living organisms under extreme conditions. A better understanding of such limited ecologies is particularly relevant to the prospects of life and methods of life detection in planetary rocks and soils, and in the assessment of potential contamination of planetary environments by adaptable terrestrial microorganisms. Although studies have been conducted to relate geologic age, stratigraphical features, microclimate, mineral composition, and radiation history to thermoluminescence (TL) of rocks, determination of the relationships (if any) between bacterial abundance and TL response of soils has not been attempted.

Because some of the many factors affecting bacterial abundance also affect TL response, this work was initiated to define any potential correlations. TL data can be more easily and quickly obtained than bacterial abundances through cultural methods; therefore, TL measurements might be useful for soil surveys of an ecological nature. TL could be used to indicate appropriate sites for bacterial abundance measurements, or it could be interpolated with limited cultural tests to determine bacterial abundances. Data reported here demonstrate an approximate inverse trend between TL response and bacterial abundance for Victoria Valley soils, and a clear relationship between salt concentration or TL response and bacterial abundance for Victoria Valley soils.

INGRAM, M.

1002 Platelet Adhesion to Heparin-Bonded and Heparin-Free Surfaces

A. Rembaum, S. P. S. Yen, M. Ingram, J. F. Newton, C. L. Hu, W. G. Frasher (University of Southern California Medical Center), and B. H. Barbour (University of Southern California Medical Center)
A considerable amount of medical apparatus, because of its incompatibility with reliable sterilization methods, is implicated in the transmission of disease-producing microorganisms. One such device, an intermittent positive-pressure breathing apparatus, was modified in conjunction with a manufacturer to demonstrate the feasibility of converting an existing apparatus to one which is compatible with dry heat sterilization. This sterilization method has been proven to be capable of highly efficient, reliable, total destruction of all bacterial and viral forms of life.

NASA-developed material, design, and sterilization technologies were utilized to effect the appropriate modifications to this apparatus. Prototype units are capable of withstanding repeated sterilization cycles at 125°C. The results of hospital field testing substantiated the effectiveness of this effort.

For abstract, see Woo, R. T.

This article describes the activities of the Development Support Group in operating and maintaining the Venus Deep Space Station. Activities included planetary-radar experiments (Venus and Mercury), radio-source sky survey using the 26-m-diameter antenna, Faraday-rotation data collection, weak-radio-source flux density measurement, X-band 400-kW radar development and testing, Block IV receiver/exciter installation and testing/checkout, 26-m-diameter antenna receiving system temperature improvement, differential very-long-baseline interferometry experiments, clock-synchronization transmissions, Mars Deep Space Station high-power transmitter maintenance support, and Pioneer 10 science support.

This article describes the activities of the Development Support Group in operating and maintaining the Venus Deep Space Station and the Microwave Test Facility. Activities noted include planetary radar experiments, station automation demonstration development, weak radio source observation, 26-m antenna pattern sidelobe measurements, and testing of an adhesive planned for use in construction of an insulated subreflector for the overseas 64-m antennas. Support for the Block IV receiver/exciter at the Mars Deep Space Station (DSS 14) is noted; a capsule progress report on the 400-kW X-band planetary radar is given; and high-power transmitter maintenance at DSS 14 and testing of DSN klystrons are discussed. Differential very-long-baseline interferometry (VLBI) transmissions and Pioneer 10 science support are also discussed.

This article describes the activities of the Development Support Group in operating and maintaining the Venus Deep Space Station and the Microwave Test Facility. Activities include interferometric planetary radar measurements of the surface of Venus, support of station
automation (pulsar) testing and observing, weak radio source observation for 64-m antenna gain calibration, completion of the sidelobe measurements on the 26-m antenna (with resultant changes in gain and system temperature), and extensive sky survey measurements. Additionally, major support was given to spacecraft projects with Faraday rotation data collection, support of the Block IV receiver/exciter at the Mars Deep Space Station, X-band (400-kW) radar testing and Rio Cofo Deep Space Station 100-kW transmitter testing.

**J006 Phonons in Quantum Solids With Defects**

N. Jacobi and J. S. Zmuidzinas
Technical Memorandum 33-701, September 1, 1974

This memorandum develops a formalism for temperature-dependent, self-consistent phonons in quantum solids with defects. Lattice vacancies and interstitials in solid helium and metallic hydrogen, as well as electronic excitations in solid helium, are treated as defects that modify properties of these systems. The information to be gained from the modified phonon spectrum is discussed.

JACOBSON, R. A.

**J007 Iterative Explicit Guidance for Low Thrust Spaceflight**

R. A. Jacobson and W. F. Powers (University of Michigan)

*J. Spacecraft Rockets, Vol. 11, No. 7, pp. 494–497, July 1974*

A retargeting procedure is developed for use as a nonlinear, low-thrust guidance scheme. The selection of a control program composed of a sequence of inertially fixed thrust-acceleration vectors permits all trajectory computations to be made with closed-form expressions, and allows the controls to be represented by constant parameters, thrust-acceleration vectors, and thrusting times. By requiring each trajectory to be time optimal, the guidance problem is transformed into a parameter optimization problem which is solved by a Davidon-type method. The scheme is applied to a low-thrust capture mission, and the results of computer simulations are presented.

J008 Terminal Navigation Analysis for the 1980 Comet Encke Slow Flyby Mission

*J. Spacecraft Rockets, Vol. 11, No. 8, pp. 590–596, August 1974*

This article presents the initial results of a terminal navigation analysis for the proposed 1980 solar-electric slow flyby mission to the comet Encke. The navigation technique employs onboard optical measurements with the scientific television camera, ground-based observations of the spacecraft and comet, and ground-based orbit determination and thrust vector update computation. The knowledge and delivery accuracies of the spacecraft are evaluated as a function of the important parameters affecting the terminal navigation. These in-
clude optical measurement accuracy, thruster noise level, duration of the planned terminal coast period, comet ephemeris uncertainty, guidance initiation time, guidance update frequency, and optical data rate.

J012 Mariner IX Optical Navigation Using Mars Lit Limb
N. Jerath and H. Ohtakay
Optical spacecraft navigation data, i.e., the lit limb TV image of Mars, acquired during the approach phase of the Mariner Mars 1971 spacecraft to Mars, has been successfully demonstrated to augment the radio spacecraft tracking data. Accurate in-flight calibration of the TV instrument and the scan platform was performed by referencing stars and planets. Simulated real-time processing and the detailed postflight analyses of the onboard optical data have shown that planet limb data is an important data source in a far-encounter period for which other types of onboard optical measurements, e.g., natural satellite(s) of the target planet with star background, may not be available.

JET PROPULSION LABORATORY

Jet Propulsion Laboratory
The Workshop on Photovoltaic Conversion of Solar Energy for Terrestrial Applications, organized by JPL, was held in Cherry Hill, New Jersey on October 23–25, 1973, under the sponsorship of the National Science Foundation (NSF)-Research Applied to National Needs program (Grant No. AG-485). The meeting was called in recognition of the pressing need for the exchange of information among researchers in this field and to promote a dialogue between the researchers on the one hand and representatives of manufacturing, marketing, government, and utilities on the other. Considerable effort was devoted to obtaining participation from a broad representation of the manufacturing, marketing, and user fields having an interest in large-scale photovoltaic applications for national energy needs. The meeting was also intended to aid NSF in planning resources and in developing reasonable goals and milestones for the photovoltaic program within the constraints of expected funding.

The proceedings of this Photovoltaic Workshop (NSF document NSF-RA-N-74-013) have been published in two volumes. Volume I covers the introductory remarks by NSF, the working group summaries and discussions, and the panel discussions, and includes the agenda for the entire three-day workshop and the list of attendees.

Jet Propulsion Laboratory
Special Publication 43-3, Vol. II, April 1974
The Workshop on Photovoltaic Conversion of Solar Energy for Terrestrial Applications, organized by JPL, was held in Cherry Hill, New Jersey on October 23–25, 1973, under the sponsorship of the National Science Foundation (NSF)-Research Applied to National Needs program (Grant No. AG-485). The meeting was called in recognition of the pressing need for the exchange of information among researchers in this field and to promote a dialogue between the researchers on the one hand
and representatives of manufacturing, marketing, government, and utilities on the other. Considerable effort was devoted to obtaining participation from a broad representation of the manufacturing, marketing, and user fields having an interest in large-scale photovoltaic application for national energy needs. The meeting was also intended to aid NSF in planning resources and in developing reasonable goals and milestones for the photovoltaic program within the constraints of expected funding.

The proceedings of this Photovoltaic Workshop (NSF document NSF-RA-N-74-013) have been published in two volumes. Volume II encompasses the five sessions of technical presentations and discussions. The questions, answers, and comments following each presentation were transcribed as completely as possible from tape recordings, with some editing being employed to improve readability.

JOHNSON, E. T.

J018 Metaphase Spread Detection and Focus Using Closed Circuit Television
E. T. Johnson and L. J. Goforth
J. Histochem. Cytochem., Vol. 22, No. 7, pp. 536-545, July 1974

Automatic focus and detection of metaphase chromosome spreads have been implemented in an automated light microscope system and performance has been evaluated. The video signal from a standard closed circuit television camera is used to generate focus quality and spread presence parameters that are input to a computer. The computer, through its operating software, controls lateral and vertical motion of the microscope stage to search the slide for metaphase chromosome spreads and to focus them. The video signal processing required to generate the parameters, its implementation, and the operating software are described. The evaluation of spread detection performance emphasizes the need for well prepared slides with clean backgrounds. The performance of two methods of obtaining a focus parameter is compared. The first method involves measuring the high spatial frequency content of the image; the second method uses the distribution of optical density within the image.

J020 Optical Properties of Carbonaceous Chondrites and Their Relationship to Asteroids
T. V. Johnson and F. P. Fanale

This article presents the diffuse reflectance measurements of nine samples of carbonaceous chondrites (one C1, three C2, four C3, and one C4) and one iron meteorite. Measurements were also made of mineral mixtures in an attempt to understand the causes of some features of the meteorite reflectances. The results of these measurements were compared with current photometry of asteroids. It is concluded that, among materials of known cosmic importance, carbonaceous material appears to provide the best match to the optical properties of some asteroids.
This memorandum describes an experiment in which optical proximity sensors were used in a feedback loop to automatically position a manipulator hand for grasping. The experiment was a simplified one, involving two-dimensional motion only. Two proximity sensors were mounted on the hand, and control signals derived from their outputs were used to drive the hand vertically and horizontally. The sensors employ a pulsed gallium-arsenide light-emitting diode together with a silicon detector. They indicate, without contact, the approximate distance between the manipulator hand and object in the range from 5 to 12 cm. Positioning within approximately ±5 mm was observed. Extension of the technique to general three-dimensional control is briefly discussed.

Testing Relativistic Gravity Theories Using Radio Tracking Data From Planetary Orbiting Spacecraft

J. F. Jordan, W. G. Melbourne, and J. D. Anderson

This article presents an analysis of a computational method for determining the numerical values of the relativities and other related dynamical parameters using two-way doppler and ranging data from planet-orbiting spacecraft. The computational method consists of the determination of Earth-planet distance values to 100 ns accuracy from the tracking data and the treatment of these values, along with planetary radar and meridian-circle data, as raw data in a regression analysis to solve for the significant solar-system parameters. The main conclusions of the article are that a 5% determination of the metric parameter $\beta$ is attainable using a time base that spans both Mariner Mars 1971 and Viking Mars 1975 and includes ground-based radar tracking of Mars. Over the same span $\gamma$ is determined to at least 1%.

A Proposed Method of Reducing the Gravity Distortions of the 64-Meter Antenna Main Reflector

M. S. Katow

The surface panels of the 64-m-diameter main reflector at Goldstone are presently set to a prescribed paraboloid for a 45-deg elevation angle. Rotation about the elevation axis to the horizon or zenith introduces additional root-mean-square (rms) distortions due to the change in the direction of the gravity vector with respect to the symmetry axis. This article proposes a method of reducing the bumps or humps over the unyielding "hard" portions of the elevation wheel assembly supporting the reflector structure, thus reducing the rms distortions due to gravity for the structure. The bumps can be effectively removed by controlling the height of the panels above the reflector structure by means of mechanical leverage connections to the elevation motion, thus maintaining the simplicity and reliability of the reflector system. A table of overall rms distortions resulting from the summations of various options is included.

Wind Tunnel Experiments Relating to Supersonic and Hypersonic Boundary Layer Transition

J. M. Kendall

Hot-wire anemometry is used to study the origin and growth of "natural" fluctuations in zero-pressure-gradient boundary layers and the location of transition to turbulence for several Mach numbers between 1.6 and 8.5. The importance to transition of certain physical mechanisms is examined through comparison of the fluctuation growth with the sound-forcing and stability theories of Mack. The mechanisms are shown to assume
varying importance in low supersonic, high supersonic and hypersonic regimes. The effect on transition of cone angle of attack, tip heating, and model vibration is mentioned.

KLASCIUS, A. F.

K013 Microwave Radiation Hazards Around Large Microwave Antenna
A. F. Klascius
The microwave radiation hazards associated with the use of large antennas become increasingly more dangerous to personnel as the transmitters go to ever higher powers. The near-field area is of the greatest concern. It has
spillover from the sub-reflector and reflections from nearby objects. Centimeter waves meeting in phase will reinforce each other and create hot spots of microwave energy. This has been measured in front of and around several 26-m antennas. Hot spots have been found and are going to be the determining factor in delineating safe areas for personnel to work. Better techniques and instruments to measure these fields are needed for the evaluation of hazard areas.

KLEIN, M. J.

K014 Flux-Density Measurements of Selected Radio Sources Relative to Cassiopeia A at 21.84 GHz

M. J. Klein

This article reports new measurements of the flux-density ratios of seven radio sources relative to Cassiopeia A at 21.84 GHz. Based on the assumption that the flux density of Cassiopeia A was 266.6 flux units at the mean epoch 1971.1, the flux densities of the program sources are given. The DR 21 flux density agrees with the short wavelength flux-density scale proposed by Dent. The fluxes of the other sources are consistent with their extrapolated spectra except Cygnus A, which appears to exhibit a microwave spectrum with greater convex curvature than previously believed.

KLIMASAUASKAS, C. C.

K015 Observations on Microprocessors and Computing Efficiency

C. C. Klimasauskas and J. W. Layland

This article presents results of a continuation of a previous study of computing efficiency in DSN-related tasks. The two task models considered here are manipulation of man-readable character-string data, and a very simple process-variable monitoring operation. Several currently available minicomputers and microprocessors are compared. The principal result is that the microprocessors appear considerably more cost-effective than the more powerful machines for simple, repetitive tasks, but that the opposite is true for more complex operations.

K018 Efficient Implementation of a Variable Projection Algorithm for Nonlinear Least Squares Problems

F. T. Krogh

Nonlinear least-squares problems frequently arise for which the variables to be solved for can be separated into a linear and a nonlinear part. A variable projection algorithm has been developed recently which is designed to take advantage of the structure of a problem whose variables separate in this way. This article gives a slightly more efficient and slightly more general version of this algorithm than has appeared previously.

K021 The Importance of Aerodynamics in the Design of Intra-Urban Trains Traveling in Tunnels
D. W. Kurtz and B. Dayman, Jr.

Aerodynamics can be a major factor in the design and operation of intraurban subway-train transportation systems. In order to develop an adequate understanding of the aerodynamic characteristics of such systems, an experimental program was carried out. The major portion of the testing was conducted under equilibrium, incompressible conditions so that the fundamental aerodynamic characteristics could be isolated. The effects of geometric parameters (such as train speed, blockage ratio, wall roughness, and train and tunnel length) upon train drag and tunnel flow velocities were determined and compared with a simple theoretical model. The effect of aerodynamic forces upon typical subway-train operations is shown in order to give proper perspective to the importance of aerodynamics.

K023 Intensities of Rotational Lines in First Overtone Bands for Axially Symmetric Molecules of the Group \( \text{C}_3 \)
Y. Y. Kwan

The interaction of vibration and rotation is considered in the computation of the intensities of rotational lines in the first overtone bands of axially symmetric molecules of the group \( \text{C}_3 \). The calculation utilizes the contact transformation method through first order of approximation as outlined by Hanson and Nielsen. General formulas for the intensities of the lines in the first overtone bands \( 2\nu_n \) and \( 2\nu_m \) are obtained, where \( n \) and \( m \) denote normal modes of species \( A_1 \) and \( E \), respectively. It is found that to this order of approximation the usual selection rules are observed for the overtone band \( 2\nu_n \), but for the overtone band \( 2\nu_m \), the selection rules are more complicated.

LANDEL, R. F.

L001 On the Phenomenology of Rubberlike Behavior
R. F. Landel and R. F. Fedors

A simple functional statement of stress–strain response can be used as the basis for a phenomenological investigation of the response, including rupture. Experimental observations on time–temperature or time–chain concentration superposition, time–strain factorizability, and the proportionality of stress with chain concentration can all be invoked to produce a simple, all-encompassing representation of the response. The results turn out to be very similar for all elastomers.

A semiquantitative molecular theory is reviewed which, though incomplete, accounts for much of the response in the rubbery region. Nine molecular parameters are identified. Unsolved problems include the origin and molecular description of the slow relaxation processes associated with entanglements and a molecular theory of finite-strain elastic and viscoelastic response.

K023 Recent Advances in Elastomer Service-Life Prediction
R. F. Landel, R. F. Fedors, and J. Moacanin

The mechanical properties of an elastomer, including rupture and its time dependence, are defined uniquely by a “tensile property surface” in normalized stress–time coordinates. In practice, the “property surface” is determined from short time constant strain-rate uniaxial tests. By using the time reduction properties of both temperature and crosslink density, an effective time scale of over ten decades of log time can be covered. Changes in crosslink density, filler content, or swelling do not affect the limits of the “property surface” when plotted in logarithmic coordinates but merely shift their positions. The shape, however, may be modified in certain cases.

The service life of an elastomer in the absence of aging reactions can be estimated from the “property surface,” especially its limits, along with the knowledge of ex-
pected in-use conditions such as strains (static or dynamic). When an elastomer experiences aging reactions, some of the parameters will change with time in a manner determined by the kinetics of the aging reactions. Consequently, the position of the "property surface" will shift with time. The parameters which are of primary interest are crosslink density and the extent of plasticization (sol fraction, swelling, etc.). This means that the performance of an elastomer can be anticipated from the knowledge of the kinetics of changes of very few parameters.

This article compares the characteristics and performance of two near-optimal constraint-length 7, rate 1/3 convolutional codes. Performance estimates are based upon software simulations for the additive white Gaussian noise channel.

L012 Buffer Management for Sequential Decoding

J. W. Layland

Sequential decoding has been found to be an efficient means of communicating at low undetected error rates from deep space probes, but another failure mechanism known as erasure or computational overflow remains a significant problem. The erasure of a block occurs when the decoder has not finished decoding that block at the time that it must be output. The erasure rate can be unacceptably high even when the decoder is spending over half of its time idly awaiting incoming data. By drawing upon analogies in computer time sharing, this article develops a buffer-management strategy which reduces the decoder idle time to a negligible level, and therefore improves the erasure probability of a sequential decoder. For a decoder with a speed advantage of ten and a buffer size of ten blocks, operating at an erasure rate of $10^{-2}$, use of this buffer-management strategy reduces the erasure rate to less than $10^{-4}$.

LEIBOWITZ, L. P.

Jupiter Entry Simulation With the ANAA Shock Tube

L. P. Leibowitz

Preprint 74-610, AIAA Eighth Aerodynamic Testing Conference, Bethesda, Maryland, July 8–10, 1974

An annular-arc-accelerator (ANAA) shock tube has been built which produces shock velocities and pressures that simulate entry into the atmosphere of Jupiter. The ANAA driver deposits the energy of an arc discharge into a flowing gas, which then expands and cools without any delay for the opening of a diaphragm. A flow transducer, trigger system and spark gap switches have been developed to coordinate the flow from a high pressure helium driver with the discharge from a 300-kjoule capacitor bank.

Shock velocities up to 47 km/s have been produced in 1.0 torr of hydrogen with the ANAA shock tube, compared with a 35 km/s velocity produced in a conical arc driver with three times the available energy. Attenuation with the ANAA shock tube is comparable to that of a conical arc driver shock tube and initial spectroscopic measurements indicate that an impurity-free test slug is formed behind the shock wave.

Radiative Relaxation Behind Strong Shock Waves in Hydrogen–Helium Mixtures

L. P. Leibowitz, W. A. Menard, and G. H. Stickford, Jr.

This paper investigates radiative-relaxation rates in a series of hydrogen–helium mixtures over a range of temperatures encountered during outer-plant atmospheric
entry. Using a conical electric-arc shock tube, shock waves with velocities between 10 and 36 km/s were studied in mixtures of 10 to 65% hydrogen in helium diluent. Intensities for several hydrogen-continuum wavelengths and the Hβ and Hγ lines of hydrogen were measured as a function of time. Time resolved measurements of the electron density within the nonequilibrium zone were made by monitoring the growth of the Hγ line with a fiber-optics slit system.

The nonequilibrium relaxation times were longer than expected for shock velocities greater than 18 km/s and reached a plateau at higher shock velocities. Data from all mixtures were found to correlate with shock-wave temperature. Numerical calculations of the ionization kinetics and radiation relaxation predict the variation of the experimental data with shock velocity and mixture ratio when the dissociation rate of molecular hydrogen is the same or slower than the ionization rate of hydrogen. Good agreement was found between the electron densities obtained from the Hγ line shape measurements and the kinetics calculations.

LEPPERT, E. L.

L029 Modal Test of the Viking Orbiter
E. L. Leppert, B. K. Wada, and R. Miyakawa (Martin Marietta Corporation)
Technical Memorandum 33-688, July 15, 1974

A modal test of the Viking Mars 1975 Orbiter Development Test Model (ODTM) has been conducted to verify, or update, the mathematical model used for load analysis. The approach used to assure the quality and validity of the experimental data is defined, the modal test is described, and test results are presented and compared with analysis results. Good correlation between the analyses and the test data assures an acceptable model for incorporation into the mathematical model of the launch system.

L031 Verification of Commands From the Transmitting Medium
J. R. Lesh

This article describes a system for bit-by-bit verification of Pioneer command modulation by sampling the S-band transmitted signal directly at the antenna. This system was installed at the Mars Deep Space Station and operated flawlessly during the entire 60-day Pioneer 10 encounter sequence.

LEVIN, M. D.

L035 Computer Determination of Depth Maps
M. D. Levine, D. A. O’Handley, and G. M. Yagi

The research in support of the integrated robot project at JPL is partially directed towards the problem of visual perception by computer. It is anticipated that the autonomous behavior of the robot will be predicated on the feedback obtained by an analysis of the environment. Thus the robot will be equipped with a pair of identical television cameras which will provide a digitized stereoinput. Using the latter, one approach to representing three-dimensional objects in a scene is the depth map. This article describes a computer method for obtaining the depth map which mirrors the detail in the original scene. To this end, an adaptive correlation window is incorporated as an aid in the solution of the correspondence problem. Heuristic strategies based on local context and texture measures have also been invoked. Results are included which demonstrate the success of the technique.

LEVITT, B. K.

L036 DSN Progress Report for November–December 1973: Frame Synchronization Performance Analysis for MVM’73 Uncoded Telemetry Modes
B. K. Levitt

This article describes a practical frame-synchronization acquisition and maintenance algorithm based on the Hamming distance metric, which is a generalization of the algorithm developed for the Mariner Venus/Mercury 1973 (MVM’73) mission. For the special case of uncoded phase-shift-keyed data received over the binary symmetric channel, formulas are derived for computing an upper
bound on the probability of false-synchronization acquisition, the mean time to synchronization acquisition and the mean time to the subsequent loss of synchronization, as functions of the bit error rate, frame length, synchronization word length, and algorithm parameters. These formulas are directly applicable to the uncoded MVM73 telemetry modes, and a numerical example relating to the 117.6 kilobits/s real time TV mode is included.

LO37 Effects of Lognormal Amplitude Fading on Bit Error Probability for Uncoded Binary PSK Signaling
B. K. Levitt and M. Y. Rhee

The 1978 Pioneer Venus mission will require direct communication links between the planetary probes and Earth. Data from the Russian spacecraft Venera 4 indicate that these links will be subjected to lognormal fading resulting from atmospheric turbulence. This article analyzes the bit error rate degradation for uncoded binary phase-shift-keyed telemetry in the presence of such fading.

LO38 Performance Degradation of Uncoded and Sequentially Decoded PSK Systems Due to Log- Normal Fading
B. K. Levitt

The Pioneer Venus 1978 (PV'78) orbiter will dispatch several probes into the planet's atmosphere. The telemetry from these probes will be transmitted directly to Earth as coherent, binary phase-shift-keyed (PSK) uncoded or convolutionally-encoded/sequentially-decoded data. These communication links will be subjected to log-normal fading due to turbulence in the atmosphere of Venus. This article offers a theoretical model for predicting the effects of the channel fading on PV'78 telemetry performance. Because this model considers the effects of a noisy carrier reference on the telemetry performance, it permits the determination of the optimum modulation angle which minimizes the link error rate for a given system. The model predicts that the fading will cause a 1.1 to 1.3 dB increase in the signal-to-noise levels required to achieve a frame deletion rate of 10^-3 for the PV'78 coded telemetry modes.

LO39 Pioneer Venus 1978: Telemetry Performance Predicts
B. K. Levitt

The Pioneer Venus 1978 probe-to-Earth telemetry links will be degraded by fading in the atmosphere of Venus. The severity of this fading is characterized by the variance $\sigma^2$, where the amplitude fading is represented by the lognormal random variable $e^\gamma$. For the convolutionally-encoded/sequentially decoded telemetry modes, the link performance depends on $\sigma^2$, the total received signal-to-noise ratio $P_t/N_0$, the modulation index $\theta$, and the decoder computational capacity $N$. Using nominal values for anticipated system losses, and assuming a maximum deletion rate requirement of $10^{-4}$ the minimum required $P_t/N_0$ and optimum $\theta$ are profiled as functions of $N$ and $\sigma^2$ for the 256-bps large-probe telemetry mode. These predictions are based on a recently developed theoretical model for the combined effects of lognormal fading and noisy carrier reference on sequentially decoded phase-shift-keyed telemetry.

LO40 Optimum Frame Synchronization for Biorthogonally Coded Data
B. K. Levitt

The optimum procedure for locating a synchronization word periodically inserted in uncoded binary data received over a binary symmetric channel is based on the Hamming or bit-distance metric. This article addresses the corresponding frame-synchronization problem for biorthogonally coded data transmitted over the additive white Gaussian noise channel. For conceptual convenience, the k-bit words from the decoder output are treated as "super symbols" from an alphabet of dimension $2^k$. It is argued that the optimum synchronization-word search over the decoded data stream is based on a super-symbol distance rule matched to the properties of the biorthogonally coded transmissions over the noisy channel. An optimum frame-synchronization acquisition algorithm based on this distance rule is formulated, and its performance is investigated. As an example, the performance of this optimum frame-synchronization algorithm is contrasted analytically with that of a Hamming-distance algorithm operating on decoded $(32, 3)$ biorthogonal data, a case of interest to some recent unmanned American space missions.

LEWIS, R. A.

L045 Autonomous Manipulation on a Robot: Summary of Manipulator Software Functions
R. A. Lewis
Technical Memorandum 33-679, March 15, 1974
This memorandum examines a six-degrees-of-freedom computer-controlled manipulator and derives the relationships between the arm's joint variables and 3-space. Arm trajectories using sequences of third-degree polynomials to describe the time history of each joint variable are presented and two approaches to the avoidance of obstacles are given. The equations of motion for the arm are derived and then decomposed into time-dependent factors and time-independent coefficients. Several new and simplifying relationships among the coefficients are proven; and two sample trajectories are analyzed in detail for purposes of determining the most important contributions to total force in order that relatively simple approximations to the equations of motion can be used.

LI, S. P.

L046 A Measurement Technique of Time-Dependent Dielectric Breakdown in MOS Capacitors
S. P. Li
The statistical nature of time-dependent dielectric breakdown characteristics in metal-oxide-semiconductor capacitors was evidenced by testing large numbers of capacitors fabricated on single wafers. A multi-point probe and an automatic electronic visual display technique are introduced that will yield statistical results which are necessary for the investigation of temperature, electric field, thermal annealing, and radiation effects in the breakdown characteristics, and an interpretation of the physical mechanisms involved. It is shown that capaci-
tors of area greater than $2 \times 10^{-3}$ cm$^2$ may yield worst-case results, and that a multi-point probe of capacitors of smaller sizes can be used to obtain a profile of non-uniformities in the SiO$_2$ films.

LIESKE, J. H.

L048 A Method of Revitalizing Sampson's Theory of the Galilean Satellites
J. H. Lieske
This article describes a method for revitalizing Sampson's theory of motion for Jupiter's Galilean satellites by use of algebraic-manipulation software on a digital computer. The objectives are: (1) to remove algebraic errors existing in the current Sampson theory, (2) to introduce some neglected effects due to solar interactions and the 3–7 commensurability between the outer two satellites, (3) to allow for non-zero amplitude and phase of the libration, (4) to allow future revision of the arbitrary constants of integration, (5) to express the final results as analytic functions of variations in the numerous arbitrary constants of integration and arbitrary parameters, and (6) to provide analytic partial derivatives by means of which one can adjust the numerical values of coefficients in the expressions for the coordinates. The level of precision desired is one arc second (jovicentric) for the coordinates (2 km, 3.3 km, 5.2 km, and 9.1 km, respectively, for satellites I through IV). The method makes extensive use of algebraic-manipulation computer software capable of handling Poisson series with up to 73 polynomial variables and up to 28 trigonometric arguments in algebraic form.

LIKINS, P. W.

L049 Dynamic Analysis of a System of Hinge-Connected Rigid Bodies With Nonrigid Appendages
P. W. Likins
Technical Report 32-1576, February 1, 1974
Equations of motion are derived for use in simulating a spacecraft or other complex electromechanical system amenable to idealization as a set of hinge-connected rigid bodies of tree topology, with rigid axisymmetric rotors and nonrigid appendages attached to each rigid body in the set. This report provides a complete minimum-dimension formulation suitable for generic programming for digital-computer numerical integration.

L050 Attitude Dynamics Simulation Subroutines for Systems of Hinge-Connected Rigid Bodies
G. E. Fleischer and P. W. Likins
Technical Report 32-1592, May 1, 1974
For abstract, see Fleischer, G. E.

L051 Analytical Dynamics and Nonrigid Spacecraft Simulation
P. W. Likins
Technical Report 32-1593, July 15, 1974
This report contains an exposition of several alternative methods of analytical dynamics, and the application of these methods to alternative models of nonrigid spacecraft. This information permits the comparative evaluation of these methods for spacecraft simulation. Applications to idealized spacecraft are considered both for multiple-rigid-body models and for models consisting of combinations of rigid bodies and elastic bodies, with the elastic bodies being defined either as continua, as finite-element systems, or as a collection of given modal data. Several specific examples are developed in detail by alternative methods of analytical mechanics, and results are compared to a Newton–Euler formulation.

L052 Hybrid-Coordinate Spacecraft Dynamics Using Large-Deformation Modal Coordinates
P. W. Likins
For a vehicle amenable to idealization as a set of $n + 1$ rigid bodies interconnected by $n$ line hinges (implying tree topology), a set of minimum-dimension matrix equations of motion is recorded in terms of variables including the relative rotations of contiguous bodies. When a substructure or portion of the vehicle is subjected to large gross deformations but restricted to small strains or local deformations, the $n$-body model is (for sufficiently large $n$) assumed to experience small relative rotations of contiguous bodies within the substructure, and the equations of motion are linearized in these variables. The application of coordinate transformations and truncations to the linearized subset of the system equations of
motion then produces a hybrid-coordinate formulation of the problem involving both discrete and distributed coordinates. The resulting equations promise to be much more amenable to stable and efficient numerical integration than are the original discrete-coordinate equations.

LIU, A. S.

L053 DSN Progress Report for November–December 1973: Range Measurements to Pioneer 10 Using the Digitally Controlled Oscillator
A. S. Liu

Analysis of the new doppler data from the Mars Deep Space Station using the digitally controlled oscillator (DCO) has established that range measurements to Pioneer 10 can be obtained without the use of a ranging system per se by ramping the carrier frequency with the DCO. The accuracy of these measurements is on the order of 10 km.

L054 Three Topocentric Range Measurements to Pioneer 10 Near Jupiter Encounter and a Preliminary Estimate of an Earth Barycenter to Jupiter Barycenter Distance
A. S. Liu

By using ground digitally controlled oscillator (DCO) apparatus installed at the Mars Deep Space Station and Ballina Deep Space Station, ramped carrier frequency doppler data were received from Pioneer 10 just prior to and shortly after Jupiter encounter. The analysis of these DCO doppler data resulted in three independent topocentric range measurements. These range measurements were individually accurate to at least ±5 km. The observed accuracy was 500 m, but because of suspected systematic errors which were masked by the orbit adjustment procedure the actual accuracy was probably worse than 500 m. From the data residuals based on local orbit adjustments, the DCO data were no different from conventional doppler. The data error was on the order of 2 mHz. A longer solution was also attempted, whereby a Jupiter barycenter to Earth barycenter distance was found. The difference between the estimated barycenter-to-barycenter distance and that from the reference planetary ephemeris, Development Ephemeris 84, was ~107 km. This difference was not significant because Development Ephemeris 84 has a one standard deviation error of ±50 km.

LYON, R. F.

L063 Convolutional Codes for M-ary Orthogonal and Simplex Channels

R. F. Lyon

Convolutional codes chosen for greatest free distance or lowest error probability on a binary channel are not necessarily good codes for an M-ary channel. A rate $k/v$ coder generates a $2^v$-ary output symbol for each $k$ input bits. If a binary channel is used, the appropriate measure of distance between these symbols is Hamming distance (number of bit disagreements). But if either a $2^v$-ary orthogonal channel, or a $2^v$-ary simplex channel is used, the distance between any two different symbols is unity (number of symbol disagreements). Other distance measures are appropriate on other M-ary channels.

Good rate 1/2 and 1/3 codes have been found by computer search for the orthogonal 4-ary and 8-ary channels. The result is a reduction of error probabilities by about a factor of two below previously tabulated codes. The computer technique used is described. At a fixed constraint length, further performance improvement results from increasing $v$, up to a limit at $v = K$ (constraint length) on the orthogonal $2^v$-ary channel.

LYTTLETON, R. A.

L064 On the Status of the Rotation of Venus

R. A. Lyttleton

Owing to its extremely slow rotation, Venus must be regarded as a triaxial body with differences of all three principal moments of inertia comparable in magnitude, thus rendering it a body essentially different from a rapidly rotating planet. The dynamical problem then arises of how such a body, with a rotation-period comparable to its orbital period, would be affected by couples exerted upon it by the gravitational action of the Sun. Equations for the rotational motion are set up in a form suitable for numerical solution by machine-calculations, but the problem so presented can be adequately investigated only for a hypothetical planet with far larger differences of principal moments than could hold for Venus.
Results obtained on this limited basis nevertheless suggest that for Venus the direction of the rotation axis may move almost randomly between the two hemispheres defined by the orbital plane and thus that the present direction near the south celestial pole of the orbit may be only a temporary situation. Order-of-magnitude considerations based on the equations of motion suggest that a time-scale of order $10^7$ to $10^8$ yr may on the average be required for large changes in the direction of the rotation axis to take place.

MACK, L. M.

MO04 On the Application of Linear Stability Theory to the Problem of Supersonic Boundary-Layer Transition

L. M. Mack

Linear stability theory is used to calculate the amplitude ratio of constant-frequency disturbances as a function of Reynolds number for insulated and cooled-wall flat-plate boundary layers between Mach numbers 1.3 and 5.8. The growth curves are used to examine the consequences of using a fixed amplitude of the most unstable frequency as a transition criterion. The effect of the free-stream Mach number $M_1$ on insulated-wall boundary layers is calculated with three different assumptions concerning the initial disturbance level $A_0$: (1) $A_0$ constant, (2) $A_0$ proportional to $M_1^2$, and (3) $A_0$ proportional to $M_1^2$ and to the square root of the energy density of the one-dimensional power spectra of free-stream disturbances measured in supersonic wind tunnels.

The shape of the transition Reynolds number $R_t$ vs $M_1$ curve observed in wind tunnels is closely duplicated with (3), but even with (1) there is a pronounced minimum in $R_t$ near $M_1 = 4$ which points to the minimum as an inherent feature of stability theory. As a second example, the effect of wall cooling at $M_1 = 3.0$ is calculated with assumptions (1) and (3). A much faster increase of $R_t$ with cooling is obtained than is observed experimentally. However, when $A_0$ is determined from the forced response of the boundary layer to irradiated sound and from the measured free-stream power spectrum, a rise in $R_t$ similar to what is observed is obtained for a certain amplitude criterion.

MACLAY, J. E.

MO05 DSN Monitor and Control System

J. E. Maclay

The last major upgrade to the DSN Monitor and Control System was during preparation for support of the Mariner Mars 1971 mission. Since then, several improvements have been made, specifically: incremental improvements in the deep space station Monitor and Control Subsystem, implementation by the Block I Network Control System (NCS) Project of the network operations control functions, and implementation by the Block II NCS Project of the design of the Network Control Monitor and Control Subsystem. These changes are described in this article.
MACOMBER, H. L.

**M006** California Four Cities Program 1971–1973

H. L. Macomber and J. H. Wilson

Special Publication 43-4, May 15, 1974

A pilot project in aerospace-to-urban technology application, co-sponsored by NASA and the National Science Foundation and managed by JPL, was begun in 1971.

Four companies each assigned a senior engineering professional to serve as Science and Technology Advisor in one of four participating city governments. Technical support was provided by the companies and JPL. The four cities, Anaheim, Fresno, Pasadena, and San Jose, California, provided the working environment and general service support. Each city/company team developed and carried out one or more technical or management pilot projects together with a number of less formalized technology efforts and studies.

This document provides an account and evaluation of the initial two-year phase of the program, which has been continued and extended.

The initial effort demonstrated the effectiveness of this mode of technology application and communication. The capability of companies and advisors to contribute needed new techniques to urban management, and of cities to use and institutionalize research and development product and methodology, was shown. Specific management methods, software systems, and to a lesser extent advanced hardware were introduced and used.

MADRID, G. A.

**M007** Tracking System Analytic Calibration Activities for the Mariner Mars 1971 Mission

Technical Report 32-1587, March 1, 1974

This report describes the functions of the tracking-system analytic calibration activity for Mariner Mars 1971 (MM'71), its objectives for this and future missions, and the support provided to the MM'71 navigation team during operations. The support functions encompass calibration of tracking data by estimating physical parameters whose uncertainties represent limitations to navigational accuracy, and detailed analysis of the tracking data to uncover and resolve any anomalies. Separate articles treat the activities and results of producing calibrations for the various error sources.

The titles and authors of these articles are:

“Station Locations” by N. A. Mottinger and J. W. Zielenbach

“Charged Particles” by G. A. Madrid

“The Tropospheric Calibration Model for Mariner Mars 1971” by C. C. Chao

MANCINI, R. A.

M013 Data Decoder Assembly Reliability Modifications
R. A. Mancini
While the Data Decoder Assembly has met the required goals of the decoding and processing of telemetry data in the DSN, it has exhibited a higher than desired failure rate. These failures were predominately of an intermittent nature and occurred more consistently in the controlling processor, the Interdata Model 4 (ID4) minicomputer. General lack of mechanical rigidity and the electromechanical construction used on the selector channels were determined to be the main contributors to these intermittent failures. These weaknesses in design initiated the bulk of the problems by causing connector contacts to become intermittent during operation. Mechanical redesign of the ID4 front panel hinges and a design for a cabinet strut stiffener were implemented in the DSN. Newer design, more reliable selector channels were purchased and installed in all ID4s in the DSN. These changes significantly reduced the failure rate, however, there still remains a much lower failure rate, the source of which is being investigated.

MARGOLIS, J. S.

M015 Abundance and Rotational Temperature of Telluric Methane as Determined From the 2ν3 Band
J. S. Margolis, J. V. Martonchik, R. Beer, and R. H. Norton
The rotational temperature of the 2ν3 methane absorptions in the solar/telluric spectrum and the methane abundance in the Earth’s atmosphere have been measured and are found to be 243.4 ± 5.3 K and 1.137 ± 0.117 cm-atm (STP) in a vertical column, respectively. The data were reduced using the results of laboratory measurements with proper allowance for the fine-structure of the methane absorption manifolds and the effects of vibration-rotation interaction (which causes an enhancement of the R-branch of this band).

M016 The Measurement of the Absorption Strengths of Some Lines in the ν1 + ν2 and ν2 + ν3 Bands of Ammonia
J. S. Margolis and Y. Y. Kwan
The absorption strengths of more than 200 lines in the combination bands ν1 + ν2 (parallel) and ν2 + ν3 (perpendicular) of ammonia at 2.3 μm have been measured, using the curve-of-growth method and an average spectral resolution of 0.05 cm−1. The measurements have been performed at low pressures so that the lines are nearly doppler shaped, thereby reducing the effects of collision broadening. The measured line strengths deviate, to a considerable extent, from those calculated on the basis of a rigid symmetric top model, revealing the effects of vibration-rotation interactions.
Nonlinear least-squares analyses were performed on the observed line strengths, using the intensity formulas derived by Kwan, which include the effects of vibration-rotation interaction up to first order approximation. Values for the intensity parameters were determined from the analysis.
MARSH, E. L.

M017 Attitude Stability of a Flexible Solar Electric Spacecraft: A Parametric Study
E. L. Marsh

J. Spacecraft Rockets, Vol. 11, No. 2, pp. 89-96, February 1974

This article analyzes the influence of large-area solar-array flexibility on the attitude control of a solar-electric spacecraft. The spacecraft consists of a rigid central body, two flexible roll-out solar arrays, and a cluster of three electric-propulsion engines. Each engine has gimballing or translational capacity, or both, for attitude control purposes. A parametric stability study of various spacecraft configurations was made, using hybrid coordinate techniques in an eigenvalue analysis. The variable parameters were solar-array aspect ratio, solar-array first natural frequency, solar-array rotation angle about the yaw axis, and sensor gain factors. Only the first six modes of solar-array vibration were included in the study.

The attitude response characteristics of the various spacecraft configurations were obtained by means of a digital computer simulation program of the system's equations of motion. The feasibility of using the thrusters for attitude control of electric-propulsion spacecraft is demonstrated. It is also shown that although the dynamics effects of large-area, flexible solar arrays can be harmful, changes in the control system parameters can insure stable attitude control.

MASERJIAN, J.

M020 Tunneling Through Thin MOS Structures: Dependence on Energy (E - \kappa)
J. Maserjian and G. Petersson

The tunneling characteristics of Cr/SiO_2/Si structures in the thickness range 23-34 \AA are reported. The E - \kappa dependence in the energy range extending 3.5 eV below the oxide conduction band is determined by the thickness dependence to be approximately of the Franz form with an effective mass ratio of 0.42. Tunneling into the indirect conduction band of silicon is reduced by a thickness-independent factor which decreases approximately exponentially with the energy below the direct band edge.

M021 Saturation Capacitance of Thin Oxide MOS Structures and the Effective Surface Density of States of Silicon
J. Maserjian, G. Petersson (Chalmers University of Technology, Sweden), and C. Svensson (Chalmers University of Technology, Sweden)

Solid-State Electron., Vol. 17, No. 4, pp. 335-339, April 1974

The capacitance vs voltage curve of thin oxide (30-40\AA) MOS structures in strong accumulation was studied. The results were interpreted in terms of equivalent surface density of state masses, which was found to be 0.2m_0 for the silicon valence band and 0.06m_0 for the conduction band. The dimensions of state masses were shown to be much lower than the bulk values. Equivalent densities of states masses were calculated from a surface quantization model and in this case agreement with the experiments was obtained for the valence band only.

MASSIER, P. F.

M022 Comparison of Results Obtained With Various Sensors Used To Measure Fluctuating Quantities in Jets
S. P. Parthasarathy, P. F. Massier, and R. F. Cuffel

For abstract, see Parthasarathy, S. P.
This article presents a model which explains the observations of sodium D-line emission from Io. Our model involves: (1) charged-particle sputtering of sodium from Io's surface, (2) ejection of sodium into a cloud surrounding Io, and (3) resonant scattering of incident sunlight. Observational consequences and tests of the proposed model are also discussed.

McALLASTER, J. R.

M024 Evaluation of a Flutter Compensator for DSN Predetection Recording

J. R. McAllaster

This article presents and discusses results of evaluation tests conducted on an R&D model digital flutter compensator designed to reduce the effects of flutter, or time-base error, in an instrumentation-quality magnetic tape recorder/reproducer. These tests were conducted using machines exhibiting a wide range of transport-servo stability in an effort to determine the effectiveness of the flutter compensator as a machine-independent device. The flutter compensation technique is potentially useful in the DSN for improving the reproduction capability of the pre-/post-detection recording subsystem.

McCLURE, J. P.

J. P. McClure

The outages experienced on the present Ground Communications Facility 4800-bits/s high-speed data subsystem have been examined. An outage is defined as any interval when 10 or more consecutive high-speed data blocks were received in error or were not received at all. For a 3-month period in 1973, outages ranged from 2.5 s to 4.8 h in length. The median outage was 15 s. Approximately 18% of the outages exceeded 1 min, and only 1.5% exceeded 15 min.

M026 High-Speed Data Block Bursts

J. P. McClure

It is well established that ground communications bit errors occur in groups, or bursts. A recent study shows that in 1200-bit high-speed data blocks that contain errors, the errors also tend to occur in groups. A study of these block bursts indicates that single block errors are most common, but that about 10% of the block bursts are composed of seven or more blocks. A significant number of good blocks are contained within these bursts. The single block errors are apparently the result of random happenings, while the longer bursts represent deteriorating circuit conditions.

M027 High-Speed Data Throughput

J. P. McClure

A study of inbound high-speed data (HSD) at the JPL Ground Communications Facility over a 25-week period shows an overall throughput of 99.46% from the deep space stations. Of the faulty blocks, 19% contained bit errors and the remaining 81% were either not received or were not recognizable. Throughput performance is plotted on a weekly basis for each station.

M028 4800- bps High-Speed Data Error Statistics

J. P. McClure

Analysis of Ground Communications Facility 4800-bps high-speed data error statistics information shows error bursts have a median length of 26 bits, though the range of burst lengths is very wide. Approximately 70% of the bits within a typical burst are error free, and an error block usually contains only one burst. Several burst characteristics are directly related to bit error rate, and there is a small time correlation between errors experienced in opposite directions of transmission.

M034 Viking Orbiter 1975 Thrust Vector Control System Accuracy

L. F. McGlinchey

Technical Memorandum 33-703, October 15, 1974

The purpose of the Viking Mars 1975 Orbiter Thrust Vector Control (TVC) System is to point the engine thrust at the vehicle center of mass and thus maintain attitude stability during propulsive maneuvers. This is accomplished by mounting the engine in a two-axis gimbal system. The TVC system then controls the pointing of the engine by closed-loop control of two linear actuators which extend or retract and rotate the engine in its gimbal system. The velocity vector AV pointing error incurred during a propulsive maneuver is made up of several parts, and the TVC system error is one of these. This error arises because the center of mass and engine thrust are not perfectly aligned.

This memorandum assesses the magnitude of the TVC system portion of the AV pointing error and provides simplified and linearized models for predicting its magnitude for the various propulsive maneuvers. The accuracy of the linearized analysis is verified using a detailed nonlinear six-degrees-of-freedom computer simulation.

McLYMAN, C. W. T.

M035 Design Parameters for Toroidal and Bobbin Magnetics

C. W. T. McLyman

Technical Memorandum 33-651, Rev. 1, July 1, 1974

The adoption by NASA of the metric system imposes a requirement on the U.S. transformer designer to convert from the familiar English units to the less familiar metric equivalents. Material is presented to assist in that transition for the field of transformer design and fabrication. The conversion data makes it possible for the designer to obtain a fast and close approximation of significant parameters such as size, weight, and temperature rise. Nomographs are included to provide a close approximation for breadboarding purposes. For greater convenience, derivations of some of the parameters are also presented.

M036 Simplified Cut Core Inductor Design

C. W. T. McLyman

Technical Memorandum 33-697, July 1, 1974

Although filter inductor designers have routinely tended to specify molypermalloy powder cores for use in high-frequency power converters and pulse-width modulated switching regulators, there are significant advantages in specifying C cores and cut toroids fabricated from grain oriented silicon steels which should not be overlooked. Such steel cores can develop flux densities of 1.6 tesla.
with useful linearity to 1.2 tesla, whereas molypermalloy cores carrying dc current have useful flux density capabilities only to about 0.3 tesla. The use of silicon steel cores thus makes it possible to design more compact cores, and therefore inductors of reduced volume, or conversely to provide greater load capacity in inductors of a given volume.

This memorandum presents information which makes it possible to obtain quick and close approximations of significant parameters such as size, weight, and temperature rise for silicon steel cores for breadboarding. Graphs, nomographs, and tables are presented for this purpose, but more complete mathematical derivations of some of the important parameters are also included for a more rigorous treatment.

MO41 The Effect of Centrifugal Distortion on CO₂-Laser Frequencies
R. T. Menzies
This article presents an analysis of the effects of higher order centrifugal distortion terms on C12O16-laser frequencies. This analysis, coupled with recent high-accuracy measurements of C12O16-laser beat frequencies by Petersen et al. at the National Bureau of Standards, points out the weakness of existing frequency tables for high J lines. Expected values for both H and L centrifugal distortion coefficients are calculated, and J values for which these terms become important are discussed.

MO42 Air Pollution: Remote Detection of Several Pollutant Gases With a Laser Heterodyne Radiometer
R. T. Menzies and M. S. Shumate
An infrared heterodyne radiometer with a spectral resolution of 0.04 cm⁻¹ has been used to remotely detect samples of ozone, sulfur dioxide, ammonia, and ethylene at room temperature, and samples of nitric oxide at 390 K. Each gas was observed in a background of nitrogen or oxygen at atmospheric pressure. Sensitivities to some of these gases are adequate for detection of ambient concentrations as low as a few parts per billion.

MILLER, R. B.

R. B. Miller

This article describes significant aspects of the successful Pioneer 10 encounter of the planet Jupiter. The extensive role of the ground support system is emphasized.

Pioneer Venus 1978 Mission Support

R. B. Miller

The current Pioneer Venus 1978 mission concept provides for a two-spacecraft mission with both launches during the 1978 Venus opportunity. One spacecraft will consist of a bus and four probes which will all enter the atmosphere of Venus. The second spacecraft will use the same basic bus but with the probes replaced by a propulsion package sufficient for achieving an orbit around Venus with a life in orbit of seven months or one Venusian year. This article is an introduction of the current DSN concept of supporting the telemetry for the probe mission.
physical characteristics, the science payload, and the telecommunications design of the multiprobe mission.

M052 Pioneer 10 and 11 Mission Support
R. B. Miller

This article describes preparations for the Pioneer 11 Jupiter encounter, including changes in the DSN implementation from that used for the Pioneer 10 encounter. The reliability of the Ground Data System with respect to commanding the spacecraft is discussed.

R. B. Miller

Technical Memorandum 33-426, Vol. XII, March 1, 1974

The Tracking and Data System supported the deep-space phases of the Pioneer 6, 7, 8, and 9 missions, with two spacecraft in an inward trajectory and two spacecraft in an outward trajectory from the Earth in heliocentric orbits. During the period covered in this memorandum, scientific instruments aboard each of the spacecraft continued to register information relative to interplanetary particles and fields, and radio metric data generated by the network continued to improve our knowledge of the celestial mechanics of the solar system. In addition to network support activity detail, network performance and special support activities are covered.

MONAHAN, K. M.

M060 Optical Properties of Mercury Ion Thruster Exhausts and Implications for Science Instruments

K. M. Monahan and R. Goldstein

Technical Memorandum 33-711, December 1, 1974

Emission from the exhaust plume of a 30-cm mercury ion thruster was measured with spectral range 160 to 600 nm as a function of axial and radial distance from the thruster discharge chamber. The spectrally dispersed absolute intensities were used to construct an empirical volume emission rate function. The function was integrated along a typical instrument field of view, and the resulting apparent brightness was compared with instrument sensitivities to evaluate the extent of optical interference.

Most of the emitted radiation came from UV lines of excited mercury atoms and ions, with no observable continuum emission. The intensity levels degraded rapidly with distance from the thruster so that optical interference was negligible for fields of view not intercepting the beam axis. The operation of only one instrument, a zodiacal photopolarimeter, was considered incompatible with simultaneous thruster operation.

M061 Cross-Section for the Dissociative Photoionization of Hydrogen by 584 Å Radiation: The Formation of Protons in the Jovian Ionosphere

K. M. Monahan (University of California, Santa Barbara), W. T. Huntress, Jr., A. L. Lane, J. M. Ajello, J. M. Burke, P. R. LeBreton (California Institute of Technology), and A. D. Williamson (California Institute of Technology)

The cross-section for dissociative photoionization of hydrogen by 584 Å radiation has been measured, yielding a value of $5 \times 10^{-20}$ cm$^2$. The process can be explained as a transition from the $1\Sigma^+_g$ ground state to a continuum level of the $X^2\Sigma^+_g^+$ ionized state of H$_2$. The branching ratio for proton (H$^+$) vs molecular ion (H$_2^+$) production at this energy is $8 \times 10^{-3}$. This process is quite likely an important source of protons in the Jovian ionosphere near altitudes where peak ionization rates are found.

MONDT, J. F.

M062 Nuclear Electric Propulsion Stage Requirements and Description

Technical Memorandum 33-647, August 1, 1974

This memorandum describes the application of a nuclear-electric propulsion (NEP) stage in the exploration of near-Earth, cometary and planetary space. The NEP stage is powered by a liquid-metal-cooled, fast-spectrum thermionic reactor capable of providing 120 kWe for 20,000 hr. This power is used to drive a number of mercury ion bombardment thrusters with specific impulse in the range of 4000–5000 s. The NEP description, characteristics, and functional requirements are discussed. These requirements are based on a set of five coordinate missions, which are described in detail. These five missions are a representative part of a larger set of missions used as a basis for an advanced propulsion comparison study. Additionally, the NEP stage development plan and test program is outlined and a schedule presented.

M063 Advanced Design Concepts in Nuclear Electric Propulsion

MOORE, D. M.

M064 Lightweight 3.66-Meter-Diameter Conical Mesh Antenna Reflector

D. M. Moore

Technical Memorandum 33-685, June 15, 1974

This memorandum describes a 3.66-m (12-ft) diameter, nonfurlable, conical mesh antenna incorporating the line source feed principle recently developed at JPL. The weight of the mesh reflector and its support structure is 162 N (36.5 lb). An area weighted rms surface deviation of 0.28 mm (0.011 in.) has been obtained. RF performance measurements showed a gain of 48.3 dB at 8.448 GHz, corresponding to an efficiency of 66%.

During the design and development of this antenna, the technology for fabricating large conical membranes of knitted mesh was developed. As part of this technology a FORTRAN computer program, COMESH, was developed which permits the user to predict the surface accuracy of a stretched conical membrane.

M070 FORTRAN Implementation of Tutorial Input

K. Moody

This article describes the FORTRAN implementation of "Tutorial Input," a computer/human interface for real-time control programs. The emphasis is on the communication between the standardized input routine and a real-time FORTRAN control program. Changes made to the Tutorial Input specifications are explained, and samples of the use of this implementation are given.

D. J. Mudgway and D. W. Johnston

This article describes the Network Operations Plan for Viking Mars 1975 and includes some DSN support requirements unique to Viking which have resulted in unusual attention to deep space station hardware-failure-mode configurations. Samples of the single point failure strategies incorporated in the Viking Mars 1975 deep space station telemetry hardware configurations are discussed, and the rationale for the implementation of 100-kW transmitter capability at the Ballima Deep Space Station and the Robledo Deep Space Station (DSSs 43 and 63) is given.

M073 Viking Mission Support

D. J. Mudgway and D. W. Johnston

In a previous article the basis for integration and data systems testing between the Compatibility Test Area (CTA 21) and the Viking Mission Control and Computing Center (VMCCC) was given, and the first eleven of these tests were described. This article describes the concluding tests in the system integration series and the results of a series of five data system compatibility tests. These tests provide an end-to-end verification of the integrity of the Ground Data System under typical mission loading conditions. Starting with the modulated RF carriers input to CTA 21, the data are sequentially processed through the station, passed across the Ground Communications Facility to VMCCC and finally displayed in the Mission Support Areas. For several of these tests, maximum data loading conditions were established which included six simultaneous telemetry data streams, two command streams, one monitor, and one tracking data stream.

MULHALL, B. D.

M074 Report of the Two-Station Doppler (VLBI) Demonstration Conducted With Mariner 9

B. D. Mulhall, C. C. Chao, D. E. Johnson, and J. W. Zielenbach

The Mariner Mars 1971 spacecraft was simultaneously tracked by the Echo Deep Space Station at the Goldstone Deep Space Communications Complex and the Woomera Deep Space Station (no longer operational) during the month and a half prior to Mars encounter. The doppler data obtained were generated using hydrogen masers in the frequency and timing system. The benefits gained by tracking with two stations simultaneously and the difficulties encountered in processing the data are described. The results indicate that it is necessary to difference the two-way and three-way doppler explicitly if batch-filtering is to be employed when there is significant process noise related to the spacecraft. The results, though promising, are not as conclusive as might be hoped for due to the limited amount of data.

MURRAY, B. C.

M080 Venus: Atmospheric Motion and Structure From Mariner 10 Pictures

B. C. Murray (California Institute of Technology), M. J. S. Belton (Kitt Peak National Observatory), G. E. Danielson, Jr., M. E. Davies (Rand Corporation), D. E. Gault (Ames Research Center), B. Hapke (University of Pittsburgh), B. O'Leary (Hampshire College), R. G. Strom (University of Arizona), V. Suomi (University of Wisconsin), and N. Trask (U.S. Geological Survey)

The Mariner Venus/Mercury 1973 television cameras imaged the planet Venus in the visible and near ultraviolet for a period of 8 days at resolutions ranging from 100 m to 130 km. The general pattern of the atmospheric circulation in the upper tropospheric/lower stratospheric region is displayed in the pictures. Atmospheric flow is symmetrical between north and south hemispheres. The equatorial motions are zonal (east-west) at approximately 100 m/s, consistent with the previously inferred 4-day retrograde rotation. Angular velocity increases with latitude. The substellar region, and the region downwind from it, show evidence of large-scale convection that persists in spite of the main zonal motion. Dynamical interaction between the zonal motion and the relatively stationary region of convection is evidenced by bowlike waves.

M081 Mercury's Surface: Preliminary Description and Interpretation From Mariner 10 Pictures

B. C. Murray (California Institute of Technology), M. J. S. Belton (Kitt Peak National Observatory), G. E. Danielson, Jr., M. E. Davies (Rand Corporation), D. E. Gault (Ames Research Center), B. Hapke (University of Pittsburgh), B. O'Leary (Hampshire College), R. G. Strom (University of Arizona), V. Suomi (University of Wisconsin), and N. Trask (U.S. Geological Survey)

Science, Vol. 185, No. 4146, pp. 169-179, July 12, 1974
The surface morphology and optical properties of Mercury resemble those of the Moon in remarkable detail and record a very similar sequence of events. Chemical and mineralogical similarity of the outer layers of Mercury and the Moon is implied, but Mercury is probably a differentiated planet with a large iron-rich core. Differentiation is inferred to have occurred very early. No evidence of atmospheric modification of landforms has been found. Large-scale scarps and ridges, unlike lunar or Martian features, may reflect a unique period of planetary compression near the end of heavy bombardment by small planetesimals.

NAKAMURA, Y.

N001 Explosive Propulsion Applications

Y. Nakamura, G. Varsi, and L. H. Back

Technical Memorandum 33-675, April 1, 1974
The feasibility and application of an explosive propulsion concept capable of supporting future unmanned missions in the post-1980 era were examined and recommendations made for advanced technology development tasks. The Venus large lander mission was selected as the first major undertaking in which the explosive propulsion concept can find application. A conceptual design was generated and its performance, weight, costs, and interaction effects with other spacecraft subsystems determined. Comparisons were made with conventional propulsion alternatives, primarily on the basis of performance and spacecraft interaction effects. The results of this study verified the feasibility of the explosive propulsion system for planetology experiments within the dense atmosphere of Venus as well as those of the outer planets. Additionally, it was determined that the Venus large lander mission could be augmented ballistically with significant delivery margin in which added mission capability could be exploited.

D. B. Nash and J. E. Conel
The Moon, Vol. 8, No. 3, pp. 346-364, September 1973
Laboratory experiments show that albedoes as low as those on the Moon can be produced by vacuum vitrification and associated chemical fractionation of ordinary terrestrial basaltic material. Vitrification is established as an unequivocal process that can account for the low albedo and apparent local darkening with age of the lunar surface. The spectral reflectance curves of glass powders are significantly different than those of the parent rock mineralogy; thus, the presence of ubiquitous glass in lunar surface material complicates compositional determinations by interpretation of spectral reflectance curves. Vitrification of rocks on the Moon may have modified the chemical composition of the resulting glass; thus, glass fragments found in lunar fines cannot be assumed to represent bulk parent-rock material. Progressive impact vitrification of lunar surface material throughout the Moon's history may have led to a fine-grain, opaque, refractory-rich material we call "ultimate glass". This unidentified and, at this point, hypothetical component may exist in dark regolith material; if found, it may be a useful indicator of regolith maturity.

N012 Observations of the Internal Structure of the Magnetopause

M. Neugebauer, C. T. Russell (University of California, Los Angeles), and E. J. Smith

Magnetic field, plasma flux, and extremely-low-frequency (ELF) wave data have been studied for several encounters of Ogo 5 with the Earth's magnetopause. In one case of a crossing in the near-Earth region of the geomagnetic tail, the structure agreed closely with a simple Chapman-Ferraro type of model with nearly complete neutralization of the charge separation electric field. The proton turning region was 4 times thicker than the electron turning region. The magnetic pressure was linearly related to the ion flux throughout most of the structure; this relation implies that pressure balance was maintained principally by a variation of proton number density across much of the field strength gradient. The computed gas dynamic constant of $0.77 \pm 0.23$ is in agreement with the value of $0.83$ predicted for such cases of aligned flow. This linear relation between $B^2$ and ion flux was not observed at all of the crossings studied, and other departures from the simple structure were observed at other magnetopause crossings.

NG, E. W.

N014 A Comparison of Computational Methods and Algorithms for the Complex Gamma Function

E. W. Ng

Technical Memorandum 33-686, May 1, 1974

This memorandum presents a survey and comparison of some computational methods and algorithms for gamma and log-gamma functions of complex arguments. These methods and algorithms, reported recently in the open literature, include Chebyshev approximations, Padé expansion, and Stirling's asymptotic series. The comparison leads to the conclusion that Algorithm 421, published in the Communications of ACM by H. Kuki, is the best program either for individual application or for the inclusion in subroutine libraries.

N015 Symbolic Integration of a Class of Algebraic Functions

E. W. Ng
This memorandum presents an algorithm, based on a series of analyses by Carlson, for the symbolic integration of a class of algebraic functions. This class consists of functions made up of rational expressions of an integration variable $x$ and square roots of polynomials, trigonometric and hyperbolic functions of $x$. The algorithm is made up of four major components: (1) reduction of input integrand to canonical form, (2) intermediate internal representation of integral, (3) classification of output, and (4) reduction and simplification of output to well-known functions.

NISHIMURA, H. G.

H. G. Nishimura

An operational DSN S-band receiver having two independent channels was modified to provide a capability for coherent simultaneous reception at S- and X-bands. Coherence at both bands was accomplished by using a base-frequency multiplier which was common to both the S- and X-band local-oscillator multiplier chains.

O002 Scene Analysis in Support of a Mars Rover

D. A. O’Handley

The NASA/JPL breadboard mobile robot is a test system for developing adaptive, variably autonomous capabilities in support of future missions to the planets. A vision subsystem is a part of this breadboard development. Scene analysis software has been developed and experiments have been conducted in order to segment a scene with irregular objects in it and to develop an algorithmic definition of the scene and relationships in that scene. The results at present have used simulated real-time TV inputs. The scenes which have been used are both contrived and natural. The results presented in this article will form the basis for implementation of the vision software on the mobile robot.

O003 Picture Analysis Applied to Biomedicine

D. A. O’Handley, E. S. Beckenbach, K. R. Castieman, R. H. Seizer, and R. J. Wall

The application of digital image-processing techniques to medical problems has been under development at JPL since 1966. The initial research concentrated on medical X-ray films and included: (1) image restoration, i.e., using digital techniques to retrieve information partially lost in the imaging system which generated the pictures, (2) image enhancement to emphasize features or remove useless data, and (3) image mensuration to provide more quantitative measurements and analyses than are available through visual inspection techniques. Research in biomedical image processing has now been expanded to include a system for the automated analysis of images.
from light and electron microscopes. The Automated Light Microscope System, around which the chromosome analysis system has been developed, allows direct scanning of specimen images into a computer for subsequent analysis.

The applications of digital image processing to biomedicine at JPL encompass 15 separate research projects. The areas selected for discussion in this article give some indication of the types of picture analysis that are being performed. The current trend in biomedical image processing is toward more human interaction in the research setting.

0007 An Evaluation of QVLBI OD Analysis of Pioneer 10 Encounter Data in the Presence of Unmodeled Satellite Accelerations

B. D. O'Reilly and C. C. Chao

Quasi-very-long-baseline interferometry (QVLBI) has been used to predict Pioneer 10 flyby B-plane coordinates from simultaneous two- and three-way doppler data in the presence of unmodeled accelerations due to the four massive satellites of Jupiter. This article concludes that the QVLBI technique for processing simultaneous two- and three-way doppler data is capable of predicting the encounter to within ~2000 km in the presence of unmodeled accelerations as large as 10^-8
Calculations using two-way doppler data alone for the same nominal trajectory and a priori parameter statistics yielded systematic B-plane errors of the order of 100,000 km, with consequently meaningless formal uncertainties.

Bridge (Massachusetts Institute of Technology), A. J. Lazarus (Massachusetts Institute of Technology), J. R. Asbridge (Los Alamos Scientific Laboratory), S. J. Bame (Los Alamos Scientific Laboratory), and C. M. Yeates

Science, Vol. 185, No. 4146, pp. 145-151, July 12, 1974

A fully developed bow shock and magnetosheath were observed by the Mariner Venus/Mercury 1973 spacecraft near Mercury, providing unambiguous evidence for a strong interaction between Mercury and the solar wind. Inside the sheath there is a distinct region analogous to the magnetosphere or magnetotail of Earth, populated by electrons with lower density and higher temperature than the electrons observed in the solar wind or magnetosheath. At the time of encounter, conditions were such that a perpendicular shock was observed on the inbound leg and a parallel shock was observed on the outbound leg of the trajectory, and energetic plasma-electron events were detected upstream from the outbound shock crossing. The interaction is most likely not atmospheric, but the data clearly indicate that the obstacle to solar wind flow is magnetic, either intrinsic or induced. The particle fluxes and energy spectra showed large variations while the spacecraft was inside the magnetosphere, and these variations could be either spatial or temporal.

OHLYSON, J. E.

OO10 A Tracking Polarimeter for Measuring Solar and Ionospheric Faraday Rotation of Signals From Deep Space Probes
J. E. Ohlson (Naval Postgraduate School), G. S. Levy, and C. T. Stelzried

A tracking polarimeter implemented on the 64-m-diameter NASA/JPL paraboloid antenna at Goldstone, Calif., is described. Its performance is analyzed and compared with measurements. The system was developed to measure Faraday rotation in the solar corona of the telemetry carrier from the Pioneer 8 spacecraft as it was occulted by the sun. It also measures rotation in the Earth's ionosphere and provides an accurate method of determining spacecraft orientation. The new feature of this system is its use of a pair of quarter-wave plates to allow the synthesis of a rotating feed system, while requiring the rotation of only a single section of waveguide. Since the polarization sensing is done at RF and the receiver operates essentially as a null detector, the system's accuracy is superior to other polarization tracking schemes. In addition, the antenna size and maser preamplifier provide unsurpassed sensitivity. The associated instrumentation used in the Pioneer 8 experiment is also described.

OSBORN, G. R.

0015 Planetary Ranging Operational Software

G. R. Osborn

The Planetary Ranging Operational Program is now in use at the Echo Deep Space Station, Ballima Deep Space Station, and Rio Cofio Deep Space Station. It provides ranging capability to several AU. The program also monitors changes in the charged particle density due to diurnal variations in Earth's ionosphere and solar outbursts. The charged particle measurement is used to correct the doppler data. Both outputs contribute to the more precise orbit determination required for multiple-encounter and orbiter missions.

0016 Continuous Spectrum Planetary Ranging Operational Software

G. R. Osborn

The Planetary Ranging Operational Software has been expanded to provide continuous spectrum ranging in addition to the already existing discrete spectrum mode. The new functions are considered in this article.

OTOSHI, T. Y.

0017 S/X Experiment: A New Configuration for Ground System Range Calibrations With the Zero Delay Device

T. Y. Otoshi and C. T. Stelzried

This article describes a new configuration for ground system range calibrations with the zero-delay device (ZDD) which was recently implemented at the Mars Deep Space Station for the S/X-band experiment. In this new configuration, the original ZDD horns and associated air paths are eliminated. The uplink test signal is now coupled out of the transmitter waveguide path and brought directly to the ZDD by calibrated cables of known delays. The downlink signals generated by the ZDD are injected directly into the masers via calibrated cables and waveguide couplers. Preliminary tests on the new system indicate that, in the absence of the air path, the ground system range change as a function of antenna elevation angle is typically less than 3 ns at S-band and X-band.

0019 S/X Experiment: DSS 14 Pre- and Post-Track Ranging Calibrations for Mariner 10 Tracking Passes and Associated Problems

T. Y. Otoshi

Ground system ranging calibration data for the Mars Deep Space Station are presented for 1974, Day 12 through Day 150. Associated ranging problems are discussed and recommendations for calibration improvements are presented.

0020 S/X Experiment: DSS 14 S/X Ground System Ranging Tests

T. Y. Otoshi and P. D. Batelaan
This article presents special ranging test data obtained on the S/X-band ground system at the Mars Deep Space Station. The test data consist of ground system range as functions of (1) uplink 100-kW transmitter power, (2) downlink S- and X-band signal levels, and (3) antenna elevation and azimuth angles via the cable path and via the air path.

O021 S/X Experiment: A Study of the Effects of Ambient Temperature on Ranging Calibrations
T. Y. Otoshi

A study has been made of the effects of the outside air temperature at the Mars Deep Space Station on ground system range calibrations. Some correlation was found on range data obtained with the 20-kW transmitter system configuration, but no correlation was found for the 100-kW transmitter system configuration.

O022 S/X-Band Experiment: A Study of the Effects of Multipath on Group Delay
T. Y. Otoshi

This article presents an analytical expression for calculating the effects of multipath on group delay. The expression was experimentally verified by tests made at the Telecommunications Development Laboratory using the Mariner Venus/Mercury 1973 Radio Frequency Subsystem, Block 3 receiver, and the Mu 1 ranging machine.

PALUKA, J. R.

P001 Redesign of High-Power Transmitter Control and Indicator Cards
J. R. Paluka and S. F. Moore (Resdel Engineering)

This article describes the control and indicator printed-circuit cards used in the DSN high-power transmitter and the high-power X-band radar transmitter which have been redesigned to incorporate short-circuit protection into their outputs. This redesign will increase the overall reliability of these transmitters by eliminating transistor burnouts resulting from shorted interconnection lines, inadvertent shorts while troubleshooting, and other overloads.

PARHAM, O. B.

O. B. Parham

A programmed controller has been designed for operation with a noise-adding radiometer (NAR) for the automatic control of certain deep space station functions. These functions include the operation of the NAR, the operation of waveguide switches, and the control of the pointing of the 26-m-diameter antenna. This article describes the design and operation of the programmed controller.

PARKER, R. H.

P003 Jupiter's Radiation Belts and Their Effects on Spacecraft
R. H. Parker, E. L. Divita, and G. Gigas

The effects of electron and proton radiation on spacecraft which will operate in the trapped radiation belts of the planet Jupiter are considered, and the techniques and results of the testing and simulation used in the radiation effects program at JPL are discussed. Available data from the Pioneer 10 encounter of Jupiter are compared with pre-encounter models of the Jupiter radiation belts. The implications that the measured Jovian radiation belts have for future missions are considered.

PARTHASARATHY, S. P.

P004 Comparison of Results Obtained With Various Sensors Used To Measure Fluctuating Quantities in Jets
S. P. Parthasarathy, P. F. Massier, and R. F. Cuffel

An experimental investigation has been conducted to compare the results obtained with six different instruments that sense fluctuating quantities in free jets. These sensors are typical of those that have recently been used
by various investigators who are engaged in experimental studies of jet noise. Intensity distributions and two-point correlations with space separation and time delay were obtained. The static pressure, density, and velocity fluctuations are well correlated over the entire cross-section of the jet and the cross-correlations persist for several jet diameters along the flow direction. The eddies appear to be flattened in the flow direction by a ratio of 0.4.

P005 Evaluation of Jet Noise Sources by Cross-Correlation of Far Field Microphone Signals
S. P. Parthasarathy
AIAA J., Vol. 12, No. 5, pp. 583-590, May 1974
The objective of this article is the evaluation of the noise sources of jet noise from the far-field measurements. A one-dimensional model is envisioned in which noise sources move along the axis of the jet downstream of the nozzle. The autocorrelation function of the noise sources in the moving frame of reference is a function of time and time delay. A theory is developed for stationary sources and then extended to moving sources. The method of obtaining the autocorrelation through a least-squares inversion method is illustrated for a high-temperature subsonic jet flow. This method can be extended to supersonic flows.

P010 Advanced Design Concepts in Nuclear Electric Propulsion
M. L. Peelgren and J. F. Mondt
Technical Memorandum 33-664, August 1, 1974
This memorandum represents the final documentation of several conceptual design efforts which were in progress at the time the nuclear propulsion programs were terminated in January 1973. Three major areas of investigation were: (1) design efforts on spacecraft configuration and heat rejection subsystem, (2) high-voltage thermionic reactor concepts, and (3) dual-mode spacecraft configuration study. No conclusions will be drawn since none of the efforts were completed. Rather, the goal is to archive the material in a concise, complete, and logical manner so that it is available for any future developments or application of nuclear thermionic reactor power or nuclear-electric propulsion.

PATTERSON, R. E.

P007 Solar Array Study for Solar Electric Propulsion Spacecraft for the Encke Rendezvous Mission
C. F. Peters
Known discrepancies between Sampson's theory and observations of the Galilean satellites produce in-plane errors of about 1200 km. Since the mean longitude is responsible for most of the discrepancy, a simple time correction may be used to significantly reduce these errors. An analysis of the time corrections derived for Sampson's theory concludes that the dominant error in the mean longitudes results from Sampson's definition of time, which was determined by the observations which he used in constructing the theory. Imposition of the libration constraint results in changes to the time corrections which are less than the standard deviation of those quantities. The individual eclipse observational errors are shown to be proportional to the square root of the period. With improved star catalogs, the attainable accuracy of the ephemerides of the Galilean satellites is about 100 km from photographic plates versus about 200 km for eclipse observations.

**Table Mountain Satellite Observations: 1971–72**

C. F. Peters

This paper presents reduced photographic plate observations for some of the satellites of Jupiter and Saturn. These observations were taken with the 24-in. (61-cm) reflector at Table Mountain Observatory during 1971–1972.

**Saturation Capacitance of Thin Oxide MOS Structures and the Effective Surface Density of States of Silicon**

J. Maserjian, G. Petersson (Chalmers University of Technology, Sweden), and C. Svensson (Chalmers University of Technology, Sweden)

Solid-State Electron., Vol. 17, No. 4, pp. 335–339, April 1974

**NCS Minicomputer Systems Status Report**

R. G. Petrie

Implementation of the Network Control System (NCS) requires the use of 17 minicomputer systems. The functional requirements for these systems within the NCS are discussed; and details of the minicomputer block diagrams, mechanical configuration, interface characteristics, and software support are presented.

**Techniques in Doppler Gravity Inversion**

R. J. Phillips
The types of doppler gravity data available for local, as opposed to planetwide, geophysical modeling are reviewed. Those gravity fields that are determined dynamically in orbit-determination programs yield a smoothed representation of the local gravity field that may be used for quantitative modeling. An estimate of the difference between smoothed and true fields can be considered as a noise limitation in generating local gravity models. A nonlinear inversion for the geometry, depth, and density of the Mare Serenitatis mascon using an ellipsoidal model yielded a global least-squares minimum in horizontal dimensions, depth, and thickness-density contrast product. It was subsequently found, by using a linear model, that there were an infinite number of solutions corresponding to various combinations of depth and lateral inhomogeneity.

Linear modeling was performed by means of generalized inverse theory. Criteria for constructing the inverse were: (1) casting out eigenvectors that were approximately orthogonal to the data vector and (2) confirming that the model thus generated had a reasonable variance. The solutions found by such techniques were consistent with subsequently obtained higher-resolution data for the boundaries of the Serenitatis mascon as well as the areal distribution of mass. The significance of the eigenvectors of the generalized inverse in terms of resolution and information density is discussed.

P019 The Apollo 17 Lunar Sounder

R. J. Phillips et al.

The Apollo Lunar Sounder Experiment, a coherent radar operated from lunar orbit during the Apollo 17 mission, had the scientific objectives of mapping lunar subsurface structure, surface profiling, surface imaging, and galactic noise measurement. Representative results from each of the four areas are presented. Subsurface reflections are interpreted in both optically and digitally processed data. Images and profiles yield detailed selenomorphological information, and the preliminary galactic noise results are consistent with earlier measurements by other workers.

P021 Stardust on the Bar: Space Fallout in Criminalistics

W. H. Pickering

This article describes applications of space technology to forensic sciences, such as criminalistics, toxicology, and medicine. Specific areas covered are: thermoluminescence, used to determine the commonality of origin of evidence materials; film scanning and digital computer processing techniques, used to improve the quality of photographic evidence; automation of crime laboratories; educational interchange between crime laboratories and centers of high technology; and application of systems-management techniques to forensic sciences and the crime problem. Included is a summary of the U.S. space program and its achievements.

PIERCE, S.

P022 Numerical Orbit Integration Efficiency of the Delaunay-Similar Elements

S. Pierce

Technical Memorandum 33-710, October 15, 1974

This memorandum investigates orbit equations with a set of conservative and a set of non-conservative perturbing potentials. Scheifele’s Delaunay-similar (DS) formulation of these equations has dependent variables similar to Delaunay’s orbital elements with the true anomaly as the independent variable. Efficiency curves of computing cost vs accuracy are constructed for Adams integrators of orders 2 through 15 with several correcting algorithms and for a Runge–Kutta integrator. Considering stability regions, choices are made for the optimally efficient integration modes for the DS elements. Integrating in these modes reduces computing costs for a specified accuracy.

POTTER, P. D.

P025 DSN Progress Report for November–December 1973: Improved Dichroic Reflector Design for the 64-m Antenna S- and X-Band Feed Systems

P. D. Potter

In support of the Mariner Venus/Mercury 1973 (MVM’73) X-band experiment and future Mariner missions, the 64-m-diameter antenna network is being supplied with S- and X-band reflex feed systems. The initial installation, for MVM’73, was implemented at the Mars Deep Space Station and provides satisfactory performance for that mission. The X-band performance of the dichroic reflector, however, is not acceptable for future missions which have more stringent X-band performance requirements. A new dichroic reflector which greatly reduces the X-band ellipticity and noise temperature degradation has been designed. This article reports the theory and experimental performance of this new design.

P026 Shaped Antenna Designs and Performance for 64-m Class DSN Antennas

P. D. Potter

Significant DSN antenna performance enhancement is possible through the use of shaped dual-reflector antenna techniques. A detailed study has been performed to optimize configurations for maximum performance. Four designs in the antenna-diameter range of 64 to 72 m were carried out and are reported in this article. Complete performance predictions and mechanical configurations are given.

PRESCOTT, S. N.

P028 Investigation of Pyrotechnic Shock

S. N. Prescott

Proceedings of the Twentieth International Instrumentation Symposium, Albuquerque, New Mexico, May 21-23, 1974, pp. 181-186

The comparative pyrotechnic shock outputs of various electroexplosive release devices have been obtained in tests on an instrumented spacecraft structure. Accelerometer data were recorded and reduced by computer analyses to shock spectra. Correlations were obtained between shock severity and actual degradation or damage to spacecraft equipment.

The spacecraft structure was of semimonocoque construction with longerons and chem-milled shear web skin. There was a simulated electronic chassis mounted in these boxes were electrically monitored for chatter, transfer, or other shock effects. High-frequency crystal shock accelerometers were mounted on the structure and chassis. Data were obtained on both nearby shock effects, and on the shock transmitted through realistic structural paths. The accelerometer data were recorded on analog tape. The reduction of analog data from the accelerometers to shock spectra was accomplished by digitizing and transforming it by a Fortran program on the Univac 1108 computer. The transformation was assigned a Q value representative of the structure. Both “primary” and “residual” shock spectra were obtained.

P030 Dual-Spacecraft Radio Metric Tracking
R. A. Preston

When two interplanetary spacecraft lie along similar geocentric lines of sight, navigational advantages may be achieved by navigating one spacecraft with respect to the other. Opportunities to employ this technique will become more common: the two Viking spacecraft will be within two degrees of each other for the last seven months of their cruise phase; the two Mariner Jupiter/Saturn 1977 spacecraft will be within three degrees of each other for the last three years of their mission. This article describes the advantages of this technique in both conceptual and mathematical terms and discusses the various data types that might be formulated. The opportunities for testing and utilizing this technique are also outlined.

PRICE, A. L.

P031 Faraday Rotation Experiment
A. L. Price

Very high frequency polarimeters, working in conjunction with the Applications Technology Satellites, form a useful tool for monitoring ionospheric weather conditions. This article describes the installation of two such polarimeters at the Venus Deep Space Station.

P033 Software Modification to the Traceability and Reporting System
M. Puchalski

The Traceability and Reporting System (TRS) is a Network Information Control function that stores, maintains, and reports on data collected during each tracking period. This article explains the TRS, the improvements made on the software, and the reasons for the software modifications.

QUINN, R. B.

Q001 Low-Noise Receivers: Microwave Maser Development
R. B. Quinn

Low-pass microwave filters have been built and tested in the laboratory and are now ready for installation in the 14.3- to 16.3-GHz traveling-wave maser presently being used on the 64-m-diameter antenna at the Goldstone Deep Space Communications Complex. These filters, when placed in the input and output lines of the traveling-wave maser, will prevent possible calibration errors caused by traveling-wave maser gain changes resulting from pump frequency radiation into the signal waveguides. These filters are matched at the signal frequency of the traveling-wave maser, have low insertion loss, and will operate at 4.5 K; therefore, no significant degradation in system performance should result with their installation.

RANSFORD, G. A.

R001 Orbit Determination Capability Analysis for the Mariner-Jupiter-Saturn 1977 Mission
G. A. Ransford, C. E. Hildebrand, and V. J. Ondrasik

J. Spacecraft Rockets, Vol. 11, No. 9, pp. 658-663, September 1974

Delivering a spacecraft to the outer planets with high precision (1σ = 200 km) and supporting the desired high accuracy instrument pointing near a planetary encounter place great demands on a navigation system. This article describes a combined Earth-based radio tracking/onboard optical data navigation system designed to meet these goals. Some results of applying this navigation system to the preliminary Mariner Jupiter/Saturn 1977 mission trajectories (the Jupiter approach of the JSX-flight and the Saturn approach of the JST-flight) are presented.

JPL BIBLIOGRAPHY 39-16
It is shown that this system is capable of providing target planet centered orbit determination accuracies in the range of 100 km, and accuracies relative to closely encountered satellites of about 200–250 km, provided there is accurate modeling of the natural satellite motions. Analytical theories of the satellite motions would be attractive from the cost and time usage standpoint as alternatives to numerical integration of the equations of motion. An analytical theory (ignoring the mutual perturbations) is investigated for this role. It is concluded that further development of these theories will have to be undertaken before they can be used for high precision navigation.

R010 Low-Noise Microwave Receiving Systems in a Worldwide Network of Large Antennas
M. S. Reid, R. C. Clauss, D. A. Bathker, and C. T. Stelzried
Proc. IEEE, Vol. 61, No. 9, pp. 1330-1335, September 1973

The DSN consists of a world-wide network of 26-and 64-m antennas spaced approximately 120 deg apart around the world. The DSN is a precision communication system designed to communicate with and control unmanned spacecraft traveling at interplanetary ranges. The ever increasing complexity and distances of spacecraft missions require that the network capability be kept at the state of the art of telecommunications. To meet this objective, a continuing development program on large antennas, low-noise maser, phase-locked receiving systems, and high-power transmitters has been underway for some years. Recent developments in the performance and evaluation of the antennas and maser receivers are discussed, and developments which have contributed to radio science projects, such as planetary radar astronomy, very long baseline interferometry, pulsar, and other astronomical observations are described. It is also shown how these radio science measurements have been used to evaluate the performance of the antenna-receiver systems.

R013 Platelet Adhesion to Heparin-Bonded and Heparin-Free Surfaces
A. Rembaum, S. P. S. Yen, M. Ingram, J. F. Newton, C. L. Hu, W. G. Frasher (University of Southern California Medical Center), and B. H. Barbour (University of Southern California Medical Center)

Polyether polyurethanes containing positive charges in the backbone or in the side chains were synthesized from commercially available diisocyanates. These cationic polyurethanes were reacted with sodium heparin to yield polyurethane heparin complexes (heparin content: 16%) soluble in specific organic solvent systems. The homogeneous solutions were used to produce thromboreistant coatings on commercial tubing.

R014 Biological Activity of Ionene Polymers
A. Rembaum

Ionene polymers are polyammonium salts with positive nitrogens in the backbone, resulting from the polycondensation of diamines with dihalides or from the polycondensation of halo amines. The mechanism of formation of ionene polymers of different structures and their biological activity is reviewed. The antimicrobial and antifungal properties are compared with low molecular weight ammonium salts. Ionenes were found to combine with DNA by means of ionic bonds to yield similar complexes to those obtained with polyamines (spermine and spermidine). They also combine with nerve cell receptors and exercise a more powerful and longer duration ganglionic blocking action than their monomeric analogs. The antiheparin activity of ionenes and the thromboreistance of elastomeric ionene heparin coatings is described. The enhanced biological activity of ionenes as compared with low molecular weight compounds is attributed to a co-operative effect of a large number of positive charges on the polymeric chains.

RENZETTI, N. A.

R015 DSN Progress Report for November-December 1973: DSN Functions and Facilities
N. A. Renzetti
The Deep Space Network (DSN), established by the NASA Office of Tracking and Data Acquisition and under the system management and technical direction of JPL, is designed for two-way communications with unmanned spacecraft traveling approximately 18,000 km (10,000 mi) from Earth to planetary distances. The objectives, functions, and organization of the DSN are summarized, and the Deep Space Instrumentation Facility, the Ground Communications Facility, and the Network Control System are described.

R. D. Rey and E. T. Lobdell

System performance tests are executed throughout the DSN whenever a modification is made to the Network Telemetry System that affects its performance. This arti-
cle describes the telemetry performance tests executed in support of the Mariner Venus/Mercury 1973 Project, the test procedures involved, and the test software. A summary of the test results and the status of the Network Telemetry System are presented.

RO23 Fluorometric Search for Porphyrins in Apollo 15 Exhaust-Contaminated Surface Fines and Deep Drill Cores and Apollo 16 Surface Fines
J. H. Rho, A. J. Bauman, and E. A. Cohen

Portions of Apollo 15 surface fines (15013,1) from an area contaminated by landing vehicle exhaust were Soxhlet-extracted with benzene:methanol 3:2 v/v both in air and in argon. Only the argon extract contained a compound (about 1 part per billion) which fluoresced at 660 and 725 nm with maximal excitation at 425 nm, absorbed at 425 nm, and partitioned into benzene in 6 N HCl. Its emission spectrum was porphyrin-like but with a maximum shifted about 50 nm toward the red relative to that of porphyrins. Similarly, argon-extracted cores 15002 (160-200 cm down) and 15001 (200-240 cm down), each 3 g, yielded extracts free of porphyrins, as was also the case for an Apollo 16 surface fines sample 65500,10 (5 g) collected at Station 5.

RICE, R. F.

RO24 RM2: Transform Operations
R. F. Rice

Technical Memorandum 33-680, March 1, 1974

This memorandum introduces the two-dimensional transform used in the research TV source encoder, RM2. It is shown that both conceptually and in terms of the number of required computations, the RM2 transform is considerably simpler than the Fast Hadamard Transform.

The latter can in fact be generated by extending the RM2 transform.

RO25 Channel Coding and Data Compression System Considerations for Efficient Communication of Planetary Imaging Data
R. F. Rice

Technical Memorandum 33-695, June 15, 1974

This memorandum presents end-to-end system considerations involving channel coding and data compression which could drastically improve the efficiency in communicating pictorial information from future planetary spacecraft. In addition to presenting new and potentially significant system considerations, this memorandum attempts to fill a need for a comprehensive tutorial which makes much of this very subject accessible to readers whose disciplines lie outside of communication theory.

RO26 Channel Coding and Data Compression System Considerations for Efficient Communication of Planetary Imaging Data
R. F. Rice

Technical Memorandum 33-695, Rev. 1, September 1, 1974

This memorandum presents end-to-end system considerations involving channel coding and data compression which could drastically improve the efficiency in communicating pictorial information from future planetary spacecraft. In addition to presenting new and potentially significant system considerations, this memorandum attempts to fill a need for a comprehensive tutorial which makes much of this very subject accessible to readers whose disciplines lie outside of communication theory.

RIGGINS, M. C.

RO27 Portability of the MBASIC Machine-Independent Design
M. C. Riggins

Part of the current work of the DSN Software Standards Project concerns the machine-independent design of the MBASIC processor. This article describes a study effort toward a portable implementation of the machine-independent design. The method made use of the STAGE2 portable, general-purpose macro processor, by means of which it was possible to invent a set of seemingly machine-independent macro templates for translation into an arbitrary target assembly language. The conclusions reached by this study are that the macros defined seem to
form an adequate program MBASIC processor design language, that it is possible to carry structured programming concepts to the assembly language level, and that implementation by machine-independent macros may not be quite as efficient as hand coding but may yield significantly lower implementation costs.

ROBINSON, E. Y.

R030 Development of a Unique Graphite/Epoxy Antenna Subreflector
E. Y. Robinson, R. A. Stonier (Boeing Company Aerospace Group), and C. L. Lofgren (Boeing Company Aerospace Group)

Advanced concepts for large, furlable space antennas have led to an extensive development program at JPL with configurations utilizing conical main reflectors. The antenna subreflectors for these conical configurations have unusual geometries and new structural requirements. Structural efficiency of the conical antennas is improved through the use of fiber composites and, as part of JPL's development program, a subreflector was designed and fabricated with graphite/epoxy material. This was sized to fit a subscale, 6-ft-diameter model.

The subreflector is a cylindrical paraboloid with demanding criteria for contour surface precision, high thermal stability, and sufficient structural capacity for inertial launch loads in axial and transverse directions (12 to 18 g). In addition, dynamic launch environments impose constraints on allowable natural frequencies. This application presents broad design requirements and novel fabrication constraints. The paper describes the design, analysis, and fabrication of the subreflector.

For abstract, see Berman, A. L.

RODEMICH, E. R.

R032 DSN Progress Report for November-December 1973: Optimal Station Location for Two-Station Tracking
E. R. Rodemich

Three tracking stations cannot be placed on the globe to provide total coverage of the celestial sphere, but they can cover all celestial declinations that are less than a fixed amount. Typically, there is a great deal of overlap in the coverage of the celestial sphere, and this overlap can be used for two-station tracking. Since two-station tracking improves doppler and tracking data and provides interferometric data, tracking stations should be placed to maximize double coverage of the celestial sphere. This article formulates and solves the problem of the optimal placement of three tracking stations to maximize two-station tracking.

ROGERO, S.

R033 Miniaturized Piezoelectric Transducer Electronics Versus Charge Amplifiers—A Comparison of the Two Systems in Vibration and Pressure Applications
S. Rogero

94
Proceedings of the Eighteenth International Aerospace Instrumentation Symposium, Miami, Florida, May 15-17, 1972, pp. 223-229

Conventional charge amplifier systems have long been used in conjunction with piezoelectric pressure transducers and accelerometers by JPL's Edwards Test Station on propulsion system test programs that require the measurement of vibration or dynamic pressure. Recent developments in piezoelectric transducer electronics have resulted in compact, low cost devices, which appear to increase the versatility of existing transducers.

An analysis of some of the applications of piezoelectric transducer electronics as related to the measurement of vibration and dynamic pressures is presented. Piezoelectric transducer electronics are compared with charge amplifier systems, specifically in the areas of frequency response, signal-to-noise ratios over long and short transmission lines, and ease of installation. Samples of data used to illustrate the two systems' capabilities and limitations include: pressure measurements made with helium-cooled quartz pressure transducers during tests of propulsion systems utilizing space storable propellants, vibration testing and engine firings of the Mariner Mars 1971 propulsion subsystem, shock-tube tests to evaluate high-response pressure measuring systems, and semi-dynamic calibration facility for determining measurement-system time constants and sensitivity.

ROSENTHAL, L. A.

R035 A Design for a Venus Orbital Imaging Radar Mission
J. R. Rose and L. D. Friedman
Preprint 74-222, AIAA Twelfth Aerospace Sciences Meeting, Washington, D.C., January 30-February 1, 1974

This paper discusses a planetary exploration mission to map the surface of Venus. A review of the Venus exploration program provides a basis for determining the probable scientific requirements for resolution, planetary coverage, etc., for such a mission. From these requirements, the range of possible mission, radar, and spacecraft functional requirements is determined and a single "point" design is investigated in some detail. This point design, which provides full planet mapping at resolutions better than 200 m, is based on Mariner-class spacecraft technology, including a conventional bipropellant propulsion system, currently under development, capable of delivering the required payload into a 500-km circular Venus orbit. The technology investigated here is fundamentally state-of-the-art, with use of current systems capabilities satisfying the mission requirements.

ROSCHEKE, E. J.

R034 Size Comparisons of Commercial Prosthetic Heart Valves
E. J. Roschke and E. C. Harrison (University of Southern California Medical Center)

Prosthetic heart valves currently manufactured in the U.S. are compared by size according to both the tissue-annulus, or mounting, diameter and the primary orifice area. This information, presented in both graphical and tabular form for a wide variety of prostheses, will be useful to thoracic surgeons, cardiologists, valve designers, and research engineers. Also discussed is the geometric stenosis factor (GSF) defined here as the ratio of the tissue-annulus area to the primary orifice area. Average values of GSF for commercial valves are presented. It is concluded that a standardized method of expressing valve sizes, more uniform than that which exists presently, would be very beneficial to users, such as surgeons and physicians, and to the patient as well. A means of achieving this is through manufacturer participation in the Association for the Advancement of Medical Instrumentation Cardiac Valve Prostheses Standards Subcommittee.

ROURKE, K. H.

R037 Resolution of an Inconsistency in Deep Space Station Longitude Solutions
K. H. Rourke and N. A. Mottinger

This article presents analysis and results that lead to the resolution of a discrepancy in deep space station (DSS) longitude estimates that had been obtained in 1971 and
1972 from spacecraft near-encounter radio metric data. A 21-m discrepancy between the Mariner 4 and Mariner 9 DSS longitude solutions is shown to be reduced to within 3 m with the application of improved solution strategies. The resulting agreement between all encounter-arc longitude solutions for Mariners 4, 5, 6, and 9 is within 5 m.

R038 Application of Sequential Filtering to Estimation of the Interplanetary Orbit of Mariner 9
K. H. Rourke and J. F. Jordan
This paper presents the results of the application of sequential filtering to the determination of the interplanetary orbit of the Mariner Mars 1971 spacecraft. The technique is a specific extension of the Kalman filter. The special problems associated with applying this technique are discussed and the particular algorithmic implementations are outlined. The method is compared against the weighted-least-squares filters of conventional application. The results reveal that relatively simple sequential-filter configurations yield solutions superior to those of the conventional method when applied to radio measurements of the Mariner Mars 1971 spacecraft.

RUSCH, W. V. T.
R039 Double Aperture Blocking by Two Wavelength-Sized Feed-Support Struts
W. V. T. Rusch (University of Southern California)
Feed-system support structures for large-aperture ground antennas generally consist of a tripod or quadripod framework, each leg of which is made from a number of smaller structural members. The complexity of these support structures has defied rigorous attempts to analyze their effects on the rf performance of the antenna. This article reports some induced-field ratio calculations for "double-blocking" configurations (one strut lies within the shadow of another). It is shown that the effective rf blocking from composite structures may be as large as if the multiple members were placed side by side.

SAVAGE, J. E.
S001 DSN Progress Report for November–December 1973: An Algorithm for the Computation of Linear Forms
J. E. Savage
Many problems, including matrix-vector multiplication and polynomial evaluation, involve the computation of linear forms. This article presents an algorithm that offers a substantial improvement on the conventional algorithm for this problem when the coefficient set is small. In particular, this implies that every polynomial of degree $n$ with at most $s$ distinct coefficients can be realized with $O(n \log n)$ operations. It is demonstrated that the algorithm is sharp for some problems.

S012 Solar Array Study for Solar Electric Propulsion
Spacecraft for the Encke Rendezvous Mission
E. A. Sequeira and R. E. Patterson
Technical Memorandum 33-668, February 1, 1974

This memorandum describes the work performed during
1973 on the design, analysis, and performance of a 20-
kw rollup solar array capable of meeting the design
requirements of a solar-electric spacecraft for the 1980
comet Encke rendezvous mission. To meet the high
power requirements of the proposed electric propulsion
mission, solar arrays on the order of 186.6 m² have been
defined. Because of the large weights involved with ar-
rays of this size, consideration of array configurations is

JPL BIBLIOGRAPHY 39-16
limited to lightweight, large-area concepts with maximum power-to-weight ratios. Items covered include solar array requirements and constraints, array concept selection and rationale, structural and electrical design considerations, and reliability considerations. The study was concluded by identifying the areas which require further work.

SERNAS, V.

S013 Heat Transfer Model for Predicting Squib Ignition Times

V. Sernas

Technical Memorandum 33-655, January 15, 1974

This memorandum describes a squib-ignition model based on transient heat conduction from the hot bridgewire to the pyrotechnic. No Arrhenius-type chemical reaction is included. Instead, a thermal contact resistance is postulated to exist between the hot bridgewire and the pyrotechnic. Ignition is assumed to occur when a 2.5-μm layer of pyrotechnic next to the bridgewire reaches a characteristic ignition temperature for that pyrotechnic.

This model was applied to the JPL squib, which uses a 50-μm (0.002-in.) diameter Tophet A bridgewire to ignite a boron-potassium perchlorate mix. A computer program was utilized that solves the transient heat condition problem with the boundary conditions stipulated by the model. The thermal contact conductance at the interface was determined by trial and error so that the experimentally determined ignition time for one firing condition would be properly predicted by the model. With this value of the thermal contact conductance, ignition times for other test conditions were predicted and compared with experimental data. The agreement was quite good for tests run between -129°C and +93.3°C at current levels of 3.5 and 5 A. The resultant radial temperature profiles within the bridgewire-pyrotechnic system are presented for a few test conditions. Axial heat conduction along the bridgewire is shown to be negligible.

S014 The Role of Thermal Contact Resistance in Pyrotechnic Ignition

V. Sernas (Rutgers University) and A. J. Murphy

This paper describes a pyrotechnic ignition model based on transient heat conduction from a heated bridgewire to a pyrotechnic that is placed in contact with it. The boundary condition used at the interface was a thermal contact conductance estimated at 31,200 W/m²-K between the wire and the pyrotechnic. Ignition was assumed to occur when a 2.5-μm layer of pyrotechnic next to the bridgewire reached a critical ignition temperature. The times to ignition predicted by this model for constant-current firings were in good agreement with experimentally observed times to fire at 3.5 and 5 A current levels and ambient temperatures from 144 to 368 K.

SHIMA, R.

S016 Composite Film Interface Control by Sequential Sputtering

R. Shima

Contamination at the interface between layers of a multilayer metal structure can be a source of serious reliability problems, such as variable ohmic contacts and poor adhesion. This contamination can occur during the transfer from one metallization step to the next, depending on operating procedure and the residual partial pressures of gases in the system. To avoid this problem, a process has been developed for sequentially sputtering metals with virtually no interruption between layers. A commercial 8-in.-dia. dc or rf-diode sputtering system has been modified by attaching three 3-in.-dia. sputtering targets of selected materials and adding a special configuration of shields, baffles, bias grids, and a rotating substrate holder.

Results obtained from sequentially sputtered Ti/Mo/Au metallizations is described in detail. Backscattering of He ions provides data on the composition of the layers following deposition and after heat treatment at different temperatures. The results provide information on the stability of the structures and their usefulness in actual
shows, where, for example, high-temperature packaging is required. (Only the abstract is printed in this issue.)

SIMON, M. K.

S019 Data-Derived Symbol Synchronization of MASK and QASK Signals
M. K. Simon
Technical Memorandum 33-720, December 15, 1974
Much has been said in the literature with regard to the problem of establishing symbol synchronization in binary baseband digital communication systems. By comparison, the literature is virtually devoid of information relating to the extraction of symbol synchronization from multilevel baseband data. With the recent interest in multilevel amplitude-shift-keying (MASK) and quadrature amplitude-shift-keying (QASK) as signaling techniques for multilevel digital communications systems, the problem of providing symbol synchronization in the receivers of such systems becomes paramount.

This memorandum presents a technique for extracting symbol synchronization from an MASK or QASK signal. The scheme is essentially a generalization of the data transition tracking loop which has heretofore been used in phase-shift-keying systems. The performance of the loop is analyzed in terms of its mean-squared symbol synchronization jitter and its effects on the data detection process in MASK and QASK systems.

S020 Carrier Synchronization and Detection of QASK Signal Sets
M. K. Simon and J. G. Smith
This article describes a carrier regeneration loop which generates highly coherent quadrature reference signals for quadrature amplitude-shift-keying (QASK) demodulation. The loop employs the principle of decision feedback and has a structure analogous to a decision feedback loop for quadrature signals suggested earlier in the literature. The error probability performance of QASK is computed in the presence of the noisy carrier reference signals provided by the above loop. It is demonstrated that when the ratio of data rate to loop bandwidth is 50 or greater, then for all practical purposes, ideal QASK error probability performance is achieved.

SO23 Lunar Gravity via the Apollo 15 and 16 Subsatellites

W. L. Sjogren, R. N. Wimberly, and W. R. Wollenhaupt (NASA–Lyndon B. Johnson Space Center)

The Moon, Vol. 9, Nos. 1/2, pp. 115-128, January 1974

Dense doppler tracking coverage of the Apollo 15 and 16 subsatellites over ten and eighteen day periods when periapsis altitudes were 15-50 km has provided detailed gravity mapping of the lunar frontside. Many new gravity features were revealed including one that does not correlate with any visible topographic structure. All unfilled craters sampled are negative anomalies. The mascons consistently produce gravity highs that load the surface with \( \approx 800 \text{ kg cm}^{-2} \) excess mass. The Orientale region is represented with a solution grid of 177 point masses that clearly show the ringed structure. The eastern limb is also displayed with a solution grid of point masses. The gravity variations over the central portion of the frontface are shown as line-of-sight acceleration contours in milligals.

S033 Plasmaspheric Hiss Intensity Variations During Magnetic Storms
E. J. Smith, A. M. A. Frandsen, B. T. Tsurutani, R. M. Thorne (University of California, Los Angeles), and K. W. Chan (University of California, Los Angeles)

The storm time intensity variations of extremely-low-frequency electromagnetic emissions have been studied by using the Ogo 6 search coil magnetometer. Low-latitude signals exhibit a sharp low-frequency cutoff and are identified as plasmaspheric hiss. Such waves show pronounced intensification during the recovery phase of magnetic storms but remain close to background levels during the storm main phase. This behavior is consistent with cyclotron resonant generation within the plasma-sphere as the latter expands into the intensified belt of outer zone electrons during the storm recovery.

S034 The Planetary Magnetic Field and Magnetosphere of Jupiter: Pioneer 10
E. J. Smith, L. Davis, Jr. (California Institute of Technology), D. E. Jones (Brigham Young University), P. J. Coleman, Jr. (University of California, Los Angeles), D. S. Colburn (Ames Research Center), P. Dyal (Ames Research Center), C. P. Sonett (University of Arizona), and A. M. A. Frandsen

Data obtained by the Pioneer 10 vector helium magnetometer are presented along with models of the intrinsic magnetic field of Jupiter and its magnetosphere. Data acquired between 2.84 and 6.0 \( R_J \), where the intensity of the planetary field ranged between 1900 and 18,400 \( \gamma \), were used to develop a six-parameter eccentric dipole model of the field. The dipole so derived has a moment of 4.0 \( G R_J^3 \) and a tilt angle with respect to Jupiter's rotation axis of 11 deg. The system III (epoch 1957) longitude of the magnetic pole in the northern hemisphere, which is a north-seeking pole, is 222 deg. The pole is displaced from the center of Jupiter by 0.11 \( R_J \) in the direction of latitude 16 deg and system III longitude 176 deg. The dipole tilt and the longitude of the pole are in good agreement with values inferred from radio astronomy measurements.

A model of the Jovian magnetosphere is presented in which the essential feature is an eastward current sheet that forms an annulus with Jupiter at the center. At large distances from the planet the current sheet is nearly parallel to Jupiter's equator, but, in general, does not lie in it. The current sheet is warped, so that it is above the equator on one side and below it on the other. The current sheet rotates with the planet, more or less like a rigid body; this behavior causes an apparent up and down motion and periodic crossings of the current sheet by Pioneer 10. The origin of the current sheet appears to be the very large centrifugal force, associated with Jupiter's great size and rapid rotation, acting on trapped low-energy magnetospheric plasma. The density of this plasma is estimated to be approximately 1 particle \( \text{cm}^{-3} \). A retrograde spiraling of field lines out of meridian planes is also observed, presumably as a result of azimuthal drag forces exerted on the outer magnetosphere.

S039 Short-Term Frequency Measurement Capability in DSN Equipment Maintenance Facilities
R. M. Smith, D. Crawford, and C. H. Fourtner
This article describes a short-term frequency-measuring capability that has been established at the Goldstone and Madrid DSN Complex Maintenance Facilities to afford rapid, complete service to DSN synthesizers. Future development of the capability may include the testing of station frequency standards.

SMITH, R. E.
R. E. Smith and O. Sumner
The DSN hydromechanical service program has progressed satisfactorily along the lines originally intended. Oil sampling and analysis have been particularly rewarding, detecting early signs of wear and forestalling catastrophic failures.

SMITH, R. H.
S038 Fourth Harmonic Analyzer
R. H. Smith
The X-band downlink receiver frequency is situated very close to the fourth harmonic of the S-band high-power transmitter. When wideband modulation is applied to the high-power transmitter, the sidebands of the fourth harmonic are of such magnitude relative to the X-band receiver that they interfere with X-band downlink and may saturate the X-band maser. To alleviate this problem, a fourth-harmonic filter was added to the output of the high-power transmitter. No quantitative results of this experiment were obtained. To make an analytic measurement, a fourth-harmonic analyzer has been developed to measure the power at the fourth-harmonic of the S-band high-power transmitter with and without a fourth-harmonic filter.

STANDISH, E. M., JR.

S045 The Figure of Mars and Its Effect on Radar-Ranging
E. M. Standish, Jr.
Formulae are given which indicate the errors made in computing the radar-range to a planet when one assumes the planet to have a spherical surface, centered at the center of mass. These formulae are evaluated for Mars, using an ellipsoidal fit of the Martian surface obtained from the occultation measurements of the Mariner Mars 1971 spacecraft. The secular-like part of the errors amounts to about 4 km in range over the past 3 oppositions, due mainly to the flattening of 0.006 and to a 3-km southerly displacement of the center of figure from the center of mass. The method of solution is given in the appendix along with a method for applying the ellipsoidal model to the reduction of radar-range data.

STARKS, G. T.

S046 Mariner Mars 1971 Inertial Reference Unit

G. T. Starks
Technical Memorandum 33-662, March 1, 1974
This memorandum presents the design concept of an inertial reference unit using a gyroscope in the rate mode in conjunction with a unique application of a drift-compensated and temperature-stabilized solid-state integrator for the inertial mode. A typical test program and the results for an inertial reference unit as applied to the Mariner Mars 1971 program to achieve highly reliable spacecraft operation are also described.

The Deep Space Network: January and February 1974, DSN Progress Report 42-20, pp. 64-68, April 15, 1974
This article presents representative data for the original Block 3 and Block 4 zero-delay devices as a function of antenna elevation angle. Instabilities on the order of 33 ns as obtained with the original S-band Block 3 system are reduced by relocation of the zero-delay-device (ZDD) horn. However, unsatisfactory performance at X-band for the Mariner Venus/Mercury 1973 S/X-band experiment ZDD requires a reconfiguration eliminating the horns and associated air path.

S052 A Re-Examination of the AGC Calibration Procedure

G. L. Stevens

The Deep Space Network: May and June 1974,
DSN Progress Report 42-22, pp. 197-201,
August 15, 1974

In this article, a re-examination of automatic gain control (AGC) calibration errors was made to determine if an improvement in reported spacecraft carrier power could be obtained by modifying the signal-level tracking calibration procedure. The calibration errors (as a function of the number of independently obtained calibration points) were evaluated to determine if a new AGC calibration procedure using 15 independent calibration points should be adopted. Results of this study indicate that the improvement in calibration accuracy is insignificant and would not warrant a new calibration procedure requiring considerably more time and effort.

S053 AGC Calibration Accuracy

G. L. Stevens

The Deep Space Network: July and August 1974,
DSN Progress Report 42-23, pp. 104-110,
October 15, 1974

Currently, measurement of received signal power at the DSN stations is performed by calibrating the automatic gain control (AGC) voltage as an indicator of received signal power level. Errors in the AGC voltage vs signal power level calibration are identified and the overall AGC calibration accuracy is estimated.

S057 Microwave Doppler Shift Technique for Determining
Solid Propellant Transient Regression Rates

L. D. Strand, A. L. Schultz, and G. K. Reedy

J. Spacecraft Rockets, Vol. 11, No. 2, pp. 75-83,
February 1974

A microwave doppler-shift system, with increased resolution over earlier microwave techniques, was developed for measuring the regression rates of solid propellants during rapid pressure transients ($10^4$ to $10^5$ N/cm$^2$). The system was used in two different transient combustion experiments: a rapid depressurization bomb and the high-frequency acoustic pressure environment of a T-burner. In the rapid depressurization tests the measured regression rates generally fell near or below the
steady-state rate at the corresponding pressure and exhibited oscillations in tests near the critical depressurization rates for extinguishment. Unreasonably high oscillatory regression rates were obtained in the T-burner experiments. The results of a set of parametric calculations indicated that flame ionization effects could be of sufficient magnitude to account for these anomalies. A direct comparison of the analytical predictions and experimental results yielded the conclusions that flame ionization effects probably produced some errors in the absolute values, but not the general characteristics, of the rapid depressurization regression rate measurements.

TANG, C. C. H.

**T001 Multiple Scattering From Finite Inhomogeneous Media**

C. C. H. Tang

This article presents a theoretical analysis on the multiple scattering of electromagnetic waves in finite inhomogeneous media by utilizing the characteristic information on the apparent phase constant difference between the electric and magnetic fields propagating in an inhomogeneous medium. The solution is obtained by first approximating the coefficients of a pair of exact, coupled, first-order differential equations and then solving the equations by first-order iteration. The present first-order approximate solution with multiple scattering considerations is shown to be more accurate than the WKB solution. Methods to improve the accuracy of the first-order solution further are discussed. Application of the solution to slowly varying finite media with periodic properties demonstrates the validity of the solution. The same approach can be extended to frequencies in the optical region by retaining additional terms in the coefficients of the coupled differential equations. Further investigations are required to treat the case of oblique incidence in proper perspective.

TAPPAN, R. W.

**T002 DSN Progress Report for November-December 1973: Planetary Ranging**

R. W. Tappan

The planetary ranging assembly (PRA) determines the distance to spacecraft that are traveling at planetary distances from Earth by measuring the time required for a radio signal to travel to the spacecraft and back. The range data are used to improve the accuracy of the calculation of the spacecraft's trajectory and to provide information concerning the charged-particle content of space.

The PRA is able to operate at reduced signal levels because of improvements in the method of maintaining coder lock and detecting the signal in the presence of space noise. It is capable of operation with either S-band or X-band carrier frequencies and offers selectable code types to enable each project to specify the operating mode best suited to its particular mission.

TAUSWORTHE, R. C.

**T003 Program Structures for Non-proper Programs**

R. C. Tausworthe

Canonic structured programming forms the basis of an attractive software design and production methodology applicable to proper programs (programs having only one entry point and one exit point). Programs developed using this methodology tend to be easier to organize, understand, modify, and manage than are unstructured programs. However, there are notable examples in which programs either are inherently non-proper (usually, with more than one exit, rather than more than one entry), or else suffer when forced to be structured. This article addresses ways of extending the concept of structured programming to cover such cases; it is a report of an ongoing research activity to examine potential DSN software development standards.

**T004 Control-Restrictive Instructions for Structured Programming (CRISP)**

R. C. Tausworthe

This article presents a discipline and a set of control-logic statements to extend structured programming to arbitrary existing languages. These statements preempt and replace all control statements in a language, so that all programs written in Control-Restrictive Instructions for Structured Programming (CRISP) are automatically structured. Structures are provided for real-time, as well as nonreal-time programming. The principles set forth do not attempt to specify a standard programming language, but instead, a programming language standard—that is, a way of programming that contributes to stability, maintainability, readability (self-documentation), and understandability of the final product.

**T005 Data Structure Design Guidelines**

R. C. Tausworthe

Proper modularization of software designs is more than mere segmentation of a program into subfunctions as dictated by control-logic topologies, as might be suggested by classical structured programming, wherein a limited number of program control-logic structures are permitted. Analyzing data connectivity between program...
segments can be far more complex than analyzing control flow, unless conscientious precautions are taken to avert this possibility. For this reason, data connectivity design should adhere to a discipline which minimizes both data and control-flow connections. This article discusses such considerations within a top-down, hierarchical, structured-programming approach to software design.

TAYLOR, F. W.

T006 Remote Temperature Sounding in the Presence of Cloud by Zenith Scanning

F. W. Taylor

The principles of remote sounding of vertical temperature profiles in planetary atmospheres containing cloud layers are presented for an approach that uses measurements at different angles to the local vertical to eliminate the unknown cloud effects. A numerical example for a model of the Earth's atmosphere shows that soundings separated by 40 deg in zenith angle permit the recovery of the temperature profile with an error that is not significantly greater than that obtained in the clear atmosphere case, and without serious horizontal smear. It is proposed that the method will be valuable for the interpretation of measurements made by instruments on spin-stabilized spacecraft on planetary missions, since in these cases the required angular coverage is obtained automatically for most trajectories.

T008 Ion-Molecule Reactions and Vibrational Deactivation of \( \text{H}_2^+ \) Ions in Mixtures of Hydrogen and Helium

L. P. Theard and W. T. Huntress, Jr.

Ion cyclotron resonance techniques have been used to determine the thermal energy rate constants for the ion-molecule reactions of \( \text{H}_2^+ \) ions in mixtures of hydrogen and helium. Rate constants are presented for a near-Franck-Condon distribution of initial vibrational states in \( \text{H}_2^+ \). Collisional deactivation of vibrationally excited \( \text{H}_2^+ \) ions is also shown to occur in nonreactive encounters with He atoms. The rate constant \( k_v \) for this process increases with increasing vibrational quantum number \( v \) and is approximately equal to \( k_0 \) for \( \text{H}_2^+ \) ions in vibrational state \( v \).

THOMAS, J. B.

T009 DSN Progress Report for November-December 1973: Radio Interferometry Measurements of a 16-km Baseline With 4-cm Precision

J. B. Thomas, J. L. Fanselow, P. F. MacDoran, D. J. Spitzmesser, and L. Skjerve (Philco-Ford Corporation)

In order to demonstrate the feasibility of eventually using radio-interferometry techniques to measure tectonic motion, a series of interferometry experiments was conducted between two antennas at the Goldstone Deep Space Communications Complex. The primary objective of these experiments was to develop independent-station instrumentation capable of making three-dimensional baseline measurements with an accuracy of a few centimeters. To meet this objective, phase-stable instrumentation was developed to precisely measure the time delay by means of two-channel bandwidth synthesis. Delay measurements produced by this instrumentation lead to three-dimensional baseline measurements with a precision of 2-5 cm for the components of a 16-km baseline.

T010 A Reformulation of the Relativistic Transformation Between Coordinate Time and Atomic Time

J. B. Thomas

The Deep Space Network: March and April 1974, DSN Progress Report 42-21, pp. 18-26, June 15, 1974

In this article, the relativistic time transformation is reformulated to allow simpler time calculations relating analysis in a solar-system frame (using coordinate time) with Earth-fixed observations (using atomic time). After an interpretation of terms, this simplified formulation is used to explain the conventions required in the synchronization of a world-wide clock network. In addition, two synchronization techniques—portable clocks and radio interferometry—are discussed in terms of the relativistic time transformation.
THOMAS, R. F.

TO11 A Dual Hybrid Mode Feedhorn for DSN Antenna Performance Enhancement

R. F. Thomas and D. A. Bathker

This article describes a new microwave horn suitable for use in selected DSN antenna feed applications. The new horn uses two hybrid modes propagating within a corrugated conical waveguide. Expected aperture efficiency improvement, when feeding DSN reflector antennas, as well as bandwidth information, is provided. It is concluded that the new horn provides 0.38 dB gain improvement when feeding a symmetrical Cassegrain antenna; and it is estimated that 0.29 dB improvement is available when feeding an asymmetric system such as the DSN 84-m antenna tricone configuration. Bandwidth considerations suggest that application at X-band is straightforward. The S-band uplink and downlink bands cannot both be covered at this time.

THOMPSON, E. D.

TO12 Perturbation Theory for a Resistivity Shunted Josephson Element

E. D. Thompson

This paper presents a systematic perturbation theory, extendable in principle to all orders of magnitude, for the solution of the equations of motion of an ideal Josephson element shunted by a resistance and driven by a dc current source and a small time-dependent source. Second-order results are presented for the case in which the time dependence is that of a single sinusoid, and these results are compared with other numerical and analytical calculations. Near, but not on, the first constant voltage step where the perturbation theory appears divergent, the current-voltage characteristic is calculated by means of a nonperturbative adiabatic procedure. The impedance and responsivity agree with earlier results.

THOMPSON, T. W.

TO13 Atlas of Lunar Radar Maps at 70-cm Wavelength

T. W. Thompson

The intensity distribution of lunar radar echoes has been mapped for two-thirds of the Earth-visible lunar surface at a wavelength of 70 cm. The depolarizing effects of the lunar surface were observed by simultaneously receiving the radar echoes in opposite polarizations. These echoes were mapped with areal resolutions of 25-100 km². Mappings with this resolution confirmed that young craters have enhanced returns. A few craters were found to have enhanced echoes only from their rims. Backscattering differences were also observed between various areas within a mare, between different highland areas, and between maria and adjacent highlands. These scattering differences were interpreted with a simple model, which assumed that the surface backscattered with varying amounts of quasi-specular and diffuse power. Only an increase in the diffuse power was needed to give the numerical values of the enhancements.

THORMAN, H. C.

TO14 Deep Space Network Test and Training System

H. C. Thorman

The Deep Space Network: January and February 1974, DSN Progress Report 42-20, pp. 5-12, April 15, 1974

This article describes the Deep Space Station Test and Training Subsystem, the evolution and usages of the Simulation Conversion Assembly, capabilities of the present subsystem (Mark III-73) and planned expansion (Mark III-75) to meet Viking requirements. A brief discussion of present and planned capabilities of the Network Control Test and Training Subsystem is included. Both are subsystems of the Deep Space Network Test and Training System.

THORNTON, C. L.

TO16 Square-Root Algorithm for Evaluating Mismodeled Process Noise

C. L. Thornton and S. G. Finley
Unmodeled, random accelerations acting on spacecraft place severe limitations on the application of classical least-squares filters to interplanetary navigation. Various modified Kalman filters have been developed which attempt to model the random process affecting the spacecraft state. As the application of sequential filters has grown, the need has arisen to evaluate the sensitivity of these filters to mismodeling of the random process. In this article a numerically reliable square-root algorithm is presented for calculating the covariances of estimates from a sequential filter which incorrectly models process noise. Mismodeling is restricted to the correlation time and standard deviation of a random process represented as a first-order Gauss–Markov sequence. Using a computer program which employs this algorithm, a sensitivity analysis was performed for several types of Earth-based tracking data from an interplanetary spacecraft.

TOTH, R. A.

TO19 Linewidths of HCl Broadened by CO₂ and N₂ and CO Broadened by CO₂

R. A. Toth and L. A. Darnton (University of California, Santa Barbara)

J. Molec. Spectrosc., Vol. 49, No. 1, pp. 100-105, January 1974

High resolution measurements of the linewidths of HCl broadened by CO₂ and N₂ and the linewidths of CO broadened by CO₂ have been made in both the 1-0 and 2-0 bands of HCl and the 2-0 band of CO. The data were analyzed by the direct and the peak absorption methods, and the values of the linewidths obtained by the two methods are in generally good agreement. For |m| ≤ 3, for the case of HCl + CO₂, the agreement is good for both bands of HCl. However for |m| > 3, the HCl + CO₂ linewidths in the 1-0 band are smaller than for the corresponding lines in the 2-0 band by as much as 11% for |m| = 9. Lines (|m| ≤ 3) of the 1-0 and 2-0 bands of HCl broadened by CO₂ were also analyzed in terms of the super-Lorentzian line profile (proposed by Varanasi, Sarangi, and Tejwani) and the Lorentzian profile. The results indicate that near the line center (within 3γ), the shape of HCl + CO₂ lines are Lorentzian.

TOTH, R. A.

TO20 Wavenumbers, Strengths, and Self-Broadened Widths of CO₂ at 3 μm

R. A. Toth

J. Molec. Spectrosc., Vol. 53, No. 1, pp. 1-14, October 1974

Measurements of the line strengths of the 1310-0000 and 1420-0110 bands of CO₂ have been made with high resolution. The line strengths in both bands are strongly perturbed by Coriolis interactions resulting in the R-branch strengths being, on the average, greater than the P-branch strengths for comparable values of F'. Measurements of the Q-branch strength of the 1310-0000 band were also made. The strength data were analyzed to determine the vibrational-band strengths and the coefficient ξ of the F factor. Line-center frequencies of the 1420-0110 band were measured and used to determine the band-center frequency and the rotational constants. The direct method was applied to determine the self-broadened line widths in the 1310-0000 band.

TO18 Quantum-Mechanical and Experimental Study of the Excitation of the 2 1P State of He by Electron Impact at 29–40 eV

D. G. Truhlar (University of Minnesota), S. Trajmar, W. Williams, S. Ormonde (Quantum Systems, Inc.), and B. Torres (Quantum Systems, Inc.)

J. Spacecraft Rockets, Vol. 11, No. 4, pp. 223-230, April 1974

For abstract, see Truhlar, D. G.
The reaction of stratospheric N_2O with O(^1D) may provide a natural source of both NO and NO_2 which, in turn, may control the formation and destruction of stratospheric O_3. Although the presence of NO_3 in the stratosphere has been established, there have been no reports of the detection of stratospheric NO. This article describes the results of spectroscopic measurements made in the lower stratosphere, in which absorptions due to NO have been identified.

Some Correlations Between Measurements by the Apollo Gamma-Ray Spectrometer and Other Lunar Observations

J. I. Trombka (Goddard Space Flight Center), J. R. Arnold (University of California, San Diego), R. C. Reedy (University of California, San Diego), L. E. Peterson (University of California, San Diego), and A. E. Metzger

Observations by the Apollo 15 and 16 gamma-ray spectrometers are compared with those of a number of other experiments, both compositional and non-compositional. A general correspondence with topography is seen. The Van de Graaff area is a unique farside region with respect to observations by the laser altimeter, the subsatellite magnetometer, and the gamma-ray spectrometer. X-ray and alpha particle orbital measurements show a broad general agreement with gamma-ray data, though results from additional elements in the gamma-ray spectrum are needed to extend the comparison with X-ray data. A comparison of thorium concentrations with those found at various landing sites shows generally good agreement, with the orbital values tending to be somewhat higher.

The Apollo Gamma-Ray Spectrometer

T. M. Harrington (MDH Industries, Inc.), J. H. Marshall (MDH Industries, Inc.), J. R. Arnold (University of California, San Diego), L. E. Peterson (University of California, San Diego), J. I. Trombka (Goddard Space Flight Center), and A. E. Metzger

A Shock Spectra and Impedance Method To Determine a Bound for Spacecraft Structural Loads

R. M. Bamford and M. R. Trubert

Technical Memorandum 33-694, September 1, 1974

For abstract, see Bamford, R. M.

Quantum-Mechanical and Experimental Study of the Excitation of the 2P State of He by Electron Impact at 29–40 eV

D. G. Truhlar (University of Minnesota), S. Trajmar, W. Williams, S. Ormonde (Quantum Systems, Inc.), and B. Torres (Quantum Systems, Inc.)

The close-coupling approximation (c.c.), the Vainshtein-Presnyakov-Sobelman approximation (VPS), and various first-order approximations, including the first Born approximation (B), are compared to accurate normalized experimental differential cross sections (estimated error less than 20%) for excitation of the 2P state of helium for impact energies 29.6, 34, and 40.1 eV, and scattering angles 3–138 deg. The most accurate new measurements are those at 29.6 and 40.1 eV. These measurements were normalized to the experimental integral cross sections of Hall et al. The experimental differential cross sections of Hall et al. are in good agreement with these present measurements. All the calculations except B include electron exchange. The VPS has the most accurate magnitude of the present calculations at small scattering angles but it is still too large (by a factor which at 45 deg is about 2.5 at 29.6 and 34 eV and is about 1.5 at 40.1 eV). The c.c. has the most accurate magnitude at large scattering angles and the most accurate angular dependence at all scattering angles, but it is not in good agreement with the measurements at the largest scattering angles.

Relaxation Times of Remanent Magnetisation in Lunar Fines

F.-D. Tsay

On the basis of the observed equivalence between the remanence coercive force and the first-order crystalline anisotropy field for the Apollo 11-16 fines, it seems that the bulk of metallic Fe particles in the lunar fines are essentially spherical and have a short remanent relaxation time. These spherical metallic Fe particles could account for the apparently low blocking temperature observed for the unstable components of the natural remanent magnetisation (NRM) detected in the returned lunar samples. In view of the ease with which the electron-spin-resonance technique can distinguish between shape and crystalline anisotropy effects, it seems that the technique is particularly valuable for identifying the carriers of various NRM components having differing degrees of thermal stability.

T034 Metallic Fe Phases in Apollo 16 Fines: Their Origin and Characteristics as Revealed by Electron Spin Resonance Studies

F.-D. Tsay, S. L. Manatt, D. H. Live (California Institute of Technology), and S. I. Chan (California Institute of Technology)

The intense electron spin resonance (esr) signals (g = 2.08 ± 0.03) detected in the Apollo 16 fines from three sites (61141, Station 1; 64501,22, South Ray Crater; 67601,20, North Ray Crater) are found to be essentially similar in g-value, in lineshape asymmetry, and in temperature dependence to those previously observed for the Apollo 11-15 fines. On the basis of these similarities, it is concluded that these esr signals, like those detected in the Apollo 11-15 fines, are principally ferromagnetic in nature arising from metallic Fe phases having the body-centered cubic structure, and not from hematite, magnetite, or any other ferric oxides. It is shown that a quantitative correlation exists between the esr linewidth observed for the Apollo 11-16 fines and their average Ni contents in the metallic Fe phases as determined by other means.

For the three Apollo 16 fines investigated, the esr linewidths are found to be essentially identical. This together with a high Ni content in the metallic Fe phases of these samples as determined from esr linewidth correlation indicates a common source of meteoritic origin for the metallic Fe phases of these samples. Significant variations are observed in the metallic Fe content as well as in the total Ni content for these samples, in particular, between the fines from South Ray Crater and those from North Ray Crater. These variations appear to correlate with the surface-exposure ages of the samples. It is also shown that the first-order crystalline anisotropy energy determined from esr linewidth measurements is essentially equivalent to the remanence coercive force obtained in static magnetic susceptibility measurements for the lunar fines.

Tucker, T. K.

T038 DSN Progress Report for November-December 1973: Design of a High-Speed Reference Selector Switch Module for the Coherent Reference Generator Assembly

T. K. Tucker
A design effort was started in April 1973 to develop and fabricate a high-speed switch module for the coherent reference generator assembly. The major design goal was to develop a high-speed switch capable of switching between frequency standards in less than 400 ns in the event of a primary standard failure, thus providing a constant failsafe 1-MHz reference signal to the station clocks. This article reviews the overall design and provides a general overview of the completed module.

**U002** Shock System of February 2, 1969

T. W. J. Unti, M. Neugebauer, and C.-S. Wu (University of Maryland)

The shock system observed in the solar wind by Pioneer 9 and Ogo 5 on February 2, 1969, consisted of the following major discontinuities: a forward slow shock, a forward fast shock, a tangential discontinuity at which the density dropped sharply and the flow direction changed, a tangential discontinuity at which the magnetic field strength jumped to an unusually high value, two closely spaced tangential discontinuities that bracketed a region of even greater field strength and that fronted a region of very cool, very dense, helium-enriched plasma, a reverse fast shock of low Mach number, and a second reverse fast shock of very low Mach number. The event had aspects of both corotating and flare-induced shock systems; it is suggested that the source of the disturbances was a flare occurring at or near an M region. The Ogo 5 search coil magnetometer detected a high level of turbulence throughout the event; a local enhancement of this turbulence at the front of the helium enrichment is believed to have been caused by a magnetic drift wave instability. Data are also presented for two other shock pair systems, both of which had density and flow direction profiles similar to those observed on February 2, 1969.

**VOTE, F. C.**

**V004** Development of the Propulsion Subsystem for the Viking 75 Orbiter

F. C. Vote and W. J. Schatz

The development of the Viking Mars 1975 Orbiter propulsion subsystem has been completed and qualification is under way. This development required an extension of the Mariner Mars 1971 propulsion subsystem technology to meet the Viking Mars 1975 requirements of three times the burn time and five times the number of burns. Modifications have been incorporated into the rocket engine to increase the cooling margin for the 2700-second Mars orbit insertion burn. This capability has been demonstrated in both engine firings and subsystem tests. A new surface tension device has been developed...
to position the propellants (N₂O₄ and MMH) over the tank outlets during zero-g flight. Extensive scale model testing has been conducted to prove this propellant management concept. This subsystem will provide midcourse corrections, an orbit insertion burn and 20 orbit trims for the Viking Mars 1975 spacecraft. The Viking Project is managed by the Langley Research Center, National Aeronautics and Space Administration.

W002 Development and Correlation: Viking Orbiter Analytical Dynamic Model With Modal Test
B. K. Wada, J. A. Garba, and J. C. Chen
Technical Memorandum 33-690, June 1, 1974
The development of a mathematical dynamic model and its verification by a modal test is a significant milestone for many projects, including Viking Mars 1975 Orbiter (VO). Difficulties encountered include performing a modal test, establishing criteria for correlation of analysis with test, and modifying a large finite-element mathematical model to match test data if required. Often the modal test is performed near the end of the Project development schedule; consequently, the time allotted to obtain a verified mathematical model is minimal.

This memorandum describes the VO experience in the achievement of a good mathematical model. Success can be attributed to the coordination of analysis and tests using substructure modal coupling techniques. The experience would benefit the overall planning of any project, such as the Shuttle, especially if substructure modal coupling techniques are contemplated.

WAHLQUIST, H. D.

W003 Bäcklund Transformation for Solutions of the Korteweg-de Vries Equation
H. D. Wahlquist and F. B. Estabrook
This article presents a Bäcklund transformation operating on solutions of the Korteweg-de Vries equation. The transformation provides a unifying approach to the theory of solitary waves (solitons). Recursive application of the transformation to any solution of the Korteweg-de Vries equation generates a hierarchy of solutions for which an algebraic recursion relation is obtained. Every such hierarchy (one of which is the known family of pure multisoliton solutions) thus admits a nonlinear superposition principle.

W007 Simulation Study of a GCF Retransmission Scheme
L. R. Welch

This article discusses a study of a promising retransmission algorithm for correcting Ground Communications Facility (GCF) errors, using both actual GCF 4.8 kbps error data and Adeyemi’s model. The results indicate that virtually all GCF error bursts can be corrected with a fairly simple scheme.

WHANG, M. M.

W008 Three-Spacecraft Simulation for Viking 1975

M. M. Whang

A telemetry simulation capability is provided at each deep space station, by way of the Simulation Conversion Assembly (SCA), for testing station equipment and training operations personnel prior to each mission. The simulation equipment provided the DSN for support of the Viking Mars 1975 mission has been substantially more complex than that provided for previous missions. No single DSN station has had the requirement of tracking three spacecraft for any previous flight project.

Deep space stations will be required to support the equivalent of four spacecraft (two orbiters and two landers) for the Viking Mars 1975 mission. However, any single station will have a view angle of a maximum three spacecraft at any given time (two orbiters and one lander). Since each spacecraft has two telemetry channels (one science and one engineering channel), the deep space stations must be prepared to process six channels of telemetry data and hence a six-channel simulation capability must be provided. This entails the generation of an additional two channels of simulated telemetry data over the present four-channel capability of the SCA. This article describes the SCA modification necessary to prepare for the Viking Mars 1975 mission.

WHITEHEAD, A. B.

W009 The Elevation of Olympus Mons From Limb Photography

A. B. Whitehead

Using a novel photogrammetric technique, the relative elevations of a set of control points on the Martian volcano Olympus Mons (Nix Olympica) have been measured from Mariner Mars 1971 limb pictures that include the volcano in the foreground. The summit of Olympus Mons is found to be 22 ± 1 km above the mean level of the surrounding plain by correlating the elevation results with previously reported planet radii at nearby occultation points. Vertical elevation differences as great as 5 km were measured between close points on the basal scarp.

WICK, M. R.

W010 DSN Programmed Oscillator

M. R. Wick

This article describes the programmed oscillator installed in the DSN Block III receiver/exciter subsystem at the Mars Deep Space Station and Ballina Deep Space Station for Pioneer 10 support during the Jupiter flyby. A brief description is given of the Block III receiver/exciter subsystem modifications required to implement the programmed oscillator and design changes in order to add the capability of providing timed linear frequency sweeps in the manual operating mode.

WILLIAMS, J. G.

W014 Lunar Physical Librations and Laser Ranging
J. G. Williams, M. A. Slade, D. H. Eckhardt (Air Force Cambridge Research Laboratories), and W. M. Kaula (University of California, Los Angeles)
The Moon, Vol. 8, No. 4, pp. 469-483, October 1973
The analysis of lunar laser ranging data requires very accurate calculations of lunar physical librations. Libration terms are given which arise from the additive and planetary terms in the lunar theory. The large size of the recently discovered terms due to third degree gravitational harmonics will allow some of these harmonics to be measured, in addition to $\beta$ and $\gamma$, by laser ranging to the Moon. Numerical integration promises to be an effective method of calculating librations. Comparison of numerical integrations with analytic series indicates that the calculation of the series due to third and fourth degree harmonics is not yet as accurate as the more extensively developed second degree terms.

WILLIAMS, W.

W015 Elastic and Inelastic Electron Scattering at 20 and 60 eV From Atomic Cu
W. Williams and S. Trajmar
Normalized differential and integral electron-impact cross sections for elastic scattering and for the excitation of the $^2D_{3/2}$, $^2D_{3/2}$, and $^2P_{3/2,1/2}$ levels of atomic copper have been determined at 20 and 60 eV. An unexpectedly large cross section was found for the excitation of the $^2P_{3/2,1/2}$ levels, which at certain angular and energy ranges surpasses the cross section for elastic scattering. The integral cross sections in units of $10^{-16}$ cm$^2$ at 20 and 60 eV, respectively, are: elastic, 91.0 and 59.0; $^2D_{3/2}$, 1.85 and 0.38; $^2D_{3/2}$, 1.26 and 0.28; and $^2P_{3/2,1/2}$, 77.2 and 36.5.

WILLIAMS, W. F.

W017 Contoured Patterns From Reflector Systems: A Spherical Wave Expansion Solution
W. F. Williams
Preprint 74-487, AIAA Fifth Communications Satellite Systems Conference, Los Angeles, California, April 22-24, 1974
Any electromagnetic field (e.g., a contoured antenna pattern) may be expanded into a sum of spherical waves, similar to a one dimensional Fourier expansion. This expanded wave can then be scattered from a source reflector to determine a resulting required feed field in the vicinity of the focal region. This result is of questionable value and the more significant information would be the required feed pattern itself. Hence, the required contour pattern is instead scattered from the back of the reflector and the result is the required feed pattern with origin at the focus of the chosen reflector.

Absolute Radiometry and the Solar Constant

R. C. Wilson

Space Optics; Proceedings of the Ninth International Congress of the International Commission for Optics, Santa Monica, California, October 9-13, 1972, pp. 502-510

The definition of an absolute radiation scale, based on fundamental physical principles, can be effected by standard detectors or by standard sources of radiation. Standard sources, usually termed blackbody sources, are cavity radiators operated at high temperature. Calibration of secondary radiometers can be carried out in the laboratory by exposing them to the irradiance of a standard source. Measurements made in remote locations by the radiometer may then be reported on the absolute radiation scale as defined by the standard source.

The standard source method has some serious disadvantages. The calibration of secondary radiometers is an added experimental step with associated indeterminacies regarding the absolute temperature of the source and the radiative transfer between source and radiometer. The definition of the absolute radiation scale by standard detectors obviates many of the standard-source-associated problems. It is this approach that has been pursued at JPL in making absolute measurements of solar radiation. This paper describes a family of high-accuracy active-cavity radiometers developed at JPL.

DSN-MVM'73 S/X Dual-Frequency Doppler Demonstration

F. B. Winn, K. W. Yip, and S. J. Reinbold

Doppler charged-particle calibrations derived from S/X-band dual-doppler data have been demonstrated successfully. The accuracy of the S/X-band dual-doppler has been verified by comparisons to Faraday polarization data. This verification, limited by the accuracy of "mapped" Faraday data, is to the 10- to 30-cm level. The S/X-band dual-doppler exhibits subcentimeter resolution and, thus, its potential accuracy. The S/X-band dual-doppler calibrations are significant for the Mariner Venus/Mercury 1973 spacecraft (Mariner 10) Mercury-encounter orbit determination. The error of the estimate of
the Mariner 10 Mercury target plane coordinate was reduced by \(\sim 500\) km (\(\sim 80\%\) improvement).

WOICESHYN, P. M.

W027 Global Seasonal Atmospheric Fluctuations on Mars
P. M. Woiceshyn

The Mariner Mars 1971 S-band radio-occultation measurements, which were taken over half a Martian year, were examined for seasonal variations in atmospheric pressures and temperatures. Seasonally related atmospheric pressure oscillations on a global scale were discovered when the pressures were compared on equipotential levels. There was a global increase in pressure of about 13% between northern winter and spring seasons, and a global decrease in pressure of nearly 14% between northern spring and summer seasons. The maximum global pressure occurred during the northern spring season approximately one Martian month prior to aphelion. These pressure oscillations were correlated with the seasonal growth and decay, and the total area of the polar caps.

Temperatures in the mid-latitude regions near the subsolar points were highest during the northern winter season when Mars was closest to the sun. In addition, high latitudinal temperature gradients (up to 2 K per degree latitude) were found. This has important atmospheric dynamical implications, especially for the growth of baroclinic waves.

Occultation observations also indicated that the average elevation of the southern hemisphere was nearly 4 km higher than the northern hemisphere when referenced to an equipotential level. The occultation measurements showed that the atmospheric pressures near the surface in the southern hemisphere were 33 to 43% lower than the atmospheric pressures near the surface in the northern hemisphere. In addition to other parameters, the asymmetry in the density of the Martian atmosphere and the hemispheric altitude differences are important in understanding the seasonal dynamic processes that exist in the polar cap regions and in the Martian atmosphere generally.

WOO, R. T.

W032 Effects of Turbulence in the Atmosphere of Venus on Pioneer Venus Radio—Phase II
R. T. Woo and W. Kendall
Technical Memorandum 33-702, August 15, 1974

This memorandum studies two problems related to the effects of turbulence in the atmosphere of Venus on the Pioneer Venus entry-probe radio link. In the first, the cross correlation between the log-amplitude and phase fluctuations of the Pioneer Venus communications link is examined. It is seen that for fluctuation frequencies above approximately 1 Hz there is little or no correlation. For lower frequencies, the correlation is weak and the square root of the coherence has a peak value close to 0.85.

The second problem consists of inferring the turbulence characteristics of the Venus atmosphere from the Mariner Venus 1987 spacecraft (Mariner 5) phase fluctuations. It is seen that with the data processing techniques currently available, the phase error due to oscillator drift, assumed trajectory delay, and spline-curve fit exceed the turbulence induced fluctuations. It is, therefore,
not possible to infer the turbulence characteristics from the Mariner 5 phase fluctuations.

W033 Effects of Turbulence in a Planetary Atmosphere on Radio Occultation

R. T. Woo and A. Ishimaru (University of Washington)

There has been considerable interest in the amplitude and phase fluctuations of the radio signal received from a flyby spacecraft during occultation by a planetary atmosphere. For planetary flyby missions, the Fresnel-zone size exceeds the outer scale size of turbulence, and existing formulations for the frequency spectra of the amplitude and phase fluctuations are inadequate because they do not account for the inhomogeneity of the turbulence in the direction transverse to the propagation path. In this article, the formulation is given for the correlation functions for the log-amplitude and phase fluctuations is described by the product of a function of the average coordinate and a function of the difference coordinate.

The results are applied to radio occultation of a flyby space probe by the atmosphere of Venus, assuming that the turbulence in the atmosphere exists as a layer, that it is localized, isotropic, and smoothly varying, and that the localized turbulence is described by the Kolmogorov spectrum. Closed-form solutions for both variances and frequency spectra of the log-amplitude and phase fluctuations are obtained using Rytov’s method, and it is seen that the shape of the frequency spectra depends a great deal on the characteristics and extent of the turbulence.

W034 Observations of Small-Scale Turbulence in the Atmosphere of Venus by Mariner 5

R. T. Woo, A. Ishimaru (University of Washington), and W. Kendall (Mark Resources, Inc.)

Information regarding small-scale turbulence in the atmosphere of Venus is important and desirable because it contributes to our understanding of the atmosphere’s circulation. In this article, we demonstrate that the radio-occultation data of a flyby spacecraft such as Mariner Venus 1987 (Mariner 5) can provide valuable information on turbulence in the atmosphere of Venus. Unlike previous studies of the Mariner 5 data, this article is based on the frequency spectrum rather than the variance of the log-amplitude fluctuations. The excellent agreement between the processed and previously derived theoretical spectra furnishes strong evidence that the Mariner 5 fluctuations are primarily turbulence-induced. It is seen that above 35 km, turbulence is strongest in the vicinity of 45 and 60 km, and that the outer scale of turbulence is of the order of 100 m. Comparison with the results obtained from the Venera missions is also discussed.

W035 RF Voltage Breakdown and the Paschen Curve

R. T. Woo

A representation based on the similarity relations for voltage breakdown is shown to be useful in combining RF and dc voltage breakdown data. The representation for the uniform field geometry is given.

Y002 On the Recognition of Complex Structures: Computer Software Using Artificial Intelligence Applied to Pattern Recognition

Y. Yakimovsky

Technical Memorandum 33-693, May 1, 1974

This memorandum presents an approach to simultaneous interpretation of objects in complex structures so as to maximize a combined utility function. Results of the application of a computer software system to assign meaning to regions in a segmented image based on the principles described in this memorandum and on a special interactive sequential classification learning system, which is referenced, are demonstrated.
Boundary and Object Detection in Real World Images

Y. Yakimovsky

Technical Memorandum 33-709, November 15, 1974

This memorandum presents a solution to the problem of automatic location of objects in digital pictures by computer, and describes a self-scaling local edge detector which can be applied in parallel on a picture. Clustering algorithms and boundary-following algorithms which are sequential in nature process the edge data to locate images of objects.

Stress Waves Generated in Thin Metallic Films by a Q-Switched Ruby Laser

L. C. Yang

Vacuum-deposited thin films of B, C, Mg, Al, Si, Ti, Cr, Mn, Fe, Co, Ni, Cu, Zn, Ge, Zr, Mo, Ag, In, Sn, Sb, Pt, Au, Pb, and Bi, in several thicknesses and confined between glass substrates, were irradiated by a uniform Q-switched ruby laser beam. The laser pulse was 15 ns in duration, with a maximum energy of 5 J in an area 6.35 mm in diameter. The stress waves were studied using the piezoelectric response of X-cut quartz-crystal disks of the same diameter. The peak stresses are presented as a function of the energy fluence, with possible interpretations of the phenomenon.

Observations at Mercury Encounter by the Plasma Science Experiment on Mariner 10

R. K. Yasui

Technical Memorandum 33-676, March 15, 1974

The Schottky-barrier solar cell is considered a possible candidate for converting solar to electrical energy both for space and terrestrial applications. Knowledge of the optical constants of the ultrathin metal film used in the cell is essential for analyzing and designing high efficiency Schottky-barrier cells. This memorandum presents the optical constants of 7.5-nm gold films on gallium-arsenide. In addition, the absolute collection efficiency of Schottky-barrier solar cells has been determined from measured spectral response and optical constants of the gold film.

YOUNG, A. T.

Y012 Seeing: Its Cause and Cure
A. T. Young
Following Fried, the statistics of images formed by an annular telescope aperture looking through the turbulent atmosphere are calculated; the deleterious effect of a central obscuration is much larger in the presence of seeing than for the telescope alone. A method of optimizing resolution through the atmosphere is explained in detail, with particular attention to the requirements for image-motion compensation; under ideal conditions, about a factor-of-four increase in effective resolution over conventional photography can be obtained. The effective resolution can be larger or smaller than the “seeing disk,” depending on the recorded signal-to-noise ratio. Some common misconceptions about image structure and motion, and various unsound proposals for beating the seeing, are criticized. For the range of turbulent spectra actually observed in the atmosphere, no large improvement in resolution can be obtained at infrared wavelengths. Furthermore, the optimum telescope aperture is rather small; the apparent advantages of large telescopes are due solely to a good signal-to-noise ratio, not good resolution.

1974 **Surface Features on Mercury**

S. Zohar and R. M. Goldstein

A high-resolution study of the surface of Mercury with a 2.388 GHz radar reveals the existence of hills and valleys with heights (depths) of about 1 km. There is also evidence supporting the existence of craters with diameters of about 50 km and depths of about 700 km.

**ZOHAR, S.**

1975 **The Solution of a Toeplitz Set of Linear Equations**

S. Zohar

This article considers the solution of a set of $m$ linear equations with a non-Hermitian Toeplitz associated matrix. Presently available fast algorithms solve this set with $4m^2$ "operations" (an "operation" is defined here as a set of one addition and one multiplication). An improved algorithm requiring only $3m^2$ "operations" is presented.

**ZYGIELBAUM, A. I.**

1974 **"Tutorial Input"—Standardizing the Computer/Human Interface**

A. I. Zygielbaum

This article describes a new technique for implementing a human/computer interface for computer-based subsystems for the DSN. Known as "tutorial input," this technique provides convenient short input procedures for the experienced operator and a helping hand for the novice. From the programmer’s viewpoint, the technique is implemented in a compact, modular, easily modified, table-driven structure. The technique has been successfully used through two generations of R&D ranging machines.

Subject | Entry
--- | ---
principles of surface radar mapping by orbiting spacecraft | R035
radar subsystem for Venus orbital imaging-radar spacecraft | R035
effect of shape of Mars on radar-ranging | S045
atlas of lunar radar maps at 70-cm wavelength | T013
scientific utilization of 64-m-diam antenna at Goldstone, California | T023
radar observation of surface features on Mercury | Z006

Radio Astronomy
interplanetary navigation using pulsating radio sources | D018
computer-controlled pulsar receiver | F024
disk temperature measurements of Jupiter, Saturn, and Uranus at 2.07 and 3.58 cm | C005
DSN antenna scheduling for astronomical observations | H014
clock synchronization by very-long-baseline interferometry | H041
DSN radio astronomy experiments | J001, J002, J003, J004, J005
flux-density measurements of selected radio sources relative to Cassiopeia A | K014
galactic noise measurements by Apollo 17 Lunar Sounder | P019
radar and radio science applications of large antennas with low-noise receiving systems | H010
very-long-baseline-interferometry experiment between quasars and Mariner Mars 1971 spacecraft | S027
high precision measurements of distances and motion with radio interferometry | T009
scientific utilization of 64-m-diam antenna at Goldstone, California | T023

Relativity
transformations between orbital parameters for different coordinate systems of the general relativistic Schwarzschild problem | G011
testing relativistic gravity theories using radio tracking data from planet-orbiting spacecraft | J031
reformulation of relativistic transformation between coordinate time and atomic time | T010

Safety Engineering
microwave radiation hazards around large microwave antennas | K013

Scientific Instruments
integrated transmission-electron-microscope/computer system | A009
no-load RF calorimeter | C026
automatic mass-spectrometric system for biomedical applications | D019
lunar-surface electron observations with solar wind spectrometer of Apollo lunar-surface experiment package | G015
Apollo gamma-ray spectrometer | H015
scientific instruments on Mariner Venus/Mercury 1973 spacecraft | H027
automated light microscope system | J018, O003
remote detection of pollutant gases with infrared laser heterodyne radiometer | M042
science payload of Pioneer Venus 1978 spacecraft | M051
effects of mercury ion thruster exhausts on science instruments | M060
tracking polarimeter for measuring solar and ionospheric Faraday rotation of signals from deep-space probes | O010
radar subsystem for Venus orbital imaging-radar spacecraft | R035
Pioneer 10 vector helium magnetometer | S034
high-accuracy active-cavity radiometers | W021

Soil Sciences
visible and near-infrared transmission and reflectance measurements of Luna-20 soil samples | A002
implications of surface properties of Orgueil meteorite for early history of solar system volatiles | F003
exchange of adsorbed H2O and CO2 between the regolith and atmosphere of Mars caused by changes in surface insolation | F005
microbial abundance and thermoluminescence of Antarctic dry valley soils | H001
spectral reflectance systematics for powder mixtures of lunar-surface mineral phase types | N006
vitrification darkening of rock powders and its implications for optical properties of the lunar surface | N007
fluorometric search for porphyrins in lunar samples | R023
Apollo gamma-ray spectrometer measurements | T029
relaxation times of remanent magnetization in Apollo lunar fines | T033
Subject Entry

electron-spin-resonance studies of metallic-iron phases in Apollo 16 fines......................................................T034

Solar Phenomena
analysis of columnar content measurements for solar-wind turbulence ..........................................................C001
interaction of lunar photoelectron layer and solar wind .........................................................................................C015
terrestrial applications of solar photovoltaic energy .............................................................................................J013
effects of atmospheric and interplanetary charged particles on Mariner Mars 1971 tracking ........................................M007
Mariner Venus/Mercury 1973 plasma experiment at Mercury encounter............................................................O009
tracking polarimeter for measuring solar and ionospheric Faraday rotation of signals from deep-space probes ..............O010
solar radiation and its effects on solar array of solar-electric spacecraft for comet Encke rendezvous mission ...............S012
solar-wind shock system ......................................................................................................................................U002
absolute radiometry and the solar constant ..........................................................................................................W021

Solid-State Physics
low-temperature thermostatics of face-centered-cubic metallic hydrogen ..............................................................C006
theory of phonons in quantum solids with defects ................................................................................................J006
energy dependence of tunneling through thin metal-oxide-semiconductor structures ...........................................M020
effective surface density of states of silicon ...........................................................................................................M021
perturbation theory for resistivity shunted Josephson element ...............................................................................T012
stress waves generated in thin metallic films by Q-switched ruby laser .................................................................Y004

Spacecraft Environments and Shielding
analysis of columnar content measurements for solar-wind turbulence ..............................................................C001
numerical models for energy spectra of electrons and protons in inner magnetosphere of Jupiter ...............................D015
effects of atmospheric and interplanetary charged particles on Mariner Mars 1971 tracking ........................................M007
effects of Jupiter's radiation belts on spacecraft ...................................................................................................P003
solar radiation and its effects on solar array of solar-electric spacecraft for comet Encke rendezvous mission .............S012
S/X-band dual-frequency doppler charged-particle calibrations ..............................................................................W028
Spectrometry
visible and near-infrared transmission and reflectance measurements of Luna-20 soil samples ................................A002
photoionization and ion cyclotron resonance studies of vibrationally excited C$_2$H$_5^+$ ions with H$_2$ ................................B058
solar-wind turbulence spectrum ............................................................................................................................C001
Mariner Venus/Mercury 1973 infrared radiometry of Venus ..................................................................................C020
Mariner Venus/Mercury 1973 infrared radiometry of night side of Mercury ............................................................C021
far infrared beam splitters in Fourier spectroscopy ................................................................................................D013
spectrophotometry of Titan ...................................................................................................................................D014
numerical models for energy spectra of electrons and protons in inner magnetosphere of Jupiter .............................D015
automatic mass-spectrometric system for biomedical applications ..........................................................................D019
infrared measurements of stratospheric constituents ............................................................................................F007

</table>
Subject | Entry
--- | ---
effects of turbulence in atmosphere of Venus on Pioneer Venus radio | W032

**Temperature Control**

multijunction, cryogenically coolable, X-band circulator for microwave maser | C031
temperature control of Mariner-class spacecraft | D020
constant emitter temperature control for nuclear–electric propulsion | F017
parametric performance evaluation of heat pipes in lightweight heat-rejection systems | N003
heat rejection subsystem for nuclear–electric propulsion | P010
temperature control of rollup solar array for solar–electric spacecraft | S012
automatic monitoring of closed-cycle refrigerators for masers | W012

**Test Facilities and Equipment**

apparatus for testing proton irradiation of solar cells | A018
automated firearms identification system | B034
test installation for NaK–nitrogen liquid-metal magnetohydrodynamic converter tests at 30 kW | C009
apparatus for measuring temperature dependence of reactions of OH and HO₂ with O₃ | D012
test facility for forced-vibration tests of Viking Mars 1975 Lander dynamic test model and Orbiter developmental test model | F023
use of broadband square-law detector in a noise-adding radiometer | G003
experimental setup for determination of principal moments of inertia of Helios prototype spacecraft | G010
test setup for measurement of combined effects of hydrazine exposure and endurance testing on solenoid-actuated valve performance | H002
experimental setup for spin-modulation simulation tests of Helios spacecraft low-gain antenna | H008
equipment for experiments on supersonic and hypersonic boundary layer transition | K004
configuration for sequential-decoding performance tests | L009
annular-arc-accelerator shock tube | L024
development of annular-arc-accelerator shock-tube driver | L026
test facility and instrumentation for modal test of Viking Mars 1975 Orbiter | L029

**Thermodynamics**

determination of particle sizes in Saturn’s rings from their eclipse cooling and heating curves | A024
low-temperature thermostats of face-centered-cubic metallic hydrogen | C006
vertical temperature profiles of cloudy atmospheres from remote radiation measurements | C011

temperature dependence of reactions of OH and HO₂ with O₃ | D012
governing equations for Titan-atmosphere models | D014

apparatus for measurement of time-dependent dielectric breakdown in metal-oxide-semiconductor capacitors | L046
precision borescope for improved waveguide inspection | L081
high-speed data test configuration | M028
experimental setup for measurement of optical properties of mercury ion thruster exhausts | M060
apparatus for surface-deviation measurement of mesh antenna under unsymmetrical gravity load | M064
apparatus for laboratory vitrification of rock samples | N007
test configuration for S/X-band ground system ranging tests for Mars Deep Space Station | O020
sensors for measurement of fluctuating quantities in jets | P004
apparatus for measuring pyrotechnic shock | P028
test configuration for DSN telemetry-system performance tests for Mariner Venus/Mercury 1973 Project | R021
vibration and dynamic pressure measurements with charge amplifiers and piezoelectric pressure transducers | R033
application of a self-balancing bridge to thermal measurements of electroexplosive devices | R036
S-band fourth harmonic analyzer | S038
test configuration for short-term frequency measurement of DSN synthesizers | S039
apparatus for determining solid-propellant transient regression rates using microwave doppler-shift technique | S057
experimental setup for studying stress waves generated in thin metallic films by Q-switched ruby laser | Y004
test setup for power reflection measurements | Y008
