ATTITUDE ESTIMATION OF EARTH ORBITING SATELLITES
BY DECOMPOSED LINEAR RECURSIVE FILTERS

By Shauying R. Kou
Systems Dynamics Laboratory

May 1975

George C. Marshall Space Flight Center
Marshall Space Flight Center, Alabama
Attitude estimation of earth orbiting satellites (including Large Space Telescope) subjected to environmental disturbances and noises has been investigated. Modern control and estimation theory is used as a tool to design an efficient estimator for attitude estimation. This new derived estimator is called Decomposed Linear Recursive Filter. It is a statistical filter which is optimal in the sense of minimal mean square error. Comparison between this filter and Kalman filter has been discussed. This filter can overcome the computational difficulty of implementing Kalman filter digitally (integration error, roundoff error, etc.). It is shown that simplicity, accuracy and speed are the advantages of these filters. Decomposed linear recursive filters for both continuous-time systems and discrete-time systems are derived. By using this accurate estimation of the attitude of spacecrafts, state variable feedback controller may be designed to achieve (or satisfy) high requirements of system performance.
ACKNOWLEDGMENT

The author would like to express his sincere thanks to his scientific adviser Dr. Sherman M. Seltzer of the Systems Dynamics Laboratory of Marshall Space Flight Center for his discussions and help in writing this report. This research was supported by the National Research Council.

ATTITUDE ESTIMATION OF EARTH ORBITING SATELLITES
BY DECOMPOSED LINEAR RECURSIVE FILTERS

INTRODUCTION

The problem of attitude determination (or estimation) of earth orbiting satellites is considered in this report. The exactly true attitude of these satellites is not available because of the environmental disturbance torques (e.g. gravity gradient torque, earth magnetic torque, aerodynamic torque, etc.) and some undesirable noises (e.g. rate gyro noise, CMG tachometer noise, etc.). Hence it becomes necessary to estimate the attitude of satellites in some optimal way in order to obtain an estimated (or approximate) attitude and to implement a controller by state variable feedback design. It is well-known that Kalman estimation theory [1] is a useful tool used to estimate the state (or attitude) of linear dynamic systems. But a Kalman filter is difficult to be implemented for higher order systems. Furthermore, if it is implemented digitally then the computational accuracy and speed will decrease rapidly as the order of the system increases. There are several papers working for the reduction of computation burden in the Kalman filter calculations, for example, the works have been done by Johnson [2], Simon and Stubberud [3], Samant and Sorenson [4], Friedland [5], etc. The first three of these papers are so-called reduced order Kalman filters in which the required computations are greatly reduced when only part of the states are interesting and being estimated. Friedland's work [5] discussed a complete state estimation problem. In his paper only the situation of constant bias (or disturbance) is considered. This paper will extend Friedland's work [5] to include the time-varying disturbance case. It will be shown that the environmental disturbances and noises on the earth orbiting satellites are really either time-varying or random. We will use the Large Space Telescope (LST), which is an unmanned astronomical observatory facility with 3-meter diameter of the primary mirror, as an example. It is developed by NASA under the direction of Marshall Space Flight Center at Huntsville, Alabama. The description of LST system is shown in section 2. Special attention is given to model stochastic environmental disturbances and sensor noise as Gaussian stationary white noise processes. For the reason of comparison, a Kalman filter for estimating states of the LST system is included in section 3. The main result of this paper which is called "Decomposed Linear Recursive Filter" (a useful extension of Friedland's work [5]) is derived in section 4. In this filter, the covariance matrix has been transformed into smaller matrices in order to reduce the computation burden. Discussions and conclusions are in section 5. A Decomposed Linear Recursive Filter for discrete-time systems has also been develop'. Its derivation is slightly different from that of continuous-time case and is included in the Appendix. References are in section 7.
SYSTEM DESCRIPTION

In order to explain dynamics of earth orbiting satellites and some physical quantities in detail we use Large Space Telescope as an example. The mathematical model of LST system described in this section is basically according to Schiehlen [6]. The LST is modelled as a rigid body having reaction wheels as actuators and subjected to gravitational and magnetic disturbance torques. These torques are persistent, deterministic disturbances and can be effectively described by linear differential equations (see Johnson [7]). In addition, the aerodynamic torque, the solar pressure torque and the fine guidance sensor noise are also considered which can be modelled as white noise processes. Now for a single-axis analysis LST system is described, according to [6], as

\[ \dot{x} = Ax + Bu + Fw + Gs \]  \hspace{1cm} (1)

where \( x \): 2x1 state vector and \( x = \begin{bmatrix} \theta \\ \dot{\theta} \end{bmatrix} \) with \( \theta \) and \( \dot{\theta} \) represent the pitch angle and the time rate of pitch angle of LST.

\( u \): a scalar control variable which is related to the driving motor torque.

\( w \): denotes the gravity gradient torque and earth magnetic torque.

\( s \): denotes the stochastic (or random) aerodynamic and solar pressure torques.

and

\[ A = \begin{bmatrix} 0 & 1 \\ 0 & 0 \end{bmatrix}, \quad B = \begin{bmatrix} 0 \\ 1 \end{bmatrix}, \quad F = \begin{bmatrix} 0 \\ 1 \end{bmatrix}, \quad G = \begin{bmatrix} 0 \\ 1 \end{bmatrix} \]

The sensor output \( y \) corresponding to the pitch motion \( \theta \) can be represented by

\[ y = \theta + v \]

or equivalently

\[ y = Cx + v \]  \hspace{1cm} (2)

where \( C = \begin{bmatrix} 1 & 0 \end{bmatrix} \) and \( v \) is the sensor noise.
Furthermore, the dynamics of the disturbance torques $w$ can be modelled by

$$w = Hz$$

$$z = Dz$$

where $z$ is a $3 \times 1$ vector and

$$D = \begin{bmatrix} 0 & 0 & 0 \\ 0 & 0 & 2 \cdot 10^{-3} \\ 0 & -2 \cdot 10^{-3} & 0 \end{bmatrix}, \quad H = [1 \ 1 \ 0]$$

And the white noise process $s(t)$ of Eq. (1) is characterized with zero mean and spectral density $1 \cdot 10^{-12}$ arc sec$^2$/sec$^3$. The white noise process $v(t)$ of Eq. (2) is characterized by zero mean and spectral density $8.394 \cdot 10^{-6}$ arc sec$^2$/sec$^3$. (These data are obtained from Proise [3]).

For the following analysis we still need to specify the covariances of these white noise processes $s(t)$ and $v(t)$. These covariances can be derived from their spectral densities. The covariance function and the spectral density function form the Fourier transform relationship for stationary random processes. (see Astrom [9]). It is assumed that white noise processes $s(t)$ and $v(t)$ are stationary. Denote the power spectral density function of $s(t)$ by

$$p(\omega) = 1 \cdot 10^{-12}$$

for all angular frequency $\omega$; then its covariance function

$$\gamma_s(z) \triangleq \text{Cov} [s(t), s(t+z)] = \int_{-\infty}^{\infty} p(\omega) e^{i\omega z} d\omega = 2\pi \cdot 10^{-12} \delta(z)$$

$$\triangleq \frac{\Delta}{\pi} Q \delta(z)$$

where $\delta(\cdot)$ is the Dirac delta function. Similarly, for the white noise $v(t)$, we have

$$\gamma_v(z) \triangleq \text{Cov} [v(t), v(t+z)] = 2\pi \cdot 8.394 \cdot 10^{-6} \delta(z)$$

$$\triangleq \frac{\Delta}{\pi} R \delta(z)$$

Here we introduce notations $Q$ and $R$ for the use of future formulation. Let us rewrite (1) - (4) as a composed system
\[
\begin{bmatrix}
\dot{x} \\
\dot{z}
\end{bmatrix} = A \begin{bmatrix} x \\
z \end{bmatrix} + B u + G s
\]  
(7)

and

\[y = C \begin{bmatrix} x \\
z \end{bmatrix} + v
\]  
(8)

where

\[
A = \begin{bmatrix} A & FH \\ 0 & D \end{bmatrix} \quad B = \begin{bmatrix} B \\ 0 \end{bmatrix} \quad G = \begin{bmatrix} G \\ 0 \end{bmatrix}
\]  
(9)

\[C = [C \ 0] = [1 \ 0 \ 0 \ 0 \ 0]
\]

Since it is without loss of generality to omit the control term \(Bu\) in the consideration of estimation problems, let us consider the following simplified system

\[
\begin{bmatrix}
\dot{x} \\
\dot{z}
\end{bmatrix} = A \begin{bmatrix} x \\
z \end{bmatrix} + G s
\]  
(10)

and

\[y = C \begin{bmatrix} x \\
z \end{bmatrix} + v
\]  
(11)

where \(E[s(t) s^T(\tau)] = Q \delta(t-\tau),\)

i.e. \([v(t) v^T(\tau)] = R \delta(t-\tau),\)

and \(s(\tau), v(\tau)\) are independent.

**STATE ESTIMATION BY KALMAN FILTER**

The Kalman filter is a well-known state estimator for linear stochastic systems. There are numerous references about the derivation and discussions of Kalman filter (e.g. Sorenson [10]). In this section, we will show the use of a Kalman filter for state estimation of LST systems. When we apply Kalman filter to LST system described by Eqs. (10), (11), we have

\[
\begin{bmatrix}
\dot{x} \\
\dot{z}
\end{bmatrix} = A \begin{bmatrix} x \\
z \end{bmatrix} + K(t) [y(t) - C \begin{bmatrix} \hat{x} \\
\hat{z} \end{bmatrix}]
\]  
(12)

where \(\hat{x}\) and \(\hat{z}\) are the estimated states of \(x\) and \(z\) respectively and the optimal gain \(K(t)\) is defined by

\[K(t) = P(t) C^T R^{-1}
\]  
(13)
and \( P(t) \) is a 5x5 covariance matrix which satisfies the following Riccati equation

\[
P = \dot{P} + AP + PA^T + GQG^T - PC^T R^{-1} C P
\]  

From Eq. (12) we see that for the 5th order system (LST system), Kalman filter is also a 5th order dynamic system. The dynamic behavior of the covariance matrix \( P(t) \) is governed by Eq. (14) which is nonlinear matrix differential equation. Furthermore \( P(t) \) is a symmetric matrix function.

This is an optimal filter (or estimator) in the sense of minimal mean square error between the true state and the estimated state. Now for the special structures of matrices \( A, C \) and \( G \) of the LST system (see Eq. (9)), the covariance matrix \( P(t) \) and the matrix equation (14) can be partitioned as follows:

\[
P(t) = \begin{bmatrix} P_x & P_{xz} \\ P_{xz}^T & P_z \end{bmatrix}
\]  

where \( P_x \) is the 2x2 covariance matrix of estimation of \( x \). \( P_z \) is the 3x3 covariance matrix of estimation of \( z \). \( P_{xz} \) is the 2x3 cross-covariance matrix for estimation of \( x \) and \( z \). Then the matrix covariance equation (14) takes the form of the following three equations

\[
\dot{P}_x = AP_x + FP_x^T + P_x A^T + P_{xz} (FH)^T - P_x C^T R^{-1} C P_x + GQG^T
\]

\[
\dot{P}_{xz} = AP_{xz} + FP_z + P_{xz} D^T - P_x C^T R^{-1} C P_{xz}
\]

\[
\dot{P}_z = DP_z + P_z D^T - P_{xz}^T C^T R^{-1} C P_{xz}
\]  

Eqs. (16)-(18) are composed of fifteen nonlinear differential equations. These equations are coupled to each other and should be solved simultaneously. Furthermore, Eq. (12) is composed of 5 differential equations which are coupled to each other too. So to obtain the estimated state \( \hat{x} \) and \( \hat{z} \) we have to solve the simultaneous 15 differential equations (Eqs. (16)-(18)) and simultaneous 5 differential equations (12). This is quite computationally time-consuming and has severe numerical integration errors. To solve these problems, we derive the Decomposed Linear Recursive Filter in the next section.

**DECOMPOSED LINEAR RECURSIVE FILTER**

We would like to point out that the objective of Friedland's research [5] is to estimate the state of the following types of systems

\[
\begin{align*}
\dot{x} &= Ax + Bz + Gs \\
\dot{z} &= 0 \\
y &= Cx + v
\end{align*}
\]  

(19)
The second part of this composed system (19), \( \dot{\gamma} = 0 \), represents an unknown constant quantity. In this section, the Decomposed Linear Recursive Filter is derived which is an extension of the above work to include the case \( z = Dz \) where \( D \) is not a zero matrix, i.e. \( z \) is a time-varying quantity. Hence this result is applicable to the earth orbiting satellites including the LST system described by Eq. (10). The basic idea of this filter is to use matrix transformation of the covariance matrix and the particular system structure of earth orbiting satellites to simplify the estimation procedure. It turns out that we need to solve only lower order matrix equations and estimated states \( \hat{x} \) and \( \hat{z} \) can be obtained separately. This will greatly increase the computational speed and accuracy of estimation of the attitude of satellites.

At first we investigate a particular solution for the matrix equations (16)-(18). Note that Eqs. (17) and (18) are homogeneous in \( P_{xz} \) and \( P_z \). Hence, if \( P_{xz}(o) = 0 \) and \( P_z(o) = 0 \) then \( P_{xz}(t) \equiv 0 \) for all \( t > o \), then Eq. (16) becomes

\[
\dot{P}_x = A P_x + P_x A^T + G Q G^T - P_x C^T R^{-1} C P_x
\]

the notation \( P_x \) is used to point out the forms of Eqs. (16) and (20) are different. So for this particular selection of initial values of covariance matrix, let us denote the solution of Riccati equation (14) by

\[
P_1(t) = \begin{bmatrix} \bar{P}_x(t) & 0 \\ 0 & 0 \end{bmatrix}
\]

(21)

The relation between solutions of Riccati equations of the form (14) corresponding to different initial conditions can be expressed according to a result of Friedland [11].

Theorem ([11]): If \( P_1(t) \) is a solution to Riccati equation (14), any other solution \( P_2(t) \) of Eq. (14) corresponding to a different initial condition can be expressed as follows:

\[
P_2(t) = P_1(t) + VMV^T
\]

(22)

where \( V \) is a 5x3 matrix satisfying \( \dot{V} = (A - P_1 C^T R^{-1} C) V \)

(23)

and \( M \) is a 3x3 matrix satisfying \( \dot{M} = -M V^T C^T R^{-1} C V M \)

(24)

and initial condition of \( P_2(t) \) is

\[
P_2(o) = \begin{bmatrix} \bar{P}_x(o) & P_{xz}(o) \\ P_{xz}(o) & P_z(o) \end{bmatrix}
\]

(25)

where \( \bar{P}_x(o) \) is the nonzero part of the initial condition for \( P_1(t) \).

In this theorem, we see that \( M \) is a symmetric matrix and \( V \) can be
partitioned as follows

\[
V = \begin{bmatrix} V_x \\ V_z \end{bmatrix}
\]  

(26)

where \( V_x \) is 2x3 matrix and \( V_z \) is 3x3 matrix. Then by using the definition of \( A \) and \( P_1 \), Eqs. (23), (24) can be expressed by

\[
\dot{V}_x = (A - \overline{F}_x \ C^T \ R^{-1} \ C) \ V_x + FH \ V_z
\]  

(27)

\[
\dot{V}_z = D \ V_z
\]  

(28)

\[
\dot{M} = -M \ V_x^T \ C^T \ R^{-1} \ C \ V_x \ M
\]  

(29)

Now let \( P_x(t) \) be partitioned according to (15), then

\[
P_x(t) = \overline{P}_x(t) + V_x \ M \ V_x^T
\]

\[
P_{xz}(t) = V_x \ M \ V_z^T
\]

\[
P_z(t) = V_z \ M \ V_z^T
\]  

(30)

So the initial conditions \( V_x(o), V_z(o), M(o) \) of Eqs. (27)-(29) must satisfy

\[
P_x(o) = \overline{P}_x(o) + V_x(o) \ M \ V_x^T(o)
\]

\[
P_{xz}(o) = V_x(o) \ M(o) \ V_z^T(o)
\]

\[
P_z(o) = V_z(o) \ M(o) \ V_z^T(o)
\]

If \( P_{xz}(o) \) is also assumed to be zero, then we have

\[
V_x(o) = o
\]

\[
V_z(o) = I
\]

\[
M(o) = P_z(o)
\]  

(31)

We want to show that the inverse of the square matrix \( V_z \) exists. From Eqs. (28) and (31) we have

\[
V_z(t) = e^{Dt} \ V_z(o) = e^{Dt}
\]

which is nonsingular (see Brockett [12]). Hence its inverse \( V_z^{-1} \) exists. Now for the purpose of simplification of equations used for estimation of
states of LST system, we introduce new variables $V_1$ and $V_2$

$$V_1 \triangleq V V_z^{-1} = \begin{bmatrix} V_x \\ V_z \end{bmatrix} V_z^{-1} = \begin{bmatrix} V_x V_z^{-1} \\ i \end{bmatrix}$$  \hspace{1cm} (32)

$$V_2 \triangleq V_x V_z^{-1}$$  \hspace{1cm} (33)

Here we have $V_2$ is also a 5x3 matrix consisting of two parts—the lower part is a constant identity matrix. Again we introduce new variable $M_1$

$$M_1 = V_z M V_z^{-1}$$  \hspace{1cm} (34)

Now we try to express $P_z(t)$ in terms of these new matrices $V_1$, $V_2$ and $M_1$. From Eq. (22), we have

$$P_z(t) = P_1 + V_1 V_z M (V_1 V_z)$$

$$= P_1 + V_1 M_1 V_1$$  \hspace{1cm} (35)

And from Eq. (30) we have

$$P_x(t) = \bar{P}_x(t) + V_x V_z^{-1} V_z M V_z^T (V_z^{-1})^T V_x$$

$$= \bar{P}_x(t) + V_x V_z^{-1} V_z M V_z^T (V_z^{-1})^T V_x$$

$$= \bar{P}_x(t) + V_2 M_1 V_2^T$$  \hspace{1cm} (36)

$$P_{xz}(t) = V_x V_z^{-1} V_z M V_z^T$$

$$= V_2 M_1$$  \hspace{1cm} (37)

$$P_z(t) = V_z M V_z^T = M_1$$  \hspace{1cm} (38)

So far we know that to obtain $P_x$, $P_{xz}$ and $P_z$ we need only to have $V_2$, $M_1$ and $\bar{P}_x$. $\bar{P}_x$ can be obtained from Eq. (20). Now we will show that $V_2$ and $M_1$ satisfies the following equations:

$$\dot{V}_2 = \left( A - \bar{P}_x C^T R^{-1} C \right) V_2 + FH - V_2 D$$  \hspace{1cm} (39)
\[ \dot{M}_1 = D M_1 - C V_2 T C^T R^{-1} C V_2 M_1 + M_1 D^T \]  

Proof: Since \( V_2 = V_x V_z^{-1} \),
\[ \dot{V}_2 = \dot{V}_x V_z^{-1} + V_x (\dot{V}_z^{-1}) \]
\[ = \dot{V}_x V_z^{-1} - V_x V_z^{-1} \dot{V}_z V_z^{-1} \]
\[ = [(A - P_X C^T R^{-1} C) V_x + F H V_z] V_z^{-1} - V_x V_z^{-1} D V_z V_z^{-1} \]
\[ = (A - P_X C^T R^{-1} C) V_z + F H - V_2 D \]

Similarly \( \dot{M}_1 = V_z M V_z^T \), so
\[ \dot{M}_1 = \dot{V}_z M V_z^T + V_z \dot{M}_1 V_z + V_z M \dot{V}_z \]
\[ = D V_z M V_z^T + V_z (-M V_z T C^T R^{-1} C V_x M) V_z^T + V_z M (D V_z)^T \]
\[ = D M_1 - C V_2 T C^T R^{-1} C V_2 M_1 + M_1 D^T \]

Remark: In the above analysis, we see that to find covariance matrix \( P_2(t) \) (which is governed by a nonlinear coupled matrix differential equation (14) and should be solved simultaneously as shown in section 3), we need only find out \( V_2(t), M_1(t) \) and \( P_X(t) \). Now the important thing is that the equations ((20), (39) and (40)) of \( V_2, M_1 \) and \( P_X \) are not coupled in the following sense. We can solve \( P_X \) by using Eq. (20) without using any information about \( V_2 \) and \( M_1 \). Next we obtain \( V_2 \) from Eq. (39) and information \( P_X \). Finally using \( V_2, P_X \) and Eq. (40) we obtain \( M_1 \). As a matter of fact these matrices can be solved separately. It is obvious that by using the method of this analysis to find covariance matrix, we can save a lot of computation time and increase greatly the numerical integration accuracy.

Next if we substitute the results Eqs. (36)-(38) into Eqs. (12) and (13) we have
\[ \dot{\hat{x}} = A \hat{x} + F H \hat{z} + (P_X + V_2 M_1 V_2^T) C^T R^{-1} (y - C \hat{x}) \]
\[ \dot{\hat{z}} = D \hat{z} + M_1 V_2 T C^T R^{-1} (y - C \hat{x}) \]

Now we want to show that how \( \hat{x} \) and \( \hat{z} \) can be obtained separately
Theorem: The solution \( \hat{x} \) of Eq. (41) can be expressed by

\[
\hat{x} = \overline{x} + V_2 \hat{z}
\]

(43)

where \( \overline{x} \) is the solution of the following system

\[
\dot{\overline{x}} = A \overline{x} + \overline{P}_x c^T R^{-1} (y - C \overline{x})
\]

(44)

and \( V_2, \hat{z} \) satisfies Eqs. (39) and (42).

Remark: \( \overline{x}(t) \) can be obtained from Eq. (44) whenever we have \( \overline{P}_x \) and \( y(t) \). It is in fact the estimate of state \( x(t) \) when there is no deterministic external disturbance torques, i.e. \( z = 0 \).

Proof: To prove this theorem, we have to check that the expression (43) satisfies Eq. (41) or equivalently the following formula should be equal to zero

\[
\dot{x} - A x - F H \hat{z} - (\overline{P}_x + V_2 M_1 V_2^T) c^T R^{-1} (y - C \overline{x}) = 0
\]

(45)

In the following we will substitute all \( \overline{x} \) by \( \overline{x} + V_2 \hat{z} \) to the left hand side of Eq. (45). First we give an expression for \( \dot{x} \),

\[
\dot{x} = \frac{d}{dt} (\overline{x} + V_2 \hat{z}) = \dot{x} + \dot{V}_2 \hat{z} + V_2 \dot{\hat{z}}
\]

\[
= A \overline{x} + \overline{P}_x c^T R^{-1} (y - C \overline{x}) + [(A - \overline{P}_x c^T R^{-1} C) V_2 + F H - V_2 D] \hat{z}
\]

\[
+ V_2 [D \hat{z} + M_1 V_2^T c^T R^{-1} (y - C (\overline{x} + V_2 \hat{z}))]
\]

Now the left hand side of Eq. (45) becomes

\[
A \overline{x} + \overline{P}_x c^T R^{-1} (y - C \overline{x}) + [(A - \overline{P}_x c^T R^{-1} C) V_2 + F H - V_2 D] \hat{z}
\]

\[
+ V_2 [D \hat{z} + M_1 V_2^T c^T R^{-1} (y - C (\overline{x} + V_2 \hat{z}))] - A (\overline{x} + V_2 \hat{z}) - F H \hat{z}
\]

\[
- (\overline{P}_x + V_2 M_1 V_2^T) c^T R^{-1} (y - C (\overline{x} + V_2 \hat{z}))
\]

\[
= (- \overline{P}_x c^T R^{-1} C V_2 - V_2 D) \hat{z} + V_2 [D \hat{z} + M_1 V_2^T c^T R^{-1} (y - C (\overline{x} + V_2 \hat{z}))]
\]

\[
- V_2 M_1 V_2^T c^T R^{-1} (y - C (\overline{x} + V_2 \hat{z})) + \overline{P}_x c^T R^{-1} C V_2 \hat{z}
\]

\[
= 0
\]
This completes the proof.

Remark: Based on this theorem and the above analysis, we will summarize the procedures in finding the estimated states \( \hat{x} \) and \( \hat{z} \) as follows:

(a) From Eq. (20) we have \( \overline{P}_x \).

(b) Using \( \overline{P}_x \) and Eqs. (39) and (40) we get \( V_2 \) and \( M_1 \).

(c) Again using \( \overline{P}_x \) and the system's output \( y(t) \) we get \( \overline{x}(t) \) from Eq. (44). Note that in this step we don't use any information about \( \hat{x} \) or \( \hat{z} \).

(d) Now we use the results of (a) - (c) to find \( \hat{z} \) without using any information about \( \hat{x} \). That is from Eqs. (42) and (43).

\[
\dot{\hat{z}} = D \hat{z} + M_1 V_2^T C \overline{R}^{-1} \left[ y - C (\overline{x} + V_2 \hat{z}) \right] 
\]

(e) At last from Eq. (43) we have

\[
\hat{x} = \overline{x} + V_2 \hat{z}
\]

In this procedure we see that the estimation of states of LST system has been decomposed into two parts; \( \hat{z} \) and \( \hat{x} \). Estimation of \( z \) can be obtained by using data \( \overline{x} \) instead of \( \hat{x} \). Furthermore \( \overline{x} \) and \( \hat{z} \) are obtained from Eqs. (44) and (46) which are 2nd-order and 3rd-order systems respectively. On the contrary, if the Kalman filter is used, we have to build up a fifth order dynamic system (filter) to estimate the states of the LST system. So by using the analysis and techniques of this section, filters can be implemented to obtain estimated states \( \hat{x} \) and \( \hat{z} \) by lower order systems. In addition, the simplicity in structure of this Decomposed Linear Recursive Filter gives us considerable amount of reduction in computation burden and storage requirements.
(a) Discussions

1. High order estimators usually are too complex for practical mechanization and are very parameter sensitive. Now if we use Decomposed
   Linear Recursive Filter to estimate the attitude of LST system, we need
   only to build up 2nd-order and 3rd-order dynamic systems (instead of a
   5th order Kalman filter) as an estimator.

2. If the estimators or filters are implemented digitally, the computations required by a high-order filtering algorithm may become
   excessive (in memory capacity, accuracy and computational speed).

3. The characteristic of this new filter is that the low order
   covariance matrix Eq. (20) is independent of matrices V and M of Eq. (22).
   Similarly, the 2nd-order system X can be obtained from Eq. (44) independent
   of the value of Z. This property is a kind of decomposition of a set of
   equations and greatly simplifies the estimator design.

(b) Conclusion

In this paper, a Decomposed Linear Recursive Filter has been
derived for the estimation of attitude of earth orbiting satellites in
which the disturbances and noises are either time-varying or random. Simplicity, accuracy and speed are the advantages of this filter. This filter
   can be easily implemented by the on-board digital computer and give an
accurate estimation of attitude of satellites. Furthermore, this is the
necessary information for state variable feedback controller design.

The analysis of section 4 can be generalized to linear time-varying
systems such as

\[
\begin{align*}
\dot{x} &= A(t) x + B(t) z + s \\
z &= D(t) z \\
y &= C_1 x + C_2 z + v
\end{align*}
\]

where A, B, D, C_1 and C_2 can be matrices with time-varying elements, and
y may also include the disturbance z explicitly. The proof of this fur-
ther extension is exactly the same as that of section 4.
APPENDIX

Discrete-Time Version of Decomposed Linear Recursive Filter

Most of the practical implementations of filters are by digital means. Here we derive the analog counterpart of Decomposed Linear Recursive Filter for discrete-time systems.

Consider

\[ x_k = A_{k-1} x_{k-1} + B_{k-1} z_{k-1} + s_{k-1} \]  \hspace{1cm} (A-1)

\[ z_k = D_{k-1} z_{k-1} \]  \hspace{1cm} (A-2)

where

- \( x_k \) is the value of n-dimension state at time \( t_k \),
- \( z_k \) is the value of r-dimension deterministic environmental disturbances at time \( t_k \),
- \( A_{k-1}, B_{k-1}, D_{k-1} \) are time-varying matrices with dimensions n x n, n x r, r x r respectively and assume that \( D_k \) is nonsingular for all time \( t_k \).
- \( s_{k-1} \) is n-dimension white noise sequences with
  \[ E [s_k s_j^T] = Q_k \delta_{kj} \]
  where \( \delta_{kj} \) is the Kronecker delta function.

and the measurement equation is expressed by

\[ y_k = C_k x_k + v_k \]  \hspace{1cm} (A-3)

where

- \( y_k \) is the value of m-dimension output at time \( t_k \),
- \( C_k \) is a m x n time varying matrix,
- \( v_k \) is m-dimension white noise sequences with
  \[ E [v_k v_j^T] = R_k \delta_{kj} \]
Combine (A-1) and (A-2), we have

\[
\begin{bmatrix}
    x_k \\
    z_k
\end{bmatrix} =
\begin{bmatrix}
    A_{k-1} & B_{k-1} \\
    0 & D_{k-1}
\end{bmatrix}
\begin{bmatrix}
    x_{k-1} \\
    z_{k-1}
\end{bmatrix} + G \, s_{k-1} + \gamma
\]

(A-4)

and

\[
y_k = C_k \begin{bmatrix}
    x_k \\
    z_k
\end{bmatrix} + v_k
\]

(A-5)

where

\[
A_{k-1} = \begin{bmatrix}
    A_{k-1} & B_{k-1} \\
    0 & D_{k-1}
\end{bmatrix}, \quad G = \begin{bmatrix}
    I \\
    0
\end{bmatrix}, \quad C_k = [C_k, 0]
\]

Kalman filter formulation for system (A-4), (A-5) is

\[
\begin{bmatrix}
    \hat{x}_k \\
    \hat{z}_k
\end{bmatrix} =
\begin{bmatrix}
    A_{k-1} & B_{k-1} \\
    0 & D_{k-1}
\end{bmatrix}
\begin{bmatrix}
    \hat{x}_{k-1} \\
    \hat{z}_{k-1}
\end{bmatrix} + K_k \left[ y_k - C_k \hat{x}_{k-1} \right]
\]

(A-6)

where \( \hat{x}_k \) and \( \hat{z}_k \) are the estimated values of \( x_k \) and \( z_k \),

\[
K_k = \frac{P_k}{P_k} C_k T \left[ C_k \frac{P_k}{P_k} C_k T + R_k \right]^{-1}
\]

(A-7)

\( P_k \) is the a priori covariance matrix satisfying the following difference equation

\[
P_{k+1} = A_k \left[ I - K_k C_k \right] P_k A_k T + G Q_{k+1} G^T
\]

(A-8)

Let

\[
P_k = \begin{bmatrix}
    P_x(k) & P_{xz}(k) \\
    P_{xz}^T(k) & P_z(k)
\end{bmatrix}
\]

(A-9)

\[
\begin{align*}
P_x(k) & \text{ is } n \times n \text{ covariance matrix of estimate of } x \text{ at time } t_k, \\
P_z(k) & \text{ is } r \times r \text{ covariance matrix of estimate of } z \text{ at time } t_k, \\
P_{xz}(k) & \text{ is } n \times r \text{ covariance matrix of estimates of } x \text{ and } z.
\end{align*}
\]

According to the submatrices of Eq. (A-9) and using (A-1), (A-2) and (A-3), we have Eq. (A-8) being expressed by the following three equations
\[
\begin{align*}
\mathbf{P}_{x}(k+1) &= [A_{k} (I - K_{k}^{X} C_{k}) - B_{k} K_{k}^{Z} C_{k}] [\mathbf{P}_{x}(k) A_{k}^{T} + \mathbf{P}_{xz}(k) B_{k}^{T}] \\
&\quad + B_{k} [\mathbf{P}_{xz}(k) A_{k}^{T} + \mathbf{P}_{z}(k) B_{k}^{T}] + Q_{k+1}
\end{align*}
\]  
\hspace{1cm} (A-10)

\[
\begin{align*}
\mathbf{P}_{xz}(k+1) &= [A_{k} (I - K_{k}^{X} C_{k}) - B_{k} K_{k}^{Z} C_{k}] \mathbf{P}_{xz}(k) D_{k}^{T} + B_{k} \mathbf{P}_{z}(k) D_{k}^{T}
\end{align*}
\]  
\hspace{1cm} (A-11)

\[
\begin{align*}
\mathbf{P}_{z}(k+1) &= -D_{k} K_{k}^{Z} C_{k} \mathbf{P}_{xz}(k) D_{k}^{T} + D_{k} \mathbf{P}_{z}(k) D_{k}^{T}
\end{align*}
\]  
\hspace{1cm} (A-12)

where

\[
K_{k} = \begin{bmatrix} K_{k}^{X} \\ K_{k}^{Z} \end{bmatrix}
\]

and \(K_{k}^{X}\), \(K_{k}^{Z}\) are \(n \times m\) matrices, respectively.

If \(\mathbf{P}_{z}(o) = 0\), then we have the solution of (A-8) denoted by

\[
\begin{bmatrix} \mathbf{P}_{x}(k) \\ 0 \end{bmatrix} = \begin{bmatrix} \mathbf{P}_{x}(k) \\ 0 \end{bmatrix}
\]

\hspace{1cm} (A-13)

for all \(k > o\) and \(\mathbf{P}_{x}(k)\) satisfies

\[
\begin{align*}
\mathbf{P}_{x}(k+1) &= [A_{k} - (A_{k} K_{k}^{X} + B_{k} K_{k}^{Z}) C_{k}] \mathbf{P}_{x}(k) A_{k}^{T} + Q_{k+1}
\end{align*}
\]  
\hspace{1cm} (A-14)

By Kalman filtering theory (see Sorenson [10]), a priori covariance matrix \(\mathbf{P}_{x}(k)\) can be related with a posteriori covariance matrix \(\mathbf{P}_{x}(k)\) by

\[
\mathbf{P}_{x}(k+1) = A_{k} \mathbf{P}_{x}(k) A_{k}^{T} + Q_{k+1}
\]

\hspace{1cm} (A-15)

Note: By definition, a priori covariance matrix \(\mathbf{P}_{x}(k)\) is defined by the covariance matrix of the estimate of \(x(t_{k})\) given the observations \(\{y_{1}, y_{2}, \ldots, y_{k-1}\}\) but not \(y_{k}\). A posteriori covariance matrix \(\mathbf{P}_{x}(k)\) is the covariance matrix of estimating \(x(t_{k})\) given the observation \(\{y_{1}, y_{2}, \ldots, y_{k}\}\), i.e. including the current output \(y_{k}\).

Theorem (Friedland [11]) If \(\mathbf{P}(k)\) is a solution of equation (A-8), then any other solution \(\mathbf{P}(k)\) of Eq. (A-8) corresponding to different initial conditions can be expressed by

\[
\mathbf{P}(k) = \mathbf{P}(k) + \mathbf{U}(k) \mathbf{M}(k) \mathbf{U}^{T}(k)
\]

\hspace{1cm} (A-16)

where

\[
\mathbf{U}(k)\] is a \((n + r) \times r\) matrix and \(\mathbf{M}(k)\] is a \(r \times r\) matrix satisfying

\[
\mathbf{U}(k+1) = A_{k} [I - \mathbf{P}(k) C_{k}^{T} (C_{k} \mathbf{P}(k) C_{k}^{T} + R_{k})^{-1} C_{k}] \mathbf{U}(k)
\]

\hspace{1cm} (A-17)
\[ M(k+1) = M(k) - M(k) U^T(k) C_k^T \left[ C_k \bar{P}(k) C_k^T + R_k \right]^{-1} \]

\[ \cdot C_k^T U(k) M(k) \]  

(A-18)

In terms of this transformation, (A-16) can be rewritten as

\[ P(k+1) = \bar{P}(k+1) + U(k+1) M(k+1) U^T(k+1) \]

\[ = \bar{P}(k+1) + A_k \left[ I - \bar{K}(k) C_k \right] U(k) M(k+1) U^T(k) \left[ I - \bar{K}(k) C_k \right]^T \Lambda_k^T \]  

(A-19)

where

\[ \bar{K}(k) = \bar{P}(k) C_k^T \left[ C_k \bar{P}(k) C_k^T + R_k \right]^{-1} \]  

(A-20)

Similarly, we have

\[ P(k+1) = \bar{P}(k+1) + T(k) A_k^T + G Q_{k+1} G^T \]  

(A-22)

\[ \bar{P}(k+1) = A_k \bar{T}(k) A_k^T + G Q_{k+1} G^T \]  

(A-23)

Hence (A-20) can be expressed as

\[ T(k) = \bar{T}(k) + V(k) M(k+1) V^T(k) \]  

(A-24)

where

\[ V(k) = \left[ I - \bar{K}(k) C_k \right] U(k) \]  

(A-25)

and by (A-17) we have

\[ U(k+1) = A_k V(k) \]  

(A-26)

Using (A-13), Equation (A-21) turns out to be

\[ \bar{K}(k) = \begin{bmatrix} \bar{P}_x(k) C_k^T & \bar{P}_x(k) C_k^T + R_k \end{bmatrix} \Delta \begin{bmatrix} \bar{K}_x(k) \\ 0 \end{bmatrix} \]  

(A-27)

Let \( U(k) \) and \( V(k) \) be also partitioned as follows

\[ U(k) = \begin{bmatrix} U_x(k) \\ U_z(k) \end{bmatrix}, \quad V(k) = \begin{bmatrix} V_x(k) \\ V_z(k) \end{bmatrix} \]  

(A-28)

where \( U_x \) is \( n \times r \), \( U_z \) is \( r \times r \), \( V_x \) is \( n \times r \) and \( V_z \) is \( r \times r \).

Then, using (A-27), \( V(k) \) and \( U(k+1) \) of (A-25), (A-26) become

\[
\begin{aligned}
V_x(k) &= \left[ I - \bar{K}_x(k) C_k \right] U_x(k) \\
V_z(k) &= U_z(k)
\end{aligned}
\]  

(A-29)
and
\[
\begin{align*}
U_x(k+1) &= A_k V_x(k) + B_k V_z(k) \\
U_z(k+1) &= D_k V_z(k)
\end{align*}
\]  
(A-30)

Finally, Eq. (A-19) becomes
\[
\begin{align*}
P_x(k) &= \overline{P}_x(k) + U_x(k) M(k) U_x^T(k) \\
P_{xz}(k) &= U_x(k) M(k) U_z^T(k) \\
P_z(k) &= U_z(k) M(k) U_z^T(k)
\end{align*}
\]  
(A-31)

and Eq. (A-24) becomes
\[
\begin{align*}
T_x(k) &= \overline{T}_x(k) + V_x(k) M(k+1) V_x^T(k) \\
T_{xz}(k) &= V_x(k) M(k+1) V_z^T(k) \\
T_z(k) &= V_z(k) M(k+1) V_z^T(k)
\end{align*}
\]  
(A-32)

It can be shown that 
\[
K_x = T(k) C_k^T R_k^{-1}
\]  
(A-33)

or
\[
\begin{bmatrix}
K_x(k) \\
K_z(k)
\end{bmatrix} =
\begin{bmatrix}
T_x C_k^T R_k^{-1} \\
T_{xz} C_k^T R_k^{-1}
\end{bmatrix}
\]  
(A-34)

Substituting \(T_x\) and \(T_{xz}\) according to (A-32), we have
\[
\begin{align*}
K_x(k) &= (\overline{T}_x(k) + V_x(k) M(k+1) V_x^T) C_k^T R_k^{-1} \quad (A-35) \\
K_z(k) &= V_z(k) M(k+1) V_x^T(k) C_k^T R_k^{-1} \quad (A-36)
\end{align*}
\]

Now from (A-6),
\[
\hat{x}_{k+1} = A_k \hat{x}_k + B_k \hat{2}_k + K_x(k+1) \left[ y_{k+1} - C_{k+1} A_k \hat{x}_k - C_{k+1} B_k \hat{2}_k \right] \quad (A-37)
\]

and
\[
\hat{2}_{k+1} = D_k \hat{2}_k + K_z(k+1) \left[ y_{k+1} - C_{k+1} A_k \hat{x}_k - C_{k+1} B_k \hat{2}_k \right] \quad (A-38)
\]

Theorem: The solution \(\hat{x}_k\) of Eq. (A-7) can be expressed as
\[
\hat{x}_k = \overline{x}_k + V_x(k) V_x^{-1}(k) \hat{2}_k
\]  
(A-39)
where $\bar{x}_k$ is the solution of the following equation

$$
\bar{x}_{k+1} = \bar{x}_k + \bar{K}_x(k+1) \left[ y_{k+1} - C_{k+1} A_k \bar{x}_k \right] \tag{A-40}
$$

and

$$
\bar{K}_x(k) = \bar{r}_x(k) C_k^T \left[ C_k \bar{P}_x(k) C_k^T + R_k \right]^{-1}
$$

and $V_x, V_z$ and $\hat{z}_k$ satisfying (A-29) and (A-38) respectively.

Proof: We first show that $V_z^{-1}$ exists. Since

$$
V_z(k+1) = D_k V_z(k)
$$

$$
V_z(o) = I
$$

so

$$
V_z(k+1) = D_k D_{k-1} \cdots D_0
$$

is not singular since $D_j$ are assumed to be nonsingular as in (A-2). So $V_z^{-1}$ exists.

Next we will prove that both sides of Eq. (A-37) are equal by substituting the expression (A-38) into Eq. (A-37).

Left hand side of Eq. (A-37) becomes

$$
\hat{x}_{k+1} = \bar{x}_{k+1} + V_x(k+1) V_z^{-1}(k+1) \hat{z}_{k+1}
$$

$$
= A_k \bar{x}_k + \bar{K}_x(k+1) \left[ y_{k+1} - C_{k+1} A_k \bar{x}_k \right] + V_x(k+1) V_z^{-1}(k+1) [D_k \hat{z}_k + K_z(k+1) \left( y_{k+1} - C_{k+1} A_k \bar{x}_k \right) - C_{k+1} B_k \hat{z}_k] 
$$

$$
= A_k \bar{x}_k + \bar{K}_x(k+1) \left[ y_{k+1} - C_{k+1} A_k \bar{x}_k \right] + V_x(k+1) V_z^{-1}(k+1) [D_k \hat{z}_k + K_z(k+1) \left( y_{k+1} - C_{k+1} A_k \bar{x}_k \right) - C_{k+1} (A_k V_k V_z^{-1} + B_k) \hat{z}_k] 
$$

$$
= A_k \bar{x}_k + A_k V_x(k) V_z^{-1}(k) \hat{z}_k + B_k \hat{z}_k + K_z(k+1) \left[ y_{k+1} - C_{k+1} A_k \bar{x}_k \right] - C_{k+1} B_k \hat{z}_k 
$$

Right hand side of Eq. (A-37) becomes

$$
A_k \hat{x}_k + B_k \hat{z}_k + K_z(k+1) \left[ y_{k+1} - C_{k+1} A_k \hat{x}_k - C_{k+1} B_k \hat{z}_k \right] 
$$

$$
= A_k \bar{x}_k + A_k V_x(k) V_z^{-1}(k) \hat{z}_k + B_k \hat{z}_k + K_z(k+1) \left[ y_{k+1} - C_{k+1} A_k \bar{x}_k \right] - C_{k+1} B_k \hat{z}_k 
$$
\[ \dot{x}_k = A_k \begin{bmatrix} x_k \\ x_{k-1} \end{bmatrix} + A_k \begin{bmatrix} V_z^{-1} x_k \\ x_{k-1} \end{bmatrix} + B_k \begin{bmatrix} v_k \\ v_{k-1} \end{bmatrix} + K_x(k+1) \left[ y_{k+1} - C_{k+1} \begin{bmatrix} x_k \\ x_{k-1} \end{bmatrix} - C_{k+1} \begin{bmatrix} V_z^{-1} x_k \\ x_{k-1} \end{bmatrix} \right] \]

By (A-33) and (A-32) we have

\[ K_x(k+1) = \left[ \frac{\bar{V}_x(k+1)}{x} + V_x(k+1) M(k+2) V_x^T(k+1) \right] C_{k+1}^T R_{k+1}^{-1} \]

\[ = \frac{\bar{V}_x(k+1)}{x} C_{k+1}^T R_{k+1}^{-1} + V_x(k+1) M(k+2) V_x^T(k+1) C_{k+1}^T R_{k+1}^{-1} \]

\[ = \frac{V_x(k+1)}{x} V_z^{-1}(k+1) K_z(k+1) \] (A-43)

Comparison of expressions (A-41) and (A-42), and using the relation (A-43), it turns out we need only to prove that

\[ A_k V_x(k) V_z^{-1}(k) + B_k - K_x(k+1) C_{k+1} (A_k V_x(k) V_z^{-1}(k) + B_k) = V_x(k+1) \]

\[ V_z^{-1}(k+1) D_k - V_x(k+1) V_z^{-1}(k+1) K_z(k+1) C_{k+1} (A_k V_x(k) V_z^{-1}(k) + B_k) \] (A-44)

Proof: Left-hand side of (A-44)

\[ = \dot{x}_k V_x(k) V_z^{-1}(k) + B_k - \bar{V}_x(k+1) C_{k+1} (A_k V_x(k) V_z^{-1}(k) + B_k) \]

\[ - V_x(k+1) V_z^{-1}(k+1) K_z(k+1) C_{k+1} (A_k V_x(k) V_z^{-1} + B_k) \]

\[ = (1 - \bar{V}_x(k+1) C_{k+1}) (A_k V_x(k) V_z^{-1} + B_k) - V_x(k+1) V_z^{-1}(k+1) K_z(k+1) \]

\[ C_{k+1} (A_k V_x(k) V_z^{-1} + B_k) \]

\[ = (1 - \bar{V}_x(k+1) C_{k+1}) (A_k V_x + B_k V_z) V_z^{-1} - V_x(k+1) V_z^{-1}(k+1) \]

\[ K_z(k+1) C_{k+1} (A_k V_x V_z^{-1} + B_k) \]

\[ = V_x(k+1) V_z^{-1}(k) - V_x V_z^{-1} K_z C_{k+1} (A_k V_x V_z^{-1} + B_k) \]

\[ = V_x(k+1) V_z^{-1}(k+1) D_k - V_x(k+1) V_z^{-1} K_z C_{k+1} (A_k V_x(k) V_z^{-1}(k) + B_k) \]

right hand side of Eq. (A-44).

This completes the proof.
