FOREWORD

This final report describing the formulation of the Program to Optimize Simulated Trajectories (POST) is provided in accordance with Part IV of NASA Contract NASI-13611. The report is presented in three volumes as follows:

Volume I - Program to Optimize Simulated Trajectories - Formulation Manual;

Volume II - Program to Optimize Simulated Trajectories - Utilization Manual;

This work was conducted under the direction of Joseph Rehder of the Space Systems Division, National Aeronautics and Space Administration, Langley Research Center.

FINAL REPORT
PROGRAM TO OPTIMIZE SIMULATED TRAJECTORIES (POST)

VOLUME I - FORMULATION MANUAL

By G. L. Brauer, D. E. Cornick, A. R. Habeger, F. M. Petersen, and R. Stevenson
Martin Marietta Corporation

SUMMARY

This report documents the equations and the numerical techniques used in the Program to Optimize Simulated Trajectories (POST).

POST, a generalized point mass, discrete parameter targeting and optimization program, provides the capability to target and optimize point mass trajectories for a powered or unpowered vehicle operating near a rotating oblate planet. POST has been used successfully to solve a wide variety of atmospheric flight mechanics and orbital transfer problems. The generality of the program is evidenced by its N-phase simulation capability, which features generalized planet and vehicle models. This flexible simulation capability is augmented by an efficient discrete parameter optimization capability that includes equality and inequality constraints.

POST was originally written in FORTRAN IV for the CDC 6000 series computers. However, it is also operational on the IBM 370 and the UNIVAC 1108 computers.

Other volumes in the final report are:

Volume II - Utilization Manual - Documents information pertinent to users of the program. It describes the input required and output available for each of the trajectory and targeting/optimization options.

Volume III - Programers Manual - Documents the program structure and logic, subroutine descriptions, and other pertinent programing information.
I. INTRODUCTION

POST is a general purpose FORTRAN program for simulating and optimizing point mass trajectories of aerospace type vehicles. The program can be used to solve a wide variety of performance and mission analysis problems for atmospheric and orbital vehicles. For example, typical applications of POST are outlined in Table I-1.

One of the key features of POST is an easy to use NAMELIST-type input procedure. This feature significantly reduces input deck set-up time (and costs) for studies that require the normal large amount of input data. In addition, the general applicability of POST is further enhanced by a general-purpose discrete parameter targeting and optimization capability. This capability can be used to solve a broad spectrum of problems related to the performance characteristics of aerospace vehicles.

The basic simulation flexibility is achieved by decomposing the trajectory into a logical sequence of simulation segments.
These trajectory segments, referred to as phases, enable the trajectory analyst to model both the physical and the nonphysical aspects of the simulation accurately and efficiently. By segmenting the mission into phases, each phase can be modeled and simulated in a manner most appropriate to that particular flight regime. For example, the planet model, the vehicle model, and the simulation options can be changed in any phase to be compatible with the level of detail required in that phase.

Every computational routine in the program can be categorized according to five basic functional elements. These elements are: the planet model, the vehicle model, the trajectory simulation model, the auxiliary calculations module, and the targeting and optimization module. The planet model is composed of an oblate spheroid model, a gravitational model, an atmosphere model, and a winds model. These models define the environment in which the vehicle operates. The vehicle model comprises mass properties, propulsion, aerodynamics and aeroheating and a navigation and guidance model. These models define the basic vehicle simulation characteristics. The trajectory simulation models are the event-sequencing module that controls the program cycling, table interpolation routines, and several standard numerical integration techniques. These models are used in numerically solving the translational and rotational equations of motion. The auxiliary calculations module provides for a wide variety of output calculations. For example, conic parameters, range calculations, and tracking data are among the many output variables computed. The targeting and optimization module provides a general discrete parameter iteration capability. The user can select the optimization variable, the dependent variables, and the independent variables from a list of more than 400 program variables. An accelerated projected gradient algorithm is used as the basic optimization technique. This algorithm is a combination of Rosen's projection method for nonlinear programming and Davidson's variable metric method for unconstrained optimization. In the targeting mode, the minimum norm algorithm is used to satisfy the trajectory constraints. The cost and constraint gradients required by these algorithms are computed as first differences calculated from perturbed trajectories. To reduce the costs of calculating numerical sensitivities, only that portion of the trajectory influenced by any particular independent variable is reintegrated on the perturbed runs. This feature saves a significant amount of computer time when targeting and optimization is performed.

POST is operational on several computer systems as described in the tabulation.

III. COORDINATE SYSTEMS

POST uses numerous coordinate systems to provide the necessary reference systems for calculating required and optional data. These coordinate systems and the key transformations are described below.

Coordinate System Definitions

Earth-centered inertial (ECI) axes \( (x_I, y_I, z_I) \). This system is an Earth-centered Cartesian system with \( z_I \) coincident with the North Pole, \( x_I \) coincident with the Greenwich Meridian at time zero and in the equatorial plane, and \( y_I \) completing a right-hand system. The translational equations of motion are solved in this system (fig. III-1).

Earth-centered rotating (ECR) axes \( (x_R, y_R, z_R) \). This system is similar to the ECI system except that it rotates with the Earth so that \( x_R \) is always coincident with the Greenwich Meridian (fig. III-1).

Earth position coordinates \( (\phi, \theta, h) \). These are the familiar latitude, longitude, and altitude designators. Latitude is positive in the Northern Hemisphere. Longitude is measured positive East of Greenwich. Altitude is measured positive above the surface of the planet (fig. III-1).

Geographic (G) axes \( (x_G, y_G, z_G) \). This system is located at the surface of the planet at the vehicle's current geocentric latitude and longitude. The \( x_G \) axis is in the local horizontal plane and points North, the \( y_G \) axis is in the local horizontal plane and points East, and \( z_G \) completes a right-hand system. This system is used to calculate parameters associated with azimuth and elevation angles (fig. III-2).

Inertial launch (L) axes \( (x_L, y_L, z_L) \). This is an inertial Cartesian system that is used as an inertial reference system from which the inertial attitude angles of the vehicle are measured. This coordinate system is automatically located at the
Figure III-1.- Coordinate Systems

Figure III-2.- Launch Frame
geodetic latitude and inertial longitude of the vehicle at the beginning of the simulation unless overridden by user input of LATL and LØNL. The azimuth, $A_L$, is zero unless overridden by user input. The orientation of this system is such that $x_L$ is along the positive radius vector if $\phi_L$ is input as the geocentric latitude, or along the local vertical if $\phi_L$ is not input or is input as the geodetic latitude. $z_L$ is in the local horizontal plane and is directed along the azimuth specified by $A_L$, and $y_L$ completes a right-hand system. This system is intended for use in simulating ascent problems for launch vehicles that use either inertial platform or strapdown-type angular commands. The inertial angles, $(\phi_I, \psi_I, \theta_I)$ are always measured with respect to this system and are automatically computed regardless of the steering option (IGUID) being used (fig. III-2).

Body (B) axes $(x_B, y_B, z_B)$—The body axes form a right-hand Cartesian system aligned with the axes of the vehicle and centered at the vehicle's center of gravity. The $x_B$ axis is directed forward along the longitudinal axis of the vehicle, $y_B$ points right (out the right wing), and $z_B$ points downward, completing a right-hand system. All aerodynamic and thrust forces are calculated in the body system. These forces are then transformed to the inertial (I) system where they are combined with the gravitational forces (fig. III-3)

Figure III-3.—Body Frame.
Body reference (BR) axes \( (x_{BR}, y_{BR}, z_{BR}) \). The body reference system is a right-hand Cartesian system aligned with the body axes as follows. The \( x_{BR} \) axis is directed along the negative \( x_B \) axis, the \( y_{BR} \) axis is directed along the positive \( y_B \) axis, and the \( z_{BR} \) is directed along the negative \( z_B \) axis. This system is used to locate the vehicle's center of gravity, aerodynamic reference point, and engine gimbal locations for the static trim operation (fig. III-3).

Orbital elements \( (h, h_p, i, \omega, \theta, \Omega) \). This is a nonrectangular coordinate system used in describing orbital motion. The orbital elements are apogee altitude, perigee altitude, inclination, longitude of the ascending node, true anomaly, and argument of perigee. The apogee and perigee altitudes replace the standard orbital elements of semimajor axis and eccentricity (fig. III-4).

Vernal Equinox (VE) Axes \( (x_{VE}, y_{VE}, z_{VE}) \). This is the 1950 mean equator and equinox Earth centered inertial system. The \( x_{VE} \) axis is in the equatorial plane and is directed forward of the vernal equinox of 1950, the \( z_{VE} \) axis is directed along the north pole, and \( y_{VE} \) completes the right hand system (fig. III-1).
Attitude Angles

The program contains the following standard attitude reference systems:

1) Inertial Euler angles;
2) Relative Euler angles;
3) Aerodynamic angles;
4) Inertial aerodynamic angles;

These variables are defined and illustrated below:

1) Inertial Euler angles (fig. III-5):

- $\phi_I$ - Inertial roll angle. The roll angle with respect to the L-frame (first rotation),
- $\psi_I$ - Inertial yaw angle. The yaw angle with respect to the L-frame (second rotation),
- $\theta_I$ - Inertial pitch angle. The pitch angle with respect to the L-frame (third rotation);

2) Relative Euler angles (fig. III-6):

- $\psi_R$ - Relative yaw angle. This is the azimuth angle of the $x_B$ axis measured clockwise from the reference direction (first rotation),
- $\theta_R$ - Relative pitch angle. This is the elevation angle of the $x_B$ axis above the local horizontal plane (second rotation),
- $\phi_R$ - Relative roll angle. This is the roll angle about the $x_B$ axis (third rotation).
3) Aerodynamic angles (fig. III-7):

- **\( \sigma \)** - Bank angle. Positive \( \sigma \) is a positive rotation about the atmosphere relative velocity vector (first rotation),

- **\( \beta \)** - Sideslip. Positive \( \beta \) is a nose-left (negative) rotation when flying the vehicle upright (second rotation),

- **\( \alpha \)** - Angle of attack. Positive \( \alpha \) is a nose-up (positive) rotation when flying the vehicle upright (third rotation);

![Figure III-7.- Aerodynamic Angles](image)

4) Inertial aerodynamic angles (fig. III-8):

- **\( \sigma_I \)** - Bank angle. Positive \( \sigma_I \) is a positive rotation about the atmosphere inertial velocity vector (first rotation),

- **\( \beta_I \)** - Sideslip. Positive \( \beta_I \) is a nose-left (negative) rotation when flying the vehicle upright (second rotation),

- **\( \alpha_I \)** - Angle of attack. Positive \( \alpha_I \) is a nose-up (positive) rotation when flying the vehicle upright (third rotation);

![Figure III-8.- Inertial Aerodynamic Angles](image)
Transformations

Numerous matrix transformations are required to transform data between the coordinate systems described in the previous section. The most important of these transformations is the [IB] matrix. The inverse (transpose) of this matrix is used to transform accelerations in the body frame to the planet-centered inertial frame. The remaining transformations are generally used to either compute [IB] or to transform auxiliary data into some convenient output coordinate system.

The [IB] matrix is functionally dependent on the attitude of the vehicle. This dependence is described by equations related to the attitude steering option selected by the user. The following matrix equations, which depend on this steering option, are used to compute the [IB] matrix.

\[
[IB] = [LB][IL] \text{ (body rates or inertial Euler angles)}
\]
\[
[IB] = [GB][IG] \text{ (relative Euler angles)}
\]
\[
[IB] = [AB][GA][IG] \text{ (aerodynamic angles)}
\]

The basic relationships between the coordinate systems defined by these equations are illustrated in figure III-9. The inverse transformation can generally be computed by merely transposing the matrix elements because of the orthonormality of these matrices.

![Figure III-9. - Matrix Transformations](image-url)
A summary of these matrices is given below. The symbols $s$ and $c$ denote sin and cos, respectively.

The matrix $[IL]$, inertial to launch, depends on $\theta_L$, and $A_{ZL}$, and is given by

$$
[IL] = 
\begin{bmatrix}
    c_{\phi_L} c_{\theta_L} & c_{\phi_L} s_{\theta_L} & s_{\phi_L} \\
    s_{\phi_L} c_{\theta_L} c_{A_{ZL}} - c_{A_{ZL}} s_{\theta_L} c_{\phi_L} & c_{A_{ZL}} c_{\phi_L} + s_{A_{ZL}} s_{\phi_L} s_{\theta_L} & -s_{A_{ZL}} c_{\phi_L} \\
    -s_{A_{ZL}} s_{\phi_L} c_{\theta_L} - c_{A_{ZL}} s_{\phi_L} c_{\theta_L} & s_{A_{ZL}} c_{\theta_L} - c_{A_{ZL}} s_{\phi_L} s_{\theta_L} & c_{A_{ZL}} c_{\phi_L}
\end{bmatrix}
$$

The matrix $[LB]$, launch to body, is computed indirectly from the body rates by integrating the quaternion equations, or directly from inertial Euler angles. When the body rate option is used, the quaternion rate equation

$$
\begin{bmatrix}
    \dot{e}_0 \\
    \dot{e}_1 \\
    \dot{e}_2 \\
    \dot{e}_3
\end{bmatrix} = \frac{1}{2}
\begin{bmatrix}
    -e_1 & e_2 & e_3 \\
    e_0 & e_2 & -e_3 \\
    e_0 & -e_1 & e_3 \\
    e_0 & e_1 & -e_2
\end{bmatrix}
\begin{bmatrix}
    \omega_x \\
    \omega_y \\
    \omega_z
\end{bmatrix}
$$

is integrated to compute the $[LB]$ matrix, which is then given by

$$
[LB] = 
\begin{bmatrix}
    e_0^2 + e_1^2 - e_2^2 - e_3^2 & 2(e_1 e_2 + e_0 e_3) & 2(e_1 e_3 - e_0 e_2) \\
    2(e_1 e_2 - e_0 e_3) & e_0^2 - e_1^2 + e_2^2 - e_3^2 & 2(e_0 e_1 + e_2 e_3)) \\
    2(e_1 e_3 + e_0 e_2) & 2(e_2 e_3 - e_0 e_1) & e_0^2 - e_1^2 - e_2^2 + e_3^2
\end{bmatrix}
$$

III-8
When the inertial Euler angle option is used, \([LB]\) is computed directly as

\[
[LB] = \begin{bmatrix}
    c_{\theta}^I c_{\phi}^I & c_{\phi}^I s_{\psi}^I c_{\theta}^I + s_{\phi}^I s_{\psi}^I & s_{\phi}^I s_{\psi}^I c_{\theta}^I - c_{\psi}^I s_{\phi}^I \\
    -s_{\theta}^I & c_{\theta}^I c_{\phi}^I & s_{\phi}^I c_{\phi}^I \\
    c_{\phi}^I s_{\psi}^I c_{\theta}^I - s_{\phi}^I s_{\psi}^I s_{\theta}^I & s_{\phi}^I s_{\psi}^I s_{\theta}^I + c_{\psi}^I c_{\phi}^I & c_{\phi}^I s_{\psi}^I s_{\theta}^I + c_{\phi}^I c_{\psi}^I \\
\end{bmatrix}
\]

([III-5])

\([IG]\), inertial to geographic.- The \([IG]\) matrix depends on the geocentric latitude and the inertial longitude, and is given by

\[
[IG] = \begin{bmatrix}
    -s_{\phi}^I c_{\theta}^I & -s_{\phi}^I s_{\theta}^I & c_{\phi}^I \\
    c_{\phi}^I s_{\phi}^I I & 0 & 0 \\
\end{bmatrix}
\]

([III-6])

\([GB]\), geographic to body.- The \([GB]\) matrix depends on the relative Euler angles, and is given by

\[
[GB] = \begin{bmatrix}
    c_{\psi}^R c_{\phi}^R & c_{\psi}^R s_{\phi}^R & -s_{\phi}^R \\
    s_{\psi}^R s_{\phi}^R s_{\theta}^R - c_{\phi}^R c_{\theta}^R & s_{\phi}^R s_{\phi}^R s_{\theta}^R + c_{\phi}^R c_{\theta}^R & s_{\psi}^R c_{\theta}^R \\
    c_{\psi}^R s_{\phi}^R c_{\theta}^R + s_{\phi}^R s_{\theta}^R & c_{\phi}^R s_{\theta}^R s_{\phi}^R - s_{\psi}^R c_{\theta}^R & c_{\phi}^R c_{\psi}^R \\
\end{bmatrix}
\]

([III-7])

\([GA]\), geographic to atmospheric relative velocity system (ARVS).- The \([GA]\) matrix depends on the atmospheric relative flight azimuth and flightpath angles, and is given by

\[
[GA] = \begin{bmatrix}
    c_{\psi}^A c_{\lambda}^A & c_{\psi}^A s_{\lambda}^A & -s_{\psi}^A \\
    -s_{\psi}^A & c_{\psi}^A & 0 \\
    s_{\psi}^A c_{\lambda}^A & s_{\psi}^A s_{\lambda}^A & c_{\psi}^A \\
\end{bmatrix}
\]

([III-8])

III-9
\( [AB] \), ARVS to body. - The \([AB]\) matrix depends on the aerodynamic angles, and is given by

\[
[AB] = \begin{bmatrix}
  \cos \beta & -\cos \beta \sin \sigma + \sin \beta \cos \sigma & -\cos \beta \sin \sigma - \sin \beta \cos \sigma \\
  \sin \beta & \cos \beta \cos \sigma & \cos \beta \sin \sigma \\
  \sin \beta \cos \sigma & -\sin \beta \sin \sigma & \cos \beta + \sin \beta \cos \sigma
\end{bmatrix}
\] (III-9)

Other transformations, which are not related to the calculation of the \([IB]\) matrix, are presented below.

\([IP]\), inertial to planet relative. - The \([IP]\) matrix transforms between the Earth-centered inertial frame and the Earth-centered rotating frame. This matrix depends on the rotation rate of the planet and the total elapsed time of flight, and is given by

\[
[IP] = \begin{bmatrix}
  \cos \Omega t & \sin \Omega t & 0 \\
  -\sin \Omega t & \cos \Omega t & 0 \\
  0 & 0 & 1
\end{bmatrix}
\] (III-10)

\([RB]\), body reference to body. - The \([RB]\) matrix transforms data in the body reference system to the body frame. This matrix has a constant value and is given by

\[
[RB] = \begin{bmatrix}
  1 & 0 & 0 \\
  0 & 1 & 0 \\
  0 & 0 & -1
\end{bmatrix}
\] (III-11)

\([IV]\), inertial to vernal equinox. - The \([IV]\) matrix transforms between the ECI frame and the vernal equinox frame, and is given by

\[
[IV] = \begin{bmatrix}
  1 & 0 & 0 \\
  -\sin \theta & \cos \theta & 0 \\
  0 & 0 & 1
\end{bmatrix}
\] (III-12)

where \( \theta = \text{GHA} + \dot{\Omega} (t - t_{\text{reference}}) \).
IV. PLANET MODEL

The planet model is composed of three types of data and equations. These are: (1) oblate planet geometry and constants, (2) an atmosphere model that computes atmospheric pressure, density, temperature, and speed of sound, and (3) a gravitational model that computes the gravitational accelerations. The user selects the appropriate models and inputs the corresponding data. The input data and the equations used in these models are described below.

Oblate Spheroid

The 1960 Fisher Earth model is preloaded into the program. This model is defined by the equatorial radius $R_E$, the polar radius $R_p$, the rotation rate $\Omega_p$, the gravitational constant $\mu$, and the second, third, and fourth gravitational harmonics, $J_2$, $J_3$, and $J_4$, respectively. The stored values for these constants are:

\[
\begin{align*}
R_E &= 2.0925741 \times 10^7 \text{ ft}, \\
R_p &= 2.085590 \times 10^7 \text{ ft}, \\
\Omega_p &= 7.29211 \times 10^{-5} \text{ rad/s}, \\
\mu &= 1.4066539 \times 10^{16} \text{ ft}^3/\text{s}^2, \\
J_2 &= 1.0823 \times 10^{-3}, \\
J_3 &= 0, \\
J_4 &= 0.
\end{align*}
\]

The constants $J_3$ and $J_4$ are preloaded as zero, but can be initialized by input. For example, if the Smithsonian Earth model is desired, then these constants would be input as

\[
\begin{align*}
J_2 &= 1.082639 \times 10^{-3}, \\
J_3 &= -2.565 \times 10^{-6}, \\
J_4 &= -1.608 \times 10^{-6}, \\
\mu &= 1.407645794 \times 10^{16} \text{ ft}^3/\text{s}^2,
\end{align*}
\]
\[ \hat{n}_p = 7.29211515 \times 10^{-5} \text{ rad/s}, \]
\[ R_E = 2.092566273 \times 10^7 \text{ ft}, \]
\[ R_P = 2.08550242 \times 10^7 \text{ ft}. \]

The geometry of this spheroid is illustrated in figure IV-1. The pertinent equations related to this model are:

\[
\begin{align*}
\phi_c &= \sin^{-1} \left( \frac{z_1}{r_1} \right) \\
\phi_g &= \tan^{-1} \left( k \tan \phi_c \right), \quad k = \left( \frac{R_E}{R_P} \right)^2 \\
R_s &= R_E \left( 1 + (k - 1) \sin^2 \phi_c \right)^{-\frac{1}{2}} \\
h &= r_1 - R_s,
\end{align*}
\]

where \( \phi_c \) is the geocentric latitude, \( \phi_g \) is the geodetic latitude, \( \theta_1 \) is the inertial longitude, \( \theta \) is the relative longitude with respect to the planet, \( r_1 \) is the distance from the center of the planet to the vehicle, \( R_s \) is the distance from the center of the planet to the planet surface, and \( h \) is the distance from the planet surface to the vehicle.
Gravitational Model

The gravitational model includes optionally second, third, and fourth harmonic terms. The potential function for this model is

\[
U = -\mu \left[ \frac{1}{r} - \frac{J_2}{2} \frac{R_E}{r^2} \left( \frac{3z^2}{r^5} - \frac{1}{r^3} \right) - \frac{J_3}{2} \frac{R_E}{r^2} \left( \frac{5z^3}{r^7} - \frac{3z}{r^5} \right) - \frac{J_4}{8} \frac{R_E}{r^2} \left( 35 \frac{z^4}{r^9} - 30 \frac{z^2}{r^7} + \frac{3}{r^5} \right) \right]. \tag{IV-2}
\]
The gravitational accelerations calculated from this potential function are:

\[ G_{X1} = - \frac{\partial U}{\partial x_1} \]

\[ = -\mu \frac{x}{r^3} P(z, r) \]

\[ G_{Y1} = - \frac{\partial U}{\partial y_1} \]

\[ = -\mu \frac{y}{r^3} P(z, r) \]

\[ G_{Z1} = - \frac{\partial U}{\partial z_1} \]

\[ = -\mu \frac{z}{r^3} \left[ (1 + JR^2 (3 - 5Z^2)) z + HR^3 \left( 6z^2 - 7z^2 Z^2 - \frac{3}{5} r^2 \right) \right. \]

\[ + DR^4 \left( \frac{15}{7} - 10Z^2 + 9Z^4 \right) z \] ,

where \( x = x_1, y = y_1, z = z_1, r = r_1 \), and

\[ R = \frac{R_E}{r_1} \]

\[ Z = \frac{z_1}{r_1} \]

\[ J = \frac{3}{2} J_2 \]

\[ H = \frac{5}{2} J_3 \]

\[ D = -\frac{35}{8} J_4 \]

\[ P(z, r) = \left[ 1 + JR^2 (1 - 5Z^2) + HR^3 \left( 3 - 7 Z^2 \right) z \right. \]

\[ + DR^4 \left( 9Z^4 - 6Z^2 + \frac{3}{7} \right) \]
Atmosphere Models

POST has the optional capability of three atmospheric models—the general table lookup, the 1962 U.S. standard atmosphere, and the 1963 Patrick AFB atmosphere using polynomials. The general table lookup model gives the user the flexibility of inputting his own atmospheric model if none of the preloaded models is adequate. This is particularly useful in performing trajectory analysis for planets other than Earth. The parameters required to define the atmospheric effects are the atmospheric pressure $p$, atmospheric density $\rho$, speed of sound $C_s$, and atmospheric temperature $T$. These parameters are functions of the oblate altitude $h$.

**Table lookup atmosphere model**—The table lookup atmosphere model can be defined entirely by using tables that show pressure, temperature, speed of sound, and density as functions of altitude. The speed of sound and density tables can be omitted if desired; in this case, the speed of sound and density are computed as

$$ C_s = \sqrt{K_1 \frac{T}{T}} $$

$$ \rho = K_2 \frac{P}{T} $$

where

$$ K_1 = \frac{\gamma R^* M_0}{M_0} $$

$$ K_2 = \frac{M_0}{R^*} $$

$\gamma$ = ratio of specific heats

$M_0$ = molecular weight

$R^*$ = universal gas constant.

**1962 U.S. standard atmosphere model**—The 1962 U.S. standard atmosphere model is given as a function of geopotential altitude ($H_g$), which is computed as

$$ H_g = \frac{R_A h}{R_A + h'} $$

(IV-6)
where

\[ \kappa_A = \text{average Earth radius} = \frac{1}{2} \left( R_E + R_P \right) \]

\[ h = \text{oblate altitude}. \]

The molecular scale temperature, \( T_M \), is defined by a series of linear segments \( (L_M) \) as a function of geopotential altitude \( (H_g) \).

The corner points connecting the straight-line segments are referred to as base altitudes \( (H_B) \), base temperatures \( (T_{MB}) \), etc. From a table of base altitudes, base temperatures, and \( dT_M/dH \,(L_M) \) (the slope within the linear segments), the temperature at any desired altitude can be calculated from the following equation:

\[ T_M = T_{MB} + L_{MB} (H_g - H_B). \]  \hspace{1cm} (IV-7)

Values of \( P_B, T_{MB}, \) and \( L_{MB} \) versus \( H_B \) are presented in table IV-1.

The atmospheric pressure is determined as follows:

\[ P = P_B \left\{ \begin{array}{l}
\left[ \frac{T_{MB}}{T_M} \right] \exp \left( \frac{g_0 M_0}{R^2} \right) L_{MB} \quad \text{for segments with } L_{MB} \neq 0, \text{ and} \\
\left[ - \frac{g_0 M_0}{R^2} \left( H - H_B \right) \right] \quad \text{for segments with } L_{MB} = 0,
\end{array} \right. \]  \hspace{1cm} (IV-8)

where \( P_B \) is the base pressure corresponding to the given base altitude \( H_B \). These base pressures can be calculated once the sea-level pressure, \( P_0 \), and the temperature profile have been specified.
Having calculated the temperature and pressure, the density, \( \rho \), speed of sound, \( C_s \), and atmospheric viscosity, \( \nu_A \), are determined as follows:

\[
\rho = \left( \frac{M_0}{R^*} \right) \frac{P}{T_M},
\]

\[
C_s = \left( \frac{\gamma R^*}{M_0} \right)^{\frac{1}{2}} T_M^{\frac{1}{2}},
\]

\[
\nu_A = \frac{\beta T_M^3}{T_M + S},
\]

where \( g_0 \) is the acceleration of gravity at sea level, \( M_0 \) is the molecular weight of air at sea level, \( R^* \) is the gas constant, \( \gamma \) is the ratio of specific heats, and \( \beta \) and \( S \) are Sutherland's constants.

\[
M_0 = 28.9644
\]

\[
R^* = 8.31442 \cdot 10^3 \frac{J}{(°K)(kg\text{-mol})}
\]

\[
\gamma = 1.40
\]

\[
\beta = 1.458 \times 10^{-6} \frac{kg}{sec\cdot m(°K)^{\frac{3}{2}}}
\]

\[
S = 110.4°K = 198.72°R
\]

\[
g_0 = 9.80665 \text{ m/sec}^2 = 32.174 \text{ ft/sec}^2.
\]

In the 1962 U.S. standard atmosphere, the molecular weight varies with altitude above approximately 90 km; in POST the molecular weight is assumed constant, resulting in a slight discrepancy above 90 km. In the 1962 U.S. standard atmosphere, geometric altitude is transformed to geopotential altitude, which is used throughout. Thus, above 90 km, a constant slope of molecular scale temperature versus geopotential altitude is used instead of the constant slope of temperature versus geometric altitude.

</table>
1963 Patrick AFB atmosphere using polynomials. In this model, pressure and temperature are calculated as functions of geometric altitude \((h)\). These parameters are calculated in metric units and converted to English units if required.

Pressure:

1) Altitude region = 0 to 28 000 meters:

\[
P = P_1 \exp \left( A + A_1 h + A_2 h^2 + A_3 h^3 + A_4 h^4 + A_5 h^5 \right)
\]

where \(P_1 = 10.0 \text{ Newtons/cm}^2\);

2) Altitude region = 28 000 to 83 004 meters:

\[
P = g \times 10^{-4} \exp \left( A + A_1 h + A_2 h^2 + A_3 h^3 + A_4 h^4 + A_5 h^5 \right);
\]

3) Altitude region = 83 004 to 90 000 meters:

\[
P = P_B \exp \left( \frac{-1.373301523 \times 10^{12}}{T_B (6344860 + h)} (h - h_B) \right);
\]

4) Altitude region = 90 000 to 700 000 meters:

\[
L_n (P) = L_n (P_B) + \frac{1.373301523 \times 10^{12}}{L_m (6344860 + h)} \frac{L_m (h - h_B)}{T_M} \left( \frac{T_M}{T_M + L_m (h - h_B)} \right).
\]
Temperature:

1) Altitude region = 0 to 10 832.1 meters:
\[ T = T^* = A + A_1 h + A_2 h^2 + A_3 h^3 + A_4 h^4 + A_5 h^5; \]

2) Altitude region = 10 832.1 to 83 004 meters:
\[ T = A + A_1 h + A_2 h^2 + A_3 h^3 + A_4 h^4 + A_5 h^5; \]

3) Altitude region = 83 004 to 90 000 meters:
\[ T = T_B + L_k (h - h_B); \]

However, in this region \( L_k = 0 \), and thus
\[ T = T_B = 180.65 \, ^\circ K; \]

4) Altitude region = 90 000 to 700 000 meters:
\[ T = T_M = T_M + L_m (h - h_B). \]

Density:

1) Altitude region = 0 to 28 000 meters:
\[ \rho = \rho_1 \exp \left( A + A_1 h + A_2 h^2 + A_3 h^3 + A_4 h^4 + A_5 h^5 \right); \]

2) Altitude region = 28 000 to 700 000 meters:
\[ \rho = (34.83676) \frac{P}{T}. \]

*Virtual temperature is the same as kinetic temperature above the 10 832.1-meter altitude.\]

*Altitude range: 90 000 to 700 000 meters.
Pressure and density ratios:

Altitude region = 0 to 700 000 meters:

\[
\begin{align*}
\frac{\rho_R}{\rho_o} & \quad \left(\text{IV-14}\right) \\
\frac{P_R}{P_o} & \quad \left(\text{IV-15}\right)
\end{align*}
\]

Velocity of sound:

\[V_s = (20.046707) (T)^{1.2} .\] (IV-15)

The atmosphere model-derived coefficients are presented in table IV-2. The molecular temperature gradient is documented in table IV-3 for geometric altitudes from 90 to 700 km.

Winds

The atmospheric wind velocity components are input in tables using either meteorological or vector notation. If these tables, which are normally functions of oblate altitude, are not input, then the atmosphere is assumed to rotate uniformly with the planet.

The wind velocity components can be input directly in the geographic frame by defining \(v_W\), \(v_W\), and \(w_W\), or by defining the wind speed \(V_W\), the vertical component \(V_W\), the wind azimuth \(A_{ZW}\), and the wind azimuth bias \(A_{ZWB}\). The resulting wind velocity components in the G-frame are:

\[
\begin{align*}
V_{WG} = & \left[ V_W(h) \cos (A_{ZW}(h) + A_{ZWB}) \right] \\
& \left[ V_W(h) \sin (A_{ZW}(h) + A_{ZWB}) \right] \\
& \left[ w_W(h) \right] 
\end{align*}
\] (IV-16)
It is clear from the above equation that in order to input vector wind data $A_{ZWB}$ must be input as zero, whereas for meteorologic data the preloaded value of 180° should be used.

The wind velocity in the ECI frame is then given by

$$V_{WI} = [IG]^{-1} V_{WG}$$ (IV-17)

Thus, the atmospheric relative velocity vector in the ECI frame is

$$V_{AI} = V_I - \frac{\Delta V_p}{3} \cdot V_I - V_{WI}$$ (IV-18)

and its magnitude is given by

$$V_A = \sqrt{V_{AI} \cdot V_{AI}}$$ (IV-19)
V. VEHICLE MODEL

The various physical properties of the vehicle are modeled by the user when he selects the pertinent options from the set of vehicle simulation modules. The equations used in these modules are presented below.

Mass Properties Model

The gross weight of the vehicle at the beginning of each phase is given by

\[ W_G = W_{stg} + W_{pld} \]  \hspace{1cm} (V-1)

where \( W_{stg} \) is gross weight without payload and \( W_{pld} \) is the payload weight. For phases other than the first, the gross weight can optionally be computed as

\[ W_G^+ = W_G^- - W_{jett} - W_{PR} \]  \hspace{1cm} (V-2)

where \( W_G^+ \) is the gross weight on the positive side of the current event, \( W_G^- \) is the gross weight on the negative side of the current event, \( W_{jett} \) is the jettison weight, and \( W_{PR} \) is the weight of propellant remaining. These options are obtained automatically, based on user input.

The propellant remaining is given by

\[ W_{PR} = W_{P_1} - W_{PC} \]  \hspace{1cm} (V-3)

where \( W_{P_1} \) is the initial weight of propellant and \( W_{PC} \) is the amount of propellant consumed. This latter term is given by

\[ W_{PC} = \int \dot{W} dt + W_{C_0} \]  \hspace{1cm} (V-4)

where \( \dot{W} \) is the total rate of change of the vehicle's weight.
At the beginning of each phase, the constant $W_{CO}$ can be either input or carried across the event as the total amount of weight consumed in the previous phase.

The amount of propellant jettisoned can be computed as:

1) The amount of propellant remaining at the beginning of the current phase,

2) The amount of propellant remaining at some prescribed prior event.

The constant jettison weight is either computed from an input constant value or determined from an input mass-fraction table. When a mass-fraction table is used the jettison weight is given by

$$W_{jett} = W_{Pi} \left[ \frac{1}{\lambda} - 1 \right] ,$$

where $\lambda$ is the mass fraction computed from the table.

Propulsion Calculations

POST can simulate both rocket and jet engines. The program can simulate up to 15 engines in either mode.

Rocket engines.- There are two input options for engine data in the rocket mode. In the first option, tables for vacuum thrust and maximum weight flowrate are input for each engine. In the second option, tables for vacuum thrust are input, along with the vacuum specific impulse for each engine. The vacuum specific impulse is then used to calculate the mass flowrate.

The rocket thrust per engine is given by

$$T_{R_i} = \eta T_{vac_i} A_{E_i} p(n),$$

(V-5)
where \( q \) is the throttle setting, \( T_{\text{vac},i} \) is the vacuum thrust of the \( i \)th engine, \( A_e \) is the nozzle exit area, and \( p(h) \) is the atmospheric pressure. Summing over all engines yields the total rocket thrust

\[
T_R = \sum_{i=1}^{N_{\text{eng}}} T_{R,i} \tag{V-7}
\]

where \( N_{\text{eng}} \) is the number of thrusting engines, and \( N_{\text{eng}} = 15 \).

The weight flowrate in the rocket mode is given by

\[
W = \begin{cases} 
N_{\text{eng}} \\
-\eta \sum_{i=1}^{N_{\text{eng}}} \left( \frac{T_{\text{vac}}}{I_{\text{sp},\text{vac}}} \right) \\
-\eta \sum_{i=1}^{N_{\text{eng}}} \left( \frac{w_{\text{max}}}{p} \right) 
\end{cases} \tag{V-3}
\]

Jet engines.-- In the jet engine mode the net jet thrust per engine is given by

\[
\left( \frac{T_j}{\delta} \right)_i = \frac{1}{(N, \eta)} \tag{V-9}
\]

where

\[
\delta = \frac{p(h)}{p_{\text{SL}}} \tag{V-10}
\]
and \( \frac{T_j}{\gamma} \) (M,
given by a monovariant table. The total jet thrust is then given by

\[
T_J = \sum_{i=1}^{N_{\text{eng}}} \frac{p(h)}{\rho_{SL}} (T_J/\gamma_i).
\]

(V-11)

The weight flowrate in the jet engine mode is

\[
\dot{W} = - \sum_{i=1}^{N_{\text{eng}}} \sqrt{\frac{T(h)}{\rho_{SL}} \left(\frac{p(h)}{\rho_{SL}}\right) \left(\frac{\text{SFC}}{\delta}\right)} \frac{T_J}{\delta}.
\]

(V-12)

The thrust vector components for both rocket and jet engines are determined from the thrust magnitude \( T_{R_i} \) or \( T_{J_i} \) and the thrust incidence angles \( \iota_{R_i} \) and \( \iota_{J_i} \). The thrust accelerations in the body axes are then given by

\[
A_{BA} = \sum_{i=1}^{N_{\text{eng}}} \frac{\eta_i}{m} \begin{bmatrix}
\cos \iota_i & \cos \iota_{R_i} \\
\sin \iota_i & \sin \iota_{R_i} \\
\cos \iota_i & \cos \iota_{R_i}
\end{bmatrix} = \frac{T_R}{m} \begin{bmatrix}
\cos \iota_i & \cos \iota_{R_i} \\
\sin \iota_i & \sin \iota_{R_i} \\
\cos \iota_i & \cos \iota_{R_i}
\end{bmatrix}
\]

(V-13)

In the above equation \( T_i \) denotes the thrust magnitude for the \( i^{th} \) engine (either rocket or jet) and \( m \) denotes the instantaneous mass of the vehicle. The engine gimbal angles are determined from the static trim equations in the moment balance option or by input if the moment balance option is not used. The engine gimbal angles are illustrated in figure V-1.
Figure V-1. - Engine Gimbal Angles

Note that thrust misalignments can be simulated by inputting the engine gimbal angles and using the standard three-degree-of-freedom option.

Aerodynamic Calculations

The aerodynamic force coefficients can be expressed in terms of the lift, drag, and side-force coefficients $C_L$, $C_D$, and $C_Y$ (fig. V-2), where $C_L$ and $C_L$ are directed normal to, and along the velocity projection in, the $x_B-z_B$ plane. Note that $C_Y$ produces a side-force, $F_{AYB}$, acting in the direction of $y_B$.

Lift and drag force coefficients are transformed to axial and normal force coefficients as follows:

$$
\begin{bmatrix}
C_A \\
C_N
\end{bmatrix} = \begin{bmatrix}
\cos \alpha & -\sin \alpha \\
\sin \alpha & \cos \alpha
\end{bmatrix} \begin{bmatrix}
C_D \\
C_L
\end{bmatrix}
$$

(V-14)

where $\alpha$ is the angle-of-attack.
Figure V-2.- Aerodynamic Angles

The aerodynamic coefficients can also be expressed in terms of the axial force, normal force, and side force, $C_A$, $C_N$, and $C_Y$, respectively. Here $C_A$ and $C_N$ produce forces that act in the $-x_B$ and $-z_B$ directions, and $C_Y$ produces a force acting along $y_B$.

Each aerodynamic coefficient is computed by interpolating the values in the table. In general, eight tables are allocated to each coefficient. These tables can be monovariant, bivariant, or trivariant, and seven tables per coefficient can have arbitrary hollerith mnemonic multipliers. This generality enables all standard forms of aerodynamic data to be directly input into the program.
The aerodynamic force coefficients are given by:

\[
C_D = C_{D_0} + C_{D\delta} + C_{D_{\delta p}} M_{D_{\delta p}} + C_{D_{\delta y}} M_{D_{\delta y}}
\]

\[
C_L = C_{L_0} + C_{L\delta} + C_{L_{\delta p}} M_{L_{\delta p}}
\]

\[
C_A = C_{A_0} + C_{A\delta} + C_{A_{\delta p}} M_{A_{\delta p}} + C_{A_{\delta y}} M_{A_{\delta y}}
\]

\[
C_N = C_{N_0} + C_{N\delta} + C_{N_{\delta p}} M_{N_{\delta p}}
\]

\[
C_Y = C_{Y_0} + C_{Y\delta} + C_{Y_{\delta p}} M_{Y_{\delta p}}
\]

the aerodynamic moment coefficients are given by:

\[
C_M = C_{M_0} + C_{M\delta} + C_{M_{\delta p}} M_{M_{\delta p}} + C_{M_{\delta y}} M_{M_{\delta y}}
\]

\[
C_n = C_{n_0} + C_{n\delta} + C_{n_{\delta p}} M_{n_{\delta p}} + C_{n_{\delta y}} M_{n_{\delta y}}
\]

In the above expressions, \(C_{D_0}, C_D, C_{D_{\delta p}}, C_{D_{\delta y}}\), etc., denote the tables, and \(M_{C_D}, M_{C_{\delta}}, M_{C_{\delta p}}, M_{C_{\delta y}}\), etc., denote the mnemonic table multipliers. Typical table arguments and multipliers would be \(a, b, h, R, \delta p, \delta y\).

The Mach number and dynamic pressure are given by:

\[
M = \frac{V_A}{C_S}
\]

\[
q = \frac{1}{2} \rho V_A^2
\]

where \(\rho\) is the atmospheric density, \(V_A\) is the velocity of the vehicle with respect to the atmosphere, and \(C_S\) is the speed of sound. These atmospheric parameters are determined from the atmospheric models as a function of the altitude \(h\) above the oblate spheroid; i.e.,
\[ \rho = \rho(h) \]
\[ c_s = c_s(h) \]
\[ p = p(h) \]
\[ T = T(h). \]

The angle of attack in pitch \((\alpha)\) and the angle of sideslip \((\beta)\) required to determine the aerodynamic coefficients are calculated as follows:

\[ \alpha = \tan^{-1} \left[ \frac{\sin \alpha}{\cos \alpha} \right] \]
\[ \beta = \tan^{-1} \left[ \frac{\sin \beta}{\cos \beta} \right] \]

\[ \sin \alpha = \frac{\omega_B}{\sqrt{u_B^2 + \omega_B^2}} \]
\[ \cos \alpha = \frac{u_B}{\sqrt{u_B^2 + \omega_B^2}} \]
\[ \sin \beta = \frac{\omega_B}{u_B} \]
\[ \cos \beta = \frac{\sqrt{\omega_B^2 + \omega_B^2}}{u_B} \]

The total angle of attack is

\[ \alpha_T = \cos \left( \frac{v_{ABx}}{v_A} \right). \]

The aerodynamic forces in the body frame are

\[ \mathbf{F}_{AB} = q S \begin{bmatrix} -c_A \\ c_Y \\ -c_N \end{bmatrix} \]

where \(q\) is the dynamic pressure and \(S\) is the reference area.
The resulting accelerations in the body system are then obtained from

\[ A_{AB} = \frac{1}{m} F_{AB} \]  

(V-22)

Aeroheating Calculations

POST provides for a wide variety of aeroheating calculations. Some of these options are specific in nature and apply only to particular vehicles, whereas others are quite general. The general heat rate option is based on trivariant table interpolation and provides complete flexibility with regards to vehicle shape and heat-transfer methodology. The various heat rate equations are described below.
Heat rate equations.

1) Chapman's equations. In this calculation the heat rate is given by

\[
\dot{Q} = \frac{17600}{\sqrt{R_N}} \left( \frac{\rho}{\rho_{SL}} \right)^{3.15} \left( \frac{V_R}{V_C} \right)
\]  

(V-23)

where \( R_N \) is the nose radius, \( \rho \) is the atmospheric density, and \( V_C \) is the reference circular orbital velocity.

2) General table lookup. This heat rate is given by

\[
\dot{Q} = Q_t (x_1, x_2, x_3),
\]

(V-24)

where \( x_1, x_2, \) and \( x_3 \) can be any internally computed variables. For example, the values that would normally be selected are \( x_1 = \alpha, x_2 = h, \) and \( x_3 = V_R. \)

3) Modified Chapman's equation. Here the heat rate is given by

\[
\dot{Q} = Q_t (x_1, x_2, x_3) Q_c
\]

(V-25)

where \( Q_t \) is an arbitrary table and \( Q_c \) is the standard Chapman's equation.

4) Turbulent-flow heat rate. The turbulent-flow heat rate is given by

\[
\dot{Q} = Q_t (x_1, x_2, x_3) \left[ 1500 \left( \frac{\rho}{\rho_{SL}} \right)^{0.8} \left( \frac{V_A}{10^4} \right)^{3.18} \right]
\]

(V-26)

5) Maximum centerline heating. The equations for this method are given below in sequence.

a) Altitude-velocity correction:

\[
\Delta h = 10^5 \left[ 1.06112 - 6.16586 V_A/10^4 \right]
\]

\[
+ 52.12090 \left( \frac{V_A}{10^4} \right)^4 - 20.66258 \left( \frac{V_A}{10^4} \right)^5
\]

\[
+ 22.52598 \left( \frac{V_A}{10^4} \right)^2 - 48.28080 \left( \frac{V_A}{10^4} \right)^3
\]

(V-27)

\[
\hat{h}_{ref} = h + \Delta h.
\]
b) Maximum centerline heat rate at reference conditions:

\[
\dot{q}_{\text{ref}} = \begin{cases} 
10^2 \left[ 277.93332 + 134.55760 \frac{h_{\text{ref}}}{10^5} - 807.75941 \left( \frac{h_{\text{ref}}}{10^5} \right)^2 
+ 2.90536 \left( \frac{h_{\text{ref}}}{10^5} \right)^3 + 722.36896 \left( \frac{h_{\text{ref}}}{10^5} \right)^4 - 311.40176 \left( \frac{h_{\text{ref}}}{10^5} \right)^5 \right] 
& \text{if } h_{\text{ref}} \geq 103 \text{ 600 m;} \\
10^4 \left[ 7115.39692 - 34 \ 881.13588 \frac{h_{\text{ref}}}{10^5} + 69 \ 844.23141 \left( \frac{h_{\text{ref}}}{10^5} \right)^2 
- 71 \ 534.98453 \left( \frac{h_{\text{ref}}}{10^5} \right)^3 + 37 \ 506.13054 \left( \frac{h_{\text{ref}}}{10^5} \right)^4 
- 8048.55112 \left( \frac{h_{\text{ref}}}{10^5} \right)^5 \right] 
& \text{if } h_{\text{ref}} \leq 103 \text{ 600 m;}
\end{cases}
\]

\[ (V-28) \]

\[
\dot{q}_{\max, \alpha} = \dot{q}_{\max, \alpha=50^\circ} = \left[ \ln (x) \right]^2,
\]

where \[ x = 10^2 \left[ 0.0116 + 0.01343 \frac{\alpha}{10^2} + 1.42672 \left( \frac{\alpha}{10^2} \right)^2 - 0.75623 \left( \frac{\alpha}{10^2} \right)^5 \right] + 0.30535 \left( \frac{\alpha}{10^2} \right)^2 - 1.06269 \left( \frac{\alpha}{10^2} \right)^3. \]

\[ (V-29) \]

\[
\dot{q}_{\max} = \frac{\dot{q}_{\max, \alpha}}{\dot{q}_{\max, \alpha=50^\circ}} \dot{q}_{\text{ref}}. 
\]

\[ (V-30) \]

In addition to the heat rate calculations, the program also provides the capability to calculate other aeroheating indicators that can be used for trajectory shaping purposes.

**Aerodynamic heating indicators.** The heating rate for zero total angle of attack \( \alpha_T \) is

\[
\dot{Q} = q V_A^2.
\]

\[ (V-31) \]
The aerodynamic heating indicator for zero total angle of attack is

\[ Q = \int_{0}^{t} \dot{Q} \, dt. \]  

(V-32)

The heating indicator for non-zero angles of attack is given by

\[ Q' = \int_{0}^{t} f (\alpha', M) \dot{Q} \, dt, \]  

(V-33)

where

\[ f (\alpha', M) = \left( 1 + \frac{7}{5} M^2 \sin^2 \alpha' \right)^{5/7}, \]

\[ K = \left\{ \begin{array}{ll}
1 + \frac{5}{M^2} & \text{for } \alpha' < 0^\circ \\
1 - (1 + \frac{7}{5} M^2 \sin^2 \alpha')^{2/7} & \text{for } \alpha' > 0^\circ \\
1 - (1 + \frac{7}{5} M^2 \sin^2 \alpha')^{2/7} & \text{for } \beta < 0^\circ \\
1 + \frac{5}{M^2} & \text{for } \beta > 0^\circ \\
\end{array} \right. \]

and

\[ \begin{align*}
\alpha' &= \alpha \\
Q_{\alpha} &= Q' \\
\alpha' &= \alpha \\
Q_{\beta} &= Q' \\
\alpha' &= \beta \\
Q_{\gamma} &= Q' \\
\alpha' &= \beta \\
Q_{\gamma} &= Q' \\
\end{align*} \]

(V-34)
The heating indicator for laminar flow is calculated as

\[ Q_{\text{lam}} = \int_0^t 17 \times 600 \cdot K_T \frac{\rho}{\rho_0} \left( \frac{V_A}{26 \times 000} \right)^{3.15} \, dt, \]  

(V-35)

where

\[ K_T = f (\alpha_T). \]  

(V-36)

The heating indicator for turbulent flow is calculated as

\[ Q_{\text{turb}} = \int 1500 \cdot K_T \frac{\rho}{\rho_0}^{0.8} \left( \frac{V_A}{10 \times 000} \right)^{3.18} \, dt \]  

(V-37)

Ten-Panel Vehicle Heating Model.— Special aeroheating calculations are available for a ten-panel vehicle model. The heating ratios are referenced to the heat rate calculation. The total heat for each panel is given by

\[ Q_i = H_{R_1} Q, \]  

(V-38)

where \( Q \) is the total heat and \( H_{R_1} \) is the heat ratio for panel \( i \). The weight for each panel is the product of the weight per unit area and the area of the panel. The total weight is the sum of the individual weights for each panel:

\[ W_p = \sum_{i=1}^{10} W_{uA_i} A_i \]  

(V-39)

where \( W_{uA_i} \) is the weight per unit area and \( A_i \) is the area of the \( i \)th panel.
Steering Model

The steering options control the attitude of the vehicle during the trajectory simulation. The general types of steering options available are:

1) Body rates;
2) Aerodynamic angles;
3) Inertial Euler angles;
4) Relative Euler angles.

The body rates are generally used to simulate strapdown-type systems and are computed from user-specified rate polynomials. The aerodynamic angles are generally used for re-entry problems, and the inertial and relative Euler angles are usually used to simulate vehicles that employ inertial or local horizontal reference systems. All of these angles can be computed from: (1) polynomials; (2) tables; (3) piecewise linear functions; or (4) closed-loop linear feedback systems.

The functional relationship used to compute the steering commands suggest two natural steering classifications:

1) Rate steering;
2) Angular steering.

These classifications provide an efficient outline for presenting the equations used to compute the steering commands.

Rate steering.- Rate steering uses the body rates, in conjunction with the quaternion equations, to determine the attitude of the vehicle. When using this option the user must specify:

1) The initial attitude of the vehicle;
2) The polynomial option used to compute the body rates.

The initial attitude is used internally to initialize the quaternion rate equation

\[ \dot{\hat{Q}} = \frac{1}{2} [\hat{\omega}] \hat{Q} \quad (V-40) \]
where

\[ e = (e_0, e_1, e_2, e_3), \]

\[ \omega = (\omega_x, \omega_y, \omega_z), \]

\[ [E] = \begin{bmatrix}
-e_1 & e_2 & e_3 \\
-e_0 & e_2 & -e_3 \\
e_0 & -e_1 & e_3 \\
e_0 & e_1 & -e_2
\end{bmatrix} \quad (V-41) \]

There are two options available for initializing the quaternion elements: (1) inertial Euler angles, and (2) aerodynamic angles. When inertial Euler angles are input the initial quaternion vector is given by

\[ e_0 = e (\phi_I) * e (\psi_I) * e (\theta_I) \quad (V-42) \]

where the asterisk denotes quaternion multiplication and where

\[ e (\phi_I) = \cos \left( 0.5 \phi_I \right) + \sin \left( 0.5 \phi_I \right) i \]

\[ e (\psi_I) = \cos \left( 0.5 \psi_I \right) + \sin \left( 0.5 \psi_I \right) k \quad (V-43) \]

\[ e (\theta_I) = \cos \left( 0.5 \theta_I \right) + \sin \left( 0.5 \theta_I \right) j. \]
When aerodynamic angles are input, then the initial quaternion vector is given by

\[ e_0 = e(\Lambda_{ZL}) * e(90) * e(\phi_L) * e(-\theta_L) * e(\theta_I) * e(-\phi_c) * e(-90) * e(\lambda_A) * e(\gamma_A) * e(\phi) * e(-\beta) * e(\alpha), \] (V-44)

where

\[ e(\Lambda_{ZL}) = \cos(0.5 \Lambda_{ZL}) - \sin(0.5 \Lambda_{ZL}) \hat{k} \]
\[ e(90) = \cos(45) + \sin(45) \hat{j} \]
\[ e(\phi_L) = \cos(0.5 \phi_L) + \sin(0.5 \phi_L) \hat{j} \]
\[ e(-\theta_L) = \cos(0.5 \theta_L) - \sin(0.5 \theta_L) \hat{k} \]
\[ e(\theta_I) = \cos(0.5 \theta_I) + \sin(0.5 \theta_I) \hat{k} \]
\[ e(\phi_c) = \cos(0.5 \phi_c) - \sin(0.5 \phi_c) \hat{j} \]
\[ e(\alpha) = \cos(0.5\alpha) + (\sin 0.5\alpha) \hat{i} \]
\[ e(-\beta) = \cos(0.5\beta) - (\sin 0.5\beta) \hat{k} \]
\[ e(\gamma_A) = \cos(0.5\gamma_A) + (\sin 0.5\gamma_A) \hat{j}. \]

The user must also select the option for computing the body rates. These options are combinations of the basic rate polynomials shown at the top of next page:
\[ \omega_x = \sum_{i=0}^{2} a_i x^i \]
\[ \omega_y = \sum_{i=0}^{2} b_i y^i \]
\[ \omega_z = \sum_{k=0}^{2} c_k z^i \]
\[ \hat{\omega} = \sum_{i=0}^{2} a_i x^i \]
\[ \hat{\beta} = \sum_{i=0}^{2} b_i y^i \]
\[ \hat{\sigma} = \sum_{i=0}^{2} c_i z^i \]

where \( a_i, b_i, \) and \( c_i \) are the polynomial coefficients, and \( x, y, \) and \( z \) are the polynomial arguments.

The available combinations of these basic rate polynomials are:

1) Input the coefficients and the arguments of \( \omega_x, \omega_y, \omega_z; \)
2) Input the coefficients and the arguments of \( \alpha, \beta, \sigma; \) and calculate \( \omega_x, \omega_y, \) and \( \omega_z \) via
\[ \begin{bmatrix} \omega_x \\ \omega_y \\ \omega_z \end{bmatrix} = \begin{bmatrix} a_1 + d_1\dot{\alpha} + (\sin \alpha) \dot{\beta} \\ a_2 + d_2\dot{\alpha} + \dot{\alpha} \\ a_3 + d_3\dot{\alpha} - (\cos \alpha) \dot{\beta} \end{bmatrix} \quad (V-47) \]

3) Input the coefficients of the \( \dot{\alpha}, \omega_y, \) and \( \omega_z \) polynomials and calculate \( \omega_x \) via

\[ \omega_x = a_1 + d_1\dot{\alpha} + \tan \alpha \left( a_3 + d_3\dot{\alpha} - \omega_z \right); \quad (V-48) \]

4) Input the coefficients of the \( \omega_x, \dot{\alpha}, \) and \( \omega_z \) polynomials and calculate \( \omega_y \) via

\[ \omega_y = a_2 + \dot{\alpha} + d_2 \left[ \frac{\omega_z - a_1 + \left( \frac{\omega_z - a_3}{\tan \alpha} \right) \tan \alpha}{d_1 + d_3 \tan \alpha} \right]; \quad (V-49) \]

5) Input the coefficients of the \( \omega_x, \omega_y, \) and \( \dot{\beta} \) polynomials and calculate \( \omega_z \) via

\[ \omega_z = a_3 - (\cos \alpha) \dot{\beta} + \frac{d_3}{d_1} \left[ \omega_x - a_1 - (\sin \alpha) \dot{\beta} \right]; \quad (V-50) \]

6) Input the coefficients of the \( \dot{\alpha}, \dot{\alpha}, \) and \( \omega_z \) polynomials and calculate \( \omega_x \) and \( \omega_y \) via

\[ \omega_x = a_1 + d_1\dot{\alpha} + \tan \alpha \left( a_3 + d_3\dot{\alpha} - \omega_z \right) \]

\[ \omega_y = a_2 + d_2\dot{\alpha} + \dot{\alpha} \quad (V-51) \]

7) Input the coefficients of the \( \omega_x, \alpha, \) and \( \dot{\beta} \) polynomials and calculate \( \omega_y \) and \( \omega_z \) via
\[
\begin{align*}
\omega_y &= a_2 + \dot{a} + \frac{d_2}{d_1} (\omega_x - a_1 - (\sin \alpha) \beta) \\
\omega_z &= a_3 - \cos \alpha \beta + \frac{d_3}{d_1} (\omega_x - a_1 (\sin \alpha) \beta)
\end{align*}
\]

(V-52)

\[
\begin{align*}
\omega_x &= a_1 + d_1 \dot{\varphi} + (\sin \alpha) \dot{\beta} \\
\omega_x &= a_3 + d_3 \dot{\varphi} - (\cos \alpha) \dot{\beta}
\end{align*}
\]

(V-53)

8) Input the coefficients of the \( \ddot{\varphi}, \omega_y, \) and \( \dot{\beta} \) polynomials and calculate \( \omega_x \) and \( \omega_z \) via

\[
\begin{align*}
\omega_x &= a_1 + d_1 \dot{\varphi} + (\sin \alpha) \dot{\beta} \\
\omega_x &= a_3 + d_3 \dot{\varphi} - (\cos \alpha) \dot{\beta}
\end{align*}
\]

(V-53)

9) Input the coefficients of the \( \dot{\psi}_R, \theta_R, \phi_R \) polynomials and calculate \( \omega_x, \omega_y, \) and \( \omega_z \) via

\[
\begin{bmatrix}
\omega_x \\
\omega_y \\
\omega_z
\end{bmatrix} =
\begin{bmatrix}
\dot{\psi}_R - \sin \theta_R \dot{\phi}_R \\
\cos \phi_R \dot{\psi}_R + \sin \phi_R \cos \theta_R \dot{\phi}_R \\
\cos \phi_R \cos \theta_R \dot{\psi}_R - \sin \phi_R \dot{\theta}_R
\end{bmatrix}
\]

(V-54)

where

\[
\mathbf{a} = \begin{bmatrix}
\frac{v}{r} \\
\frac{-u}{r} \\
\frac{-v}{r} \tan \phi_c
\end{bmatrix}
\]

(V-55)

V-19
The variables used in these equations are:

\[
\begin{bmatrix}
  u \\
  v \\
  w
\end{bmatrix} = [IG] \begin{bmatrix} x \\
\end{bmatrix},
\]  
\( (V-56) \)

\[
\begin{bmatrix}
  u_A \\
  v_A \\
  w_A
\end{bmatrix} = [IG] \begin{bmatrix} x_A \\
\end{bmatrix},
\]  
\( (V-57) \)

\[
\begin{align*}
  a_1 &= \begin{bmatrix}
  \frac{\ddot{v}}{r_I} - \gamma_A \sin \lambda_A \\
  -v \tan \phi_c + \dot{\lambda}_A \\
  \cos \lambda_A \cos \gamma_A
\end{bmatrix} \\
  a_2 &= [GB] \begin{bmatrix}
  -\frac{x}{r_I} + \gamma_A \cos \lambda_A \\
  -v \tan \phi_c + \dot{\lambda}_A \\
  \sin \lambda_A \cos \gamma_A
\end{bmatrix} \\
  a_3 &= [GB] \begin{bmatrix}
  \cos \lambda_A \cos \gamma_A \\
  \sin \lambda_A \cos \gamma_A \\
  -\sin \gamma_A
\end{bmatrix},
\]  
\( (V-58) \)

\[
\begin{align*}
  d_1 &= \begin{bmatrix}
  \dot{\gamma}_A - \frac{u_A \dot{v}_A - v_A \dot{u}_A}{u_A^2 + v_A^2} \\
  \frac{\ddot{v}_A \dot{w}_A - w_A \dot{v}_A}{v_A \sqrt{v_A^2 - u_A^2}}
\end{bmatrix} \\
  d_2 &= [GB] \begin{bmatrix}
  \dot{\gamma}_A - \frac{u_A \dot{v}_A - v_A \dot{u}_A}{u_A^2 + v_A^2} \\
  \frac{\ddot{v}_A \dot{w}_A - w_A \dot{v}_A}{v_A \sqrt{v_A^2 - u_A^2}}
\end{bmatrix} \\
  d_3 &= [GB] \begin{bmatrix}
  \dot{\gamma}_A - \frac{u_A \dot{v}_A - v_A \dot{u}_A}{u_A^2 + v_A^2} \\
  \frac{\ddot{v}_A \dot{w}_A - w_A \dot{v}_A}{v_A \sqrt{v_A^2 - u_A^2}}
\end{bmatrix},
\]  
\( (V-59) \)

where

\[
\dot{\lambda}_A = \frac{u_A \dot{v}_A - v_A \dot{u}_A}{u_A^2 + v_A^2},
\]  
\( (V-60) \)

\[
\ddot{\gamma}_A = \frac{-v_A \dot{w}_A + w_A \dot{v}_A}{v_A \sqrt{v_A^2 - u_A^2}}.
\]  
\( (v-20) \)
Angular steering.—Angular steering uses four different functional relationships to determine the attitude of the vehicle. These functional steering equations are:

1) Cubic polynomials;
2) Tables;
3) Piecewise linear equations;
4) Closed-loop linear feedback systems.

Each of these steering techniques is available for all of the steering angles; i.e., aerodynamic angles, inertial Euler angles, and relative Euler angles. There is also a separate channel steering capability. This option enables the user to specify different functional relationships in each triplet of steering angles. This means, for example, that the angle of attack could be computed from a polynomial, the bank angle from a table, and the sideslip angle by yet another method. However, this option does not allow the user to mix the steering triplets (i.e., mix the aerodynamic angles with the Euler angles).
In the following discussion, it is convenient to let $\theta$ denote an arbitrary steering angle. The steering equations described in terms of this variable then apply to all of the steering angles.

Polynomial steering: Under this option the steering angles are computed from a cubic polynomial

$$\theta(y) = \sum_{i=0}^{3} c_i y^i,$$  \hspace{1cm} (V-62)

where the user selects the coefficient $c_i$ and the independent variable $y$. The highest-order coefficient that is input determines the degree of the polynomial. The argument can be selected as any internally computed variable; e.g., time, velocity, altitude, etc. The constant term of the polynomial, $c_0$, can be either input at the beginning of each phase or carried across as the value of the angle at the end of the previous phase. The polynomial coefficients are generally used as the independent variables for targeting/optimization.

Table steering: Under this option the steering angles are computed via table interpolation, which is denoted by

$$\theta(y) = \theta_m t^n[f(y)].$$  \hspace{1cm} (V-63)

The user initially inputs the table multiplier $\theta_m$, the order or interpolation $t$, and the table data $(y, f(y))$. The table multiplier or the dependent table values can be used as independent variables for targeting or optimization. The order of interpolation can either be linear or cubic. The tables can be monovariant, bivariant, or trivariant functions of the table arguments.
Piecewise linear steering: Under this option the steering angles are computed from a general piecewise linear function of the form

\[ \theta(y) = c_1 + \left[ \frac{c_2 - c_1}{y_2 - y_1} \right] (y - y_1), \]  

where \( c_1 \) is equal to \( \theta \) at the beginning of the current phase, \( c_2 \) is the desired value of \( \theta \) at a designated later event, \( y \) is equal to the value of the designated event criterion at the beginning of the current phase, \( y_2 \) is the desired value of the designated event criterion at the designated event, and \( y \) is the current value of the designated event criterion.

This option is similar to the polynomial option except that the values of \( \theta \) are specified directly rather than as \( \theta_0, \dot{\theta}, \ddot{\theta} \). Clearly, \( \theta \) is linear in time if \( y = t \); otherwise \( \theta \) is only linear in \( y \). When the desired values of the steering angles are used as independent variables, the problem of cascaded steering effects is avoided and the targeting/optimization algorithm generally converges faster. This option also automatically computes the steering angle rates required to change the attitude to the desired value at the designated event, which reduces the problems related to guessing accurate initial pitch rates.

Linear feedback steering: Under this option the steering angles are computed from the linear error-error rate feedback control law

\[ \theta = c_1 + K_D (F_a - F_d) + K_R (F_a' - F_d'), \]  

where \( c_1 \) is a nominal steering angle profile, \( K_D \) is the displacement error gain, \( K_R \) is the rate gain, \( F_a - F_d \) is the error in the steering function \( F \), and \( F_a' - F_d' \) is the derivative of the steering function error.

This option is, of course, the classic path control law, and enables the user to steer to a wide variety of trajectory profiles, such as velocity vs altitude profile, acceleration vs altitude profile, etc. This option is particularly useful for reentry trajectory shaping.
Generalized Acceleration Steering. - Under this option the steering angles are computed by solving a set of user specified equations. The dependent and independent variables in these equations must be selected from the dictionary of variables already computed in POST. The only restriction is that these equations must be explicitly a function of some derivative computed in the inner loop of the program. As a consequence, this option cannot be used to solve equations that are functions of integrals of the equations of motion. For example, this option cannot be used to maintain constant altitude by zeroing \( \dot{h} \). This is because the time derivative of altitude is computed from velocity, and velocity is computed from the integral of acceleration. The linear feedback model should be used to solve problems involving integrals of the equations of motion.

In more precise terms, the steering variables are determined from the iterative solution of the problem:

For each instant of time, determine the values of the steering variables, \( \varphi \), that satisfy the steering equations,

\[
\mathbf{e}(\varphi) = \mathbf{y}(\varphi) - \mathbf{y}_d = 0,
\]

where \( \mathbf{y} \) is a \( n \)-component vector of dependent variables, \( \mathbf{y}_d \) is the desired value of these variables and \( \mathbf{e} \) the error in dependent variables.

Typical applications of this option are given as

1) Control normal acceleration to \( 1g \) and axial acceleration to \( 3g \) by calculating the angle of attack and throttle setting that solves the equations

\[
A_{\times B}(\alpha, \eta) - 96.6 = 0
\]
\[
A_{zB}(\alpha, \eta) - 32.2 = 0
\]

2) Obtain level unaccelerated flight by solving the equations

\[
\dot{V}_A(\alpha, \eta) = 0 \quad \text{(V-68)}
\]
\[
\dot{Y}_A(\alpha, r) = 0.
\]

Level unaccelerated flight is implicitly achieved in example 2 because \( \dot{V}_A = 0 \) implies constant velocity, and \( \dot{Y}_A = 0 \) implies constant altitude (that is, if \( \gamma_A = 0 \) when this option is initiated).
VI. TRAJECTORY SIMULATION

The following sections present the equations used in the trajectory simulation subroutines. These equations summarize the principal computations performed by the program, and motivate many of the program input procedures.

Events/Phases

Simulation data are input according to phase, where the phases are defined by a user-specified sequence of events. The simulation equations are then solved sequentially by phase. Therefore, the user is required to input a sequence of trajectory segments that define the problem being simulated from beginning to end. These trajectory segments, or phases, are defined by two events—a beginning event and an ending event. An event is an interruption of the trajectory simulation that occurs when a user-specified variable reaches a user-specified value. An event must be created whenever the user wishes to change any input data for the problem or to cause any change in the method of simulating the problem. For example, the sequence of events for a typical ascent problem could result in a simulation setup similar to that shown in figure VI-1.

Figure VI-1.- Event Sequence Setup
The event numbers for a given problem must be specified as real numbers by the user in monotonic increasing order. These event numbers are then used by the program to determine the order in which the events are to occur. The program requires that each problem have a minimum of two events—an initial event and a final event. Since a phase is initiated by the corresponding event, the event criterion for a given event specifies the conditions at the beginning of the corresponding phase. A problem is terminated by specifying the last event that is to occur. The problem can also be terminated in a pseudo-abort mode by specifying the maximum trajectory time, maximum altitude, or minimum altitude.

Although event numbers must be monotonic increasing, they need not be consecutive. This allows the user to easily add or delete events from an input deck.

Four types of events have been defined to provide flexibility in setting up a given problem:

1) Primary events - These describe the main sequential events of the trajectory being simulated. These events must occur, and must occur in ascending order according to the event number. Most problems will usually be simulated by a series of primary events;

2) Secondary events - These are events that may or may not occur during the specified trajectory segment. Secondary events must occur in ascending order during the interval bounded by the primary events. The occurrence of a primary event will nullify the secondary events associated with the previous primary event if they have not already occurred;

3) Roving primary events - These events can occur any time after the occurrence of all primary events with smaller event numbers. They can be used to interrupt the trajectory on the specified criterion regardless of the state of the trajectory or vehicle.

4) Repeating roving events - These events are the same as primary roving events except the interrupt values are input differently. There are two options for criteria value specifications. Option 1: Input the initial value, the increment, and the number of times the event is to be repeated. Option 2: Input an array of event criteria values.

The program monitors as many as ten events at a time, depending on the types of events to determine which event is to occur next. This gives the user a powerful tool for simulating complex problems.
Multiple events are monitored in the following sequence:

1) The next primary event is monitored;

2) As many as nine primary roving events are then monitored, provided there are no secondary events. A roving primary event is added to the list of those being monitored as soon as the primary event immediately preceding that roving event has occurred;

3) Next, as many as nine secondary events are monitored, provided there are no primary roving events. (Note that caution must be exercised when using secondary events because of their nature. Since as many as nine secondary events are monitored at a time, any one of those nine will occur as soon as its criterion has been met. Because they are secondary events, the event that occurs will cancel all secondary events with smaller event numbers.);

4) Finally, a total of nine primary roving and secondary events are monitored.

Since the program can only monitor nine events (in addition to the next primary event), the sum of the primary roving events and the secondary events must be less than or equal to nine or a fatal error will result.

The time-to-go model (TG/M) determines when the events occur during the trajectory simulation. Basically, TG/M checks the values of the criteria being monitored at each integration step. If none of the criteria values has bracketed the desired cutoff value, then another integration step is taken. If a criterion variable is bracketed with the input step size, then TG/M computes a new stepsize equal to the predicted time-to-go.

The predicted time-to-go for each event is computed from the equation

\[ \Delta t^* = -y(t) \Delta t / (y(t + \Delta t) - y(t)) \]  

where \( y(t) \) is the difference between the actual and the desired value of the event criterion. If more than one event is bracketed, then the minimum predicted time-to-go is used as the integration stepsize. This process is repeated until the criterion value is
within the specified tolerance of the desired value. If the desired condition cannot be achieved in 20 iterations, an error message is printed and the program stops. Generally this situation is caused by an input error. The fundamental features of the time-to-go logic are shown in figure VI-2.

Figure VI-2.- Illustration of Time-to-Go Logic

Translational Equations

The translational equations of motion are solved in the planet-centered inertial coordinate system. These equations are

\[ \ddot{\mathbf{r}}_I = \mathbf{v}_I \]  
\[ \dot{\mathbf{v}}_I = [\mathbf{I}_B]^{-1} \left[ \mathbf{A}_{TB} + \mathbf{A}_{AB} \right] + \mathbf{g}_I, \]

where \( \mathbf{A}_{TB} \) is the thrust acceleration in the body frame, \( \mathbf{A}_{AB} \) is the aerodynamic acceleration in the body frame, and \( \mathbf{g}_I \) is the gravitational acceleration in the ECI frame.
Initialization.- There are five options for initializing the velocity vector and two options for initializing the position vector. These options are described below.

Inertial position components \((x_I, y_I, z_I)\).—The inertial position components can be input directly since no transformation is required.

Earth-relative position \((\theta_I, \phi_I, \zeta_I, \theta, \zeta, \phi)\).—In this option the equations vary and the sequence of calculation varies according to the choice of input. However, the basic equations used are:

\[
\begin{align*}
\theta_I &= \theta + \sum p (t - t_0) \quad \text{if } \theta \text{ is input}, \\
\phi_I &= \tan^{-1} \left( k^2 \tan \theta \right) \quad \text{if } \phi \text{ is input}, \\
r_I &= h + R_s (\phi_I) \quad \text{if } h \text{ is input},
\end{align*}
\]  

\(\text{(VI-4)}\)

and

\[
r_I = r_I \begin{bmatrix} 
\cos \phi_I \\ \cos \phi_I \sin \theta_I \\ \sin \phi_I 
\end{bmatrix}
\]  

\(\text{(VI-5)}\)

Inertial velocity components \((V_{xI}, V_{yI}, V_{zI})\).—These variables can be input directly.

Inertial local horizontal \((V_I, \gamma_I, A_{zI})\).—The inertial components in the horizontal frame are first transformed to the geographic frame as

\[
V_{IG} = V_I \begin{bmatrix} 
\cos \gamma_I \cos A_{zI} \\ \cos \gamma_I \sin A_{zI} \\ -\sin \gamma_I
\end{bmatrix}
\]  

\(\text{(VI-6)}\)
and then transformed to the ECI frame by

$$V_I = [IG]^{-1} V_{IG}$$  \hspace{1cm} (VI-7)

Earth-relative local horizontal \((V_R, \gamma_R, AZ_R)\). The Earth-relative velocity components are first transformed to the geographic frame as

$$V_{RG} = V_R \begin{bmatrix} \cos \gamma_R \cos AZ_R \\ \cos \gamma_R \sin AZ_R \\ -\sin \gamma_R \end{bmatrix}$$  \hspace{1cm} (VI-8)

and then transformed to the ECI frame by

$$V_I = [IG]^{-1} V_{RG} + \Omega_p \times r_I$$  \hspace{1cm} (VI-9)

Atmospheric relative local horizontal \((V_A, \gamma_A, AZ_A)\). The atmospheric relative velocity components are first transformed to the geographic frame as

$$V_{AG} = V_A \begin{bmatrix} \cos \gamma_A \cos AZ_A \\ \cos \gamma_A \sin AZ_A \\ -\sin \gamma_A \end{bmatrix} + \begin{bmatrix} V_{WXG} \\ V_{WYG} \\ V_{WZG} \end{bmatrix}$$  \hspace{1cm} (VI-10)

and then transformed to the ECI frame by

$$V_I = [IG]^{-1} V_{AG} + \Omega_p \times r_I$$  \hspace{1cm} (VI-11)

Orbital parameters \((h_p, h_a, i, \Omega, \omega, \theta)\). This option initializes both position and velocity. The equations used to transform the orbital parameter to the ECI position and velocity are:
\[ \begin{align*}
\mathbf{r}_p &= \mathbf{h}_p + \mathbf{r}_E \\
\mathbf{r}_a &= \mathbf{h}_a + \mathbf{r}_E \\
&= \frac{(\mathbf{r}_a + \mathbf{r}_p)}{2} \\
e &= \frac{(\mathbf{r}_a - \mathbf{r}_p)}{(\mathbf{r}_a + \mathbf{r}_p)} \\
\rho &= \theta + \omega \\
p &= a (1 - e^2) \\
\mathbf{H} &= \mu p \\
r &= p/(1 + e \cos \theta)
\end{align*} \]

and

\[ \begin{align*}
\mathbf{r} &= \mathbf{r}_a \\
\mathbf{V} &= \mu \left[ \frac{2}{r} - \frac{1}{a} \right] \\
\mathbf{\gamma} &= \sin^{-1} \left( \frac{\mathbf{H}}{r \mathbf{V}} \right)
\end{align*} \]

\( (VI-12) \)

\( (VI-13) \)

\[ \begin{align*}
\mathbf{u}_r &= \begin{bmatrix} 
\cos \Omega & -\sin \Omega & 0 \\
\sin \Omega & \cos \Omega & 0 \\
0 & 0 & 1
\end{bmatrix} \begin{bmatrix} 
1 & 0 & 0 \\
0 & \cos i & -\sin i \\
1 & \sin i & \cos i
\end{bmatrix} \begin{bmatrix} 
\cos \rho \\
\sin \rho \\
0
\end{bmatrix} \\
\mathbf{u}_\gamma &= \begin{bmatrix} 
\cos \Omega & -\sin \Omega & 0 \\
\sin \Omega & \cos \Omega & 0 \\
0 & 0 & 1
\end{bmatrix} \begin{bmatrix} 
\cos \gamma \\
\sin \gamma \\
0
\end{bmatrix}
\end{align*} \]

\( VI-7 \)
Instantaneous velocity additions.- At the beginning of each event an instantaneous velocity can be added in the direction of the thrust vector. The magnitude of the velocity addition can be input directly, or can be calculated from the rocket equation from the amount of propellant consumed

$$\Delta V = \frac{I_{sp}}{\Delta \mu_G} \ln \left( \frac{W_G}{W_G - W_{PC}} \right)$$  \hspace{1cm} (VI-15)

If $\Delta V$ is input, then the amount of propellant required to achieve this change in velocity is given by

$$W_{PC} = W_G \left[ 1 - \exp \left( - \frac{\Delta V / I_{sp}}{\Delta \mu_G} \right) \right]$$  \hspace{1cm} (VI-16)

The inertial velocity after the impulse is then given by

$$v_i^+ = v_i^- + \Delta V \begin{bmatrix}
\cos i_y \\
\sin i_y \\
\cos i_p \\
\sin i_p
\end{bmatrix}$$  \hspace{1cm} (VI-17)

This option is generally used to simulate short burns for orbital maneuvers. The direction of the impulse is controlled via the attitude of the vehicle and the engine gimbal angles.

Static Trim

The static trim option is used to calculate the engine gimbal angles or the flap deflection angles required to balance the pitch and yaw moments caused by the thrust and aerodynamic forces.

The static moment equation,

$$M = 0,$$  \hspace{1cm} (VI-18)

is generally nonlinear, and thus an iterative algorithm is used to determine the required solutions. This algorithm is a successive
approximation technique based on the analytical solutions that result from small-angle approximations. The computation of the pitch and yaw moments is presented below.

**Moment equation in the pitch plane.** - The aerodynamic moment and thrust moments for the $i$th engine are shown in figure 16. The locations of the center of gravity, the aerodynamic reference, and the engine gimbal points are specified in the body references system.

![Diagram of moments in pitch](image)

**Figure VI-3. - Moments in Pitch**

The total aerodynamic moment in pitch is

$$A_{MP} = qS \left( C_M x_{RP} + C_N \Delta x_R - C_A \Delta z_R \right). \quad \text{(VI-19)}$$

The total thrust moment in pitch for the nontrimming engines is

$$T_{MP} = \sum_{i=1}^{N_T} T_i \cos i \left( \cos \theta \Delta z_i - \sin \theta \Delta x_i \right), \quad \text{(VI-20)}$$
and the moment for the trimming engines is

\[ T_{\text{M2P}} = \cos \alpha \sum_{i=1}^{N_T} T_{R_i} \cos \phi \Delta z_p \]

\[ - \sin \alpha \sum_{i=1}^{N_T} T_{R_i} \cos \phi \Delta x_p \]  

\[ (VI-21) \]

The static moment equation in the pitch plane is then given by

\[ M_p = A_{MP} + T_{M1P} + T_{M2P} \]

\[ (VI-22) \]

where \( A_{MP} \) depends on the flap deflection angles and \( T_{M2P} \) depends on the engine gimbal angles.

**Moment equation in the yaw plane.** The aerodynamic moment and the thrust moment for the \( i \)th engine are shown in figure 17.

![Diagram](image)

**Figure VI-4.** Moments in Yaw
The total aerodynamic moment in yaw is

\[ A_{MY} = qS \left( C_n \Delta x_R + C_Y \Delta y_R - C_A \Delta y_R \right). \]  

(VI-23)

The total thrust moment in yaw for the nontrimming engines is

\[ T_{MY} = \sum_{i \in N_T} T_{R1} \left( \cos \theta_1 \cos \phi_1 \Delta y_1 + \sin \theta_1 \Delta x_1 \right), \]  

(VI-24)

and the moment for the trimming engines is

\[ T_{M2Y} = \cos \theta \sum_{i \in N_T} T_{R1} \cos \phi_1 \Delta y_1 \]
\[ + \sin \phi \sum_{i \in N_T} T_{R1} \Delta x_1. \]  

(VI-25)

The static moment equation in the yaw plane is then given by

\[ M_y = A_{MY} + T_{MY} + T_{M2Y}, \]  

(VI-26)

where \( A_{MY} \) depends on the flap deflections and \( T_{M2Y} \) depends on the engine gimbal angles.

**Integration Methods**

The number of integrals computed during any particular phase is determined from the options requested by the user. As a minimum, the translational equations of motion are integrated to give the position and velocity of the center of mass of the vehicle. The user may also select additional variables to be integrated. The only restriction is that no more than 30 integrals can be computed per phase.
POST contains 3 general purpose integration methods and several special purpose orbital propagation methods. These methods are summarized below.

Runge-Kutta Methods.—POST contains two Runge-Kutta integration methods: (1) the standard 4th order method, and (2) an 8th order method. The calculations for these integration methods are based upon the formula

\[ y_{n+1} = y_n + \sum_{i=1}^{s} b_i k_i, \]

where

\[ k_i = hf\left(x_n + c_i h, y_n + \sum_{j=1}^{s} a_{ij} k_j\right), \quad i=1,2,\ldots,s. \]

These formula are represented by the array

\[
\begin{array}{cccc}
c_1 & \quad a_{11} & a_{12} & \cdots & a_{1s} \\
c_2 & \quad a_{21} & a_{22} & \cdots & a_{2s} \\
\vdots & \quad \vdots & \vdots & \ddots & \vdots \\
c_s & \quad a_{s1} & a_{s2} & \cdots & a_{ss} \\
\hline
b_1 & b_2 & \cdots & b_s
\end{array}
\]

The coefficients for the two methods are given in Tables VI-1 and VI-2, respectively.

Runge-Kutta 8th order (Shanks (1966))

Krogh Variable-Step Variable-Order Integrator

The variable-step length variable-order predictor-corrector developed by F. T. Krogh of the Jet Propulsion Laboratories procedure represents the state-of-the-art in numerical solution of systems of ordinary differential equations. It includes all of the following facilities:

1) A core integrator for advancing the solution from one uniform step to the next consisting of variable order Adams predictor-corrector equations requiring the storage of a difference table for only the highest ordered derivatives;

2) A method to scale integration with first-order equations and increase the order to as high a level as numerical stability permits;

3) Algorithms for changing the step size and updating accordingly the difference tables of the highest-order derivatives including appropriate smoothing to prevent numerical instability;

4) Algorithms for deciding when and by how much to change the step size based upon the accuracy requested by the user;

5) Tests for numerical stability of the predictor-corrector order and step size tentatively chosen in the context of the current differential equation set;
6) Test for accuracy requests that are so stringent that round-off error prevents their satisfaction;

7) Algorithms for the automatic selection of the core integrator to fit the characteristics of the set of differential equations at hand.

8) An interpolation algorithm for obtaining dependent variable values to the user-specified accuracy at values of the independent variable different from normal integration steps.

The Krogh integrator was developed to meet the conflicting goals of (1) reliability, (2) efficiency (in the sense of minimizing the number of derivative evaluations to obtain a given accuracy), (3) flexibility, (4) low integration overhead, and (5) small storage requirements. The goals are listed in the order in which they are emphasized in the procedures. The package has no equal in reliability. All the user need provide the integrator is his accuracy requirement and a tentative step size that is less than the integration interval. The integrator then uses all eight of its algorithms to provide a solution requiring as few derivative evaluations as possible while remaining within accuracy tolerances.

This documentation restricts itself to algorithms (1), (2), and (3). Algorithm (3) is thoroughly described in Reference 9. Algorithms (4) through (7) are not amenable to rigorous mathematical analysis, but rather have evolved from extensive numerical experimentation by Krogh and his associates at JPL. They are adequately described in the source code and references. Further, to simplify exposition, equations will be given for the single $d^{th}$ order differential equation

$$ y^{(d)} = f(t, Y, Y^1, \ldots, Y^{d-1}) $$

The following notation is used:

- $t$ = independent variable
- $h$ = integration step size
- $y(t)$ = corrected (final estimated) value of $Y(t)$
- $t_n$ = value of $t$ at current integration step
- $t_{n+k} = t_n + kh$
- $y_n$, $Y_n$, $y_n^1$, $\ldots$ = $y(t_n)$, $Y(t_n)$, $y^1(t_n)$, $\ldots$
- $p_n$ = predicted (initial estimated) value of $Y(t_n)$
- $f_n = f(t_n, y_n, y_n^1, \ldots, y_n^{(d-1)})$
The predictor and corrector equations of the core integrator are obtained by integrating Newton's interpolating polynomials for the most recent $q$ and $q+1$ values, respectively, of the highest order derivative, $f$. For the predictor, $f$ is approximated as the $(q-1)$th degree polynomial

$$v_{i}^{f}_{n} = \begin{cases} f_{n} & \text{for } i=0 \\ v_{i-1}^{f}_{n} - v_{i-1}^{f}_{n-1} & \text{for } i=1,2, \ldots \end{cases} \quad [10]$$

$$v_{p}^{f}_{n} = \begin{cases} f(t_{n}, p_{n}, p_{n}^{1}, \ldots, p_{n}^{d-1}) & \text{for } i=0 \\ v_{i-1}^{f}_{n} - v_{i-1}^{f}_{n-1} & \text{for } i=1,2, \ldots \end{cases} \quad [11]$$

Successively integrating approximation [12] from $s=0$ to $s=1$ yields the predictor equations.

$$f_{n+s}^{P} = \sum_{i=0}^{q-1} (s + i-1) v_{i}^{f}_{n} \approx f(x_{n} + sh). \quad [12]$$

For the corrector, $f$ is approximated as the $q^{th}$ degree polynomial

$$f_{n+s}^{C} = f_{n+s}^{P} + \sigma_{q0}(s) \gamma_{4j}^{f}_{n} \approx f(x_{n} + sh). \quad [17]$$
Successively integrating approximation [17] from \( s=0 \) to \( s=1 \) generates the corrector equations

\[
y_{n+1}^{(d-j)} = p_{n+1}^{(d-j)} + h^j \gamma_{q_j} v^{q_f} n+1 \quad \text{for } j=1, \ldots, d. \tag{18}
\]

Notice that in the equations [13] and [18] the coefficients \( \gamma_{ij} \) are independent of the order, \( q \). Hence, Adam's method has the practical advantage that its order can be increased simply by adding more terms to the predictor and corrector equations without revising their coefficients. Systems of differential equations are handled by applying equations [13] and [18] to each component of the system. Different components may have different values of \( d \) and \( q \).

The starting algorithm requires no special techniques such as Runge-Kutta equations or Taylor-series expansions. Instead, \( q \) is simply taken as 1 in the normal predictor and corrector equations. There is, nonetheless, a starting phase during which the highest-order derivative evaluation following the calculation of the corrected values of the integrals is skipped. During this starting phase, the values of \( q \) and \( h \) increase quite rapidly. When numerical stability problems appear during this initial phase, the ordinary corrector equation, [18], is replaced by

\[
y_{n+1}^{(d-j)} = p_{n+1}^{(d-j)} + h^j \alpha \gamma_{q_j} v^{q_f} n+1 \quad \text{for } j=1, 2, \ldots, d. \tag{19}
\]

Here \( \alpha \) is chosen on the closed interval from \( \frac{1}{2} \) to 1 to give optimal stability characteristics.

Algorithms [3] for changing the step size are only equipped to double or halve \( h \). Hence, algorithm [4] for selecting the step size is restricted in the same way. Both procedures are, however, very efficient so that adjustment to the optimal step length occurs as quickly as reliability permits. The two algorithms are described in detail in Reference 11.

Like the predictor and corrector equations, the interpolation equations of algorithm [8] are also generated by successively integrating a \( q \)-degree interpolating polynomial for the highest order derivative. Indeed

\[
f_{n+s}^{(d+1)} = \sum_{i=0}^{q} \left( \begin{array}{c} s + 1 - 2 \end{array} \right) v^i f_{n+1}^i \approx f(x_n + sh) \tag{20}
\]
\[ y_{n+s}^{(d-1)} = y_n^{(d-1)} + \sum_{l=0}^{q} \rho_{il} v^l f_{n+s}^\circ \approx y^{(d-1)}(x_n + sh) \quad [21] \]

where
\[ \rho_{il} = \int_0^1 \left( s + i - 2 \right) ds \quad [22] \]

Evaluating the differences, \( v^l f_{n+s}^\circ \), using definition [20] and substituting the results into definition [21] yields
\[ y_{n+s}^{(d-j)} = y_n^{(d-1)} + \sum_{l=0}^{q} \left[ \sum_{i=0}^{1} \rho_{il}^l \left( s + i - l - 2 \right) \right] v^l f_{n+l} \quad [23] \]

Generalizing this procedure to derivatives of lower order produces
\[ y_{n+s}^{(d-j)} = \sum_{k=0}^{j-1} \frac{s^k}{k!} y_n^{(d-j+k)} + h^j \sum_{i=0}^{q-j} \tau_i^j v^i f_{n+l} \quad [24] \]

for \( j=1, \ldots, d \)

where
\[ \tau_i^0 (s) = \left( s + i - 2 \right) \quad [25] \]

and
\[ \tau_i^j (s) = \sum_{k=0}^{q-j} \rho_{ik} \tau_k^{(i-k+1)} (j-1) (s) \quad [26] \]
Laplace's method.—Laplace's method is an iterative technique for propagating the position and velocity (in planet-centered coordinates) of a nonthrusting vehicle in vacuum during flight over a spherical planet. The technique is based on the analytical solution of the two-body equations, and yields the inertial state at time \( t + \Delta t \) as a function of the state at time \( t \).

The equations used in Laplace's method are:

\[
\begin{align*}
\xi_I(t + \Delta t) &= f \xi_I(t) + g \nu_I(t) \\
\nu_I(t + \Delta t) &= \dot{f} \xi_I(t) + \dot{g} \nu_I(t),
\end{align*}
\]  

(VI-27)

where the scalar coefficients \( f \), \( g \), \( \dot{f} \), and \( \dot{g} \) are given in Table VI-3.

### Table VI-3 - \( f \) and \( g \) Series

<table>

<td>( 1 - 2 \frac{a}{r_{n+1}} \sin^2 \frac{AE}{2} )</td>
<td>( 1 + 2 \frac{a}{r} \sinh^2 \frac{AE}{2} )</td>
</tr>
</tbody>
</table>

*Note that \( r_j = |r(t + j \Delta t)| \), and \( n = \frac{2\pi}{p} \).

As indicated in the above table, the \( f \) and \( g \) coefficients are computed analytically from the change in eccentric anomaly during the time period \( \Delta t \). This is in contrast to the standard Laplacian method, where these coefficients are infinite series in \( \Delta t \). The change in eccentric anomaly is calculated by solving a special version of Kepler's equation via the Newton-Raphson algorithm

\[
\Delta E_{n+1} = \Delta E_{n} - \frac{F(\Delta E)}{F'(\Delta E)}, \ n = 1, 2, \ldots, 10.
\]  

(VI-28)
This algorithm converges rapidly from the initial estimate

\[ \Delta E_0 = n \Delta t. \]  

The form of Kepler's equation that is computationally efficient for this application is

\[
F(\Delta E) = \begin{cases} 
\left(\frac{r}{a} - 1\right) \sin \Delta E + 2 \frac{r \cdot \nu_n}{\sqrt{\mu} a} \sin^2 \frac{\Delta E}{2} + \Delta E - n \Delta t, & \text{for } e < 1 \\
\left(\frac{r}{a} - 1\right) \sinh \Delta E - 2 \frac{r \cdot \nu_n}{\sqrt{\mu} a} \sinh^2 \Delta E + \Delta E - n \Delta t, & \text{for } e > 1.
\end{cases}
\]

The derivative \( dF/d\Delta E \) used in the Newton-Raphson algorithm is given by

\[
F'(\Delta E) = \begin{cases} 
\left(\frac{r}{a} - 1\right) \cos \Delta E + \frac{r \cdot \nu_n}{\sqrt{\mu} a} \sin \Delta E - 1, & \text{for } e < 1 \\
\left(\frac{r}{a} - 1\right) \cosh \Delta E - \frac{r \cdot \nu_n}{\sqrt{\mu} a} \sinh \Delta E - 1, & \text{for } e > 1.
\end{cases}
\]

Encke's method. - The Encke method used in this program is modified from the usual Encke technique in that it rectifies the reference conic at every integration step and does not use the standard Q-series expansion in calculating the gravitational increment.

The Encke method should be used for orbital problems where small perturbing accelerations, such as the oblateness of the planet, atmospheric drag, or solar electric propulsion, must be included in the simulation. Numerical results indicate that, for problems involving small perturbations from Keplerian motion, Encke's method is approximately four times faster than Cowell methods, which integrate the total acceleration.

The Encke method determines the total motion by summing the motion due to the two-body equations and the motion due to the perturbations to the two-body equations. The position and velocity in the inertial planet-centered system at time \( t + \Delta t \) is given by
\[
\begin{align*}
\mathbf{r}_1(t + \Delta t) &= \mathbf{r}_2(t + \Delta t) + \Delta \mathbf{r}(t + \Delta t) \\
\mathbf{v}_1(t + \Delta t) &= \mathbf{v}_2(t + \Delta t) + \Delta \mathbf{v}(t + \Delta t),
\end{align*}
\]  
(VI-32)

where \((\mathbf{r}_2, \mathbf{v}_2)\) denotes the Keplerian motion computed by Laplace's equations; that is,

\[
\begin{align*}
\mathbf{r}_2(t + \Delta t) &= f \mathbf{r}_2(t) + g \mathbf{v}_2(t) \\
\mathbf{v}_2(t + \Delta t) &= f \mathbf{v}_2(t) + g \mathbf{v}_2(t),
\end{align*}
\]  
(VI-33)

and \((\Delta \mathbf{r}, \Delta \mathbf{v})\) denotes the numerical solution of the differential equations

\[
\begin{align*}
\Delta \mathbf{r} &= \Delta \mathbf{v} \\
\Delta \mathbf{v} &= \left[(1b)^{-1} [A_{TB} + A_{AB}] + g_1\right] - g_2(\mathbf{r}_2 + \Delta \mathbf{r}) \\
\Delta \mathbf{r}(t) &= \Delta \mathbf{v}(t) = 0,
\end{align*}
\]  
(VI-34)

where \(g_2(\mathbf{r}_2 + \Delta \mathbf{r})\) is the two-body acceleration at \(\mathbf{r}_2 + \Delta \mathbf{r}\).
The Runge-Kutta or Adams-Bashforth method can then be used to solve the above equations.

**Integration step models.**—The integration step, \(\Delta t\), is generally specified in terms of an increment in time. However, this option enables the user to specify the integration step in terms of an input increment in true anomaly. This option is useful in orbital problems where the geometry is easily expressed as a function of true anomaly.

The following equations are then used to calculate \(\Delta t\) as a function of \(\Delta \theta\).

\[
\begin{align*}
\theta_2 &= \theta_1 + \Delta \theta \\
E_2 &= 2 \tan^{-1}\left(\frac{1-e}{1+e} \tan \frac{\theta_2}{2}\right) \\
r_2 &= a(1 - e \cos E_2) \\
\Delta E &= E_2 - E_1 \\
\Delta t &= \sqrt{\frac{a^3}{\mu}} (\Delta E - \sin \Delta E) + \frac{r_2 f_1}{H} \sin \Delta \theta.
\end{align*}
\]  
(VI-35)

In these equations, subscripts 1 and 2 denote current and future values, respectively.
Launch Options

There are two specific options for simulating particular launch conditions: (1) hold-down for vertical takeoff, and (2) hold-down for horizontal takeoff. These specialized options are required to simulate certain physical constraints that are not modeled in the equations of motion.

Hold-down for vertical takeoff.—This option is used to simulate vertical (rocket type) takeoff. When using this option, the relative position and velocity remains constant while the inertial position changes by the Earth rotation. The inertial velocity magnitude remains constant while its direction changes. This model simulates physical constraints that hold the rocket on the launch pad until the rocket is released. The equations used to calculate the accelerations that produce this motion are

\[ \mathbf{A}_I = \mathbf{\Omega} \times \mathbf{V}_I \]  \hspace{1cm} (VI-36)

Hold-down for horizontal takeoff.—This option is used to simulate horizontal (aircraft type) takeoff. When using this option the vehicle accelerates in the local horizontal plane according to the forces described by the user input. The vertical component of acceleration is internally computed to produce the proper horizontal motion. The equations used are:

\[
\begin{bmatrix}
A_x \\
A_y \\
A_h \\
A_c
\end{bmatrix} =
\begin{bmatrix}
-A_{2G} \\
\sqrt{A_{2G}^2 + A_{1G}^2} \\
\sqrt{V_{XG}^2 + V_{YG}^2} / r_I
\end{bmatrix}
\]

and

\[ \mathbf{A}_I = [\mathbf{I}_G]^{-1} \mathbf{A}_{xG} \]  \hspace{1cm} (VI-38)
VII. AUXILIARY CALCULATIONS

In addition to computing the basic variables, POST also computes numerous auxiliary variables that are related to: (1) conic parameters, (2) range calculations, (3) tracking data, (4) analytic impact calculations, (5) velocity losses, and (6) velocity margins. The equations used to calculate these variables are presented below.

Conic Calculations

The following Keplerian conic variables are computed.

\[ \delta \] energy, \( \frac{1}{2} \frac{V^2}{I} - \frac{u}{r_I} \)

\[ a \] semimajor axis, \(-\mu/2\delta\)

\[ h \] angular momentum, \( |\mathbf{x}_I \times \mathbf{v}_I| \)

\[ p \] semilatus rectum, \( h^2/\mu \)

\[ e \] eccentricity, \( \sqrt{1 - p/a} \)

\[ \Delta V \] velocity required to circularize orbit, \( \sqrt{\Delta V \cdot \Delta V} \), where

\[ u_h = h/h \]

\[ u_{RI} = r_I/r_I \]

\[ u_v = u_h \times u_{RI}/|u_h \times u_{RI}| \]

\[ v_c = (\mu/r_I)^{1/2} u_v \]

\[ \Delta V = v_c - v_I \]

\[ i \] inclination, \( \cos^{-1} (h_z/h) \)

\[ \Omega \] longitude of ascending node, \( \cos^{-1} (\mathbf{x}_I \cdot \mathbf{u}_\Omega) \), where
\[ u_q = \frac{e_I \times h}{|e_I \times h|} \]

\[ \rho \quad \text{argument of vehicle, } \rho = \cos^{-1} \left( \frac{u_T \cdot u_q}{u_T \cdot u_q} \right) \]

\[ T_{SP} \quad \text{time since perigee, } \frac{P}{2\pi} - M \]

\[ T_{TP} \quad \text{time to perigee, } P - T_{SP} \]

\[ \phi_p \quad \text{latitude of perigee, } \tan^{-1} \left( \frac{u_3}{\sqrt{u_1^2 + u_2^2}} \right), \text{ where} \]

\[ u = \cos(\omega)u_q + \sin(\omega) \left( \frac{u_h \times u_q}{u_h \times u_q} \right) \]

\[ \theta_p \quad \text{longitude of perigee, } \tan^{-1} \left( \frac{u_2}{u_1} \right) \]

\[ h_p \quad \text{altitude of perigee, } \frac{r_p - R_s(\phi_p)}{a} \]

\[ h_a \quad \text{altitude of apogee, } \frac{r_a - R_s(\phi_p)}{a} \]

\[ V_p \quad \text{velocity at perigee, } \sqrt{\frac{u}{a} \left( \frac{1 + e}{1 - e} \right)} \]

\[ V_a \quad \text{velocity at apogee, } \sqrt{\frac{u}{a} \left( \frac{1 - e}{1 + e} \right)} \]

\[ V_\infty \quad \text{hyperbolic excess velocity, } \sqrt{2\delta} \]

\[ \theta_{\text{max}} \quad \text{maximum true anomaly for hyperbolic orbit, } \cos^{-1} \left( -\frac{1}{e} \right) \]

\[ \delta_{\text{RA}} \quad \text{declination of outgoing asymptote, } \sin^{-1} \left[ \frac{u_{r_\infty}}{u_{r_\infty}}(3) \right], \text{ where} \]

\[ u_T = u_h \times u_{RI} \]

\[ u_{r_\infty} = \cos(\theta_{\text{max}} - \theta) \frac{u_{rI}}{u_{rI}} + \sin(\theta_{\text{max}} - \theta) \frac{u_T}{u_T} \]

\[ R_A \quad \text{right ascension of outgoing asymptote, } \tan^{-1} \left( \frac{u_{r_\infty} (2)}{u_{r_\infty} (3)} \right) \]
\[ \theta = \text{true anomaly, } \cos^{-1}\left(\frac{1}{e}\left(\frac{p}{r} - 1\right)\right) \]

\[ E = \text{eccentric anomaly, } 2\tan^{-1}\left(\sqrt{\frac{1-e}{1+e}}\tan\frac{\theta}{2}\right) \]

\[ M = \text{mean anomaly, } E - e\sin E \]

\[ \omega = \text{argument of perigee, } p - \theta \]

\[ r_p = \text{perigee radius, } a(1-e) \]

\[ r_a = \text{apogee radius, } a(1+e) \]

\[ P = \text{period, } 2\pi\sqrt{\frac{a^3}{\mu}} \]

Range Calculations

The program provides for various types of range calculations. The equations for these calculations are given below.

**Dot product downrange.** - The relative range angle, measured from the vehicle's initial position to its current position, is given by

\[ \phi_R = \cos^{-1}\left(\frac{u_r}{r_{so}} \cdot \frac{u_r}{r_s}\right), \quad (VII-1) \]

where \( u_{r_{so}} \) is a unit vector along the initial position vector in Earth-centered rotating coordinates and \( u_{r_s} \) is a unit vector along the current position vector in Earth-centered rotating coordinates. The range over an oblate spheroid is calculated from the average radius to the surface, and is given by

\[ R_D = \left[\frac{r_{so} + r_s}{2}\right] \phi_R, \quad (VII-2) \]

**Crossrange and downrange via orbital plane reference.** - Referring to figure VII-1, identify the vehicle's position at time \( t^* \) by \( O \), and at a later time \( t \) by \( P \). At time \( t^* \), the vehicle has a latitude of \( \phi^* \), a longitude of \( \theta^* \), and a velocity.
Note: 0 - position at initial time,
      p - position at subsequent time.

Figure VII-I.- Downrange and Crossrange Angles
heading of \( \lambda^* \). At time \( t \) the vehicle is at latitude \( \phi \) and longitude \( \theta \). The downrange angle (\( \mu \)) and the crossrange angle (\( \nu \)) shown in the illustration are measured along, and normal to, the great circle through \( O \), and are inclined to the meridian by \( \lambda^* \). From analytical geometry, \( \nu \) and \( \mu \) can be expressed as

\[
\sin \nu = -\sin \lambda^* \sin \phi \cos \phi_c \cos \theta' - \cos \lambda^* \cos \phi_c \sin \theta \\
+ \sin \lambda^* \cos \phi \sin \phi_c \\
\sin \mu = (-\cos \lambda^* \sin \phi \cos \phi \cos \theta' + \sin \lambda^* \cos \phi \sin \theta') \\
+ \cos \lambda^* \cos \phi \sin \phi_c) / \cos \nu
\]

\[
\cos \mu = \left( \cos \phi \cos \phi \cos \theta' + \sin \phi \sin \phi_c \right) / \cos \nu,
\]

where \( \theta^* \) and \( \lambda^* \) can be defined in either of two ways:

1) The great circle to which \( \nu \) and \( \mu \) are referenced is fixed and rotating with the Earth. Then

\[
\lambda^* = \text{Earth's relative heading} = \sin^{-1} \frac{v_R}{\sqrt{u_R^2 + v_R^2}}
\]

\[
\theta' = \theta - \theta^*;
\]

2) The great circle to which \( \mu \) and \( \nu \) are referenced is inertially fixed, having the Earth rotating below it. Then

\[
\lambda^* = \text{inertial heading} = \sin^{-1} \frac{v}{\sqrt{u^2 + v^2}}
\]

\[
\theta' = \theta - \theta^* + \Omega (t - t^*).
\]
Knowing \( v \) and \( \mu \), and crossrange \( C_R \) and downrange \( D_R \) distances are

\[
\begin{align*}
C_R &= R_{ave} v \\
D_R &= R_{ave} \mu,
\end{align*}
\]  

(VII-6)

where \( R_{ave} \) is the average Earth radius between the initial and final points.
Auxiliary Position and Velocity Calculations

The solution from the translational equations is then used to calculate numerous output variables. The key variables directly computed from \( (x_I, y_I, z_I) \) and \( (V_{XI}, V_{YI}, V_{ZI}) \) summarized below.

\[
\begin{align*}
r_I &= \text{geocentric radius} \\
     &= \left( \mathbf{r}_I \cdot \mathbf{r}_I \right)^{\frac{1}{2}} \\
V_I &= \text{magnitude of the inertial velocity} \\
     &= \left( V_I \cdot V_I \right)^{\frac{1}{2}} \\
V_R &= \text{relative velocity} \\
     &= V_I - \Omega_p \times r_I \\
V_A &= \text{atmospheric relative velocity} \\
     &= V_R + V_W \\
V_R &= \text{magnitude of the relative velocity} \\
     &= \left( V_R \cdot V_R \right)^{\frac{1}{2}} \\
V_A &= \text{magnitude of the atmospheric relative velocity} \\
     &= \left( V_A \cdot V_A \right)^{\frac{1}{2}} \\
u_{RI} &= \text{unit vector along radius vector} \\
     &= \frac{r_I}{r_I} \\
u_{VI} &= \text{unit vector along inertial velocity vector} \\
     &= \frac{V_I}{V_I} \\
\gamma_I &= \text{inertial flight path angle} \\
     &= \sin^{-1} \left[ u_{RI} \cdot u_{VI} \right]
\end{align*}
\]
\( \gamma_R \) = relative flight path angle
\[ = \sin^{-1} \left[ \frac{\mathbf{u}_{RI} \cdot \mathbf{u}_{VR}}{\| \mathbf{u}_{RI} \| \| \mathbf{u}_{VR} \|} \right] \]

\( \gamma_A \) = atmospheric relative flight path angle
\[ = \sin^{-1} \left[ \frac{\mathbf{u}_{RI} \cdot \mathbf{u}_{VA}}{\| \mathbf{u}_{RI} \| \| \mathbf{u}_{VA} \|} \right] \]

\( V_{IG} \) = inertial velocity in the G-frame
\[ = [IG] \mathbf{V}_I \]

\( V_{RG} \) = relative velocity in the G-frame
\[ = [IG] \mathbf{V}_R \]

\( V_{AG} \) = atmospheric relative velocity in the G-frame
\[ = [IG] \mathbf{V}_A \]

\( A_{ZI} \) = inertial azimuth
\[ = \tan^{-1} \left( \frac{V_{YG}}{V_{XG}} \right) \]

\( A_{ZR} \) = relative azimuth
\[ = \tan^{-1} \left( \frac{V_{RYG}}{V_{RXG}} \right) \]

\( A_{ZA} \) = atmospheric relative azimuth
\[ = \tan^{-1} \left( \frac{V_{AYG}}{V_{AXG}} \right) \]

\( \phi_c \) = geocentric latitude
\[ = \sin^{-1} \left( \frac{z_I}{r_I} \right) \]

\( \theta_I \) = inertial longitude
\[ = \tan^{-1} \left( \frac{y_I}{x_I} \right) \]

(VII-7)
\( \theta_R = \text{relative longitude} \)
\[ = \theta_I - \Omega_P (t - t_0) \]

\( \vec{A}_{SB} = \text{sensed acceleration in the B-frame} \)
\[ = \vec{A}_{TB} + \vec{A}_{AB} \]

\( A_S = \text{magnitude of the sensed acceleration} \)
\[ = (\vec{A}_S \cdot \vec{A}_S)^{\frac{1}{2}} \]

\( \vec{A}_{SI} = \text{sensed acceleration in the ECI-frame} \)
\[ = [IB]^{-1} \left[ \vec{A}_{TB} + \vec{A}_{AB} \right] \]

(VII-7)
Auxiliary Attitude Calculations

The attitude angles that are not used to generate the steering commands are computed for output in the auxiliary calculation subroutine. These equations are summarized below:

1) Aerodynamic angles:

\[
\begin{align*}
\alpha &= \tan^{-1} \left( \frac{V_{AZB}}{V_{XB}} \right), \\
\beta &= \tan^{-1} \left( \frac{V_{AYB}}{\sqrt{V_{XZB}^2 + V_{AZB}^2}} \right), \\
\sigma &= \tan^{-1} \left( \frac{GB_{23} + \sin \beta \sin A}{GB_{22} \cos A_Z - GB_{21} \sin A_Z \cos A} \right). \\
\end{align*}
\]

(VII-8)

2) Inertial Euler angles:

\[
\begin{align*}
\phi_I &= \tan^{-1} \left( \frac{LB_{23}}{LB_{22}} \right), \\
\psi_I &= -\sin^{-1} \left( \frac{LB_{21}}{\sqrt{LB_{22}^2 + LB_{23}^2}} \right), \\
\theta_I &= \tan^{-1} \left( \frac{LB_{31}}{LB_{11}} \right); \\
\end{align*}
\]

(VII-9)

3) Relative Euler angles:

\[
\begin{align*}
\psi_R &= \tan^{-1} \left( \frac{GB_{12}}{GB_{11}} \right), \\
\theta_R &= -\sin^{-1} \left( \frac{GB_{13}}{\sqrt{GB_{12}^2 + GB_{13}^2}} \right), \\
\phi_R &= \tan^{-1} \left( \frac{GB_{23}}{GB_{33}} \right). \\
\end{align*}
\]

(VII-10)
The relationship between the body rates and the attitude angles are:

1) Aerodynamic angles:

\[
\begin{bmatrix}
\dot{\omega}_x \\
\dot{\omega}_y \\
\dot{\omega}_z \\
\end{bmatrix}
= \begin{bmatrix}
a_1 + d_1 \dot{\sigma} + (\sin \alpha) \dot{\beta} \\
a_2 + d_2 \dot{\sigma} + \dot{\alpha} \\
a_3 + d_3 \dot{\sigma} - (\cos \alpha) \dot{\beta}
\end{bmatrix}
\]

(VII-11)

2) Inertial Euler angles:

\[
\begin{bmatrix}
\dot{\omega}_x \\
\dot{\omega}_y \\
\dot{\omega}_z \\
\end{bmatrix}
= \begin{bmatrix}
\dot{\theta}_I \cos \psi_I \cos \theta_I - \dot{\psi}_I \sin \theta_I \\
\dot{\theta}_I - \dot{\phi}_I \sin \psi_I \\
\dot{\phi}_I \cos \psi_I \sin \theta_I + \dot{\psi}_I \cos \theta_I
\end{bmatrix}
\]

(VII-12)

3) Relative Euler angles:

\[
\begin{bmatrix}
\dot{\omega}_x \\
\dot{\omega}_y \\
\dot{\omega}_z \\
\end{bmatrix}
= \begin{bmatrix}
\frac{\nu}{r} \\
-\frac{u}{r} \\
\frac{-v \tan \phi_c}{r}
\end{bmatrix}
+ \begin{bmatrix}
\dot{\psi}_R \sin \theta_R \\
\dot{\theta}_R \cos \psi_R + \dot{\psi}_R \sin \theta_R \cos \phi_R \\
\dot{\phi}_R \cos \psi_R \cos \theta_R - \dot{\theta}_R \sin \phi_R
\end{bmatrix}
\]

(VII-13)
POST computes tracking information for as many as ten tracking stations per phase. The tracking stations are located on a reference ellipsoid and are specified in terms of their latitude, longitude, and altitude above the ellipsoid. These variables are illustrated in figure VII-2.
The position components of the tracker in the Earth-relative frame are given by

\[
\mathbf{r}_{TR} = (\mathbf{R}_S + h_T) \begin{bmatrix} \cos \phi_T \cos \theta_T \\ \cos \phi_T \sin \theta_T \\ \sin \phi_T \end{bmatrix},
\]\n
(VII-14)

where \( h_T \) is the altitude of the tracker, \( \phi_T \) the latitude of the tracker, and \( \theta_T \) the longitude of the tracker.

The slant range vector in the ECI frame is given by

\[
\mathbf{r}_{SR} = \mathbf{r}_{I} - [IP]^{-1} \mathbf{r}_{TR},
\]\n
(VII-15)

and the slant range is then computed as

\[
\mathbf{r}_{SR} = \sqrt{\mathbf{r}_{SR}^2 - \mathbf{r}_{SR}'^2}.
\]\n
(VII-16)

The elevation angle can then be computed as

\[
\gamma_T = \sin^{-1} \left( \frac{\mathbf{u}_{TR} \cdot \mathbf{r}_{SR}}{\mathbf{r}_{SR}} \right),
\]\n
(VII-17)

where

\[
\mathbf{u}_{TR} = [IP]^{-1} \mathbf{r}_{TR} / |[IP]^{-1} \mathbf{r}_{TR}|.
\]\n
(VII-18)

The slant range vector, transformed to the geographic frame, is

\[
\mathbf{r}_{SRG} = [IG] \mathbf{r}_{SR},
\]\n
(VII-19)

and thus the tracker's azimuth is given by

\[
\alpha_{ZT} = \tan^{-1} \left( \frac{y_{SRG}}{x_{SRG}} \right).
\]\n
(VII-20)

The look angles are calculated from the slant range vector transformed to the body frame; i.e.,

\[
\mathbf{r}_{SRB} = [IB] \mathbf{r}_{SR}.
\]\n
(VII-21)
Using the components of $\mathbf{r}_{\text{SRB}}$, the cone angle is then given by

$$\psi_T = \cos^{-1}\left(\frac{x_{\text{SRB}}}{r_{\text{SR}}}ight),$$

(VII-22)

and the clock angle is given by

$$\alpha_c = \tan^{-1}\left(\frac{y_{\text{SRB}}}{z_{\text{SRB}}}ight),$$

(VII-23)

Space losses are calculated for the tracking stations as follows:

$$\begin{align*}
SL_1 &= 36.56 + 20 \log_{10} \left( \frac{R_{\text{SLM}}}{\text{FR}_1} \right) \\
SL_2 &= 36.56 + 20 \log_{10} \left( \frac{R_{\text{SLM}}}{\text{FR}_2} \right) \\
SL_3 &= 36.56 + 20 \log_{10} \left( \frac{R_{\text{SLM}}}{\text{FR}_3} \right),
\end{align*}$$

(VII-24)

where

$$\begin{align*}
\text{FR}_1 &= 420.0 \text{ (command frequency)} \\
\text{FR}_2 &= 2287.5 \text{ (telemetry frequency)} \\
\text{FR}_3 &= 5765.0 \text{ (tracking frequency)} \\
R_{\text{SLM}} &= \text{slant range distance in statute miles.}
\end{align*}$$

Analytic Impact Calculations

The analytic impact calculations predict the geodetic latitude, longitude, and time of flight at impact for a vehicle with a given position and velocity to its intersection with the surface of the oblate planet. These calculations assume Keplerian motion and are not corrected for drag effects.

The basic problem in determining an impact point from a specified position and velocity $(x_{10}, y_{10})$ is in calculating the impact eccentric anomaly. This angle is determined by iteratively solving the equation

VII-14
\[ r_{1}(E) = R_{s} \left( \phi_{c} \right) + h_{ip} \]  

(VII-25)

where \( h_{ip} \) is the desired impact altitude above the oblate planet and the position vector is given by

\[ r_{1}(E) = f(E) \cdot I_{10} + g(E) \cdot V_{10} \]

\[ f(E) = \left( \cos \left( E - E_{0} \right) - e \cos E_{0} \right) / \left( 1 - e \cos E_{0} \right) \]  

(VII-26)

\[ g(E) = \sqrt{\frac{a^{3}}{\mu}} \left( \sin \left( E - E_{0} \right) - e \sin E + e \sin E_{0} \right) . \]

Once the impact eccentric anomaly, \( E_{ip} \), is determined, then the time, latitude, and longitude of impact are calculated as

\[ t_{ip} = t_{0} + \sqrt{\frac{a^{3}}{\mu}} \left( E_{ip} - E_{0} - e \sin E_{ip} + e \sin E_{0} \right) \]  

(VII-27)

\[ \phi_{ip} = \tan^{-1} \left( \frac{kz_{ip}}{\sqrt{x_{ip}^{2} + y_{ip}^{2}}} \right) \]

\[ \theta_{ip} = \tan^{-1} \left( \frac{y_{ip}}{x_{ip}} \right) - \Omega t_{ip} \]
Velocity Losses

There are two velocity loss options: (1) inertial velocity losses, and (2) atmospheric relative velocity losses. The inertial losses are used for orbital problems while the atmospheric relative losses are used for atmospheric flight problems.

The total change in the magnitude of the velocity is given by:

\[ V_f - V_i = \Delta V = \Delta V^* - \Delta V_{TV} - \Delta V_{AERO} - \Delta V_g - \Delta V_{atm} \]  

(VII-28)

where

\[ \Delta V^* = \int \frac{n_i T_v}{m} \, dt \quad \text{ideal velocity} \]

\[ \Delta V_{TV} = \int \frac{1}{m} \left( T_R - T_R \cdot U \right) \, dt \quad \text{thrust vector loss} \]

\[ \Delta V_{AERO} = \int - \frac{1}{m} F_A \cdot U \quad \text{aerodynamic loss} \]

\[ \Delta V_g = \int g \sin \gamma \, dt \quad \text{gravity loss} \]

\[ \Delta V_{atm} = \int \frac{p}{m} \sum \Delta E_i \, dt \quad \text{atmospheric pressure loss} \]

Inertial losses are computed when \( U = [IB] \cdot V_i / V_f \), and similarly atmospheric relative losses are computed when \( U = [IB] \cdot V_A / V_A \).

Velocity Margins

The program computes the amount of velocity margin available and the amount required, based on a percentage of the ideal velocity.

The velocity margin is calculated as

\[ \Delta V_M = \frac{S_0}{\text{SP}} \ln \left[ \frac{W_G'}{W_G - W_P} \right] \]  

(VII-29)

The excess velocity is then given by

\[ \Delta V_E = \Delta V_M - \Delta V_A \sqrt{\sum \gamma_i^2} \]  

(VII-30)
Sun-Shadow Calculations

The program computes several sun-shadow variables. These variables are used to calculate the sun-vehicle orientation angles, the sun-shadow conditions, and the position and velocity of the vehicle in the vernal equinox system. These auxiliary variables are based upon the Greenwich hour angle (GHA), the Greenwich hour angle of the Sun (GHAS), the declination of the Sun $\delta_S$, and the time of reference past midnight (TRPM). The Greenwich hour angle, the right ascension and declination of the Sun remain constant during the simulation.

The vehicle position and velocity vectors in the vernal equinox system are given by

$$\mathbf{x}_{\text{VE}} = \begin{bmatrix} x_1 \\ x_2 \\ x_3 \end{bmatrix}$$  \hspace{1cm} (VII-31)

and

$$\mathbf{v}_{\text{VE}} = \begin{bmatrix} v_1 \\ v_2 \\ v_3 \end{bmatrix},$$  \hspace{1cm} (VII-32)

The Sun unit vector in the (VE) system is

$$\mathbf{u}_s = \begin{bmatrix} c\delta_s \\ c\Omega_s \\ s\delta_s \end{bmatrix}$$  \hspace{1cm} (VII-33)

where

$$\Omega_s = \text{GHA} + \text{GHAS}.$$  

The Sun unit vector in the ECI system is calculated as

$$\mathbf{u}_{\text{EI}} = [IV]^{\dagger} \mathbf{u}_s.$$  

The cone and clock angles of the Sun vector in the body system are given as

$$\delta_{\text{cone}} = \cos^{-1} \left( \mathbf{u}_B \cdot \mathbf{u}_{\text{EI}} \right), \hspace{1cm} (VII-34)$$

$$\delta_{\text{clock}} = \tan^{-1} \left( \frac{y_s/s_s}{z_s/s_s} \right).$$

VII-17
where $u_B$ is a unit vector in the direction of the $x_B$ axis, and

$$
\begin{bmatrix}
x_sB \\
y_sB \\
z_sB
\end{bmatrix} = [IB]u_{sI}.
$$

(VII-35)

The program also computes a shadow function, which is used to determine when the vehicle is in or out of the Earth's shadow. This function is based upon a cylindrical shadow model and is given by

$$
S = \begin{cases}
A - \frac{1}{2} \left( R_E + R_p \right) & : \text{if } x_I \cdot u_s < 0, \\
-\left( x_I \cdot u_s I - \left( x_I \cdot u_{sI} \right) u_{sI} \right) & : \text{if } x_I \cdot u_{sI} \geq 0,
\end{cases}
$$

(VII-36)

where

$$
A = \sqrt{A \cdot A} \\
A = x_I - \left( x_I \cdot u_{sI} \right) u_{sI}
$$

If $S < 0$, then the vehicle is in the shadow of the Earth. If $S \geq 0$, then the vehicle is in the sunlight. The vehicle is entering the shadow if $S \leq 0$, and exiting if $S > 0$.

**Multiple Vehicle**

The program has the capability to simultaneously simulate the motion of two independent vehicles. One of the vehicles is active in the sense that it can be controlled using propulsion and/or aerodynamic forces. The other vehicle is passive in the sense that it cannot be controlled and is assumed to be out of the atmosphere and nonthrusting. As a result, the active vehicle is referred to as the pursuer, and the passive vehicle the target. The relative geometry between these two vehicles is defined in Figure VII-3.

A large number of output variables are calculated for the target vehicle. These variables are computed using equations that are identical to those used for the active vehicle. A complete list of these equations is given in Volume II - Utilization Manual. Only the key equations are in this section.
The increment in position, velocity, and acceleration between the active and the target vehicle are given by

\[
\Delta \mathbf{r} = \mathbf{r}_I - \mathbf{r}_{It} = \Delta \mathbf{r}_0 + \int \Delta \mathbf{v} \, dt
\]

(VII-37)

\[
\Delta \mathbf{v} = \mathbf{v}_I - \mathbf{v}_{It} = \Delta \mathbf{v}_0 + \int \Delta \mathbf{a} \, dt
\]

\[
\Delta \mathbf{a} = \mathbf{a}_I - \mathbf{a}_{It}
\]

Figure VII-3.- Relative Geometry between Active and Target Vehicles
POST uses an accelerated projected gradient algorithm (PGA) as the basic targeting/optimization technique. PGA is a combination of Rosen's projection method for nonlinear programming (refs. 3, 4, and 5) and Davidon's variable metric method for unconstrained optimization (ref. 6). The program also contains backup single-penalty function methods that use steepest descent, conjugate gradients, and/or the Davidon method. These standard gradient method are well documented in references 6 and 7 and are only briefly described in the following discussion.

The projected gradient algorithm is an iterative technique designed to solve a general class of nonlinear programming problems. PGA employs cost-function and constraint gradient information to replace the multidimensional optimization problem by an equivalent sequence of one-dimensional searches. In this manner, it solves a difficult multidimensional problem by solving a sequence of simpler problems. In general, at the initiation of the iteration sequence, PGA is primarily a constraint-satisfaction algorithm. As the iteration process proceeds, the emphasis changes from constraint satisfaction to cost-function reduction. The logic used to effect this changeover process will be discussed below.

Since numerous analytical developments of this technique are available (see ref. 3, 4, and 5), this presentation will primarily emphasize the geometrical aspects of the algorithm. This geometric interpretation clearly motivates the equations and logic contained in PGA, and a basic understanding of these concepts is usually sufficient to enable the user to efficiently use the algorithm.

Problem Formulation

The projected gradient method solves the following nonlinear programming problem:

Determine the values of the independent variables, \( u \), that minimize the cost function (optimization variable)

\[
F(u), \quad \text{(VIII-1)}
\]
subject to the constraints (dependent variables)

\[ c(u) > 0, \]  

(VIII-2)

where \( u \in \mathbb{R}^m; \) \( c \) is a vector-valued function, i.e., \( c: \mathbb{R}^m \rightarrow \mathbb{R}^n; \) and \( F \) is a scalar-valued function, i.e., \( F: \mathbb{R}^m \rightarrow \mathbb{R}^1. \)

The algorithm is actually more versatile than this simple formulation might indicate. In order to maximize any particular function, say \( W(u) \), all that is required is to define \( F(u) = -W(u) \) and determine the minimum of \( F(u) \). The equality constraint case is also contained within the above formulation since constraint equations of the form

\[ c_j(u) = 0 \]  

(VIII-3)

are special cases of Eq (VIII-2).

In the trajectory optimization, the cost function and the constraints are not explicitly a function of the independent variables, but rather depend explicitly on the state variables \( x_1, V_1, m, \) and \( Q \). The explicit equations relating the state (dependent) variables to the independent variables are the integrals

\[
\begin{align*}
\dot{r}_1 &= r_{10} + \int V_1 dt \\
V_1 &= V_{10} + \int ([IB]^{-1}[A_{TB} + A_{AB}] + C_1) dt \\
m &= m_0 + \int m dt \\
Q &= \int Q dt.
\end{align*}
\]  

(VIII-4)
If $x_n$ denotes the above state variables of the system being simulated at the $n^{th}$ event, and $x_n^+$ and $x_n^-$ denote the value of $x_n$ on the plus and minus sides of that event, then

$$x_{n+1}^-=T_n[x_n^+, u_n], \quad (VIII-5)$$

where $u_n$ are the independent variables in phase $n$, and $T_n$ represent the solution of the state differential equations over phase $n$. The values of the state variables on the positive side of event $n$ are then

$$x_n^+=x_n^-+\Delta x_n \quad (VIII-6)$$

where $\Delta x_n$ represents the discontinuity in state (e.g., velocity impulse at the $n^{th}$ event).

The cost function and the trajectory constraints are computed at the positive side of the specified events, and are therefore given by

$$F(u) = f(x_{v_f}^+) \quad (VIII-7)$$

and

$$c(u) = \begin{bmatrix}
  c_{v_1}(x_{v_1}^+) \\
  \vdots \\
  c_{v_j}(x_{v_j}^+)
\end{bmatrix}, \quad (VIII-8)$$

where $v_f$ denotes the event at which the optimization variable is specified and $v_j$ denotes the events at which the dependent variables are specified. This generality enables the program to solve problems in which intermediate constraints are defined, as well as problems where the cost function is not specified at the final event.
The trajectory propagator, $T_n$, can represent either numerical integration or analytical Keplerian equations.

**Fundamental Concepts and Nomenclature**

To facilitate the discussion of the projected gradient algorithm, the following nomenclature and basic concepts will be introduced.

A real k-dimensional Euclidean vector space is denoted by $\mathbb{R}^k$, and $\mathbf{x}$ denotes a column matrix whose elements are $x_i$, where $i = 1, 2, \ldots, k$. The vector inequality $\mathbf{x} \succeq 0$ implies $x_i \geq 0$ for each $i$, and $A^\top$ denotes the transpose of the real matrix $A$.

The cost gradient is an $m$-vector of partial derivatives denoted as $\nabla F$, or $\partial F/\partial \mathbf{u}$, and is defined as

$$\nabla F = \frac{\partial F}{\partial \mathbf{u}}.$$ (VIII-9)

The gradient to the $i^{th}$ constraint is similarly represented.

The Jacobian matrix of the constraint vector function with respect to the independent variable is a matrix whose $i^{th}$ row is the gradient vector $\nabla c_i$. This matrix is denoted as

$$J(u) = \frac{\partial c}{\partial \mathbf{u}}.$$ (VIII-10)

and contains $n$ rows and $m$ columns. Clearly,

$$J_{ij} = \frac{\partial c_i}{\partial u_j}.$$ (VIII-11)
The $j$th constraint is said to be active at $\hat{u}$ if and only if

\begin{equation}
    c_j(\hat{u}) < 0, \quad \text{(VIII-12)}
\end{equation}

An active constraint is said to be unconstrained if and only if

\begin{equation}
    c_j(\hat{u}) = 0 \text{ and } r_j = [(SS^{-1}) S]\_j < 0. \quad \text{(VIII-13)}
\end{equation}

Condition a) implies that the $j$th constraint is either violated at $\hat{u}$, while b) indicates that the negative of the cost function gradient "points" outside the feasible region.

The sensitivity matrix is the matrix whose rows are the gradients to the active constraints, and is denoted by

\begin{equation}
    S(u) = \frac{\partial \hat{e}}{\partial u}, \quad \text{(VIII-14)}
\end{equation}

where $\hat{e}$ is the $n_A$-vector of active constraints. Equality constraints are always active and thus are loaded into the upper elements of the $\hat{e}$. Thus, $\hat{e}$ is essentially the error vector for the active constraints. The error function is defined to be

\begin{equation}
    E(u) = e^T \hat{e}. \quad \text{(VIII-15)}
\end{equation}

The sensitivity matrix, $S$, is obtained from the Jacobian matrix, $J$, simply by deleting those rows that correspond to inactive constraints.

Corresponding to each constraint function $c_i(u)$ is a boundary hypersurface, $B_i$, defined by

\begin{equation}
    B_i = \left\{ u: c_i(u) = 0 \right\}. \quad \text{(VIII-16)}
\end{equation}

Clearly, $B_i$ is an $m$-dimensional nonlinear manifold. It can, however, be approximated at each point $\bar{u}$ in $\mathbb{R}^m$ by an $m$-dimensional linear manifold

\begin{equation}
    c_i(\bar{u}) = \left\{ u: c_i(\bar{u}) (u - \bar{u}) + c_i(\bar{u}) = 0 \right\}. \quad \text{(VIII-17)}
\end{equation}
The feasible region for the $i^{th}$ inequality constraint is the half-space in the independent-variable space defined by the set

$$R_i = \{u; c_i(u) \geq 0\}, \quad (VIII-18)$$

while the complete feasible region for all of the constraints is

$$R = \bigcap_{i=1}^{n} R_i. \quad (VIII-19)$$

The boundary of the complete feasible region must be

$$B(R) = \bigcup_{i=1}^{n} (B_i \cap R) \quad (VIII-20)$$

The intersection in the preceding equation is required to select from the unbounded boundary, $B_i$, of the feasible region of the $i^{th}$ constraint that portion which is adjacent to the feasible region, $R$, for all of the constraints.

At any particular $\hat{0} \in \mathbb{R}^m$ it is useful to define the local boundary hypersurface, $B(\hat{0})$, to the complete feasible region as the intersection of the active constraints at $\hat{0}$. Let $N(\hat{0})$ denote the set of indices of the $m-k_a$ tight constraints at $\hat{0}$. Then, symbolically, $B(\hat{0}) = \bigcap_{i \in K(\hat{0})} B_i \quad (VIII-21)$

Clearly $B(\hat{0})$ is an $m-k_a$ dimensional nonlinear manifold in the $m$-dimensional independent variable space.

An $m-k_a$ dimensional linear manifold $C(\hat{0})$ approximating $B(\hat{0})$ is the intersection of the active linearized constraints at $\hat{0}$; that is,
\[ C(\tilde{u}) = \bigcap_{i \in K(\tilde{u})} C_i(\tilde{u}) \]  
\[ = \left\{ u : S(\tilde{u})(u - \tilde{u}) + e(\tilde{u}) = 0 \right\} \]

\[ \text{(VIII-22)} \]

Now let \( \tilde{Q}(\tilde{u}) \) denote the linear space spanned by the gradients to the active constraints; that is,

\[ \tilde{Q}(\tilde{u}) = \left\{ u : \exists \alpha_1, \ldots, \alpha_{n_a} \text{ for which } u = \sum_{i=1}^{k_a} \alpha_i S_{ij}(\tilde{u}) \right\} \]

\[ \text{(VIII-24)} \]

and let \( Q(\tilde{u}) \) denote the orthogonal complement to \( \tilde{Q}(\tilde{u}) \); that is,

\[ \mathbb{R}^m = Q(\tilde{u}) \oplus \tilde{Q}(\tilde{u}). \]

\[ \text{(VIII-25)} \]

It can be shown that \( Q(\tilde{u}) \) is the unique linear space that can be translated to obtain the linear manifold \( C(\tilde{u}) \).

Furthermore, there exist unique orthogonal projection operators \( P(\tilde{u}) \) and \( \tilde{P}(\tilde{u}) \) that resolve any vector in the independent-variable space into its corresponding components in \( Q(\tilde{u}) \) and \( \tilde{Q}(\tilde{u}) \), respectively; that is, for any \( u \in \mathbb{R}^m \)

\[ u = P(\tilde{u})u + \tilde{P}(\tilde{u})u, \]

\[ \text{(VIII-26)} \]

where

\[ P(\tilde{u})u \in Q(\tilde{u}) \quad \text{and} \quad \tilde{P}(\tilde{u})u \in \tilde{Q}(\tilde{u}). \]

\[ \text{(VIII-27)} \]

In particular,

\[ \tilde{P} = S'(SS')^{-1} S \]

\[ \text{(VIII-28)} \]

and

\[ P = I - \tilde{P}. \]

\[ \text{(VIII-29)} \]
An additional concept is the idea of problem scaling. The purpose of problem scaling is to increase the efficiency of the targeting/optimization algorithms by transforming the original problem into an equivalent problem that is numerically easier to solve.

To numerically scale a problem, two general types of scaling are required: (1) independent-variable scaling, and (2) dependent-variable scaling. Independent-variable scaling is accomplished by defining a positive diagonal scaling matrix, \( W_u \), such that, the weighted independent variables are given by

\[
\tilde{u} = \begin{bmatrix} W_u \end{bmatrix} u. \tag{VIII-30}
\]

Similarly, dependent-variable weighting is accomplished by defining an optimization-variable scale factor, \( W_F \), and a positive, diagonal, dependent-variable scaling matrix, \( W_e \), such that the weighted optimization variable is

\[
P_1 = W_F F(u) \tag{VIII-31}
\]

and the weighted dependent variables are given by

\[
\tilde{x}(u) = \begin{bmatrix} W_e \end{bmatrix} \begin{bmatrix} \begin{bmatrix} W_u \end{bmatrix}^{-1} \tilde{u} \end{bmatrix}. \tag{VIII-32}
\]

yielding a weighted error function

\[
P_2 = \tilde{e}, \tilde{e}^T (\tilde{x}). \tag{VIII-33}
\]

The program contains several options for computing the independent-variable weighting matrix. However, the option most often used is the percentage scaling matrix

\[
\begin{bmatrix} W_u \end{bmatrix} = \frac{1}{u}. \tag{VIII-34}
\]
The dependent-variable weighting matrix is always computed as the reciprocal of the constraint tolerances, and is given by

$$W_{ii} = \frac{1}{\varepsilon_i}$$  \hspace{1cm} (VIII-35)

where \( \varepsilon_i \) is the tolerance for the \( i^{th} \) constraint. The optimization scale factor is merely input so that \( P_2 \) is approximately equal to one.

For simplicity, the following discussion of the algorithm assumes an appropriately scaled problem. However, the scaled equations can be obtained by making the following simple substitutions:

- \( u \) replaced by \( \hat{u} \)
- \( F \) replaced by \( P_1 \)
- \( c \) replaced by \( \hat{c} \)
- \( b \) replaced by \( P_2 \)
- \( S \) replaced by \( [W_e][S][W_u]^{-1} \)
- \( \mathcal{V}F \) replaced by \( W_F W_u^{-1} \mathcal{V}F \).

The final key concept employed by PGA is the idea of a direction of search. Heuristically, the direction of search is nothing more than a particular line in the independent-variable space along which the constraint error is reduced, or along which the cost-function is decreased. In a more precise sense, the direction of search at \( \hat{u} \) is a half-ray emanating from \( \hat{u} \). Thus, for any positive scalar, \( \gamma \), the equation

$$u = \hat{u} + \gamma \hat{s}$$  \hspace{1cm} (VIII-36)

sets the limits of this half-ray and represents "movement" in the direction \( \hat{s} \) from \( \hat{u} \). This is illustrated in figure VIII-1.
Figure VIII-1.- Direction of Search in the Independent-Variable Space

If \( \hat{\mathbf{g}} \) is a unit vector, then \( \gamma \) represents the actual distance "moved" in the direction \( \hat{\mathbf{g}} \). This concept of direction-of-search is particularly important since it enables the m-dimensional nonlinear programming problem to be replaced by a sequence (hopefully finite) of one-dimensional minimizations. What remains to be explained then is: (1) how to select the direction-of-search; and (2) how to determine the step size in that direction. All "direct" optimization methods employ this concept and, hence, differ only in their answers to the two preceding questions. The technique by which \( s_n \) and \( \gamma_n \) are selected by PGA will be described in subsequent sections.

Direction of Search

The projected gradient method uses two basic search directions. For this discussion, they will be termed the constraint and optimization directions, respectively. PGA proceeds by taking successive steps in one or the other of these two directions. The computation of each of these search directions is described below at a particular point \( \hat{\mathbf{u}} \) in the independent-variable space where \( \hat{a}_a \) of the constraints are active.
Constraint direction. - The constraint direction depends critically on the number of active constraints. Three cases are distinguished below:

1) Case 1.- If \( n_a < m \), then that unique control correction \( \Delta u \) is sought, which solves the linearized constraint equation

\[
S(\tilde{u}) \Delta u + e(\tilde{u}) = 0
\]

and minimizes the length of \( \Delta u \). The solutions to the preceding vector equations define the \( m-n_a \) dimensional linear manifold \( C(\tilde{u}) \), which approximates the local boundary at \( \tilde{u} \) as described in detail in the preceding section. The desired minimum norm correction, \( \Delta u \), is then the vector of minimum length in the independent-variable space from \( \tilde{u} \) to the linear manifold \( C(\tilde{u}) \). Analytically, it is given as

\[
\Delta \tilde{u} = -S^{-1}S'[SS']^{-1}e(\tilde{u}).
\]

This correction is illustrated in figure VIII-2.

The direction of search then is simply taken to be this minimum-norm correction to the locally active linearized constraints; that is,

\[
\Delta C(\tilde{u}) = \Delta \tilde{u}.
\]

Figure VIII-2. - Illustration of Minimum-Norm Constraint, Direction for \( n_a = 2 < m = 3 \)
2) If $\mathbf{n}_a = m$, then the linearized local boundary $C(\mathbf{u})$ reduces to a single point. Thus, there is a unique solution to the linearized constraint equations without the additional requirement that the length of the independent-variable correction be minimized. The minimum-norm correction formula then reduces to the familiar Newton-Raphson formula for solving $m$ equations in $m$ unknowns; namely

$$\Delta \mathbf{u} = - S^{-1} \mathbf{e}(\mathbf{u}).$$  \hspace{1cm} \text{(VIII-40)}$$

The Newton-Raphson correction is illustrated geometrically in figure VIII-3.

\begin{figure}[h]
\centering
\includegraphics[width=\textwidth]{figureVIII-3.png}
\caption{Illustration of Newton-Raphson Constraint, Direction for $\hat{\mathbf{n}} = m = 3$}
\end{figure}

The direction of search is taken to be this unique correction vector satisfying the linearized constraints; that is,

$$\mathbf{e}_C(\mathbf{u}) = \Delta \mathbf{u}.$$  \hspace{1cm} \text{(VIII-41)}$$
3) If \( n_a > m \), then \( C(\hat{u}) \) is empty, since a simultaneous solution of all of the linearized constraint equations does not exist. Hence, an entirely new method for choosing the search direction must be devised. PGA deals with this problem by seeking the unique independent-variable correction \( \Delta \hat{u} \) that minimizes the sum of the squares of the deviations from the linearized constraints. Thus, the function

\[
f(\Delta u) = |S(\hat{u}) \Delta u + e(\hat{u})|^2.
\]  

(VIII-42)

is minimized with respect to \( \Delta u \). Gauss demonstrated that the formula for this "least squares" correction is

\[
\Delta \hat{u} = -(S^T S)^{-1} S^T e(\hat{u}).
\]  

(VIII-43)

Figure VIII-4 illustrates the least-squares correction pictorially. As in the preceding two cases, the search direction is then taken to be this optimal correction; that is,

\[
\hat{e}^c(\hat{u}) = \Delta \hat{u}.
\]  

(VIII-44)

![Diagram](image-url)
Optimization direction. - When the number of active constraints is less than the number of independent variables, it is then possible to reduce the nonminimal cost function. Obviously the steepest descent direction, \(-\nabla F(\tilde{u})\), would be the best local search direction for reducing the cost function. Such a direction, however, would generally produce unacceptable constraint violations. To avoid this difficulty PGA orthogonally projects the unconstrained negative gradient, \(-\nabla F(\tilde{u})\), into a direction parallel to the local linearized constraint boundary \(C(\tilde{u})\). By searching in the direction of this negative-projected gradient the algorithm can guarantee that there is no further constraint violation than that of \(\tilde{u}\) for the case of linear constraints. To calculate this direction, it is only necessary to apply to the unconstrained negative gradient the projection operator \(P(\tilde{u})\), which maps any vector in the independent-variable space into its component in \(Q(\tilde{u})\), the unique linear space that can be translated into coincidence with the linear manifold \(C(\tilde{u})\). Thus,

\[
\begin{align*}
\mathbf{s}^0(\tilde{u}) &= -P(\tilde{u}) \nabla F(\tilde{u}) \\
&= -[\mathbf{I} - \hat{g}'(\tilde{u})] \nabla F(\tilde{u}) \\
&= -[\mathbf{I} - \mathbf{S}'(\mathbf{S} \mathbf{S}')^{-1} \mathbf{S}(\tilde{u})] \nabla F(\tilde{u})
\end{align*}
\]

(VIII-45)

The direction of search for the accelerated projected gradient method is

\[
\mathbf{s}_n^0(\tilde{u}) = -\mathbf{H}_n \mathbf{P} \nabla F(\tilde{u})
\]

(VIII-46)

where

\[
\mathbf{H}_0 = \mathbf{I}
\]

(VIII-47)

and

\[
\begin{align*}
\mathbf{H}_n &= \mathbf{H}_{n-1} + \mathbf{A}_n + \mathbf{B}_n, \text{ where } n = 2 \\
\mathbf{A}_n &= \left[ \frac{\Delta X_n \Delta X_n'}{\Delta X_n' \mathbf{g}_n} \right], \\
\mathbf{B}_n &= -\left[ \mathbf{H}_{n-1} \mathbf{g}_n \mathbf{g}_n' \mathbf{H}_{n-1}' \right]/\mathbf{g}_n' \mathbf{H}_{n-1} \mathbf{g}_n', \\
\Delta X_n &= u_n - u_{n-1}, \\
\mathbf{g}_n &= \nabla F(u_n) - \nabla F(u_{n-1}).
\end{align*}
\]

(VIII-48)
Figure VIII-5 illustrates the direction of the negative-projected gradient for the case of a single active constraint.

If there are no equality constraints, and all the inequality constraints are inactive, then $S$ is the zero matrix and the direction of search becomes the standard deflected gradient direction

$$ a^\circ(u) = -H_n \nabla F(u). \quad \text{(VIII-49)} $$

Similarly, if the single-penalty-function methods are used, then the directions of search that minimize

$$ P_2 = F + W a^\circ e \quad \text{(VIII-50)} $$

are:

1) Steepest-descent method

$$ a^\circ(u) = -\nabla P_2(u); $$
2) Conjugate gradient method (steepest-descent starter)

\[ s_n^0 = -\nabla P_2(u_n) + \left( \frac{\nabla P_2(u_n)}{\nabla P_2(u_{n-1})} \right) s_{n-1}, \text{ where } n > 2, \]

3) Davidon's method (steepest-descent starter)

\[ s_n^0 = -H_n \nabla P_2(u_n), \text{ where } n \geq 2 \]

and

\[ H_n = H_{n-1} + A_n + B_n, \]

where \( A_n \) and \( B_n \) have the same definitions as in the accelerated projected gradient mode.

Step-Size Calculation

At any particular point \( \bar{u} \) in the independent-variable space, the PGA algorithm proceeds by reducing the multidimensional problem to a one-dimensional search along the constraint direction to minimize the sum of the squares of the constraint violations, or along the optimization direction to minimize the estimated net cost-function. In either case, once the initial point \( u \) and the direction of search \( \bar{s} \) are specified, the problem reduces to the numerical minimization of a function of a single variable—namely, the step size. PGA performs this numerical minimization via polynomial interpolation, based on function values along the search ray and the function's value and slope at the starting point. Consider then, in detail, the calculation of this latter pair of quantities for the respective functions associated with the constraint and optimization directions.

Constraint direction.—The function to be minimized along the constraint direction, \( h_c(\cdot) = \|u + s_c^c\|^2 \) (VIII-51).
Clearly
\[ h_c(0) = |e(u)|^2. \quad (VIII-52) \]

Differentiation via the chain rule yields
\[ h_c'(0) = 2e'(u)S(u)s^c. \quad (VIII-53) \]

Recall that the search direction \( s^c \) was obtained as an independent-variable correction either satisfying all the linearized constraint equations if \( \hat{n}_a \leq m \), or minimizing their violation if \( m < \hat{n}_a \). Thus, if the constraints are reasonably linear, a good initial estimate for the \( s^c \) minimizing \( h_c \) is one.

**Optimization direction.** The function to be minimized along the optimization direction, \( \hat{s}^o \), is the estimated net cost-function which is defined as
\[
h_o(\gamma) = F(\hat{u} + s^o) - F(\hat{u}) + \nabla F(\hat{u}) \left[ -s'(SS')^{-1} e(u + \gamma s^o) \right].
\] (VIII-54)

- change in cost-function produced by step of length \( \gamma \) along \( s^o \)
- linearized approximation to change in cost-function required to perform minimum-norm correction back to the feasible region

Clearly
\[
h_o(0) = -\nabla F(\hat{u}) s'(SS')^{-1}(u)e(u). \quad (VIII-55)\]

By expanding \( h_o \) in a Taylor series in \( \gamma \) about \( \gamma = 0 \), and by making use of the fact that \( \hat{F}s^o = 0 \) since \( s^o \) lies in \( Q(u) \), it can be shown that
\[
h_o'(0) = \nabla F(\hat{u}) \hat{s}^o. \quad (VIII-56)\]

These properties of \( h_o \) are illustrated in figure 25.
Both the constraint and optimization directions are based on a sensitivity matrix that depends critically on which constraints are active. Hence, for searches in either direction, it is important to limit the step size so that the set of active constraints does not grow. Such a limit can be obtained based on linear approximation and suffices to deal with inactive constraints becoming active.

The reverse situation—of active constraints becoming inactive—poses no difficulty. To see this, note that because of our treatment of the active constraints as linear manifolds, a first-order approximation of the distance to a particular active constraint boundary would not change along the optimization direction. Furthermore, along the constraint direction any change in the status of an active constraint will be appropriately treated by minimizing $h_c$ with respect to the step length.
Let \( K(\bar{u}) \) denote the set of active constraint indices at \( \bar{u} \), and let

\[
    r_k = s(\bar{u})Vc_k(\bar{u}),
\]

where \( s(\bar{u}) \) is the search direction at vector \( \bar{u} \). Then assign to each \( k \) in \( K \) the number

\[
    \lambda(k) = \begin{cases} 
    -c_k(\bar{u})/r_k & \text{if } r_k < 0 \\
    R & \text{if } r_k \geq 0 
    \end{cases}
\]

where \( R \) is a very large real number. Then \( \lambda(k) \) is a linear approximation to the distance along the search ray from \( \bar{u} \) to the boundary, \( B_k \), of the \( k \)th constraint. Hence a reasonable upper bound for the step length is

\[
    \lambda = \min_{k \in K} [\lambda(k)].
\]

One-Dimensional Minimization

Monovariant minimization in PGA is performed exclusively by polynomial interpolation. First the actual function, \( f \), to be minimized is fitted with one or more quadratic or cubic polynomials until a sufficiently accurate curve fit, \( p \), is obtained; that is,

\[
    p(\gamma) = \sum_{i=0}^{n} a_i \gamma^i \approx f(\gamma) \quad \text{for all } \gamma \text{ of interest}. \tag{VIII-60}
\]

Then the independent variable value, \( \gamma^m \), that minimizes \( f \) is approximated by the value, \( \gamma_p^m \), which minimizes \( p \). Clearly, \( \gamma_p^m \) can be determined analytically if \( n \leq 3 \).
The minimization routine makes ingenious use of all the information it accumulates about \( f \) to obtain a good curve fit. First, \( f \) is fitted with a quadratic polynomial, \( p_1 \), based on:

1) \( f(0) \)
2) \( f'(0) \)
3) \( f(\gamma^m_0) \), where \( \gamma^m_0 > 0 \) is an initial estimate of the \( \gamma \) value that minimizes \( f \).

The coefficients of this quadratic polynomial are then calculated from the formulas:

\[
\begin{align*}
    a_0 &= f(0) \\
    a_1 &= f'(0) \\
    a_2 &= \left[ f(\gamma^m_0) - a_0 \right] / \gamma^m_0 + a_1 / \gamma^m_0.
\end{align*}
\]

The value of the independent variable that minimizes this polynomial is

\[
\gamma^m_1 = -a_1 / 2a_2. \tag{VIII-62}
\]

If \( \gamma^m_1 \) and \( \gamma^m_0 \) do not differ significantly, \( \gamma^m \) is taken to be \( \gamma^m_1 \) and the minimization procedure is considered complete. Similarly, if \( p_1(\gamma^m_1) \) is not significantly different from \( f(\gamma^m_1) \), then \( \gamma^m \) is taken to be equal to \( \gamma^m_1 \) and the process is terminated. Otherwise \( f \) is fitted with a cubic polynomial, \( p_2 \), based on

1) \( f(0) \)
2) \( f'(0) \)
3) \( f(\gamma^m_0) \) and \( \gamma^m_0 > 0 \)
4) \( f(\gamma^m_1) \).

VIII-20
If \( f \) is fitted using \( p_2 \), then coefficients are calculated from the following formulas:

\[

c_0 = f(0) \\
c_1 = f'(0) \\
\lambda = \max \left( \frac{m}{0}, \frac{m}{1} \right) \\
\alpha = \min \left( \frac{m}{0}, \frac{m}{1} \right) / \lambda \\
a_2 = \left[ \lambda a_1 a_0 (1 + \alpha) + (a^2 f(\lambda) - f(\alpha)) / (1 - \alpha) \right] / (\lambda^3 \alpha^2) \\
a_3 = \left[ (f(\alpha) - a^3 f(\lambda)) / (1 - \alpha) - \lambda \alpha (1 + \alpha) a_1 (1 + \alpha = a^2) a_0 \right] / (\lambda^3 \alpha^2)
\]

The value of the independent variable, \( \lambda_2 \), that minimizes this cubic polynomial is

\[
\gamma_2 = -a_2 + \sqrt{a_2^2 - 2a_2 a_1} / 3a_3.
\]

If \( \gamma_2 \) and \( \gamma_1 \) do not differ significantly, \( \gamma \) is taken to be \( \gamma_2 \) and the minimization is stopped. Similarly, if \( p_2(\gamma_2) \) is not significantly different from \( f(\gamma_2) \), then \( \gamma \) is taken to be equal to \( \gamma_2 \) and the procedure is terminated.

If none of these stopping conditions is met, a third quadratic curve-fit is attempted. The accumulated set of sample points on \( f \), namely \([0, f(0)], [\gamma_0, f(\gamma_0)], [\gamma_1, f(\gamma_1)], \) and \([\gamma_2, f(\gamma_2)]\), is arranged in the order of their ascending abscissa values. Then the first point whose ordinate value is less than that of the following point is selected.

To simplify the notation in the following pages, relabel this point as \([\gamma_2, f(\gamma_2)]\), the preceding point as \([\gamma_1, f(\gamma_1)]\), and the following point as \([\gamma_3, f(\gamma_3)]\).
Another quadratic polynomial, \( p_3 \), is then fitted to

1) \( f(y_1) \)
2) \( f(y_2) \)
3) \( f(y_3) \).

The formulas for these quadratic coefficients are as follows:

\[
\begin{align*}
    b_{ij} &= y_i y_j \\
    c_{ij} &= y_i + y_j \\
    d_{ij} &= y_i - y_j \\
    a_0 &= \frac{b_{23}}{d_{12} d_{13}} f(y_1) + \frac{b_{13}}{d_{21} d_{23}} f(y_2) + \frac{b_{12}}{d_{31} d_{32}} f(y_3) \\
    a_1 &= \frac{c_{23}}{d_{12} d_{13}} f(y_1) - \frac{c_{13}}{d_{21} d_{23}} f(y_2) - \frac{c_{12}}{d_{31} d_{32}} f(y_3) \\
    a_2 &= \frac{1}{d_{12} d_{13}} f(y_1) + \frac{1}{d_{21} d_{23}} f(y_2) + \frac{1}{d_{31} d_{32}} f(y_3).
\end{align*}
\]  

\( (\text{VIII-65}) \)

The value of the independent variable that minimizes this quadratic is

\[
y_m = \frac{-a_1}{2a_2}, \\
(\text{VIII-66})
\]

If \( y_m \) and \( y_m^* \) do not differ significantly, \( y_m \) is taken to be \( y_3 \) and the search is discontinued. On the other hand, if \( p_3(y_3) \) is not significantly different from \( f(y_3) \), then \( y_m^* \) is taken to be \( y_3 \) and the process is terminated.

If neither of these stopping conditions is met, then a cubic polynomial is fitted to
The formulas for these coefficients are as follows:

\[
\begin{align*}
D_1 &= (Y_2 - Y_1)(Y_3 - Y_1)(Y_4 - Y_1) \\
D_2 &= (Y_1 - Y_2)(Y_3 - Y_2)(Y_4 - Y_2) \\
D_3 &= (Y_1 - Y_3)(Y_2 - Y_3)(Y_4 - Y_3) \\
D_4 &= (Y_1 - Y_4)(Y_3 - Y_4)(Y_3 - Y_4)
\end{align*}
\]

\[
\begin{align*}
a_0 &= \frac{Y_2Y_3Y_4}{D_1} f(Y_1) + \frac{Y_1Y_3Y_4}{D_2} f(Y_2) + \frac{Y_1Y_2Y_4}{D_3} f(Y_3) + \frac{Y_1Y_2Y_3}{D_4} f(Y_4) \\
a_1 &= \frac{Y_2Y_3 + Y_2Y_4 + Y_3Y_4}{D_1} f(Y_1) + \frac{(Y_1Y_2 + Y_1Y_4 + Y_4Y_3)}{D_2} f(Y_2) \\
&\quad + \frac{(Y_1Y_2 + Y_1Y_3 + Y_2Y_3)}{D_3} f(Y_3) + \frac{(Y_1Y_2 + Y_1Y_4 + Y_4Y_3)}{D_4} f(Y_4) \\
a_2 &= \frac{Y_2 + Y_3 + Y_4}{D_1} f(Y_1) + \frac{(Y_1 + Y_3 + Y_4)}{D_2} f(Y_2) \\
&\quad + \frac{(Y_1 + Y_2 + Y_4)}{D_3} f(Y_3) + \frac{(Y_1 + Y_2 + Y_4)}{D_4} f(Y_4) \\
a_3 &= -\frac{1}{D_1} f(Y_1) - \frac{1}{D_2} f(Y_2) - \frac{1}{D_3} f(Y_3) - \frac{1}{D_4} f(Y_4)
\end{align*}
\]

The value of the independent variable minimizing this fourth cubic polynomial is

\[
\gamma_4^m = \frac{-a_2 + \sqrt{a_2^2 - 3a_3a_1}}{3a_3}.
\]

(VIII-68)
If \( \gamma_4^m \) and \( \gamma_3^m \) do not differ significantly, \( \gamma^m \) is taken to be \( \gamma_4 \) and the minimization is stopped. Similarly, if \( P_u(\gamma_4^m) \) is not significantly different from \( f(\gamma_4) \), then \( \gamma^m \) is taken to be equal to \( \gamma_4^m \) and the procedure is terminated.

If none of these stopping conditions is met, the accumulated set of sample points is searched for the point with the minimum ordinate value. The abscissa value of this point is taken to be \( \gamma^m \), and the minimization is considered complete.

Algorithm Macrologic

After being initialized the projected gradient algorithm proceeds as a sequence of iterations, each consisting of an optimization step followed by a constraint-correction step (see fig. VIII-7). The very first step from the user's initial independent-variable estimate is however, one of constraint correction. Furthermore, the optimization step is also omitted on any iteration for which the constraint-violation function, \( h_c \), was not reduced by the constraint correction step of the preceding iteration.

The optimization search direction that emanates for \( u_n \) is based on the sensitivity matrix, \( S(u_n) \); that is,

\[
\frac{s^o}{s_n} = s^o(u_n) = -P_{nF}(u_n), \quad (VIII-69)
\]

as discussed previously. Hence, \( \frac{s^o}{s_n} \) lies in the subspace \( Q(u_n) \).

The value of the independent-variable vector, \( u_n^o \), after the optimization is

\[
u_n^o = u_n + \gamma_o \frac{s^o}{s_n}, \quad (VIII-70)
\]

where \( \gamma_o \) is the optimum step size.
Figure VIII-7: Macrologic of Projected Gradient Algorithm
The direction of the constraint-correction search emanates from $\frac{\mathbf{u}}{n}_0$; however, since generating a new sensitivity matrix is such an expensive calculation, the old Jacobian matrix, $J$, of the constraints with respect to the controls evaluated at $\frac{\mathbf{u}}{n}$ is used in conjunction with the error at $\frac{\mathbf{u}}{n}_0$. Thus,

$$s^c_n = -S'(SS')^{-1}(\frac{\mathbf{u}}{n})s[\frac{\mathbf{u}}{n}_0].$$

(VIII-71)

It can be shown by direct computation that

$$\hat{\mathbf{p}}(\frac{\mathbf{u}}{n})s^c_n = s^c_n,$$

(VIII-72)

where $\hat{\mathbf{p}}(\frac{\mathbf{u}}{n})$ is based on $S(\frac{\mathbf{u}}{n})$. Thus, $s^c_n$ lies in the subspace $Q(\frac{\mathbf{u}}{n})$ in the independent-variable space.

Since $Q(\frac{\mathbf{u}}{n})$ and $\hat{Q}(\frac{\mathbf{u}}{n})$ are orthogonal complements, it follows that the optimization and constraint directions for any iteration are exactly orthogonal; that is,

$$\left(s^o_n\right)'s^c_n = 0.$$ 

(VIII-73)

The result of the constraint correction step is then the independent-variable vector for the next iteration. Thus

$$\frac{\mathbf{u}}{n+1} = \frac{\mathbf{u}}{n}_0 + \gamma_c s^c_n.$$ 

(VIII-74)

Figure VIII-8 geometrically illustrates a complete PGA iteration.
Finally, the algorithm has two stopping conditions. First, the search is stopped if the change in the cost function and the change in the length of the independent-variable vector between two successive iterations fall below their respective input tolerances; that is, if

\[ |F(u_{n+1}) - F(u_n)| < c_1 \]
\[ |u_{n+1} - u_n| < c_2. \]

Second, the procedure is discontinued if the number of the current iteration equals the maximum permissible number input by the user.

APPENDIX A
DECOMPOSITION BY PARTITIONING INTO FULL-RANK SUBPROBLEMS

Consider a trajectory consisting of a mission segments each of which may consist of one or more phases. Suppose that each segment has its own physical control vector, \( \mathbf{u}^k \), containing \( m_k \) components and its own constraint vector \( \mathbf{c}^k \) having \( n_k \) components.

Let \( v^k \) be the target value of the constraint vector for segment \( k \). Finally, suppose there are \( n \) constraints \( C_i \), which are best associated with the mission as a whole rather than any particular segment. Let \( V_i \) denote the target values of these constraints.

The problem is then

\[
\begin{align*}
\text{minimize:} & \\
& F \left( \bigcup_{k=1}^s \mathbf{u}^k \right) - \sum_{k=1}^s f^k \left( \bigcup_{i=1}^{n_k} \mathbf{u}^i \right) \\
\text{subject to:} & \\
& v_i^k = c_i^k \left( \bigcup_{i=1}^{n_k} \mathbf{u}^i \right) \quad \text{for } k=1,\ldots,s \\
& V_i = c_i \left( \bigcup_{k=1}^s \mathbf{u}^k \right) \quad \text{for } i=1,\ldots,n.
\end{align*}
\]

[1]

When numerous segments are present with varying degrees of influence on the overall objective, \( F \), solution of problem [1] in a single piece by means of any existing equality-constraint minimization procedure becomes impractical if not impossible. By solving coordinated sets of subproblems representing the individual segments, the decomposition procedure is able to solve problem [1] routinely. The decomposition technique thus both imitates and extends the intuitive approach of the experienced trajectory designer.

---

The notation \( \bigcup_{k=1}^S \) denotes the ordered union of the indexed quantity \( k=1 \) immediately to its right.

A-1
The process of decomposing a problem by partitioning it into full-rank subproblems is based upon two fundamental ploys. The first is the use in each segment of certain key control variables to satisfy the constraints of that segment. Thus segment $k$ is made into a full-rank subproblem by designating $n_k$ of the physical control vector components as subproblem variables and using them to satisfy the $n_k$ constraints of that segment. The remaining control vector components of segment $k$ are grouped together with similar variables from the other segments. This collection of controls, together with the overall mission objective, $F$, and constraints, $C$, are made into a master problem of minimization subject to equality constraints. This partitioning of the original problem lends itself well to computation. The subproblems, which must be re-solved for each new choice of master problem controls, are solved by the highly efficient Newton-Raphson procedure. The master-problem, which serves to coordinate the subproblem solutions, uses the equally efficient but more time-consuming accelerated projected-gradient algorithm.

The second fundamental ploy is use of constraint target values of the various subproblems as master-problem independent variables. To obtain an optimum composite trajectory from a set of mission segments, the mission analyst typically varies the segment aim points parametrically and chooses the endpoint combination that results in the lowest overall cost. Indeed, in trajectory analysis the decision "where to go" is usually more important than "how to get there." By using subproblem constraint targets as master-problem controls the decomposition procedure automates the analyst's successful design approach.

The successful convergence of the decomposition procedure demands a reasonable partitioning of the original controls and constraints into the master-problem and subproblem categories. To be more precise, the subproblem controls and constraints must be so chosen that each subproblem will have a solution for any set of subproblem constraint target values that might reasonably arise during the master-problem iteration process. Thus, for a given subproblem, the controls that have the most substantial effect on that subproblem's constraint set should be chosen. Similarly if a particular constraint cannot be assigned to any subproblem whose controls can achieve its satisfaction, it should be designated a master-problem constraint. Finally, the number of master-problem constraints should be held to a minimum. Indeed the master-problem should be kept as simple as possible because each of its iterations requires the re-solution of all the subproblems.
The decomposition procedure maintains simulation flexibility in obtaining master-problem control sensitivity information by using numerical differencing. Solution of the master-problem by descent requires constrained derivatives—quotients of dependent perturbations in the master-problem objectives and constraints by independent perturbations in the master-problem controls assuming that the subproblem controls adjust uniquely to keep the subproblem targeted. These derivatives could be approximated by the numerical differencing of master-problem trajectories consisting of iteratively targeted subproblems. This approach, however, must be rejected because it is both susceptible to numerical error and demanding in computational effort. Instead formulas are used that relate the constrained derivatives to the partial derivatives of the master-problem objective and constraints with respect to all of the physical controls of the original problem. These partial derivatives are approximated conveniently by numerical differencing of the master-problem trajectories without subproblem targeting. Thus, the need for deriving variational equations for each simulated trajectory is eliminated for a reasonable computational price. Any trajectory that can be simulated, can be shaped with no additional analytical effort.

To precisely define the procedure, considerable nomenclature must be established. Most of the user supplied parameters have already been defined. Two, however, remain. The first is $p_k$, the number of subproblem constraint target values from segment $k$ which are to be used as master-problem independent variables. The second is $q_k$, the number of master-problem constraints arising from segment $k$.

Consider next the procedure's working variables. To simplify notation, the subproblem and master-problem controls are given distinct literal symbols and resequenced. Indeed, let $y_j^k$ denote the $j$th subproblem control arising from segment $k$ and $z_j^k$ be the $j$th master-problem control from that segment. Similarly, the segment constraint target values are assigned new symbols to distinguish those that are to be held fixed from those that are to be used as master-problem independent variables. Indeed, let $r_i^k$ denote the $i$th constraint target value from segment $k$ that is to be used as a master-problem independent variable, and $t_i^k$, the $i$th constraint target value to be held fixed for that segment. Finally, the master-problem constraint vector is resequenced so that its first $q_1$ components denoted by $C_1^1$ arise from the first subproblem, and the next $q_2$ components denoted by $C_2^2$ arise from the second subproblem, and so forth. In terms of this new notation, the original problem [1] becomes

$$A - 3$$
minimize:
\[ F \left( \bigcup_{k=1}^{s} (\bar{x}^k \cup \bar{z}^k) \right) = f \left( \bigcup_{k=1}^{s} (\bar{y}^k \cup \bar{z}^k) \right) \]
subject to:
\[ c^* \left( \bigcup_{k=1}^{s} (\bar{x}^k \cup \bar{z}^k) \right) = c^* \left( \bigcup_{k=1}^{s} (\bar{y}^k \cup \bar{z}^k) \right) \quad \text{for } i=1, \ldots, s \]}

where:
- \( \bar{x}^k \) is a master-problem independent variable
- \( \bar{z}^k \) is a master-problem independent variable
- \( \bar{y}^k \) is the unique vector of subproblem independent variables for subproblem \( k \), satisfying that subproblem's constraint set for the current set of master-problem independent variables.

To solve problem [2], a procedure must first be established for solving the subproblems, that is, for determining the unique \( \bar{y}^k \) given the \( \bar{x}^k \) and \( \bar{z}^k \). As noted above, the Newton-Raphson algorithm for solving full-rank systems of nonlinear equations is the technique selected. To start the iterative solution, the user must input a good estimate, \( (\bar{y}^k)_0 \), for the physical-control vector of subproblem \( k \), which approximately yield the constraint target values for that subproblem. The procedure, then, successively refines this estimate using the Newton-Raphson recursion formula
\[ (\bar{y}^k)_{v+1} = (\bar{y}^k)_v - (A^k)_{v}^{-1} (F^k - y^k) \quad \text{for } i=1, \ldots, s \]}

where
\[ A^k = \frac{\partial y^k}{\partial \bar{z}^k} \quad \text{for } i=1, \ldots, s \]
\[ \text{for } k=1, \ldots, i \]
After the first set of subproblems are solved, the converged subproblem control values from one subproblem set are used as the starting estimates for the next subproblem set. Further, the Jacobian matrix, $A^{kk}$, is updated from one iteration to the next only if the old Jacobian does not reduce the constraint errors in norm by a user specified fraction, $p$.

The equality constrained minimization that is the master-problem is carried out by the projected gradient algorithm already familiar to POST users. The only new technique involved is the computation of the constrained derivatives in terms of the partial derivatives of the master-problem objective and constraints with respect to all of the physical controls of the original problem. First, the perturbation of the subproblem independent variables caused by perturbations in the master-problem independent variables must be determined. Both master-problem physical controls and subproblem constraint target values must be considered. Once these constrained derivatives of the subproblem independent variables are determined, they can be used to calculate the desired constrained derivatives of the master-problem objective and constraints with respect to all of the master-problem independent variables.

The constrained derivatives of the subproblem controls are all derived from the basic subproblem equation

$$
A^{kk} \frac{\delta y}{\delta x} = \frac{\delta z}{\delta x} - \sum_{k=1}^{k-1} A^{kk} \frac{\delta z}{\delta x} - \sum_{k=1}^k B^{kk} \frac{\delta z}{\delta x} \quad \text{for } k=1,\ldots,s
$$  \quad [5]

where

$$
B^{kk} = \frac{\delta c}{\delta x} \quad \text{for } k=1,\ldots,s.
$$  \quad [6]

$$
B_k = \frac{\delta c}{\delta x} \quad \text{for } k=1,\ldots,s.
$$  \quad [6]

The constrained derivatives with respect to the master-problem physical controls are given by the equation

$$
\frac{\delta y}{\delta z} = (A^{kk})^{-1} \left[ B_k + \sum_{o=k}^{k-1} A^{oo} \frac{\delta y}{\delta z} + \frac{\delta y}{\delta z} \right] \quad \text{for } k=1,\ldots,s
$$  \quad [7]
The constrained derivatives with respect to the subproblem constraint target values are computed from the two formulas

\[
\frac{\delta Y^k}{\delta X^k} = (A^k)_{kk}^{-1} E_{n_k} P_k \quad \text{for } k=1,\ldots,s
\]

where \( E_{n_k} \) is the matrix consisting of the first \( p_k \) columns of the identity matrix of order \( n_k \).

The constrained derivatives of the master-problem objective with respect to both the master-problem physical controls and the subproblem constraint target values follow from the "chain-rule" for differentiation. They are computed as

\[
\frac{\delta F}{\delta Z^k} = \sum_{i=k}^{s} \left[ b^k + \sum_{o=k}^{i-1} a^{i,o} \frac{\delta Y^o}{\delta X^k} \right] \quad \text{for } k=1,\ldots,s
\]

and

\[
\frac{\delta F}{\delta X^k} = \sum_{i=k}^{s} \sum_{o=k}^{i-1} a^{i,o} \frac{\delta Y^o}{\delta X^k} \quad \text{for } k=1,\ldots,s
\]

where

\[
a^k = \frac{\partial f}{\partial Y^k} \quad \text{for } i=1,\ldots,s
\]

and

\[
b^k = \frac{\partial f}{\partial Z^k} \quad \text{for } i=1,\ldots,s
\]
Finally, the constrained derivatives of the master-problem constraints with respect to the master-problem physical controls and the subproblem constraint target values follow from a straightforward application of the "chain rule." They are related to the appropriate partial derivatives by the equations

\[
\frac{\delta C^{\ell}}{\delta z} = D^{\ell k} + \sum_{o=k}^{k} G^{lo} \frac{\delta y^{o}}{\delta z^{k}} \quad \text{for } \ell = 1, \ldots, s \quad \text{for } k = 1, \ldots, \ell' \tag{14}
\]

and

\[
\frac{\delta C^{\ell}}{\delta r} = \sum_{o=k}^{k} G^{lo} \frac{\delta y^{o}}{\delta r^{k}} \quad \text{for } \ell = 1, \ldots, s \quad \text{for } k = 1, \ldots, \ell' \tag{15}
\]

where

\[
D^{\ell k} = \frac{\partial C^{\ell}}{\partial z^{k}} \quad \text{for } \ell = 1, \ldots, s \quad \text{for } k = 1, \ldots, \ell' \tag{16}
\]

and

\[
G^{lo} = \frac{\partial C^{\ell}}{\partial y^{o}} \quad \text{for } \ell = 1, \ldots, s \quad \text{for } k = 1, \ldots, \ell' \tag{17}
\]
