FOREWORD

This final report describing the formulation of the Six-Degree-of-Freedom Program to Optimize Simulated Trajectories (6D POST) is provided in accordance with Part 3.0 of NASA Contract NAS1-13300. The report is presented in three volumes as follows:

Volume I - 6D POST - Formulation Manual; NASA CR-132741
Volume II - 6D POST - Utilization Manual; NASA CR-132742
Volume III - 6D POST - Programmer's Manual; NASA CR-132743

This work was conducted under the direction of Mr. Howard Stone and Mr. Richard Powell of the Space Systems Division, National Aeronautics and Space Administration, Langley Research Center.

SUMMARY

This report documents the basic equations and models used in the six-degree-of-freedom version of the program to optimize simulated trajectories (6D POST).

6D POST, a direct extension of the point mass version of POST, is a general purpose rigid body six-degree-of-freedom program. The program can be used to solve a wide variety of atmospheric flight mechanics and orbital transfer problems for powered or unpowered vehicles operating near a rotating oblate planet. The principal features of 6D POST are: an easy to use NAMELIST type input procedure, an integrated set of Flight Control System (FCS) modules, and a general-purpose discrete parameter targeting and optimization capability.

6D POST is written in FORTRAN IV for the CDC 6000 series computers.

Other volumes in the final report are:

Volume II - Utilization Manual - Documents information pertinent to users of the program. It describes the input required and output available for each of the trajectory and targeting/optimization options.

Volume III - Programmers Manual - Documents the program structure and logic, subroutine descriptions, and other pertinent programming information.

I. INTRODUCTION

The six (6)-degree-of-freedom program to optimize simulated trajectories is a general purpose FORTRAN program for simulating rigid body trajectories of aerospace type vehicles. The program can be used to solve a wide variety of performance, guidance, and flight control problems for atmospheric and orbital vehicles. For example, typical applications of 6D POST include:

1) Guidance and flight control system simulation and analysis;
2) Loads and dispersion type analyses;
3) General-purpose 6D simulation of controlled and uncontrolled vehicles;
4) 6D performance validation.

One of the key features of 6D POST is an easy to use NAMELIST-type input procedure. This feature significantly reduces input deck set-up time (and costs) for 6D studies that require the normal large amount of input data. In addition, the general applicability of 6D POST is further enhanced by a general-purpose discrete parameter targeting and optimization capability. This capability can be used to solve a broad spectrum of problems related to the impact of the control system design on the performance characteristics of aerospace vehicles.

The basic simulation flexibility is achieved by decomposing the trajectory into a logical sequence of simulation segments. These trajectory segments, referred to as phases, enable the trajectory analyst to model both the physical and the nonphysical aspects of the simulation accurately and efficiently. By segmenting the mission into phases, each phase can be modeled and simulated in a manner most appropriate to that particular flight regime. For example, the planet model, the vehicle model, and the simulation options can be changed in any phase to be compatible with the level of detail required in that phase.

Every computational routine in the program can be categorized according to five basic functional elements. These elements are: the planet model, the vehicle model, the trajectory simulation model, the auxiliary calculations module, and the targeting and optimization module. The planet model is composed of an oblate spheroid model, a gravitational model, an atmosphere model, and a winds model. These models define the environment in which the vehicle operates. The vehicle model comprises mass properties, propulsion, aerodynamics and aeroheating, an st-frame model, a navigation and guidance model, and a flight control system model. These models define the basic vehicle simulation characteristics. The trajectory simulation models are the event-sequencing module.
that controls the program, cycling, table interpolation routines, and several standard numerical integration techniques. These models are used in numerically solving the translational and rotational equations of motion. The auxiliary calculations module provides for a wide variety of output calculations. For example, conic parameters, range calculations, and tracking data are among the many output variables computed. The targeting and optimization module provides a general discrete parameter iteration capability. The user can select the optimization variable, the dependent variables, and the independent variables from a list of more than 400 program variables. An accelerated projected gradient algorithm is used as the basic optimization technique. This algorithm is a combination of Rosen's projection method for nonlinear programming and Davidon's variable metric method for unconstrained optimization. In the targeting mode, the minimum norm algorithm is used to satisfy the trajectory constraints. The cost and constraint gradients required by these algorithms are computed as first differences calculated from perturbed trajectories. To reduce the costs of calculating numerical sensitivities, only that portion of the trajectory influenced by any particular independent variable is re-integrated on the perturbed runs. This feature saves a significant amount of computer time when targeting and optimization is performed.

Basic program macrologic is outlined in figure I-1, which illustrates the linkage between the simulation and the iteration modules.

III. COORDINATE SYSTEMS

6D POST uses numerous coordinate systems to provide the necessary reference systems for calculating required and optional data. These coordinate systems and the key transformations are described below.

Coordinate System Definitions

Earth-centered inertial (ECI) axes \( (x_I, y_I, z_I) \). - This system is an Earth-centered Cartesian system with \( z_I \) coincident with the North Pole, \( x_I \) coincident with the Greenwich Meridian at time zero and in the equatorial plane, and \( y_I \) completing a right-hand system. The translational equations of motion are solved in this system (fig. III-1).

Earth-centered rotating (ECR) axes \( (x_R, y_R, z_R) \). - This system is similar to the ECI system except that it rotates with the Earth so that \( x_R \) is always coincident with the Greenwich Meridian (fig. III-1).

Earth position coordinates \( (\phi, \theta, h) \). - These are the familiar latitude, longitude, and altitude designators. Latitude is positive in the Northern Hemisphere. Longitude is measured positive East of Greenwich. Altitude is measured positive above the surface of the planet (fig. III-1).

Geographic (G) axes \( (x_G, y_G, z_G) \). - This system is located at the surface of the planet at the vehicle's current geocentric latitude and longitude. The \( x_G \) axis is in the local horizontal plane and points North, the \( y_G \) axis is in the local horizontal plane and points East, and \( z_G \) completes a right-hand system. This system is used to calculate parameters associated with azimuth and elevation angles (fig. III-2).

Inertial launch (L) axes \( (x_L, y_L, z_L) \). - This is an inertial Cartesian system that is used as an inertial reference system from which the inertial attitude angles of the vehicle are measured. This coordinate system is automatically located at the
Figure III-1.- Coordinate Systems

Figure III-2.- Launch Frame
geodetic latitude and inertial longitude of the vehicle at the
beginning of the simulation unless overridden by user input of
LATL and LONL. The azimuth, AZL, is zero unless overridden by
user input. The orientation of this system is such that xL is
along the positive radius vector if φL is input as the geocentric
latitude, or along the local vertical if φL is not input
or is input as the geodetic latitude. zL is in the local hori-
Ztonal plane and is directed along the azimuth specified by AZL,
and yL completes a right-hand system. This system is intended
for use in simulating ascent problems for launch vehicles that
use either inertial platform or strapdown-type angular commands.
The inertial angles, (φI, ψI, θI) are always measured with
respect to this system and are automatically computed regardless
of the steering option (IGUID) being used (fig. III-2).

Body (B) axes (xB, yB, zB).--The body axes form a right-
hand Cartesian system aligned with the axes of the vehicle and
centered at the vehicle’s center of gravity. The xB axis is
directed forward along the longitudinal axis of the vehicle, yB
points right (out the right wing), and zB points downward, com-
pleting a right-hand system. All aerodynamic and thrust forces
are calculated in the body system. These forces are then trans-
formed to the inertial (I) system where they are combined with
the gravitational forces (fig. III-3)

Figure III-3.—Body Frames
Body reference (BR) axes \((x_{BR}, y_{BR}, z_{BR})\). - The body reference system is a right-hand Cartesian system aligned with the body axes as follows. The \(x_{BR}\) axis is directed along the negative \(x_B\) axis, the \(y_{BR}\) axis is directed along the positive \(y_B\) axis, and the \(z_{BR}\) is directed along the negative \(z_B\) axis. This system is used to locate the vehicle's center of gravity, aerodynamic reference point, and engine gimbal locations for the static trim operation (fig. III-3).

Orbital elements \((h_a, h_p, i, \Omega, \theta, \omega)\). - This is a nonrectangular coordinate system used in describing orbital motion. The orbital elements are apogee altitude, perigee altitude, inclination, longitude of the ascending node, true anomaly, and argument of perigee. The apogee and perigee altitudes replace the standard orbital elements of semimajor axis and eccentricity (fig. III-4).

Figure III-4.- Orbital Parameters
Attitude Angles

The program contains the following standard attitude reference systems:

1) Inertial Euler angles;
2) Relative Euler angles;
3) Aerodynamic angles;
4) Inertial aerodynamic angles;

These variables are defined and illustrated below:

1) Inertial Euler angles (fig. III-5):

\( \phi_I \) - Inertial roll angle. The roll angle with respect to the L-frame (first rotation),

\( \psi_I \) - Inertial yaw angle. The yaw angle with respect to the L-frame (second rotation),

\( \theta_I \) - Inertial pitch angle. The pitch angle with respect to the L-frame (third rotation);

2) Relative Euler angles (fig. III-6):

\( \psi_R \) - Relative yaw angle. This is the azimuth angle of the \( x_B \) axis measured clockwise from the reference direction (first rotation),

\( \theta_R \) - Relative pitch angle. This is the elevation angle of the \( x_B \) axis above the local horizontal plane (second rotation),

\( \phi_R \) - Relative roll angle. This is the roll angle about the \( x_B \) axis (third rotation).
3) Aerodynamic angles (fig. III-7):

- **σ**: Bank angle. Positive σ is a positive rotation about the atmosphere relative velocity vector (first rotation),

- **β**: Sideslip. Positive β is a nose-left (negative) rotation when flying the vehicle upright (second rotation),

- **α**: Angle of attack. Positive α is a nose-up (positive) rotation when flying the vehicle upright (third rotation);

4) Inertial aerodynamic angles (fig. III-8):

- **σ_I**: Bank angle. Positive σ_I is a positive rotation about the atmosphere inertial velocity vector (first rotation),

- **β_I**: Sideslip. Positive β_I is a nose-left (negative) rotation when flying the vehicle upright (second rotation),

- **α_I**: Angle of attack. Positive α_I is a nose-up (positive) rotation when flying the vehicle upright (third rotation);
Transformations

Numerous matrix transformations are required to transform data between the coordinate systems described in the previous section. The most important of these transformations is the [IB] matrix. The inverse (transpose) of this matrix is used to transform accelerations in the body frame to the planet-centered inertial frame. The remaining transformations are generally used to either compute [IB] or to transform auxiliary data into some convenient output coordinate system.

The [IB] matrix is functionally dependent on the attitude of the vehicle. This dependence is described by equations related to the attitude steering option selected by the user. The following matrix equations, which depend on this steering option, are used to compute the [IB] matrix.

\[
\begin{align*}
[IB] &= [LB][IL] \text{ (body rates or inertial Euler angles)} \\
[IB] &= [GB][IG] \text{ (relative Euler angles)} \\
[IB] &= [AB][GA][IG] \text{ (aerodynamic angles)}
\end{align*}
\] (III-1)

The basic relationships between the coordinate systems defined by these equations are illustrated in figure III-9. The inverse transformation can generally be computed by merely transposing the matrix elements because of the orthonormality of these matrices.

![Matrix Transformations Diagram](image)

**Figure III-9.** - Matrix Transformations
A summary of these matrices is given below. The symbols c and s denote \( \sin \) and \( \cos \), respectively.

\( [\text{IL}], \text{inertial to launch}. \) - The \( [\text{IL}] \) matrix depends on \( \phi_L \), \( \chi_L \), and \( \Lambda_{ZL} \), and is given by

\[
[\text{IL}] = \begin{bmatrix}
  c_\phi L c_\theta L & c_\phi L s_\theta L & s_\phi L \\
  s_\phi L c_\theta L - c_\Lambda_{ZL} s_\theta L & c_\Lambda_{ZL} c_\theta L + s_\Lambda_{ZL} s_\phi L s_\theta L & -s_\Lambda_{ZL} c_\phi L \\
  -s_\Lambda_{ZL} s_\phi L - c_\Lambda_{ZL} s_\theta L c_\phi L & s_\Lambda_{ZL} c_\theta L - c_\Lambda_{ZL} s_\phi L s_\theta L & c_\Lambda_{ZL} c_\phi L
\end{bmatrix}
\] (III-2)

\( [\text{LB}], \text{launch to body}. \) - The \( [\text{LB}] \) matrix is computed indirectly from the body rates by integrating the quaternion equations, or directly from inertial Euler angles. When the body rate option is used, the quaternion rate equation

\[
\begin{bmatrix}
  \dot{e}_0 \\
  \dot{e}_1 \\
  \dot{e}_2 \\
  \dot{e}_3
\end{bmatrix} = \frac{1}{2} \begin{bmatrix}
  -e_1 & e_2 & e_3 \\
  e_2 & e_1 & -e_3 \\
  -e_3 & e_1 & e_2 \\
  e_0 & e_1 & e_2
\end{bmatrix} \begin{bmatrix}
  \omega_x \\
  \omega_y \\
  \omega_z
\end{bmatrix}
\] (III-3)

is integrated to compute the \( [\text{LB}] \) matrix, which is then given by

\[
[\text{LB}] = \begin{bmatrix}
  e_0^2 + e_1^2 - e_2^2 - e_3^2 & 2(e_1 e_2 + e_0 e_3) & 2(e_1 e_3 - e_0 e_2) \\
  2(e_1 e_2 - e_0 e_3) & e_0^2 - e_1^2 + e_2^2 - e_3^2 & 2(e_0 e_1 + e_2 e_3) \\
  2(e_1 e_3 + e_0 e_2) & 2(e_2 e_3 - e_0 e_1) & e_0^2 - e_1^2 - e_2^2 + e_3^2
\end{bmatrix}
\] (III-4)
When the inertial Euler angle option is used, \([LB]^\dagger\) is computed directly as

\[
[LB]^\dagger = \begin{bmatrix}
    c^\psi_I c^\theta_I & -s^\psi_I & c^\psi_I s^\theta_I \\
    c^\phi_I s^\psi_I c^\theta_I + s^\phi_I s^\theta_I & c^\phi_I c^\psi_I & c^\phi_I s^\psi_I s^\theta_I - s^\phi_I c^\theta_I \\
    s^\phi_I s^\psi_I c^\theta_I - c^\phi_I s^\theta_I & c^\phi_I s^\psi_I & s^\phi_I s^\psi_I s^\theta_I + c^\phi_I c^\theta_I
\end{bmatrix}
\]  

(III-5)

\([IG]\), inertial to geographic.- The \([IG]\) matrix depends on the geocentric latitude and the inertial longitude, and is given by

\[
[IG] = \begin{bmatrix}
    -s^\phi c^\theta_I & -s^\phi s^\theta_I & c^\phi \\
    -s^\theta_I & c^\theta_I & 0 \\
    -c^\phi c^\theta_I & -c^\phi s^\theta_I & -s^\phi_c
\end{bmatrix}
\]

(III-6)

\([GB]\), geographic to body.- The \([GB]\) matrix depends on the relative Euler angles, and is given by

\[
[GB] = \begin{bmatrix}
    c^\theta_R c^\phi & c^\theta_R s^\psi & -s^\theta_R \\
    s^\phi_R s^\theta_R c^\psi - c^\phi_R s^\psi & s^\phi_R s^\theta_R s^\psi + c^\phi_R c^\psi & s^\phi_R c^\theta_R \\
    c^\phi_R s^\theta_R c^\psi + s^\phi_R s^\psi & c^\phi_R s^\theta_R s^\psi - s^\phi_R c^\psi & c^\phi_R c^\theta_R
\end{bmatrix}
\]

(III-7)

\([GA]\), geographic to atmospheric relative velocity system (ARVS).- The \([GA]\) matrix depends on the atmospheric relative flight azimuth and flightpath angles, and is given by

\[
[GA] = \begin{bmatrix}
    c^\gamma_A c^\lambda_A & c^\gamma_A s^\lambda_A & -s^\gamma_A \\
    -s^\lambda_A & c^\lambda_A & 0 \\
    s^\gamma_A c^\lambda_A & s^\gamma_A s^\lambda_A & c^\gamma_A
\end{bmatrix}
\]

(III-8)
[AB] ARVS to body. - The [AB] matrix depends on the aerodynamic angles, and is given by

\[
[AB] = \begin{bmatrix}
c_{\alpha \beta} & -s_{\alpha \beta} c_{\delta} & -s_{\alpha \beta} s_{\delta} - c_{\alpha \beta} c_{\delta}
s_{\alpha \beta} & c_{\alpha \beta} & c_{\alpha \beta} 
s_{\delta} & -s_{\delta} c_{\alpha \beta} - c_{\delta} s_{\alpha \beta} & -s_{\delta} s_{\alpha \beta} + c_{\delta} c_{\alpha \beta}
\end{bmatrix}
\]  

(III-9)

Other transformations, which are not related to the calculation of the [IP] matrix, are presented below.

[IP], inertial to planet relative. - The [IP] matrix transforms between the Earth-centered inertial frame and the Earth-centered rotating frame. This matrix depends on the rotation rate of the planet and the total elapsed time of flight, and is given by

\[
[IP] = \begin{bmatrix}
c_{\Omega t} & s_{\Omega t} & 0 
-s_{\Omega t} & c_{\Omega t} & 0 
0 & 0 & 1
\end{bmatrix}
\]  

(III-10)

[R], body reference to body. - The [RB] matrix transforms data in the body reference system to the body frame. This matrix has a constant value and is given by

\[
[R_B] = \begin{bmatrix}
-1 & 0 & 0 
0 & 1 & 0 
0 & 0 & -1
\end{bmatrix}
\]  

(III-11)
IV. PLANET MODEL

The planet model is composed of three types of data and equations. These are: (1) oblate planet geometry and constants, (2) an atmosphere model that computes atmospheric pressure, density, temperature, and speed of sound, and (3) a gravitational model that computes the gravitational accelerations. The user selects the appropriate models and inputs the corresponding data. The input data and the equations used in these models are described below.

Oblate Spheroid

The 1960 Fisher Earth model is preloaded into the program. This model is defined by the equatorial radius $R_E$, the polar radius $R_P$, the rotation rate $\Omega_P$, the gravitational constant $\mu$, and the second, third, and fourth gravitational harmonics, $J_2$, $J_3$, and $J_4$, respectively. The stored values for these constants are:

$$R_E = 2.0925741 \times 10^7 \text{ ft},$$
$$R_P = 2.085590 \times 10^7 \text{ ft},$$
$$\Omega_P = 7.29211 \times 10^{-5} \text{ rad/s},$$
$$\mu = 1.4076539 \times 10^{16} \text{ ft}^3/\text{s}^2,$$
$$J_2 = 1.0823 \times 10^{-3},$$
$$J_3 = 0,$$
$$J_4 = 0.$$

The constants $J_3$ and $J_4$ are preloaded as zero, but can be initialized by input. For example, if the Smithsonian Earth model is desired, then these constants would be input as

$$J_2 = 1.082639 \times 10^{-3},$$
$$J_3 = -2.565 \times 10^{-6},$$
$$J_4 = -1.608 \times 10^{-6},$$
$$\mu = 1.407645794 \times 10^{16} \text{ ft}^3/\text{s}^2,$$
\[ \Omega_p = 7.29211515 \times 10^{-5} \text{ rad/s}, \]
\[ R_E = 2.092566273 \times 10^7 \text{ ft}, \]
\[ R_p = 2.08550242 \times 10^7 \text{ ft}. \]

The geometry of this spheroid is illustrated in figure IV-1. The pertinent equations related to this model are

\[
\begin{align*}
\phi_c &= \sin^{-1} \left( \frac{z_I}{r_I} \right) \\
\phi &= \tan^{-1} \left( k \tan \phi_c \right) , \quad k = \left( \frac{R_E}{R_P} \right)^2 \\
R_s &= R_E \left( 1 + (k - 1) \sin^2 \phi_c \right)^{-\frac{1}{2}} \\
h &= r_I - R_s,
\end{align*}
\]

where \( \phi_c \) is the geocentric latitude, \( \phi \) is the geodetic latitude, \( \theta_I \) is the inertial longitude, \( \psi \) is the relative longitude with respect to the planet, \( r_I \) is the distance from the center of the planet to the vehicle, \( R_s \) is the distance from the center of the planet to the planet surface, and \( h \) is the distance from the planet surface to the vehicle.
Gravitational Model

The gravitational model includes optionally second, third, and fourth harmonic terms. The potential function for this model is

\[
U = -\mu \left[ \frac{1}{r} - \frac{J_2}{2} \frac{R_s^2}{R_E^2} \left( \frac{3z^2}{r^5} - \frac{1}{r^3} \right) - \frac{J_3}{2} \frac{R_s^3}{R_E^3} \left( \frac{5}{r^7} - \frac{3z}{r^5} \right) - \frac{J_4}{8} \frac{R_s^4}{R_E^4} \left( 35 \frac{z^4}{r^9} - 30 \frac{z^2}{r^7} + \frac{3z}{r^5} \right) \right].
\]

\(IV-2\)
The gravitational accelerations calculated from this potential function are:

\[
G_{xI} = -\frac{3U}{3x_I} = -\mu \frac{x}{r^3} P(z, r)
\]

\[
G_{yI} = -\frac{3U}{3y_I} = -\mu \frac{y}{r^3} P(z, r)
\]

\[
G_{zI} = -\frac{3U}{3z_I} = -\frac{H}{r^3} \left[ \left( 1 + J R^2 (3 - 5 z^2) \right) z + H \frac{R^3}{r} \left( 6 z^2 - 7 z^2 - \frac{3}{5} r^2 \right) \right. \\
\left. + BR^4 \left( \frac{15}{7} - 10 z^2 + 9 z^4 \right) \right]
\]

where \( x = x_I, y = y_I, z = z_I, r = r_I, \) and

\[
R = \frac{R_E}{r_I}
\]

\[
Z = \frac{z_I}{r_I}
\]

\[
J = \frac{3}{2} J_2
\]

\[
H = \frac{5}{2} J_3
\]

\[
D = -\frac{35}{8} J_4
\]

\[
P(z, r) = \left[ 1 + J R^2 (1 - 5 z^2) + H \frac{R^3}{r} (3 - 7 z^2) z \right. \\
\left. + BR^4 \left( 9 z^4 - 6 z^2 + \frac{3}{7} \right) \right]
\]

IV-4
Atmosphere Models

POST has the optional capability of three atmospheric models—the general table lookup, the 1962 U.S. standard atmosphere, and the 1963 Patrick AFB atmosphere using polynomials. The general table lookup model gives the user the flexibility of inputting his own atmospheric model if none of the preloaded models is adequate. This is particularly useful in performing trajectory analysis for planets other than Earth. The parameters required to define the atmospheric effects are the atmospheric pressure $p$, atmospheric density $\rho$, speed of sound $C_s$, and atmospheric temperature $T$. These parameters are functions of the oblate altitude $h$.

**Table lookup atmosphere model.**—The table lookup atmosphere model can be defined entirely by using tables that show pressure, temperature, speed of sound, and density as functions of altitude. The speed of sound and density tables can be omitted if desired; in this case, the speed of sound and density are computed as

$$C_s = \sqrt{K_1 T}$$

$$\rho = K_2 \frac{p}{T},$$

where

$$K_1 = \frac{\gamma R^*}{M_0}$$

$$K_2 = \frac{M_0}{R^*}$$

$\gamma$ = ratio of specific heats

$M_0$ = molecular weight

$R^*$ = universal gas constant.

**1962 U.S. standard atmosphere model.**—The 1962 U.S. standard atmosphere model is given as a function of geopotential altitude $(H_g)$, which is computed as

$$H_g = \frac{R_A h}{R_A + h},$$

$$\text{IV-5}$$
where
\[ R_A = \text{average Earth radius} = \frac{1}{2} (R_E + R_F) \]
\[ h = \text{oblate altitude}. \]

The molecular scale temperature, \( T_M \), is defined by a series of linear segments \( (L_M) \) as a function of geopotential altitude \( (H_g) \):

The corner points connecting the straight-line segments are referred to as base altitudes \( (H_B) \), base temperatures \( (T_{MB}) \), etc. From a table of base altitudes, base temperatures, and \( dT/M/dH \) \( (L_M) \) (the slope within the linear segments), the temperature at any desired altitude can be calculated from the following equation:

\[ T_M = T_{MB} + L_M (H_g - H_B). \]  \hspace{1cm} (IV-7)

Values of \( P_B, T_{MB} \), and \( L_M \) versus \( H_B \) are presented in table IV-1.

The atmospheric pressure is determined as follows:

\[
\begin{align*}
P &= P_B \left[ \frac{T_{MB}}{T_M} \right] \exp \left[ \left( \frac{g_0 M_0}{R^2} \right) \left( \frac{L_M}{T_{MB}} \right) \right] \quad \text{for segments with } L_M \neq 0, \text{ and} \\
P &= P_B \exp \left[ - \frac{g_0 M_0}{R^2} \frac{(H - H_B)}{T_{MB}} \right] \quad \text{for segments with } L_M = 0,
\end{align*}
\]  \hspace{1cm} (IV-8)

where \( P_B \) is the base pressure corresponding to the given base altitude \( H_B \). These base pressures can be calculated once the sea-level pressure, \( P_0 \), and the temperature profile have been specified.

IV-6
Having calculated the temperature and pressure, the density, $\rho$, speed of sound, $C_s$, and atmospheric viscosity, $\mu_A$, are determined as follows:

\[
\rho = \left( \frac{M_0}{R^*} \right) \frac{P}{T_M}
\]

\[
C_s = \left( \frac{\gamma R^*}{M_0} \right)^{1/2} T_M^{1/4}
\]

\[
\mu_A = \frac{\beta T_M^{3/2}}{T_M + S},
\]

where $g_0$ is the acceleration of gravity at sea level, $M_0$ is the molecular weight of air at sea level, $R^*$ is the gas constant, $\gamma$ is the ratio of specific heats, and $\beta$ and $S$ are Sutherland's constants.

\[
M_0 = 28.9644
\]

\[
R^* = 8.31432 \times 10^3 \frac{J}{(\text{K})(\text{kg-mol})}
\]

\[
\gamma = 1.40
\]

\[
\beta = 1.458 \times 10^{-6} \frac{\text{kg}}{\text{sec m (\text{K})}^{1/2}}
\]

\[
S = 110.4 \text{ K} = 198.72 \text{ R}
\]

\[
g_0 = 9.80665 \text{ m/sec}^2 = 32.174 \text{ ft/sec}^2.
\]

In the 1962 U.S. standard atmosphere, the molecular weight varies with altitude above approximately 90 km; in POST the molecular weight is assumed constant, resulting in a slight discrepancy above 90 km. In the 1962 U.S. standard atmosphere, geometric altitude is transformed to geopotential altitude, which is used throughout. Thus, above 90 km, a constant slope of molecular scale temperature versus geopotential altitude is used instead of the constant slope of temperature versus geometric altitude.

</table>
1963 Patrick AFB atmosphere using polynomials.- In this model, pressure and temperature are calculated as functions of geometric altitude (h). These parameters are calculated in metric units and converted to English units if required.

Pressure:

1) Altitude region = 0 to 28000 meters:

\[ P = P_1 \exp (A + A_1 h + A_2 h^2 + A_3 h^3 + A_4 h^4 + A_5 h^5) \]

where \( P_1 = 10.0 \) Newtons/cm².

2) Altitude region = 28000 to 83004 meters:

\[ P = 8.0 \times 10^{-4} \exp (A + A_1 h + A_2 h^2 + A_3 h^3 + A_4 h^4 + A_5 h^5) \]

3) Altitude region = 83004 to 90000 meters:

\[ P = P_B \exp \left( \frac{-1.373301523 \times 10^{12} h - h_B}{T_B (6344860 + h) (6344860 + h_B)} \right) \]

4) Altitude region = 90000 to 700000 meters:

\[ \ln (P) = \ln (P_B) + \frac{1.373301523 \times 10^{12}}{L_m (6344860 + h) (6344860 + h_B)} \]

\[ \ln \left( \frac{T_B}{T_B + L_m (h - h_B)} \right) \]
Temperature:

1) Altitude region = 0 to 10 832.1 meters:
   \[
   T = T^* = A + A_1 h + A_2 h^2 + A_3 h^3 + A_4 h^4 + A_5 h^5;
   \]

2) Altitude region = 10 832.1 to 83 004 meters:
   \[
   T = A + A_1 h + A_1 h' + A_3 h^3 + A_4 h^4 + A_5 h^5;
   \]

3) Altitude region = 83 004 to 90 000 meters:
   \[
   T = T_B + L_k (h - h_B);
   \]
   However, in this region \( L_k = 0 \), and thus
   \[
   T = T_B = 180.65 \text{K};
   \]

4) Altitude region = 90 000 to 700 000 meters:
   \[
   T = T_M = T_{M_B} + L_m (n - h_B);
   \]

Density:

1) Altitude region = 0 to 28 000 meters:
   \[
   \rho = \rho_1 \exp \left( A + A_1 h + A_2 h' + A_3 h^3 + A_4 h^4 + A_5 h^5 \right);
   \]

2) Altitude region = 28 000 to 700 000 meters:
   \[
   \rho = (34.83676) \frac{P}{T};
   \]

*Virtual temperature is the same as kinetic temperature above the 10 832.1-meter altitude.

*Altitude range: 90 000 to 700 000 meters.
Pressure and density ratios:

Altitude region = 0 to 700,000 meters:

\[
\begin{align*}
\nu_R &= \frac{\rho}{\rho_0} \\
\rho_R &= \frac{\rho}{\rho_0} \\
\end{align*}
\] (IV-14)

Velocity of sound:

\[
V_S = (20.046707) \ (T)^{\frac{3}{2}}.
\] (IV-15)

The atmosphere model-derived coefficients are presented in table IV-2. The molecular temperature gradient is documented in table IV-3 for geometric altitudes from 90 to 700 km.

Winds

The atmospheric wind velocity components are input in tables using either meteorological or vector notation. If these tables, which are normally functions of oblate altitude, are not input, then the atmosphere is assumed to rotate uniformly with the planet.

The wind velocity components can be input directly in the geographic frame by defining \( u, v, \) and \( w, \) or by defining the wind speed \( V_W, \) the wind azimuth \( A_W, \) and the wind azimuth bias \( A_{ZWB}. \) The resulting wind velocity components in the G-frame are:

\[
V_{WG} = \begin{bmatrix}
V_W(h) \cos (A_{ZW}(h) + A_{ZWB}) \\
V_W(h) \sin (A_{ZW}(h) + A_{ZWB}) \\
n_W(h)
\end{bmatrix}
\] (IV-16)
It is clear from the above equation that in order to input vector wind data $A_{WB}$ must be input as zero, whereas for meteorologic data the preloaded value of 180° should be used.

The wind velocity in the ECI frame is then given by

$$V_{WI} = [I_G]^{-1} V_{WG}$$  \hfill (IV-17)

Thus, the atmospheric relative velocity vector in the ECI frame is

$$V_{AI} = V_1 - \frac{\Omega}{P} \times \bar{r}_1 - V_{WI}$$  \hfill (IV-18)

and its magnitude is given by

$$V_A = \sqrt{V_{AI} \cdot V_{AI}}$$  \hfill (IV-19)
V. VEHICLE MODEL

The various physical properties of the vehicle are modeled by the user when he selects the pertinent options from the set of vehicle simulation modules. The equations used in these modules are presented below.

Mass Properties Model

The gross weight of the vehicle at the beginning of each phase is given by

\[ W_G = W_{stg} + W_{pld} \]  \hspace{1cm} (V-1)

where \( W_{stg} \) is gross weight without payload and \( W_{pld} \) is the payload weight. For phases other than the first, the gross weight can optionally be computed as

\[ W_G^+ = W_G - W_{jett} - W_{PR} \]  \hspace{1cm} (V-2)

where \( W_G^+ \) is the gross weight on the positive side of the current event, \( W_G^- \) is the gross weight on the negative side of the current event, \( W_{jett} \) is the jettison weight, and \( W_{PR} \) is the weight of propellant remaining. These options are obtained automatically, based on user input.

The propellant remaining is given by

\[ W_{PR} = W_{p_i} - W_{PC} \]  \hspace{1cm} (V-3)

where \( W_{p_i} \) is the initial weight of propellant and \( W_{PC} \) is the amount of propellant consumed. This latter term is given by

\[ W_{PC} = \int \dot{W} \, dt + W_{C0} \]  \hspace{1cm} (V-4)

where \( \dot{W} \) is the total rate of change of the vehicle's weight.
The composite inertia matrix is input with respect to the body axis system which is located at the instantaneous composite center of gravity of the vehicle.* In 6D POST, the moments and products of inertia are defined as the integrals

\[
\begin{align*}
I_{xx} &= \int y'z' \, dv \\
I_{xy} &= \int xy \, dv \\
I_{xz} &= \int xz \, dv \\
I_{yy} &= \int x'y' + z' \, dv \\
I_{yz} &= \int yz \, dv \\
I_{zz} &= \int x'y' + y' \, dv
\end{align*}
\]  

(V-5)

The inertia matrix is then given by

\[
\mathbf{I} = \begin{bmatrix}
I_{xx} & -I_{xy} & -I_{xz} \\
-I_{xy} & I_{yy} & -I_{yz} \\
-I_{xz} & -I_{yz} & I_{zz}
\end{bmatrix}
\]  

(V-6)

and is generally input as a function of the weight of the vehicle.

The composite center of gravity is referenced with respect to the vehicle reference frame, and the components \((x_{cg}^*, y_{cg}^*, z_{cg}^*)\) are generally input as a function of vehicle weight.

**Propulsion Calculations**

**6D POST** can simulate both rocket and jet engines. The program can simulate up to 15 engines in either mode.

**Rocket engines**—There are two input options for engine data in the rocket mode. In the first option, tables for vacuum thrust and maximum weight flow rate are input for each engine. In the second option, tables for vacuum thrust are input, along with the vacuum specific impulse for each engine. The vacuum specific impulse is then used to calculate the mass flow rate.

The rocket thrust per engine is given by

\[
T_{R1} = T_{vac1} - A_{E1} p(h)
\]

(V-7)

*In 6D POST the center of gravity is assumed to coincide with the center of mass.*
where $n$ is the throttle setting, $T_{\text{vac}_i}$ is the vacuum thrust of the $i^{th}$ engine, $A_p$ is the nozzle exit area, and $p(h)$ is the atmospheric pressure. Summing over all engines yields the total rocket thrust

$$T_R = \sum_{i=1}^{N_{\text{eng}}} T_{\text{R}_i}$$

where $N_{\text{eng}}$ is the number of thrusting engines, and $N_{\text{eng}} \leq 15$.

The weight flowrate in the rocket mode is given by

$$W = \left\{ \begin{array}{l}
-n \sum_{i=1}^{N_{\text{eng}}} (w_{\text{p}_i}^{\text{max}}) \\
-n \sum_{i=1}^{N_{\text{eng}}} \left( \frac{T_{\text{vac}_i}}{\text{I}_{\text{sp, vac}}_i} \right) 
\end{array} \right. \quad (V-9)$$

Jet engines. - In the jet engine mode the net jet thrust per engine is given by

$$\left( \frac{T_j}{\delta} \right)_i = f(M, n), \quad (V-10)$$

where

$$\delta = \frac{p(h)}{p_{\text{SL}}}$$
and $\frac{T_J}{\delta}$ (M) is a monovariant table. The total jet thrust is then given by

$$T_J = \sum_{i=1}^{N_{\text{eng}}} \frac{p(h)}{P_{\text{SL}}} \left( \frac{T_J}{\delta_i} \right).$$  \hspace{1cm} (V-11)

The weight flowrate in the jet engine mode is

$$\dot{W} = \sum_{i=1}^{N_{\text{eng}}} \sqrt{\frac{T(h)}{T_{\text{SL}}} \left( \frac{p(h)}{P_{\text{SL}}} \frac{\text{SFC}}{\delta_i} \right) \left( \frac{T_J}{\delta} \right)_i \delta}.$$ \hspace{1cm} (V-12)

The thrust equation for each engine is given by

$$F_{TB_i} = T_{B_i} \begin{bmatrix} \cos \delta e_p & \cos \delta e_y \\ \sin \delta e_p \\ \sin \delta e_y \end{bmatrix},$$ \hspace{1cm} (V-13)

where the pitch and yaw engine deflection angles $\delta e_p$ and $\delta e_y$ are defined in Figure V-1.

![Figure V-1. Engine Gimbal Angles](image-url)
Aerodynamic Calculations

The aerodynamic force coefficients can be expressed in terms of the lift, drag, and side-force coefficients \( C_L \), \( C_D \), and \( C_Y \) (fig. V-2), where \( C_L \) and \( C_D \) are directed normal to, and along the velocity projection in, the \( x_B-z_B \) plane. Note that \( C_Y \) produces a side-force, \( F_{AYB} \), acting in the direction of \( y_B \).

Lift and drag force coefficients are transformed to axial and normal force coefficients as follows:

\[
\begin{bmatrix}
C_A \\
C_N
\end{bmatrix} = 
\begin{bmatrix}
\cos \alpha & -\sin \alpha \\
\sin \alpha & \cos \alpha
\end{bmatrix}
\begin{bmatrix}
C_D \\
C_L
\end{bmatrix},
\]

(V-14)

where \( \alpha \) is the angle-of-attack.

![Diagram of aerodynamic forces](image)

**Figure V-2: Aerodynamic Angles**

The aerodynamic coefficients can also be expressed in terms of the axial force, normal force, and side force, \( C_A \), \( C_N \), and \( C_Y \), respectively. Here \( C_A \) and \( C_N \) produce forces that act in the \(-x_B\) and \(-z_B\) directions, and \( C_Y \) produces a force acting along \( y_B \).
Each aerodynamic coefficient is computed by interpolating the values in the table. In general, eight tables are allocated to each coefficient. These tables can be monovariant, bivariant, or trivariant, and seven tables per coefficient can have arbitrary hollerith mnemonic multipliers. This generality enables all standard forms of aerodynamic data to be directly input into the program.

The aerodynamic force coefficients are obtained by summing the individual contributions as follows:

\[ C_A = C_{A_0} + C_A(\alpha, M) + C_A \delta a + C_A \delta e + C_A \delta r + \sum_{i=1}^{3} C_{A_i} \delta f_i, \quad (V-15) \]

\[ C_N = C_{N_0} + C_N(\alpha, M) + C_N \delta a + C_N \delta e + C_N \delta r + \sum_{i=1}^{3} C_{N_i} \delta f_i, \quad (V-16) \]

or optionally

\[ C_D = C_{D_0} + C_D(\alpha, M) + C_D \delta a + C_D \delta e + C_D \delta r + \sum_{i=1}^{3} C_{D_i} \delta f_i, \quad (V-17) \]

\[ C_L = C_{L_0} + C_L(\alpha, M) + C_L \delta a + C_L \delta e + C_L \delta r + \sum_{i=1}^{3} C_{L_i} \delta f_i, \quad (V-18) \]

and

\[ C_Y = C_{Y_0} + C_Y(\beta, M) + C_Y \delta a + C_Y \delta e + C_Y \delta r + \sum_{i=1}^{3} C_{Y_i} \delta f_i. \quad (V-19) \]

The aerodynamic moment coefficients are given by:

\[ C_\alpha = C_{\alpha_0} + C_\alpha(\rho, \beta) + C_\alpha \delta a + C_\alpha \delta e + C_\alpha \delta r + \sum_{i=1}^{3} C_{\alpha_i} \delta f_i, \quad (V-20) \]

\[ + \sum_{i=1}^{3} C_{\alpha_i} \delta f_i \]

V-6
\[ C_m = C_{m_0} + C_m(\alpha, \theta) + C_{m_{\delta a}} \delta a + C_{m_{\delta e}} \delta e + C_{m_{\delta r}} \delta r \]
\[ + \sum_{i=1}^{3} C_{m_{\delta f_i}} \delta f_i + C_{m_q} q', \]
\[ C_n = C_{n_0} + C_n(\beta, \theta) + C_{n_{\delta a}} \delta a + C_{n_{\delta e}} \delta e + C_{n_{\delta r}} \delta r \]
\[ + \sum_{i=1}^{3} C_{n_{\delta f_i}} \delta f_i + C_{n_p} p' + C_{n_r} r', \]

where \( \delta f_i, i = 1, 2, 3, \) are arbitrary user defined deflection angles; and

\[ p' = p d_r/2V_A = \omega x d_r/2V_A \]
\[ q' = q d_p/2V_A = \omega y d_p/2V_A \]
\[ r' = r d_y/2V_A = \omega z d_y/2V_A. \]

The Mach number and dynamic pressure are given by:

\[ M = \frac{V_A}{C_S} \]
\[ q = \frac{1}{2} \rho \frac{V_A^2}{2} \]

where \( \rho \) is the atmospheric density, \( V_A \) is the velocity of the vehicle with respect to the atmosphere, and \( C_S \) is the speed of sound. These atmospheric parameters are determined from the atmospheric models as a function of the altitude \( h \) above the oblate spheroid; i.e.,

\[ \rho = \rho(h) \]
\[ C_S = C_S(h) \]
\[ p = p(h) \]
\[ T = T(h). \]

(V-24)
The angle of attack in pitch (α) and the angle of sideslip (β) required to determine the aerodynamic coefficients are calculated as follows:

\[
\alpha = \tan^{-1} \left[ \frac{\sin \alpha}{\cos \alpha} \right]
\]

\[
\beta = \tan^{-1} \left[ \frac{\sin \beta}{\cos \beta} \right]
\]

\[
\sin \alpha = \frac{w_B}{\sqrt{u_B^2 + w_B^2}}
\]

\[
\cos \alpha = \frac{u_B}{\sqrt{u_B^2 + w_B^2}}
\]

\[
\sin \beta = \frac{v_B}{v_A}
\]

\[
\cos \beta = \frac{\sqrt{u_B^2 + w_B^2}}{v_A}
\]

The total angle of attack is

\[
\alpha_T = \cos \left( \frac{V_{AB}}{V_A} \right)
\]

The aerodynamic forces in the body frame are

\[
F_{AB} = q S \begin{bmatrix}
-C_A \\
C_Y \\
-C_N
\end{bmatrix}
\]

where \( q \) is the dynamic pressure and \( S \) is the reference area.

Aerohcating Calculations.

6D POST provides for a wide variety of aeroheating calculations. Some of these options are specific in nature and apply only to particular vehicles, whereas others are quite general. The general heat rate option is based on trivariant table interpolation and provides complete flexibility with regards to vehicle shape and heat-transfer methodology. The various heat rate equations are described below.

V-8
Heat rate equations.

1) Chapman's equations. In this calculation the heat rate is given by

\[
\dot{Q} = \frac{17600}{\sqrt{R_N}} \left( \frac{\rho}{\rho_{SL}} \right)^{1.8} \left( \frac{V_R}{V_C} \right)^{3.15}.
\]

(V-28)

where \( R_N \) is the nose radius, \( \rho \) is the atmospheric density, and \( V_C \) is the reference circular orbital velocity.

2) General table lookup. This heat rate is given by

\[
\dot{Q} = Q_t(x_1, x_2, x_3),
\]

(V-29)

where \( x_1 \), \( x_2 \), and \( x_3 \) can be any internally computed variables. For example, the values that would normally be selected are \( x_1 = \alpha \), \( x_2 = h \), and \( x_3 = V_R \).

3) Modified Chapman's equation. Here the heat rate is given by

\[
\dot{Q} = Q_t(x_1, x_2, x_3) Q_c,
\]

(V-30)

where \( Q_t \) is an arbitrary table and \( Q_c \) is the standard Chapman's equation.

4) Turbulent-flow heat rate. The turbulent-flow heat rate is given by

\[
\dot{Q} = \dot{Q}_t(x_1, x_2, x_3) \left[ 1500 \left( \frac{\rho}{\rho_{SL}} \right)^{0.8} \left( \frac{V_A}{10^4} \right)^{3.18} \right].
\]

(V-31)

5) Maximum centerline heating. The equations for this method are given below in sequence.

a) Altitude-velocity correction:

\[
\Delta h = 10^5 \left[ 1.06112 - 6.16586 \frac{V_A}{10^4} \right] + 51.12090 \left( \frac{V_A}{10^4} \right)^4 - 20.66258 \left( \frac{V_A}{10^4} \right)^5 + 22.52598 \left( \frac{V_A}{10^4} \right)^2 - 48.28080 \left( \frac{V_A}{10^4} \right)^3
\]

(V-32)

\[
h_{\text{ref}} = h + \Delta h.
\]
b) Maximum centerline heat rate at reference conditions:

\[
\dot{q}_{\text{ref}} = \begin{cases} 
10^2 \left[ 277.93332 + 134.55760 \frac{h_{\text{ref}}}{10^5} - 807.75941 \left( \frac{h_{\text{ref}}}{10^5} \right)^2 + 2.90536 \left( \frac{h_{\text{ref}}}{10^5} \right)^3 + 722.36896 \left( \frac{h_{\text{ref}}}{10^5} \right)^4 - 311.40176 \left( \frac{h_{\text{ref}}}{10^5} \right)^5 \right] & \text{if } h_{\text{ref}} \geq 103,600 \text{ m;} \\
10^4 \left[ 7115.39692 - 34,881.13588 \frac{h_{\text{ref}}}{10^5} + 69,844.29141 \left( \frac{h_{\text{ref}}}{10^5} \right)^2 - 71,534.98453 \left( \frac{h_{\text{ref}}}{10^5} \right)^3 + 37,506.13054 \left( \frac{h_{\text{ref}}}{10^5} \right)^4 - 8048.55112 \left( \frac{h_{\text{ref}}}{10^5} \right)^5 \right] & \text{if } h_{\text{ref}} \leq 103,600 \text{ m;}
\end{cases}
\]  

(V-33)

\[
\dot{q}_{\text{max},a} / \dot{q}_{\text{max},a=50^\circ} = [\ln(x)]^2,
\]

where

\[
x = 10^2 \left[ 0.01136 + 0.01343 \frac{a}{10^2} + 1.42672 \left( \frac{a}{10^2} \right)^3 - 0.75623 \left( \frac{a}{10^2} \right)^5 + 0.30535 \left( \frac{a}{10^2} \right)^2 - 1.06269 \left( \frac{a}{10^2} \right)^3 \right].
\]  

(V-34)

d) Maximum centerline heat rate:

\[
\dot{q}_{\text{max}} = \frac{\dot{q}_{\text{max},a}}{\dot{q}_{\text{max},a=50^\circ}} \cdot \dot{q}_{\text{ref}}.
\]  

(V-35)

In addition to the heat rate calculations, the program also provides the capability to calculate other aeroheating indicators that can be used for trajectory shaping purposes.

**Aerodynamic heating indicators.** The heating rate for zero total angle of attack \( \alpha_T \) is

\[
\dot{Q} = q V_A^2.
\]  

(V-36)
The aerodynamic heating indicator for zero total angle of attack is

\[ Q = \int_{0}^{t} \dot{Q} \, dt. \]  \hspace{1cm} (V-37)

The heating indicator for non-zero angles of attack is given by

\[ Q' = \int_{0}^{t} f(\alpha', M) \dot{Q} \, dt, \]  \hspace{1cm} (V-38)

where

\[ f(\alpha', M) = \left( 1 + \frac{7}{5} M^2 \sin^2 \alpha' \right)^{5/7} \] 

\[ K = \left\{ \begin{array}{c} 1 + \frac{5}{7} M^2 \left[ 1 - \left( 1 + \frac{7}{5} M^2 \sin^2 \alpha' \right)^{2/7} \right]^{1/4} \\ \end{array} \right. \]

and

\[ \begin{array}{l} \alpha' = a \quad \text{for } \alpha < 0^\circ \\ Q_T' = Q' \\ \end{array} \] 

\[ \begin{array}{l} \alpha' = a \quad \text{for } \alpha > 0^\circ \\ Q_T' = Q' \\ \end{array} \] 

\[ \begin{array}{l} \alpha' = \beta \quad \text{for } \beta < 0^\circ \\ Q_L' = Q' \\ \end{array} \] 

\[ \begin{array}{l} \alpha' = \beta \quad \text{for } \beta > 0^\circ. \\ Q_R' = Q' \\ \end{array} \]  \hspace{1cm} (V-39)
The heating indicator for laminar flow is calculated as

\[ Q_{\text{lam}} = \int_{0}^{t} 17600 \, K_{aT} \left( \frac{\rho}{\rho_0} \right)^{1.5} \left( \frac{V_A}{26000} \right)^{3.15} \, dt, \]  

\[ (V-40) \]

where

\[ K_{aT} = f (a_T). \]  

\[ (V-41) \]

The heating indicator for turbulent flow is calculated as

\[ Q_{\text{turb}} = \int \, 1500 \, K_{aT} \left( \frac{\rho}{\rho_0} \right)^{0.8} \left( \frac{V_A}{10000} \right)^{3.18} \, dt \]  

\[ (V-42) \]

**Ten-Panel Vehicle Heating Model.** Special aeroheating calculations are available for a ten-panel vehicle model. The heating ratios are referenced to the heat rate calculation. The total heat for each panel is given by

\[ Q_i = H_{R_i} Q_s, \]  

\[ (V-43) \]

where \( Q_s \) is the total heat and \( H_{R_i} \) is the heat ratio for panel \( i \). The weight for each panel is the product of the weight per unit area and the area of the panel. The total weight is the sum of the individual weights for each panel:

\[ W_p = \sum_{i=1}^{10} W_{uA_i} A_i, \]  

\[ (V-44) \]

where \( W_{uA_i} \) is the weight per unit area and \( A_i \) is the area of the \( i^{th} \) panel.
Sensor Module

The sensor module computes information that describes the behavior of the sensing elements of the vehicle's navigation system. Thus, the primary functional responsibility of the module is that of simulating hardware characteristics of sensors. For example, the behavior of an inertial measurement unit (IMU) can be described by a mathematical model of the platform and the accelerometers. Frequently this module is used for error analysis purposes.

Sensor models called by this module are necessarily vehicle and subsystem dependent. As a consequence, the sensor model must be designed and implemented for each particular application.

There are many applications of the program that do not require a specific simulation of the sensors. Therefore, for convenience, a "perfect" sensor model is coded into this routine. This "perfect" sensor model sets the sensed program variables equal to their actual values as calculated in the simulation models.

Navigation Module

The function of the navigation model is to estimate the state (position, velocity, etc) of the vehicle based on the sensor outputs. Clearly, this module is also vehicle and subsystem dependent and must be designed and implemented for each specific application. This version of the program contains no navigation models. As a consequence, the estimated state is set equal to the actual state. This is equivalent to simulation of perfect navigation.

Guidance Module

The guidance module takes the output of the navigation model and computes a guidance command. Typically, the guidance command represents a desired change in the current attitude of the vehicle. This command is computed on the basis of meeting some specified trajectory condition, such as, inject conditions or landing conditions. The autopilot is designed to remove the errors between the commanded values of the guidance variables and their actual (or sensed) values. This is accomplished by deflecting engines, control surfaces, and/or firing RCS jets.
The current version of 6D POST contains three preloaded guidance options: (1) an open-loop profile steering; (2) a closed loop v-h profile ascent algorithm; and (3) the constant drag Space Shuttle reentry scheme (ref. H-1). If these methods are inadequate, the user may implement his own guidance algorithm into this module.

Autopilot Module

The function of the autopilot module is the generation of a command, which, when implemented through the deflection equations contained in the controls module, causes the vehicle to respond as prescribed by the guidance module. This functional responsibility is depicted in Figure V-3.

Nomenclature:

- $\theta_c$ - Guidance command
- $\theta_a$ - Actual or sensed values of guidance variables
- $e$ - Generalize error signal
- $\delta\theta$ - Pitch, yaw, and roll autopilot command
- $\delta$ - Deflection (engine or aerodynamic surfaces) angles

Figure V-3.- Functional Flow
The autopilot module calculates only autopilot commands based on the input guidance commands, and does not calculate engine or control surface deflections. The engine and control surface deflections are computed in the controls module as a linear function of the autopilot commands. The autopilot commands $\delta_\theta$, $\delta_\psi$, $\delta_\gamma$ represent changes in vehicle attitude. The mixing equations determine the engine and control surface deflections that create the control forces and moments.

Currently, there are two Space Shuttle autopilot models available in 6D POST. One autopilot is for ascent and the other for reentry. The ascent autopilot is somewhat standard and could be used on most ascent problems with little or no modification. The basic inputs to this model are: attitude commands from the guidance, inertial attitude angles, body rotational rates, translational accelerations, and preloaded engine deflection commands. The outputs are pitch, yaw, and roll autopilot commands, which are sent to the controls module to determine the engine deflection angles. The reentry autopilot is Space Shuttle oriented and is probably not applicable to other vehicle configurations. This model is intended to provide attitude control for Space Shuttle beginning at approximately 400,000-ft altitude and ending in the high subsonic flight regime. The control logic makes use of both aerodynamic control surface torques and reaction control jets. A complete description of this model is presented in ref. H-2.

**Controls Model**

The controls model converts pitch, yaw, and roll autopilot commands into aerodynamic control surface deflection angles and/or engine gimbal angles. The conversion of the autopilot commands into deflection angles is implemented through the matrix mixing logic given by the equation

$$ \delta = \delta_0 + [M] \delta_\theta, \quad (V-45) $$

where $\delta$ denotes a general deflection angle with a null position of $\delta_0$, $[M]$ the mixing gains, and $\delta_\theta$ the autopilot commands. The gains contained in the mixing matrix, $[M]$, and the null deflections, $\delta_0$, are specified by user input.
The standard aerodynamic surface deflection mixing equations used in the program are:

\[
\begin{align*}
\delta_a^* &= \delta_a^* + KR \delta_a + KP \delta_a + KY \delta_a \delta^*, \\
\delta_e^* &= \delta_e^* + KR \delta_e + KP \delta_e + KY \delta_e \delta^*, \\
\delta_R^* &= \delta_R^* + KR \delta_R + KP \delta_R + KY \delta_R \delta^*,
\end{align*}
\]  \hspace{1cm} (V-46, V-47, V-48)

and the standard engine deflection angle mixing equations are similarly:

\[
\begin{align*}
\delta e_{p1}^* &= \delta e_{p1}^* + KP \delta e_{p1} + KR \delta e_{p1} \delta^*, \\
\delta e_{y1}^* &= \delta e_{y1}^* + KY \delta e_{y1} + KR \delta e_{y1} \delta^*,
\end{align*}
\]  \hspace{1cm} (V-49, V-50)

where \( \delta_a, \delta_e, \) and \( \delta_R \) are the pitch, yaw, and roll autopilot commands.

**Airframe Model**

The airframe model computes the total thrust and moments acting on the vehicle. The forces and moments are computed from the engine and aerodynamic deflection angles and the RCS thrust and moments.

The non-gravitational force acting on the vehicle is computed in the body frame as:

\[
F_B = F_{TB} + F_{AB} + F_{RCS}
\]  \hspace{1cm} (V-51)

where \( F_{TB} \) is the total force due to the engines, \( F_{AB} \) is the total force due to aerodynamic effects, and \( F_{RCS} \) is the total force resulting from the reaction-control system. Similarly, the total moment acting on the vehicle is computed as:

\[
M_B = M_{TB} + M_{AB} + M_{RCS}
\]  \hspace{1cm} (V-52)

The thrust vector components for both rocket and jet engines are determined from the thrust magnitude \( T_{R1} \) or \( T_{J1} \) and the engine gimbal angles \( \delta e_{p1} \) and \( \delta e_{y1} \). The total thrust force in the body frame is given by:

V-16
\[
E_{TB} = \sum_{i=1}^{N_{eng}} E_{TB_i},
\]
where the individual engine components, \(E_{TB_i}\), are given by
\[
E_{TB_i} = T_{R_i} \begin{bmatrix}
\cos \delta e & \cos \delta e \\
\sin \delta e & -\cos \delta e \\
\end{bmatrix}
\]
For roll nozzles, the thrust vector is given by
\[
E_{TB_1} = [K] T_{R_1} \begin{bmatrix}
\cos \delta e & \cos \delta e \\
\sin \delta e & -\cos \delta e \\
\end{bmatrix}
\]
where for a roll nozzle the deflection matrix \([K]\) is given by
\[
K = \begin{bmatrix}
1 & 0 & 0 \\
0 & c\phi & s\phi \\
0 & -s\phi & c\phi \\
\end{bmatrix}
\]
where
\[
\phi = \text{input value}
\]
or
\[
\phi = \tan^{-1}\left(\frac{z_{gP_1}}{y_{gP_1}}\right) \text{ if not input.}
\]

V-17
The thrust moments are obtained by summing the thrust moments for each engine as follows:

\[
N_{\text{eng}} \sum_{i=1}^{N_{\text{eng}}} F_{TBi} \times \Delta R_{BTi} \quad (V-57)
\]

where

\[
\Delta R_{BTi} = \begin{bmatrix}
-x_{\text{cg}i} \\
y_{\text{cg}i} \\
z_{\text{cg}i}
\end{bmatrix}
\]

The aerodynamic forces and moments are given by:

\[
F_{AB} = \begin{bmatrix}
F_{AXB} \\
F_{AYB} \\
F_{AZB}
\end{bmatrix} = qS \begin{bmatrix}
-C_A \\
C_Y \\
-C_N
\end{bmatrix} (V-59)
\]

and

\[
M_{AB} = qS \begin{bmatrix}
d_R C_A \\
d_p C_m \\
d_Y C_n
\end{bmatrix} - F_{AB} \times \Delta R_{AB} \quad (V-60)
\]

where

\[
\Delta R_{AB} = \begin{bmatrix}
-x_{\text{ref}} \\
y_{\text{ref}} \\
z_{\text{ref}}
\end{bmatrix}
\]

The aerodynamic reference point \((x_{\text{ref}}, y_{\text{ref}}, z_{\text{ref}})\) is calculated from tabular input.

The RCS forces and moments are computed in the autopilot model and are merely added to obtain the resultant force and moment vectors.

V-18
VI. TRAJECTORY SIMULATION

The following sections present the equations used in the trajectory simulation subroutines. These equations summarize the principal computations performed by the program, and motivate many of the program input procedures.

Events/Phases

Simulation data are input according to phase, where the phases are defined by a user-specified sequence of events. The simulation equations are then solved sequentially by phase. Therefore, the user is required to input a sequence of trajectory segments that define the problem being simulated from beginning to end. These trajectory segments, or phases, are defined by two events—a beginning event and an ending event. An event is an interruption of the trajectory simulation that occurs when a user-specified variable reaches a user-specified value. An event must be created whenever the user wishes to change any input data for the problem or to cause any change in the method of simulating the problem. For example, the sequence of events for a typical ascent problem could result in a simulation setup similar to that shown in figure VI-1.

Figure VI-1.—Event Sequence Setup

</tbody>
</table>
The event numbers for a given problem must be specified as real numbers by the user in monotonic increasing order. These event numbers are then used by the program to determine the order in which the events are to occur. The program requires that each problem have a minimum of two events—an initial event and a final event. Since a phase is initiated by the corresponding event, the event criterion for a given event specifies the conditions at the beginning of the corresponding phase. A problem is terminated by specifying the last event that is to occur. The problem can also be terminated in a pseudo-abort mode by specifying the maximum trajectory time, maximum altitude, or minimum altitude.

Although event numbers must be monotonic increasing, they need not be consecutive. This allows the user to easily add or delete events from an input deck.

Three types of events have been defined to provide flexibility in setting up a given problem:

1) Primary events - These describe the main sequential events of the trajectory being simulated. These events must occur, and must occur in ascending order according to the event number. Most problems will usually be simulated by a series of primary events;

2) Secondary events - These are events that may or may not occur during the specified trajectory segment. Secondary events must occur in ascending order during the interval bounded by the primary events. The occurrence of a primary event will nullify the secondary events associated with the previous primary event if they have not already occurred;

3) Roving primary events - These events can occur any time after the occurrence of all primary events with smaller event numbers. They can be used to interrupt the trajectory on the specified criterion regardless of the state of the trajectory or vehicle.

The program monitors as many as ten events at a time, depending on the types of events to determine which event is to occur next. This gives the user a powerful tool for simulating complex problems.
Multiple events are monitored in the following sequence:

1) The next primary event is monitored;

2) As many as nine primary roving events are then monitored, provided there are no secondary events. A roving primary event is added to the list of those being monitored as soon as the primary event immediately preceding that roving event has occurred;

3) Next, as many as nine secondary events are monitored, provided there are no primary roving events. (Note that caution must be exercised when using secondary events because of their nature. Since as many as nine secondary events are monitored at a time, any one of those nine will occur as soon as its criterion has been met. Because they are secondary events, the event that occurs will cancel all secondary events with smaller event numbers.);

4) Finally, a total of nine primary roving and secondary events are monitored.

Since the program can only monitor nine events (in addition to the next primary event), the sum of the primary roving events and the secondary events must be less than or equal to nine or a fatal error will result.

The time-to-go model (TGΩM) determines when the events occur during the trajectory simulation. Basically, TGΩM checks the values of the criterion being monitored at each integration step. If none of the criterion values has bracketed the desired cutoff value, then another integration step is taken. If a criterion variable is bracketed with the input step size, then TGΩM computes a new stepsize equal to the predicted time-to-go.

The predicted time-to-go for each event is computed from the equation

$$\Delta t^* = -\frac{y^2(t)}{(y(t + \Delta t) - y(t))} \quad (VI-1)$$

where $y(t)$ is the difference between the actual and the desired value of the event criterion. If more than one event is bracketed, then the minimum predicted time-to-go is used as the integration stepsize. This process is repeated until the criterion value is
within the specified tolerance of the desired value. If the desired condition cannot be achieved in 20 iterations, an error message is printed and the program stops. Generally this situation is caused by an input error. The fundamental features of the time-to-go logic are shown in Figure VI-2.

![Figure VI-2: Illustration of Time-to-Go Logic](image)

### Translational Equations

The translational equations of motion are solved in the planet-centered inertial coordinate system. These equations are

\[
\begin{align*}
\ddot{r}_I &= v_I \\
\ddot{v}_I &= [IB]^{-1} \left[ A_{TB} + A_{AB} \right] + \mathbf{g}_I,
\end{align*}
\]

where \( A_{TB} \) is the thrust acceleration in the body frame, \( A_{AB} \) is the aerodynamic acceleration in the body frame, and \( \mathbf{g}_I \) is the gravitational acceleration in the ECI frame.
Initialization. - There are five options for initializing the velocity vector and two options for initializing the position vector. These options are described below.

Inertial position components \((x_I, y_I, z_I)\). - The inertial position components can be input directly since no transformation is required.

Earth-relative position \((\theta_I, \phi_c, \phi_g, h, r)\). - In this option the equations vary and the sequence of calculation varies according to the choice of input. However, the basic equations used are:

\[
\begin{align*}
\theta_I &= \theta + \Omega_p (t - t_0) \quad \text{if } \theta \text{ is input}, \\
\phi_c &= \tan^{-1} (k^2 \tan \phi_g) \quad \text{if } \phi_g \text{ is input}, \\
r_I &= h + R_s (\phi_c) \quad \text{if } h \text{ is input}, \\
\end{align*}
\]

and

\[
X_I = r_I \begin{bmatrix}
\cos \phi_c \cos \theta_I \\
\cos \phi_c \sin \theta_I \\
\sin \phi_c
\end{bmatrix}
\]

Inertial velocity components \((V_{xI}, V_{yI}, V_{zI})\). - These variables can be input directly.

Inertial local horizontal \((V_I, \gamma_I, A_{zI})\). - The inertial components in the horizontal frame are first transformed to the geographic frame as

\[
V_{xI} = V_I \begin{bmatrix}
\cos \gamma_I \cos A_{zI} \\
\cos \gamma_I \sin A_{zI} \\
-\sin \gamma_I
\end{bmatrix}
\]
and then transformed to the ECI frame by

$$V_I = [IG]^{-1} V_{IG}.$$  \hfill (VI-7)

Earth-relative local horizontal \((V_R, \gamma_R, A_{ZR})\). - The Earth-relative velocity components are first transformed to the geographic frame as

$$V_{RG} = V_R \begin{bmatrix} \cos \gamma_R \cos A_{ZR} \\ \cos \gamma_R \sin A_{ZR} \\ -\sin \gamma_R \end{bmatrix}$$  \hfill (VI-8)

and then transformed to the ECI frame by

$$V_I = [IG]^{-1} V_{RG} + \frac{\Omega}{p} \times r_I.$$  \hfill (VI-9)

Atmospheric relative local horizontal \((V_A, \gamma_A, A_{ZA})\). - The atmospheric relative velocity components are first transformed to the geographic frame as

$$V_{AG} = V_A \begin{bmatrix} \cos \gamma_A \cos A_{ZA} \\ \cos \gamma_A \sin A_{ZA} \\ -\sin \gamma_A \end{bmatrix} + \begin{bmatrix} V_{WXG} \\ V_{WYG} \\ V_{WZG} \end{bmatrix},$$  \hfill (VI-10)

and then transformed to the ECI frame by

$$V_I = [IG]^{-1} V_{AG} + \frac{\dot{\Omega}}{p} \times r_I.$$  \hfill (VI-11)

Orbital parameters \((h_p, h_a, i, \Omega, \omega_p, \theta)\). - This option initializes both position and velocity. The equations used to transform the orbital parameter to the ECI position and velocity are:
\[ r_p = h_p + R_Z \]
\[ r_a = h_a + R_Z \]
\[ a = \frac{(r_a + r_p)}{2} \]
\[ e = \frac{(r_a - r_p)}{(r_a + r_p)} \]
\[ \rho = \theta + \omega \]
\[ p = a (1 - e^2) \]
\[ H = u_p \]
\[ r = \frac{p}{(1 + e \cos \theta)} \]
\[ \mathbf{u}_r = \begin{bmatrix} \cos \Omega & -\sin \Omega & 0 \\ \sin \Omega & \cos \Omega & 0 \\ 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} 1 & 0 & 0 \\ 0 & \cos i & -\sin i \\ 1 & \sin i & \cos i \end{bmatrix} \begin{bmatrix} \cos \rho \\ \sin \rho \end{bmatrix} \]

and

\[ \mathbf{r} = \mathbf{r}_u \]
\[ \mathbf{v} = \mathbf{v}_u \begin{bmatrix} \frac{2}{r} - \frac{1}{a} \end{bmatrix} \]
\[ \gamma = \sin^{-1} \left( \frac{H}{r v} \right) \]
\[ \mathbf{u}_v = \begin{bmatrix} \cos \rho & -\sin \rho & 0 \\ \sin \rho & \cos \rho & 0 \\ 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} 1 & 0 & 0 \\ 0 & \cos i & -\sin i \\ 0 & \sin i & \cos i \end{bmatrix} \begin{bmatrix} \cos \Omega & -\sin \Omega & 0 \\ \sin \Omega & \cos \Omega & 0 \\ 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} \cos \gamma \\ \sin \gamma \end{bmatrix} \begin{bmatrix} \cos \gamma \\ \sin \gamma \end{bmatrix} \begin{bmatrix} 0 \end{bmatrix} \]

(VI-12)
Rotational Equations

The rotational equations of motion are solved in the body-centered coordinate system. These equations are

\[ \dot{e} = \frac{1}{2} [E] \omega_B \]  
\[ \dot{\omega}_B = [I]^{-1} [M_B - [I] \omega_B - \omega_B \times [I] \omega_B], \]  
\[ M_B = M_{TB} + M_{AB} + M_{RCS} \]

where \( e \) is a four dimensional vector of quaternion parameters, \([E]\) is the quaternion matrix, \( \omega_B \) is the inertial angular velocity expressed in the body frame; \( M_B \) is the total external moment acting in the vehicle as a result of the thrust, the RCS, and the aerodynamic forces, and \([I]\) is the inertia matrix for the composite vehicle. The \([I]\) and \([E]\) matrices are given by

\[ [I] = \begin{bmatrix}
  I_{XX} & I_{XY} & I_{XZ} \\
  I_{XY} & I_{YY} & I_{YZ} \\
  I_{XZ} & I_{YZ} & I_{ZZ}
\end{bmatrix} \]

\[ [E] = \begin{bmatrix}
  -e_1 & e_2 & e_3 \\
  e_0 & e_2 & -e_1 \\
  e_0 & -e_1 & e_2 \\
  e_0 & e_1 & -e_2
\end{bmatrix} \]

The body rates are defined below and illustrated in Figure VI-3.

- \( \omega_x \) - Roll body rate. The angular rate about the \( x_B \)-axis in deg/sec,
- \( \omega_y \) - Pitch body rate. The angular rate about the \( y_B \)-axis in deg/sec,
- \( \omega_z \) - Yaw body rate. The angular rate about the \( z_B \)-axis in deg/sec.

Figure VI-3.- Body Rates

VI-8
Initialization. - The rotational equations of motion are initialized by defining both the attitude angles and the attitude rates. There are three options for initializing the attitude: (1) inertial Euler angles; (2) relative Euler angles; and (3) aerodynamic angles. There are three options for initializing the attitude rates: (1) body rates; (2) inertial Euler angle rates and (3) relative Euler angles rates. The attitude angles are used to compute initial values of the quaternions in order to initialize equation VI-14. The rates are used to initialize the moment equations. The equations for these options are presented below.

When inertial Euler angles are input the initial quaternion vector is given

\[ \mathbf{q}_0 = \mathbf{q}(\phi_1) \ast \mathbf{q}(\psi_1) \ast \mathbf{q}(\theta_1) \quad (VI-18) \]

where the asterisk denotes quaternion multiplication and where

\[
\begin{align*}
\mathbf{q}(\phi_1) &= \cos \left(0.5 \phi_1\right) + \sin \left(0.5 \phi_1\right) \mathbf{i} \\
\mathbf{q}(\psi_1) &= \cos \left(0.5 \psi_1\right) + \sin \left(0.5 \psi_1\right) \mathbf{k} \\
\mathbf{q}(\theta_1) &= \cos \left(0.5 \theta_1\right) + \sin \left(0.5 \theta_1\right) \mathbf{j}.
\end{align*}
\]

(VI-19)

When aerodynamic angles are input, then the initial quaternion vector is given by

\[ \mathbf{q}_0 = \mathbf{q}(\lambda_A) \ast \mathbf{q}(\gamma_A) \ast \mathbf{q}(\alpha) \ast \mathbf{q}(-\beta) \ast \mathbf{q}(\alpha) \ast \mathbf{q}(-90) \ast \mathbf{q}(90) \ast \mathbf{q}(\phi_L) \ast \mathbf{q}(-\theta_L) \ast \mathbf{q}(\theta_1) \ast \mathbf{q}(-\phi) \quad (VI-20) \]
where
\[
\mathbf{e} (A_{ZL}) = \cos (0.5 A_{ZL}) - \sin (0.5 A_{ZL}) \mathbf{k}
\]
\[
\mathbf{e}(90) = \cos (45) + \sin (45) \mathbf{j}
\]
\[
\mathbf{e} (\phi_L) = \cos (0.5 \phi_L) + \sin (0.5 \phi_L) \mathbf{j}
\]
\[
\mathbf{e} (-\theta_L) = \cos (0.5 \theta_L) - \sin (0.5 \theta_L) \mathbf{k}
\]
\[
\mathbf{e} (\theta_I) = \cos (0.5 \theta_I) + \sin (0.5 \theta_I) \mathbf{k}
\]
\[
\mathbf{e} (\phi_c) = \cos (0.5 \phi_c) - \sin (0.5 \phi_c) \mathbf{j}
\]
\[
\mathbf{e}(\psi) = \cos 0.5\psi + (\sin 0.5\psi) \mathbf{k}
\]
\[
\mathbf{e}(\theta) = \cos 0.5\theta + (\sin 0.5\theta) \mathbf{j}
\]
\[
\mathbf{e}(\phi) = \cos 0.5\phi + (\sin 0.5\phi) \mathbf{i}
\]

When relative Euler angles are input, then the initial quaternion vector is given
\[
\mathbf{q}_0 = \mathbf{e} (A_{ZL}) * \mathbf{e}(90) * \mathbf{e} (\phi_L) * \mathbf{e} (-\theta_L) * \mathbf{e} (\theta_I) * \mathbf{e} (-\phi_c) * \mathbf{e}(-90) * \\
* \mathbf{e}(\psi) * \mathbf{e}(\theta) * \mathbf{e}(\phi).
\]

VI-10
The available options for initializing the moment equation are:

1) Input \( \omega_x, \omega_y, \omega_z \) directly

2) Input the inertial Euler angle rates \( \dot{\phi}_I, \dot{\psi}_I, \dot{\theta}_I \) and calculate \( \omega_x, \omega_y, \omega_z \) via

\[
\begin{bmatrix}
\omega_x \\
\omega_y \\
\omega_z
\end{bmatrix} =
\begin{bmatrix}
\dot{\phi}_I \cos \psi_I \cos \theta_I - \dot{\psi}_I \sin \theta_I \\
\dot{\theta}_I - \dot{\phi}_I \sin \psi_I \\
\dot{\psi}_I \cos \psi_I \sin \theta_I + \dot{\psi}_I \cos \theta_I
\end{bmatrix}
\]  \hspace{1cm} (VI-24)

3) Input the relative Euler angle rates \( \dot{\psi}_R, \dot{\theta}_R, \dot{\phi}_R \) and calculate \( \omega_x, \omega_y, \omega_z \) via

\[
\begin{bmatrix}
\omega_x \\
\omega_y \\
\omega_z
\end{bmatrix} =
\begin{bmatrix}
\dot{\phi}_R - \sin \theta_R \dot{\psi}_R \\
\cos \theta_R \dot{\phi}_R + \sin \dot{\phi}_R \cos \theta_R \dot{\psi}_R + \sin \phi_R \cos \theta_R \psi_R - \sin \phi_R \theta_R \\
\cos \dot{\phi}_R \psi_R - \sin \phi_R \theta_R
\end{bmatrix},
\]  \hspace{1cm} (VI-25)

where

\[
A = [GB] \begin{bmatrix}
\frac{V}{r_I} \\
-\frac{\mu}{r_I} \\
\frac{V \tan \phi}{r_I}
\end{bmatrix}
\]

and

\[
\begin{bmatrix}
u \\
v \\
w
\end{bmatrix} = [IG] V_I,
\]  \hspace{1cm} VI-11
Integration Variables

The number of integrals computed during any particular phase is determined from the options requested by the user. As a minimum, the translational equations of motion are integrated to give the position and velocity of the center of mass of the vehicle. The user may also select additional variables to be integrated. The only restriction is that no more than 40 integrals can be computed per phase.

VI-12
VII. AUXILIARY CALCULATIONS

In addition to computing the basic variables, POST also computes numerous auxiliary variables that are related to: (1) conic parameters, (2) range calculations, (3) tracking data, (4) analytic impact calculations, (5) velocity losses, and (6) velocity margins. The equations used to calculate these variables are presented below.

Conic Calculations

The following Keplerian conic variables are computed.

\[
\begin{align*}
\delta & \quad \text{energy, } \frac{V_1^2}{2} - \frac{\mu}{r_1} \\
a & \quad \text{semimajor axis, } -\mu/2\delta \\
h & \quad \text{angular momentum, } |\mathbf{r}_1 \times V_1| \\
p & \quad \text{semilatus rectum, } h^2/\mu \\
e & \quad \text{eccentricity, } \sqrt{1 - p/a} \\
\Delta V & \quad \text{velocity required to circularize orbit, } \sqrt{\Delta V - \Delta V}, \text{ where} \\
\frac{h}{h} & \quad \frac{h}{h} \\
\frac{r_1}{r_1} & \quad \frac{r_1}{r_1} \\
\frac{u_h}{u_r} & \quad \frac{u_h}{u_r} / |u_h \times u_r| \\
\frac{V_c}{V_c} & \quad (\mu/r_1)^{\frac{1}{2}} u_v \\
\Delta V & \quad V_c - V_1 \\
\iota & \quad \text{inclination, } \cos^{-1}\left(\frac{h_z}{h}\right) \\
\Omega & \quad \text{longitude of ascending node, } \cos^{-1}\left(\hat{r}_1 \cdot \frac{\mathbf{u}}{h}\right), \text{ where}
\end{align*}
\]
$$u_\Omega = \hat{Z}_I \times \frac{\hat{y}}{|\hat{Z}_I \times \hat{h}|}$$

$\rho$ argument of vehicle, $\rho = \cos^{-1} \left( \frac{u_T \cdot u_\Omega}{|u_T| |u_\Omega|} \right)$

$T_{SP}$ time since perigee, $\frac{P}{2\pi} M$

$T_{TP}$ time to perigee, $P - T_{SP}$

$\phi_p$ latitude of perigee, $\tan^{-1} \left( \frac{u_3/\sqrt{u_1^2 + u_2^2}}{u_3/\sqrt{u_1^2 + u_2^2}} \right)$, where

$$u = \cos(\omega)u_\Omega + \sin(\omega)\left( u_h \times u_\Omega \right)$$

$\theta_p$ longitude of perigee, $\tan^{-1} \left( \frac{u_2/u_1}{u_3/u_1} \right)$

$h_p$ altitude of perigee, $r_p - R_s(\phi_p)$

$h_a$ altitude of apogee, $r_a - R_s(\phi_p)$

$V_p$ velocity at perigee, $\sqrt{\frac{\mu}{a} \left( \frac{1 + e}{1 - e} \right)}$

$V_a$ velocity at apogee, $\sqrt{\frac{\mu}{a} \left( \frac{1 - e}{1 + e} \right)}$

$V_\infty$ hyperbolic excess velocity, $\sqrt{2\mu}$

$\theta_{\max}$ maximum true anomaly for hyperbolic orbit, $\cos^{-1} \left( -\frac{1}{e} \right)$

$\delta_{RA}$ declination of outgoing asymptote, $\sin^{-1} \left[ \frac{u_\infty}{u_\infty} \right]$, where

$$u_T = u_h \times u_{RI}$$

$$u_\infty = \cos(\theta_{\max} - \theta) \frac{u_\infty}{u_\infty} + \sin(\theta_{\max} - \theta) \frac{u_T}{u_T}$$

$R_A$ right ascension of outgoing asymptote, $\tan^{-1} \left( \frac{u_\infty}{u_\infty} \right)$

VII-2
\[ \theta = \cos^{-1} \left( \frac{1}{e} \left( \frac{P}{r} - 1 \right) \right) \]

\[ E = \text{eccentric anomaly}, \quad 2 \tan^{-1} \left( \sqrt{\frac{1-e}{1+e}} \tan \frac{\theta}{2} \right) \]

\[ M = \text{mean anomaly}, \quad \omega = e \sin E \]

\[ \rho = \text{argument of perigee}, \quad \rho = \theta \]

\[ r_p = \text{perigee radius}, \quad a(1-e) \]

\[ r_a = \text{apogee radius}, \quad a(1+e) \]

\[ P = \text{period}, \quad 2\pi \sqrt{\frac{a^3}{\mu}}. \]

**Range Calculations**

The program provides for various types of range calculations. The equations for these calculations are given below.

**Dot product downrange.** - The relative range angle, measured from the vehicle's initial position to its current position, is given by

\[ \phi_R = \cos^{-1} \left( \frac{u_{r_{so}} \cdot u_{r_s}}{r_{so}} \right). \]  \hspace{1cm} (VII-1)

where \( u_{r_{so}} \) is a unit vector along the initial position vector in Earth-centered rotating coordinates and \( u_{r_s} \) is a unit vector along the current position vector in Earth-centered rotating coordinates. The range over an oblate spheroid is calculated from the average radius to the surface, and is given by

\[ R_D = \left[ \frac{r_{so} + r_s}{2} \right] \phi_R. \]  \hspace{1cm} (VII-2)

**Crossrange and downrange via orbital plane reference.** - Referring to figure VII-1, identify the vehicle's position at time \( t^* \) by \( O \), and at a later time \( t \) by \( P \). At time \( t^* \), the vehicle has a latitude of \( \phi^* \), a longitude of \( \theta^* \), and a velocity

VII-3
Note: O - position at initial time,
P - position at subsequent time.

Figure VII-1.- Downrange and Crossrange Angles
heading of \( \lambda^* \). At time \( t \) the vehicle is at latitude \( \phi \) and longitude \( \theta \). The downrange angle \( (\mu) \) and the crosstrange angle \( (\nu) \) shown in the illustration are measured along, and normal to, the great circle through 0, and are inclined to the meridian by \( \lambda^* \). From analytical geometry, \( \nu \) and \( \mu \) can be expressed as

\[
\sin \nu = -\sin \lambda^* \sin \phi \cos c \cos \theta^* - \cos \lambda^* \cos \phi \sin \theta^* \\
+ \sin \lambda^* \cos \phi \sin \phi^c \tag{VII-3}
\]

\[
\sin \mu = (-\cos \lambda^* \sin \phi \cos \theta^* + \sin \lambda^* \cos \phi \sin \theta^*) \\
+ \cos \lambda^* \cos \phi \sin \phi^c) / \cos \nu,
\]

\[
\cos \mu = (\cos \phi \cos \phi \cos \theta^* + \sin \phi \sin \phi^c) / \cos \nu,
\]

where \( \theta^* \) and \( \lambda^* \) can be defined in either of two ways:

1) The great circle to which \( \nu \) and \( \mu \) are referenced is fixed and rotating with the Earth. Then

\[
\lambda^* = \text{Earth's relative heading} = \sin^{-1} \frac{v_R}{\sqrt{u^2 + v^2}} \tag{VII-4}
\]

\[
\theta^* = \theta - \theta^*;
\]

2) The great circle to which \( \mu \) and \( \nu \) are referenced is inertially fixed, having the Earth rotating below it. Then

\[
\lambda^* = \text{inertial heading} = \sin^{-1} \frac{\nu}{\sqrt{u^2 + v^2}} \tag{VII-5}
\]

\[
\theta^* = \theta - \theta^* + \Omega(t - t^*).
\]
Knowing $v$ and $\mu$, and crossrange $C_R$ and downrange $D_R$ distances are

$$
\begin{align*}
C_R &= \overline{R}_{ave} \cdot v \\
D_R &= \overline{R}_{ave} \cdot \mu,
\end{align*}
$$

(VII-6)

where $\overline{R}_{ave}$ is the average Earth radius between the initial and final points.
Auxiliary Position and Velocity Calculations

The solution from the translational equations is then used to calculate numerous output variables. The key variables directly computed from \((x_I, y_I, z_I)\) and \((V_{XI}, V_{YI}, V_{ZI})\) summarized below.

\[ r_I = \text{geocentric radius} \]
\[ = (x_I - x_I)^2 \]

\[ V_I = \text{magnitude of the inertial velocity} \]
\[ = (v_{XI} - v_{YO})^2 \]

\[ V_R = \text{relative velocity} \]
\[ = v_I - \Omega_p \times r_I \]

\[ V_A = \text{atmospheric relative velocity} \]
\[ = V_R + V_W \]

\[ V_R = \text{magnitude of the relative velocity} \]
\[ = (v_{XI} - v_{YO})^2 \]

\[ V_A = \text{magnitude of the atmospheric relative velocity} \]
\[ = (v_{XI} - v_{YO})^2 \]

\[ u_{RI} = \text{unit vector along radius vector} \]
\[ = x_I / r_I \]

\[ u_{VI} = \text{unit vector along inertial velocity vector} \]
\[ = v_I / v_I \]

\[ \gamma_I = \text{inertial flight path angle} \]
\[ = \sin^{-1}[u_{RI} \cdot u_{VI}] \]

(VII-7)
\( \gamma_R \) = relative flight path angle
\[ = \sin^{-1} \left( \frac{u_{RI} \cdot u_{VR}}{} \right) \]

\( \gamma_A \) = atmospheric relative flight path angle
\[ = \sin^{-1} \left( \frac{u_{RI} \cdot u_{VA}}{} \right) \]

\( V_{IG} \) = inertial velocity in the G-frame
\[ = [IG] \ V_I \]

\( V_{RG} \) = relative velocity in the G-frame
\[ = [IG] \ V_R \]

\( V_{AG} \) = atmospheric relative velocity in the G-frame
\[ = [IG] \ V_A \]

\( A_{ZI} \) = inertial azimuth
\[ = \tan^{-1} \left( \frac{V_{YG}}{V_{XC}} \right) \]

\( A_{ZR} \) = relative azimuth
\[ = \tan^{-1} \left( \frac{V_{RYG}}{V_{RXG}} \right) \]

\( A_{ZA} \) = atmospheric relative azimuth
\[ = \tan^{-1} \left( \frac{V_{AYG}}{V_{AXG}} \right) \]

\( \phi_c \) = geocentric latitude
\[ = \sin^{-1} \left( \frac{z_I}{x_I} \right) \]

\( \theta_I \) = inertial longitude
\[ = \tan^{-1} \left( \frac{y_I}{x_I} \right) \]

VII-8
\( \theta_R \) = relative longitude
\[ \theta_R = \theta_I - \Omega_p (t - t_0) \]

\( A_{SB} \) = sensed acceleration in the B-frame
\[ A_{SB} = A_{TB} + A_{AB} \]

\( A_s \) = magnitude of the sensed acceleration
\[ A_s = (A_s \cdot A_s)^{1/2} \]

\( A_{SI} \) = sensed acceleration in the ECI-frame
\[ A_{SI} = [IB]^{-1} \left[ A_{TB} + A_{AB} \right] \]
Auxiliary Attitude Calculations

The attitude angles that are not used to generate the steering commands are computed for output in the auxiliary calculation subroutine. These equations are summarized below:

1) Aerodynamic angles:

\[
\begin{align*}
\alpha &= \tan^{-1} \left( \frac{v_B}{u_B} \right) \\
\beta &= \tan^{-1} \left( \frac{v_B^2}{\sqrt{u_B^2 + v_B^2}} \right) \\
\gamma &= \tan^{-1} \left( \frac{GB_{23} + \sin \beta \sin A}{GB_{22} \cos A - GB_{21} \sin A \cos \gamma} \right)
\end{align*}
\]

2) Inertial Euler angles:

\[
\begin{align*}
\phi_I &= \tan^{-1} \left( \frac{LB_{23}}{LB_{22}} \right) \\
\psi_I &= -\sin^{-1} \left( \frac{LB_{21}}{LB_{23}} \right) \\
\theta_I &= \tan^{-1} \left( \frac{LB_{31}}{LB_{11}} \right)
\end{align*}
\]

3) Relative Euler angles:

\[
\begin{align*}
\psi_R &= \tan^{-1} \left( \frac{GB_{12}}{GB_{11}} \right) \\
\theta_R &= -\sin^{-1} \left( \frac{GB_{13}}{GB_{11}} \right) \\
\phi_R &= \tan^{-1} \left( \frac{GB_{23}}{GB_{33}} \right)
\end{align*}
\]
Tracking Data

POST computes tracking information for as many as ten tracking stations per phase. The tracking stations are located on a reference ellipsoid and are specified in terms of their latitude, longitude, and altitude above the ellipsoid. These variables are illustrated in figure VII-2.

Figure VII-2.—Radar Tracking Schematic
The position components of the tracker in the Earth-relative frame are given by

\[
\mathbf{r}_{\text{TR}} = (\mathbf{R}_n + h_T) \begin{bmatrix}
\cos \phi_T \cos \theta_T \\
\cos \phi_T \sin \theta_T \\
\sin \phi_T 
\end{bmatrix},
\]  

(VII-11)

where \( h_T \) is the altitude of the tracker, \( \phi_T \) the latitude of the tracker, and \( \theta_T \) the longitude of the tracker.

The slant range vector in the ECI frame is given by

\[
\mathbf{r}_{\text{SR}} = \mathbf{r}_1 - [\mathbf{IP}]^{-1} \mathbf{r}_{\text{TR}},
\]  

(VII-12)

and the slant range is then computed as

\[
r_{\text{SR}} = \sqrt{\mathbf{r}_{\text{SR}} \cdot \mathbf{r}_{\text{SR}}},
\]  

(VII-13)

The elevation angle can then be computed as

\[
\gamma_T = \sin^{-1} \left( \frac{\mathbf{w}_{\text{TR}} \cdot \mathbf{r}_{\text{SR}}}{r_{\text{SR}}} \right),
\]  

(VII-14)

where

\[
\mathbf{w}_{\text{TR}} = [\mathbf{IP}]^{-1} \mathbf{r}_{\text{TR}} / \left| [\mathbf{IP}]^{-1} \mathbf{r}_{\text{TR}} \right|.
\]  

(VII-15)

The slant range vector, transformed to the geographic frame, is

\[
\mathbf{r}_{\text{SRG}} = [\mathbf{IG}] \mathbf{r}_{\text{SR}},
\]  

(VII-16)

and thus the tracker's azimuth is given by

\[
A_{\text{ZT}} = \tan^{-1} \left( \frac{y_{\text{SRG}}}{x_{\text{SRG}}} \right).
\]  

(VII-17)

The look angles are calculated from the slant range vector transformed to the body frame; i.e.,

\[
\mathbf{r}_{\text{SRB}} = [\mathbf{IB}] \mathbf{r}_{\text{SR}}.
\]  

(VII-18)
Using the components of \( r_{SRB} \), the cone angle is then given by

\[
\psi_T = \cos^{-1} \left( \frac{r_{SRB}}{r_{SR}} \right),
\]  
(VII-19)

and the clock angle is given by

\[
\alpha_c = \tan^{-1} \left( \frac{\gamma_{SRB}}{\beta_{SRB}} \right),
\]  
(VII-20)

Space losses are calculated for the tracking stations as follows:

\[
\begin{align*}
SL_1 &= 36.56 + 20 \log_{10} \left( \frac{R_{SLM} \cdot FR_1}{R_{SLM}} \right) \\
SL_2 &= 36.56 + 20 \log_{10} \left( \frac{R_{SLM} \cdot FR_2}{R_{SLM}} \right) \\
SL_3 &= 36.56 + 20 \log_{10} \left( \frac{R_{SLM} \cdot FR_3}{R_{SLM}} \right),
\end{align*}
\]  
(VII-21)

where

\[
\begin{align*}
FR_1 &= 420.0 \text{ (command frequency)} \\
FR_2 &= 2287.5 \text{ (telemetry frequency)} \\
FR_3 &= 5765.0 \text{ (tracking frequency)} \\
R_{SLM} &= \text{slant range distance in statute miles}.
\end{align*}
\]

Analytic Impact Calculations

The analytic impact calculations predict the geodetic latitude, longitude, and time of flight at impact for a vehicle with a given position and velocity to its intersection with the surface of the oblate planet. These calculations assume Keplerian motion and are not corrected for drag effects.

The basic problem in determining an impact point from a specified position and velocity \( (r_{10}, \nu_{10}) \) is in calculating the impact eccentric anomaly. This angle is determined by iteratively solving the equation
\[ r_1(E) = R_A(\phi_c) + h_{1p} \]  \hspace{1cm} (VII-22)

where \( h_{1p} \) is the desired impact altitude above the oblate planet and the position vector is given by

\[ r_1(E) = r(E) r_{10} + g(E) \psi_{10} \]

\[ r(E) = \left( \frac{\sin (E - E_0) - e \cos E_0}{(1 - e \cos E_0)} \right) \]

\[ g(E) = \sqrt{\frac{a^3}{b}} \left( \sin E - E_0 \right) - e \sin l + e \sin E_0. \]  \hspace{1cm} (VII-23)

Once the impact eccentric anomaly, \( E_{ip} \), is determined, then the time, latitude, and longitude of impact are calculated as

\[ t_{ip} = t_0 + \frac{\theta}{2} \left( E_{ip} - t_0 - e \sin E_{ip} - e \sin E_0 \right) \]  \hspace{1cm} (VII-24)

\[ \delta_{ip} = \tan^{-1} \left( \frac{kz_{ip}}{\sqrt{x_{ip}^2 + y_{ip}^2}} \right) \]

\[ \lambda_{ip} = \tan^{-1} \left( \frac{y_{ip}}{x_{ip}} \right) - \pi t_{ip} \]
VIII. TARGETING-AND OPTIMIZATION

POST uses an accelerated projected gradient algorithm (PGA) as the basic targeting/optimization technique. PGA is a combination of Rosen's projection method for nonlinear programming (refs. 3, 4, and 5) and Davidon's variable metric method for unconstrained optimization (ref. 6). The program also contains backup single-penalty function methods that use steepest descent, conjugate gradients, and/or the Davidon method. These standard gradient methods are well documented in references 6 and 7 and are only briefly described in the following discussion.

The projected gradient algorithm is an iterative technique designed to solve a general class of nonlinear programming problems. PGA employs cost-function and constraint gradient information to replace the multidimensional optimization problem by an equivalent sequence of one-dimensional searches. In this manner, it solves a difficult multidimensional problem by solving a sequence of simpler problems. In general, at the initiation of the iteration sequence, PGA is primarily a constraint-satisfaction algorithm. As the iteration process proceeds, the emphasis changes from constraint satisfaction to cost-function reduction. The logic used to effect this changeover process will be discussed below.

Since numerous analytical developments of this technique are available (see refs. 3, 4, and 5), this presentation will primarily emphasize the geometrical aspects of the algorithm. This geometrical interpretation clearly motivates the equations and logic contained in PGA, and a basic understanding of these concepts is usually sufficient to enable the user to efficiently use the algorithm.

Problem Formulation

The projected gradient method solves the following nonlinear programming problem:

Determine the values of the independent variables, \( u \), that minimize the cost function (optimization variable)

\[
F(u),
\]

(VIII-1)
subject to the constraints (dependent variables)

\[ c(u) > 0, \]  

(VIII-2)

where \( u \in \mathbb{R}^m \); \( c \) is a vector-valued function, i.e., \( c: \mathbb{R}^m \to \mathbb{R}^n \); and \( F \) is a scalar-valued function, i.e., \( F: \mathbb{R}^m \to \mathbb{R}^1 \).

The algorithm is actually more versatile than this simple formulation might indicate. In order to maximize any particular function, say \( W(u) \), all that is required is to define \( F(u) = -W(u) \) and determine the minimum of \( F(u) \). The equality constraint case is also contained within the above formulation since constraint equations of the form

\[ c_j(u) = 0 \]  

(VIII-3)

are special cases of Eq (VIII-2).

In the trajectory optimization, the cost function and the constraints are not explicitly a function of the independent variables, but rather depend explicitly on the state variables \( I, V, m, \) and \( Q \). The explicit equations relating the state (dependent) variables to the independent variables are the integrals

\[
\begin{align*}
I & = I_0 + \int V \, dt \\
V & = V_0 + \int [(1B)^{-1}[A_{TB} + A_{AB}] + G_L] \, dt \\
m & = m_0 + \int \dot{m} \, dt \\
Q & = \int \dot{Q} \, dt.
\end{align*}
\]  

(VIII-4)
If \( x_n \) denotes the above state variables of the system being simulated at the \( n \)th event, and \( x_n^+ \) and \( x_n^- \) denote the value of \( x_n \) on the plus and minus sides of that event, then

\[
x_{n+1}^- = T_n[x_n^+, u_n],
\]

where \( u_n \) are the independent variables in phase \( n \), and \( T_n \) represent the solution of the state differential equations over phase \( n \). The values of the state variables on the positive side of event \( n \) are then

\[
x_n^+ = x_n^- + \Delta x_n
\]

where \( \Delta x_n \) represents the discontinuity in state (e.g., velocity impulse at the \( n \)th event).

The cost function and the trajectory constraints are computed at the positive side of the specified events, and are therefore given by

\[
F(u) = f(x_{v_f}^+)
\]

and

\[
c(u) = \begin{bmatrix}
c_{v_1}(x_{v_1}^+)
\vdots
\vdots
\vdots
\end{bmatrix},
\]

where \( v_f \) denotes the event at which the optimization variable is specified and \( v_j \) denotes the events at which the dependent variables are specified. This generality enables the program to solve problems in which intermediate constraints are defined, as well as problems where the cost function is not specified at the final event.
The trajectory propagator, \( T_n \), can represent either numerical integration or analytical Keplerian equations.

**Fundamental Concepts and Nomenclature**

To facilitate the discussion of the projected gradient algorithm, the following nomenclature and basic concepts will be introduced.

A real \( k \)-dimensional Euclidean vector space is denoted by \( \mathbb{R}^k \), and \( \mathbf{x} \) denotes a column matrix whose elements are \( x_i \), where \( i = 1, 2, \ldots, k \). The vector inequality \( \mathbf{x} \geq 0 \) implies \( x_i \geq 0 \) for each \( i \), and \( \mathbf{A}^T \) denotes the transpose of the real matrix \( \mathbf{A} \).

The cost gradient is an \( m \)-vector of partial derivatives denoted as \( \nabla F \) or \( \partial F/\partial \mathbf{u} \), and is defined as

\[
(\nabla F)_j = \frac{\partial F}{\partial u_j} \quad \text{(VIII-9)}
\]

The gradient to the \( i^{\text{th}} \) constraint is similarly represented.

The Jacobian matrix of the constraint vector function with respect to the independent variable is a matrix whose \( i^{\text{th}} \) row is the gradient vector \( \mathbf{c}_i \). This matrix is denoted as

\[
\mathbf{J}(\mathbf{u}) = \frac{\partial \mathbf{c}}{\partial \mathbf{u}} \quad \text{(VIII-10)}
\]

and contains \( n \) rows and \( m \) columns. Clearly,

\[
J_{ij} = \frac{\partial c_i}{\partial u_j} \quad \text{(VIII-11)}
\]
The $j^{th}$ constraint is said to be active at $u$ if and only if

$$c_j(u) = 0,$$  \hfill (VIII-12)

An active constraint is said to be unconstraining if and only if

$$c_j(u) = 0 \text{ and } r_j = \begin{bmatrix} (SS')^{-1} s_k \end{bmatrix} \leq 0.$$ \hfill (VIII-13)

Condition a) implies that the $j^{th}$ constraint is either violated at $u$, while b) indicates that the negative of the cost function gradient "points" outside the feasible region.

The sensitivity matrix is that matrix whose rows are the gradients to the active constraints, and is denoted by

$$S(u) = \frac{\partial e}{\partial u},$$ \hfill (VIII-14)

where $e$ is the $n_a$-vector of active constraints. Equality constraints are always active and thus are loaded into the upper elements of the $e$. Thus, $e$ is essentially the error vector for the active constraints. The error function is defined to be

$$E(u) = e' e.$$ \hfill (VIII-15)

The sensitivity matrix, $S$, is obtained from the Jacobian matrix, $J$, simply by deleting those rows that correspond to inactive constraints.

Corresponding to each constraint function $c_i(u)$ is a boundary hypersurface, $B_i$, defined by

$$B_i = \{ u : c_i(u) = 0 \}.$$ \hfill (VIII-16)

Clearly, $B_i$ is an $m-1$ dimensional nonlinear manifold. It can, however, be approximated at each point $q$ in $R^m$ by an $m-1$ dimensional linear manifold

$$c_i(q) = \{ u : c_i(q)(u - q) + c_i(q) = 0 \}.$$ \hfill (VIII-17)
The feasible region for the $i^{th}$ inequality constraint is the half-space in the independent-variable space defined by the set

$$R_i = \{ u : c_i(u) \geq 0 \},$$

(VIII-18)

while the complete feasible region for all of the constraints is

$$R = \cap_{i=1}^{n} R_i.$$  

(VIII-19)

The boundary of the complete feasible region must be

$$B(R) = \cup_{i=1}^{n} (B_i \cap R),$$

(VIII-20)

The intersection in the preceding equation is required to select from the unbounded boundary, $B_i$, of the feasible region of the $i^{th}$ constraint that portion which is adjacent to the feasible region, $R$, for all of the constraints.

At any particular $\hat{u} \in \mathbb{R}^m$ it is useful to define the local boundary hypersurface, $B(\hat{u})$, to the complete feasible region as the intersection of the active constraints at $\hat{u}$. Let $N(\hat{u})$ denote the set of indices of the $n_a$ tight constraints at $\hat{u}$. Then, symbolically,

$$B(\hat{u}) = \cap_{i \in N(\hat{u})} B_i$$

(VIII-21)

Clearly $B(\hat{u})$ is an $m-k_a$ dimensional nonlinear manifold in the $m$-dimensional independent variable space.

An $m-k_a$ dimensional linear manifold $C(\hat{u})$ approximating $B(\hat{u})$ is the intersection of the active linearized constraints at $\hat{u}$; that is,
\[ C(\mathcal{Q}) = \bigcap_{i: \mathcal{K}(Q)} C_i(u) \] 
\[ = \left\{ u : s(u)(u - q) + q = 0 \right\} \]  
\[ \text{(VIII-22)} \]
\[ \text{(VIII-23)} \]

Now let \( \mathcal{Q}(u) \) denote the linear space spanned by the gradients to the active constraints; that is,
\[ \mathcal{Q}(u) = \left\{ u : \exists \alpha_1, \ldots, \alpha_n \text{ for which } u = \sum_{i=1}^{k_n} \alpha_i s_{ij}(u) \right\} \]  
\[ \text{(VIII-24)} \]
and let \( Q(u) \) denote the orthogonal complement to \( \mathcal{Q}(u) \); that is,
\[ \mathbb{R}^m = Q(u) \oplus \mathcal{Q}(u). \]  
\[ \text{(VIII-25)} \]
It can be shown that \( Q(u) \) is the unique linear space that can be translated to obtain the linear manifold \( C(u) \).

Furthermore there exist unique orthogonal projection operators \( P(u) \) and \( \hat{P}(u) \) that resolve any vector in the independent-variable space into its corresponding components in \( Q(u) \) and \( \mathcal{Q}(u) \), respectively; that is, for any \( u \in \mathbb{R}^m \)
\[ u = P(u)u + \hat{P}(u)u, \]  
\[ \text{(VIII-26)} \]
where
\[ P(u)u \in Q(u) \] and \( \hat{P}(u)u \in \mathcal{Q}(u). \]  
\[ \text{(VIII-27)} \]

In particular,
\[ \hat{P} = s'(ss^-1)s \]  
\[ \text{(VIII-28)} \]
and
\[ P = I - \hat{P}. \]  
\[ \text{(VIII-29)} \]
An additional concept is the idea of problem scaling. The purpose of problem scaling is to increase the efficiency of the targeting/optimization algorithms by transforming the original problem into an equivalent problem that is numerically easier to solve.

To numerically scale a problem, two general types of scaling are required: (1) independent-variable scaling, and (2) dependent-variable scaling. Independent-variable scaling is accomplished by defining a positive diagonal scaling matrix, \( W_u \), such that, the weighted independent variables are given by

\[
\hat{u} = [W_u] u. \tag{VIII-30}
\]

Similarly, dependent-variable weighting is accomplished by defining an optimization-variable scale factor, \( W_e \), and a positive, diagonal, dependent-variable scaling matrix, \( W_e \), such that the weighted optimization variable is

\[
P_1 = W_e F(u) \tag{VIII-31}
\]

and the weighted dependent variables are given by

\[
\hat{c}(u) = [W_e] c (W_u^{-1} \hat{u}), \tag{VIII-32}
\]

yielding a weighted error function

\[
P_2 = \hat{c}^T \hat{c} \tag{VIII-33}
\]

The program contains several options for computing the independent-variable weighting matrix. However, the option most often used is the percentage scaling matrix

\[
[W_u]_{ii} = \frac{1}{|u_i|} \tag{VIII-34}
\]
The dependent-variable weighting matrix is always computed as the reciprocal of the constraint tolerances, and is given by

\[
[W_e]_{il} = \frac{1}{\epsilon_i},
\]  

(VIII-35)

where \(\epsilon_i\) is the tolerance for the \(i^{th}\) constraint. The optimization scale factor is merely input so that \(P_2\) is approximately equal to one.

For simplicity, the following discussion of the algorithm assumes an appropriately scaled problem. However, the scaled equations can be obtained by making the following simple substitutions:

- \(u\) replaced by \(\hat{u}\)
- \(F\) replaced by \(P_1\)
- \(c\) replaced by \(\hat{c}\)
- \(h_c\) replaced by \(P_2\)
- \(S\) replaced by \([W_e][S][W_u]^{-1}\)
- \(VF\) replaced by \(W_F W_u^{-1} VF\).

The final key concept employed by PGA is the idea of a direction of search. Heuristically, the direction of search is nothing more than a particular line in the independent-variable space along which the constraint error is reduced, or along which the cost-function is decreased. In a more precise sense, the direction of search at \(\bar{a}\) is a half-ray emanating from \(\bar{a}\). Thus, for any positive scalar, \(v\), the equation

\[
u = \bar{a} + v\hat{a}
\]

sets the limits of this half-ray and represents "movement" in the direction \(\hat{a}\) from \(\bar{a}\). This is illustrated in figure VIII-1.
Figure VIII-1. - Direction of Search in the Independent-Variable Space

If \( \mathbf{u} \) is a unit vector, then \( \gamma \) represents the actual distance "moved" in the direction \( \mathbf{u} \). This concept of direction-of-search is particularly important since it enables the \( m \)-dimensional nonlinear programming problem to be replaced by a sequence (hopefully finite) of one-dimensional minimizations. What remains to be explained then is: (1) how to select the direction-of-search; and (2) how to determine the step size in that direction. All "direct" optimization methods employ this concept and, hence, differ only in their answers to the two preceding questions. The technique by which \( \gamma_n \) and \( s_n \) are selected by PGA will be described in subsequent sections.

**Direction of Search**

The projected gradient method uses two basic search directions. For this discussion, they will be termed the constraint and optimization directions, respectively. PGA proceeds by taking successive steps in one or the other of these two directions. The computation of each of these search directions is described below at a particular point \( \mathbf{u} \) in the independent-variable space where \( \mathbf{u} \) of the constraints are active.
Constraint direction. - The constraint direction depends critically on the number of active constraints. Three cases are distinguished below:

1) Case 1. - If \( \hat{n}_a < m \), then that unique control correction \( \Delta \hat{u} \) is sought, which solves the linearized constraint equation

\[
S(\hat{u}) \Delta \hat{u} + s(\hat{u}) = 0
\]  

(VIII-37)

and minimizes the length of \( \Delta \hat{u} \). The solutions to the preceding vector equations define the \( m-\hat{n}_a \) dimensional linear manifold \( C(\hat{u}) \), which approximates the local boundary at \( \hat{u} \) as described in detail in the preceding section. The desired minimum norm correction, \( \Delta \hat{u} \), is then the vector of minimum length in the independent-variable space from \( \hat{u} \) to the linear manifold \( C(\hat{u}) \). Analytically, it is given as

\[
\Delta \hat{u} = -S^{-1}[SS^T]^{-1} s(\hat{u}).
\]  

(VIII-38)

This correction is illustrated in figure VIII-2.

The direction of search then is simply taken to be this minimum-norm correction to the locally active linearized constraints; that is,

\[
s^c(\hat{u}) = \Delta \hat{u}.
\]  

(VIII-39)

![Diagram](image-url)

Figure VIII-2. - Illustration of Minimum-Norm Constraint, Direction for \( \hat{n}_a = 2 < m = 3 \)

VIII-11
2) If $n_a = m$, then the linearized local boundary $C(\hat{u})$ reduces to a single point. Thus, there is a unique solution to the linearized constraint equations without the additional requirement that the length of the independent-variable correction be minimized. The minimum-norm correction formula then reduces to the familiar Newton-Raphson formula for solving $m$ equations in $m$ unknowns; namely

$$\Delta \hat{u} = -S^{-1} e(\hat{u}).$$  \hspace{1cm} (VIII-40)

The Newton-Raphson correction is illustrated geometrically in figure VII-3.

![Diagram](image)

**Figure VIII-3.** Illustration of Newton-Raphson Constraint, Direction for $n_a = m = 3$

The direction of search is taken to be this unique correction vector satisfying the linearized constraints; that is,

$$e^c(\hat{u}) = \Delta \hat{u}.$$  \hspace{1cm} (VIII-41)
3) If \( n_a > m \), then \( C(\hat{u}) \) is empty, since a simultaneous solution of all of the linearized constraint equations does not exist. Hence, an entirely new method for choosing the search direction must be devised. PGA deals with this problem by seeking the unique independent-variable correction \( \Delta \hat{u} \) that minimizes the sum of the squares of the deviations from the linearized constraints. Thus, the function

\[
f(\Delta u) = \left| S(\hat{u}) \Delta u + e(\hat{u}) \right|^2
\]

is minimized with respect to \( \Delta u \). Gauss demonstrated that the formula for this "least squares" correction is

\[
\Delta \hat{u} = -(S' S)^{-1} S' e(\hat{u}).
\]

Figure VIII-4 illustrates the least-squares correction pictorially. As in the preceding two cases, the search direction is then taken to be this optimal correction; that is,

\[
\hat{x}(\hat{u}) = \Delta \hat{u}.
\]

---

**Figure VIII-4.** Illustration of Least-Squares Constraint, Direct for \( n_a = 4 > m = 3 \)
Optimization direction. - When the number of active constraints is less than the number of independent variables, it is then possible to reduce the nonminimal cost-function. Obviously the steepest descent direction, \(-\nabla F(\bar{u})\), would be the best local search direction for reducing the cost function. Such a direction, however, would generally produce unacceptable constraint violations. To avoid this difficulty PGA orthogonally projects the unconstrained negative gradient, \(-\nabla F(\bar{u})\), into a direction parallel to the local linearized constraint boundary \(C(\bar{u})\). By searching in the direction of this negative-projected gradient the algorithm can guarantee that there is no further constraint violation than that of \(\bar{u}\) for the case of linear constraints. To calculate this direction, it is only necessary to apply to the unconstrained negative gradient the projection operator \(P(\bar{u})\), which maps any vector in the independent-variable space into its component in \(Q(\bar{u})\), the unique linear space that can be translated into coincidence with the linear manifold \(C(\bar{u})\). Thus,

\[
\begin{align*}
\mathbf{s} (\bar{u}) &= -P(\bar{u}) \nabla F(\bar{u}) \\
&= -[I - P(\bar{u})] \nabla F(\bar{u}) \\
&= -[I - S^* (SS^*)^{-1} S(\bar{u})] \nabla F(\bar{u})
\end{align*}
\]

(VIII-45)

The direction of search for the accelerated projected gradient method is

\[
\mathbf{s}_n^O (\bar{u}) = -\mathbf{H}_n P \nabla F(\bar{u})
\]

(VIII-46)

where

\[
\mathbf{H}_0 = I
\]

(VIII-47)

and

\[
\begin{align*}
\mathbf{H}_n &= \mathbf{H}_{n-1} + \mathbf{A}_n + \mathbf{B}_n, \quad \text{where } n = 2 \\
\mathbf{A}_n &= \left[ \frac{\Delta \mathbf{x}_n \Delta \mathbf{x}_n^*}{\Delta \mathbf{x}_n^* \mathbf{s}_n} \right] \\
\mathbf{B}_n &= -\left[ \mathbf{H}_{n-1} + \mathbf{s}_n \mathbf{s}_n^* \mathbf{H}_{n-1}^* \right] / \mathbf{s}_n^* \mathbf{H}_{n-1} \mathbf{s}_n, \\
\Delta \mathbf{x}_n &= \mathbf{u}_n - \mathbf{u}_{n-1}, \\
\mathbf{s}_n &= \nabla F(\mathbf{u}_n) - \nabla F(\mathbf{u}_{n-1}).
\end{align*}
\]

(VIII-48)
Figure VIII-5 illustrates the direction of the negative-projected gradient for the case of a single active constraint.

![Diagram](image-url)

Figure VIII-5. Direction of Negative-Projected Gradient for \( n_a = 1 \) and \( m = 3 \) (Feasible region is that region inside paraboloid, above lower plane, and below upper plane; cost-function is vertical height)

If there are no equality constraints, and if all the inequality constraints are inactive, then \( S \) is the zero matrix and the direction of search becomes the standard deflected gradient direction

\[
\mathbf{s}^0(\hat{d}) = -H_{nn} \mathbf{VF}(\hat{d}). \quad \text{(VIII-49)}
\]

Similarly, if the single-penalty-function methods are used, then the directions of search that minimize

\[
\mathbf{P}_2 = \mathbf{F} + \mathbf{W} \mathbf{e}^* \mathbf{e} \quad \text{(VIII-50)}
\]

are:

1) Steepest-descent method

\[
\mathbf{s}^0(\hat{d}) = -\nabla \mathbf{P}_2(\hat{d});
\]
2) Conjugate gradient method (steepest-descent starter)

\[ s_n^0 = -\nabla P_2 u_n + \left[ \frac{\nabla P_2 (u_n) \nabla P_2 (u_{n-1})}{\nabla P_2 (u_{n-1}) \nabla P_2 (u_{n-1})} \right] s_{n-1}, \text{ where } n > 2; \]

3) Davidon's method (steepest-descent starter)

\[ s_n^0 = -H_n \nabla P_2 (u_n), \text{ where } n \geq 2 \]

and

\[ H_n = H_{n-1} + A_n + B_n, \]

where \( A_n \) and \( B_n \) have the same definitions as in the accelerated projected gradient mode.

**Step-Size Calculation**

At any particular point \( \mathbf{u} \) in the independent-variable space, the PGA algorithm proceeds by reducing the multidimensional problem to a one-dimensional search along the constraint direction to minimize the sum of the squares of the constraint violations, or along the optimization direction to minimize the estimated net cost-function. In either case, once the initial point \( \mathbf{u} \) and the direction of search \( \mathbf{s} \) are specified, the problem reduces to the numerical minimization of a function of a single variable—namely, the step size. PGA performs this numerical minimization via polynomial interpolation, based on function values along the search ray and the function's value and slope at the starting point. Consider then, in detail, the calculation of this latter pair of quantities for the respective functions associated with the constraint and optimization directions.

**Constraint direction.**—The function to be minimized along the constraint direction, \( s^c \), is the sum of the squares of the constraint violations; namely

\[ h_c(\gamma) = |s(\mathbf{u} + \gamma s^c)|^2. \]  \hspace{1cm} (V\textsc{nI}-51)

**VIII-16**
Clearly

\[ h_c(0) = |\hat{e}(\hat{u})|^2. \]  

(VIII-52)

Differentiation via the chain rule yields

\[ h_c'(0) = 2\hat{e}^T(\hat{u}) S(\hat{u}) \hat{s}_c. \]  

(VIII-53)

Recall that the search direction \( \hat{s}_c \) was obtained as an independent-variable correction either satisfying all the linearized constraint equations if \( \hat{n}_s < m \), or minimizing their violation if \( m < \hat{n}_s \). Thus, if the constraints are reasonably linear, a good initial estimate for the \( \gamma \) minimizing \( h_c \) is one.

**Optimization direction.**—The function to be minimized along the optimization direction, \( \hat{s}_c \), is the estimated net cost-function which is defined as

\[
\begin{align*}
\hat{h}_o(\gamma) &= F(\hat{u} + \gamma \hat{s}_c) - F(\hat{u}) + \nabla^T F(\hat{u}) \left[ -S^{-1}(SS')^{-1} \hat{e}(\hat{u} + \gamma \hat{s}_c) \right].
\end{align*}
\]  

(VIII-54)

\[
\text{change in cost-function produced by step of length } \gamma \text{ along } \hat{s}_c
\]

\[
\text{linearized approximation to change in cost-function required to perform minimum-norm correction back to the feasible region}
\]

Clearly

\[ h_o(0) = -\nabla^T F(\hat{u}) S^{-1}(SS')^{-1} \hat{e}(\hat{u}). \]  

(VIII-55)

By expanding \( h_o \) in a Taylor series in \( \gamma \) about \( \gamma = 0 \), and by making use of the fact that \( \hat{y}_o^0 = 0 \) since \( \hat{s}_o \) lies in \( Q(\hat{u}) \), it can be shown that

\[ h_o'(0) = \nabla^T F(\hat{u}) \hat{s}_o. \]  

(VIII-56)

These properties of \( h_o \) are illustrated in figure 25.
Both the constraint and optimization directions are based on a sensitivity matrix that depends critically on which constraints are active. Hence, for searches in either direction, it is important to limit the step size so that the set of active constraints does not grow. Such a limit can be obtained based on linear approximation and suffices to deal with inactive constraints becoming active.

The reverse situation—of active constraints becoming inactive—poses no difficulty. To see this, note that because of our treatment of the active constraints as linear manifolds, a first-order approximation of the distance to a particular active constraint boundary would not change along the optimization direction. Furthermore, along the constraint direction any change in the status of an active constraint will be appropriately treated by minimizing $h_c$ with respect to the step length.
Let $K(\theta)$ denote the set of active constraint indices at $\theta,$ and let

$$r_k = s^t(\theta)\nabla c_k(\theta),$$  \hfill (VIII-57)

where $s(\theta)$ is the search direction at vector $\theta.$ Then assign to each $k$ in $K$ the number

$$\lambda(k) = \begin{cases} 
-c_k(\theta)/r_k & \text{if } r_k < 0 \\
 r_k & \text{if } r_k > 0
\end{cases}$$  \hfill (VIII-58)

where $R$ is a very large real number. Then $\lambda(k)$ is a linear approximation to the distance along the search ray from $\hat{u}$ to the boundary, $B_k,$ of the $k$th constraint. Hence a reasonable upper bound for the step length is

$$\lambda = \min_{k \in K} [\lambda(k)].$$  \hfill (VIII-59)

One-Dimensional Minimization

Monovariant minimization in PGA is performed exclusively by polynomial interpolation. First the actual function, $f,$ to be minimized is fitted with one or more quadratic or cubic polynomials until a sufficiently accurate curve fit, $p,$ is obtained; that is,

$$p(\gamma) = \sum_{i=0}^{n} a_i \gamma^i \approx f(\gamma) \text{ for all } \gamma \text{ of interest.}$$  \hfill (VIII-60)

Then the independent variable value, $\gamma^m,$ that minimizes $f$ is approximated by the value, $\gamma^m_p,$ which minimizes $p.$ Clearly, $\gamma^m_p$ can be determined analytically if $n \leq 3.$
The minimization routine makes ingenious use of all the information it accumulates about \( f \) to obtain a good curve fit. First, \( f \) is fitted with a quadratic polynomial, \( p_1 \), based on:

1) \( f(0) \)
2) \( f'(0) \)
3) \( f(\gamma^m_o) \), where \( \gamma^m_o > 0 \) is an initial estimate of the \( \gamma \) value that minimizes \( f \).

The coefficients of this quadratic polynomial are then calculated from the formulas:

\[
\begin{align*}
a_0 &= f(0) \\
a_1 &= f'(0) \\
a_2 &= \frac{f(\gamma^m_o) - a_0}{\gamma^m_o} + a_1/\gamma^m_o.
\end{align*}
\]

(VIII-61)

The value of the independent variable that minimizes this polynomial is

\( \gamma^m_1 = -a_1/2a_2 \).

(VIII-62)

If \( \gamma^m_1 \) and \( \gamma^m_0 \) do not differ significantly, \( \gamma^m \) is taken to be \( \gamma^m_1 \) and the minimization procedure is considered complete. Similarly, if \( p_1(\gamma^m_1) \) is not significantly different from \( f(\gamma^m_1) \), then \( \gamma^m \) is taken to be equal to \( \gamma^m_1 \) and the process is terminated. Otherwise \( f \) is fitted with a cubic polynomial, \( p_2 \), based on:

1) \( f(0) \)
2) \( f'(0) \)
3) \( f(\gamma^m_0) \) and \( \gamma^m_0 > 0 \)
4) \( f(\gamma^m_1) \).

VIII-20
If \( f \) is fitted using \( p_2 \), then coefficients are calculated from the following formulas:

\[
\begin{align*}
a_0 &= f(0) \\
a_1 &= f'(0) \\
\lambda &= \max \left( \gamma_0, \gamma_1 \right) \\
\alpha &= \min \left( \gamma_0, \gamma_1 \right) / \lambda
\end{align*}
\]

\[
\begin{align*}
a_2 &= \left[ \lambda a_1 + a_0 (1 + \alpha) + (\alpha^2 f(\lambda) - f(\lambda))/ (1 - \alpha) \right] / (\lambda^3 a^2) \\
a_3 &= \left[ (f(\alpha \lambda) - \alpha^3 f(\lambda))/ (1 - \alpha) - \lambda a(1 + \alpha) a_1 - (1 + \alpha = \alpha^2) a_0 \right] / (\lambda^2 a^2)
\end{align*}
\]

The value of the independent variable, \( \gamma^m \), that minimizes this cubic polynomial is

\[
\gamma^m_2 = \left( -a_2 + \sqrt{a_2^2 - 3a_3 a_1} \right) / 3a_3.
\]

If \( \gamma^m_2 \) and \( \gamma^m_1 \) do not differ significantly, \( \gamma^m \) is taken to be \( \gamma^m_2 \) and the minimization is stopped. Similarly, if \( p_2(\gamma^m_2) \) is not significantly different from \( f(\gamma^m_2) \), then \( \gamma^m \) is taken to be equal to \( \gamma^m_2 \) and the procedure is terminated.

If none of these stopping conditions is met, a third quadratic curve-fit is attempted. The accumulated set of sample points on \( f \), namely \( [0, f(0)], [\gamma^m_0, f(\gamma^m_0)], [\gamma^m_1, f(\gamma^m_1)], \) and \( [\gamma^m_2, f(\gamma^m_2)] \), is arranged in the order of their ascending abscissa values. Then the first point whose ordinate value is less than that of the following point is selected.

To simplify the notation in the following pages, reliable this point as \( [\gamma_2, f(\gamma_2)] \), the preceding point as \( [\gamma_1, f(\gamma_1)] \), and the following point as \( [\gamma_3, f(\gamma_3)] \).
Another quadratic polynomial, $p_3$, is then fitted to

1) $f(y_1)$
2) $f(y_2)$
3) $f(y_3)$.

The formulas for these quadratic coefficients are as follows:

\[
\begin{align*}
    b_{ij} &= y_i y_j \\
    c_{ij} &= y_i + y_j \\
    d_{ij} &= y_i - y_j \\
    a_0 &= \frac{b_{23}}{d_{12}d_{13}} f(y_1) + \frac{b_{13}}{d_{21}d_{23}} f(y_2) + \frac{b_{12}}{d_{31}d_{32}} f(y_3) \\
    a_1 &= \frac{c_{23}}{d_{12}d_{13}} f(y_1) - \frac{c_{13}}{d_{21}d_{23}} f(y_2) - \frac{c_{12}}{d_{31}d_{32}} f(y_3) \\
    a_2 &= \frac{1}{d_{12}d_{13}} f(y_1) + \frac{1}{d_{21}d_{23}} f(y_2) + \frac{1}{d_{31}d_{32}} f(y_3).
\end{align*}
\] (VIII-65)

The value of the independent variable that minimizes this quadratic is

\[
y_m^3 = -a_1/2a_2. \tag{VIII-66}
\]

If $y_m^3$ and $y_m^2$ do not differ significantly, $y_m^m$ is taken to be $y_m^3$ and the search is discontinued. On the other hand, if $p_3(y_m^3)$ is not significantly different from $f(y_m^3)$, then $y_m^m$ is taken to be $y_m^3$ and the process is terminated.

If neither of these stopping conditions is met, then a cubic polynomial is fitted to

VIII-22
1) \( f(y_1), y_1 \)
2) \( f(y_2), y_2 \)
3) \( f(y_3), y_3 \)
4) \( f(y_4), y_4 = y_3^m \).

The formulas for these coefficients are as follows:

\[
\begin{align*}
D_1 &= (y_2 - y_1)(y_3 - y_1)(y_4 - y_1) \\
D_2 &= (y_1 - y_2)(y_3 - y_2)(y_4 - y_2) \\
D_3 &= (y_1 - y_3)(y_2 - y_3)(y_4 - y_3) \\
D_4 &= (y_1 - y_4)(y_3 - y_4)(y_4 - y_4)
\end{align*}
\]

\[
\begin{align*}
a_0 &= \frac{y_2y_3y_4}{D_1} f(y_1) + \frac{y_1y_3y_4}{D_2} f(y_2) + \frac{y_1y_2y_4}{D_3} f(y_3) + \frac{y_1y_2y_3}{D_4} f(y_4) \\
&\quad + \frac{(y_1y_2 + y_1y_4 + y_2y_4)}{D_3} f(y_3) + \frac{(y_1y_2 + y_1y_3 + y_2y_3)}{D_4} f(y_4) \\
a_1 &= \frac{y_2y_3 + y_2y_4 + y_3y_4}{D_1} f(y_1) + \frac{(y_1y_3 + y_1y_4 + y_3y_4)}{D_2} f(y_2) \tag{VIII-67} \\
&\quad + \frac{(y_1y_2 + y_1y_4 + y_2y_4)}{D_3} f(y_3) + \frac{(y_1y_2 + y_1y_3 + y_2y_3)}{D_4} f(y_4) \\
a_2 &= \frac{y_2 + y_3 + y_4}{D_1} f(y_1) + \frac{(y_1 + y_3 + y_4)}{D_2} f(y_2) \\
&\quad + \frac{(y_1 + y_2 + y_4)}{D_3} f(y_3) + \frac{(y_1 + y_2 + y_4)}{D_4} f(y_4) \\
a_3 &= -\frac{1}{D_1} f(y_1) - \frac{1}{D_2} f(y_2) - \frac{1}{D_3} f(y_3) - \frac{1}{D_4} f(y_4).
\end{align*}
\]

The value of the independent variable minimizing this fourth cubic polynomial is

\[ y_4^m = \left( -a_2 + \sqrt{a_2^2 - 3a_3a_4} \right) / 3a_3. \tag{VIII-68} \]
If \( y^m_1 \) and \( y^m_3 \) do not differ significantly, \( y^m \) is taken to be \( y^m_4 \) and the minimization is stopped. Similarly, if \( P_n(y^m) \) is not significantly different from \( f(y^m) \), then \( y^m \) is taken to be equal to \( y^m_4 \) and the procedure is terminated.

If none of these stopping conditions is met, the accumulated set of sample points is searched for the point with the minimum ordinate value. The abscissa value of this point is taken to be \( y^m \), and the minimization is considered complete.

**Algorithm Macrologic**

After being initialized the projected gradient algorithm proceeds as a sequence of iterations, each consisting of an optimization step followed by a constraint-correction step (see fig. VIII-7). The very first step from the user's initial independent-variable estimate is however, one of constraint correction. Furthermore, the optimization step is also omitted on any iteration for which the constraint-violation function, \( h_c \), was not reduced by the constraint correction step of the preceding iteration.

The optimization search direction that emanates for \( u_n \) is based on the sensitivity matrix, \( S(u_n) \); that is,

\[
s^o_n = s^o(u_n) = -PyF(u_n),
\]

as discussed previously. Hence, \( s^o_n \) lies in the subspace \( Q(u_n) \).

The value of the independent-variable vector, \( u^o_n \), after the optimization is

\[
u^o_n = u_n + \gamma_o s^o_n
\]

where \( \gamma_o \) is the optimum step size.
Figure VIII-7.— Macrologic of Projected Gradient Algorithm
The direction of the constraint-correction search emanates from $u_n^0$; however, since generating a new sensitivity matrix is such an expensive calculation, the old Jacobian matrix, $J$, of the constraints with respect to the controls evaluated at $u_n$ is used in conjunction with the error at $u_n^0$. Thus,

$$s_n^c = -S'(SS')^{-1}(u_n) s(u_n^0). \quad (VIII-71)$$

It can be shown by direct computation that

$$\tilde{\nabla}(u_n) s_n^c = s_n^c, \quad (VIII-72)$$

where $\tilde{\nabla}(u_n)$ is based on $S(u_n)$. Thus, $s_n^c$ lies in the subspace $Q(u_n)$ in the independent-variable space.

Since $Q(u_n)$ and $\tilde{Q}(u_n)$ are orthogonal complements, it follows that the optimization and constraint directions for any iteration are exactly orthogonal; that is,

$$\begin{pmatrix} s_n^c \end{pmatrix}^T s_n^c = 0. \quad (VIII-73)$$

The result of the constraint correction step is then the independent-variable vector for the next iteration. Thus

$$u_{n+1} = u_n^0 + \gamma_c s_n^c. \quad (VIII-74)$$

Figure VIII-8 geometrically illustrates a complete PGA iteration.
Finally, the algorithm has two stopping conditions. First, the search is stopped if the change in the cost function and the change in the length of the independent-variable vector between two successive iterations fall below their respective input tolerances; that is, if

\[
\begin{align*}
|F(u_{n+1}) - F(u_n)| &< \epsilon_1 \\
|u_{n+1} - u_n| &< \epsilon_2,
\end{align*}
\]

Second, the procedure is discontinued if the number of the current iteration equals the maximum permissible number input by the user.
