A STUDY OF SOUND
GENERATION IN SUBSONIC ROTORS

Report No. ME 73-11
Volume 2 of 2

J. D. Chalupnik, Associate Professor
L. T. Clark, Research Assistant Professor

University of Washington
Department of Mechanical Engineering
Seattle, Washington 98195
1.0 **INTRODUCTION**

Volume 2 of the final report is used to outline four computer programs which were developed during the grant period. All were coded in FORTRAN IV Language for usage on the University of Washington CDC 6600 digital computer.

The discussions here are primarily user input instructions. For two of the programs, ROTOR and AIRFOIL, the background models are developed in some detail in Volume 1 of the report. Program TONE is developed herein and SDATA is outlined here with reference to the literature where the detailed development requires a book to describe. The function of each program is discussed below.

(1) **Program AIRFOIL**: This program computes the spectrum of radiated sound from a single airfoil immersed in a laminar flow field. The mechanism is force fluctuations which are related to the unsteady wake momentum. Input required is the aerodynamic properties of the turbulent wake.

(2) **Program ROTOR**: The purpose of program ROTOR is to provide an extension of the single airfoil in AIRFOIL to a rotating frame. This is a model for sound generation in subsonic rotors. The only broad band mechanism currently in the program is the airfoil wake mechanism. Program ROTOR also computes tone sound generation due to the steady state forces on the blades (the Gutin result). Input requirements are similar to those for AIRFOIL.
(3) Program TONE: A moving source analysis is used to generate a time series for an array of forces moving in a circular path as would be the case for a rotor. This analysis has great flexibility in that arbitrary blade spacings, blade forces and source motions can be easily accommodated. Broad band effects have been included using autoregression methods. The resultant time series are Fourier transformed using a Fast Fourier Transform to present the sound radiation in the more normal spectral form. With some study, a user can make this program a very valuable tool in sound generation investigations.

(4) Program SDATA: This program is a standard time series analysis package. It will read in two discrete time series and form auto and cross covariances and normalize these to form correlations. The program will then transform the covariances to yield auto and cross power spectra by means of a Fourier transformation. The spectral data are presented in terms of amplitude and phase as well as the coherency spectrum.

A final note on these programs is in order. These were developed as tools to be used in the work performed under the grant. There was no intention to provide the programs as complete packages for general usage. The content is general enough, however, that with some effort a user should be able to employ the programs to advantage. He is cautioned to understand the analytical models before he becomes too involved in turning around decks. No program is a substitute for this understanding. Tools must be skillfully used.
To the end of providing a usable tool the programs are coded in variable names which read very like those of the physical variables they represent. For example the density will be RHO and the longitudinal turbulence covariance will be UIUL, etc. This should facilitate the reading of the program listings.

Each of the programs is discussed in the following sections.
2.0 PROGRAM AIRFOIL

The fortran program AIRFOIL is used to compute the sound radiated from a single airfoil due to those mechanisms related to the airfoil wake turbulence. A development of the model was presented in detail in Volume 1 of this report. Through the model, the sound radiation is related to the turbulent structure in the wake of the airfoil.

The equation which forms the basic result of the model and that programmed here is

\[
G_\rho(x, \omega) = \frac{2}{L} \sum_{i=1}^{2} \sum_{j=1}^{2} 16 S L^2_i(u_i, u_j, \omega) L^2_i(u_i, u_j, \omega) L^3_3(u_i, u_j, \omega)
\]

\[
\omega^4 \int_{y_2} A_1 A_j \overline{u_i u_j}(y_2, \omega) \, dy_2
\]

with:

\[
A_1 = \rho_o \overline{U_1} \sin \psi/(4\pi\rho_o |x|)
\]

\[
A_2 = \rho_o \overline{U_1} \cos \psi/(4\pi\rho_o |x|).
\]

Nomenclature used here is the same as that of Volume 1.

The integration noted above is performed using a Lagrangian method. This subroutine is part of the University of Washington Computer Library. Any simple numerical integration scheme may be substituted for this subroutine. In the program the subroutine is labeled LAGRAN.

2.1 Program Input

AIRFOIL is a simple computational program. It consists of three subprograms. The main program is AIRFOIL in which the actual computations are made. The next is subroutine DREAD in which data are read into and
conditioned to form the variables used in the actual computations. Finally, DWRITE in which the results of the computations are written out.

Input to the program is accomplished using IBM cards. In the following we will list each card type, the variable names and their descriptions.

CARD 1, FORMAT(7F10.2)

<table>
<thead>
<tr>
<th>Var</th>
<th>Description</th>
<th>Units</th>
</tr>
</thead>
<tbody>
<tr>
<td>PATM</td>
<td>atmospheric static pressure</td>
<td>atm</td>
</tr>
<tr>
<td>TATM</td>
<td>&quot; &quot; temperature</td>
<td>°C</td>
</tr>
<tr>
<td>SPAN</td>
<td>airfoil length</td>
<td>cm</td>
</tr>
<tr>
<td>XLM</td>
<td>length in the stream direction (this is a dead variable in the current program so any input is okay)</td>
<td>cm</td>
</tr>
<tr>
<td>DEL</td>
<td>wake thickness</td>
<td>cm</td>
</tr>
<tr>
<td>RAD</td>
<td>distance from airfoil to sound observer</td>
<td>m</td>
</tr>
</tbody>
</table>

CARD 2, FORMAT(2I5)

<table>
<thead>
<tr>
<th>Var</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NPF</td>
<td>number of frequency points where data will be input</td>
</tr>
<tr>
<td>NPY</td>
<td>number of positions in the wake where data will be given</td>
</tr>
</tbody>
</table>

CARD 3, FORMAT(7F10.2)

<table>
<thead>
<tr>
<th>Var</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Y(I)</td>
<td>positions in the wake measured relative to the wake centerline</td>
</tr>
<tr>
<td>I = 1, NPY</td>
<td></td>
</tr>
</tbody>
</table>

Note that if more than 7 entries are needed, additional cards will be required for this variable.

CARD 4, FORMAT(7F10.2)

<table>
<thead>
<tr>
<th>Var</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>FREQ(I)</td>
<td>frequencies at which the following correlation lengths are to correspond</td>
</tr>
<tr>
<td>XL(I)</td>
<td>correlation length in stream direction for the longitudinal turbulent component</td>
</tr>
</tbody>
</table>
YL(I) correlation length across the wake for the longitudinal turbulence component (cm)

ZL(I) correlation length in the span direction for the longitudinal turbulence component (cm)

CARD 5, FORMAT(7F10.2)

FREQ(I) same as for CARD 4

XT(I) same as for CARD 4, but for the transverse turbulence component (cm)

YT(I) same as for CARD 4, but for the transverse turbulence component (cm)

ZT(I) same as for CARD 4, but for the transverse turbulence component (cm)

Notice that CARD's 4 and 5 are read inside a DO loop. The statements are

DO 16 I = 1,NPF
READ(5,3) FREQ(I),XL(I),YL(I),ZL(I)
16 READ(5,3) FREQ(I),XT(I),YT(I),ZT(I)

Certainly more than just the two cards will be required here since more than one spectral point will generally be required. For this outline, we will continue with CARD 6 keeping in mind that CARD 6 refers to a new input type of data rather than the actual number of the card in the input file.

CARD 6, FORMAT(7F10.2)

XI(I) ratio of wake velocity at Y(I) to the velocity in the free stream UMEAN

1 = 1,NFY

CARD 7, FORMAT(7F10.2)

DDB1(I) ratio of spectral level at FREQ(I) to the RMS level; this is for the longitudinal component of turbulence (dB)

1 = 1,NPF
DDB1 can be interpreted from the equation for its usage which is

\[ u_1'(f) = u_1^2 \times 10. **(-DDB1(I)/10.) \]

\[ u_1'(f) \] is the actual spectral level sought, and
\[ u_1^2 \] is the RMS level for the longitudinal component of turbulence.

CARD 8, FORMAT(7F10.2)

DDB2(I) the ratio of the spectral level at FREQ(I)
I = 1,NFF to the RMS level for the shear component
of turbulence (dB)

see the note for DDB1

CARD 9, FORMAT(7F10.2)

DDB3(I) the ratio of the spectral level at FREQ(I)
I = 1,NFF to the RMS level for the transverse component
of turbulence (dB)

CARD 10, FORMAT(7F10.2)

U11(I) spatial distribution of the RMS level of
I = 1,NFY longitudinal turbulence across the wake,
normalized with UMEAN

CARD 11, FORMAT(7F10.2)

U12(I) spatial distribution of the RMS level of the
I = 1,NFY shear stress across the wake, normalized
with UMEAN

CARD 12, FORMAT(7F10.2)

U22(I) spatial distribution of the RMS level of the
transverse turbulence across the wake, normal-
ized with UMEAN

This completes the input for the program.
Program output consists of a listing of the input variables and of the spectral distribution of the radiated sound pressure at each radiation angle $0^\circ$ through $180^\circ$ in $10^\circ$ increments. The radiated sound is presented in dB by normalizing the pressure with a reference $20\mu N/m^2$.

3.0 PROGRAM ROTOR

The purpose of developing program ROTOR was to provide a method for the prediction of sound generation from turbomachinery rotors. Aerodynamic operation was limited to the subsonic flow regime. Both tone noise and broad band effects were included. The tone noise part of the model was simply the steady state forces on the rotor blades. The broad band mechanism was taken as the force fluctuations which were relatable to the wake turbulence of the individual airfoils of the rotor. The mathematical model used for the basis of the sound radiation was that presented by Ffowcs Williams and Hawkings.*

To use the program one must supply the aerodynamic parameters for the particular design. Program ROTOR then computes the spectrum of sound radiated by the machine due to the mechanisms noted above.

The program is divided into five subroutines. A brief discussion of the contents of these subroutines will be given to provide some familiarization with the program structure. The names of the subroutines are: DATAIN, WAKE, ORTH1, TONE, and ORTH2.

3.1 Subroutine DATAIN

As the name implies, DATAIN is used to read and condition the input data. The data input can be listed with the required FORMAT and physical units. The following are the only inputs required to run the program.

<td>(-)</td>
</tr>
</tbody>
</table>

In the remaining inputs a FORMAT(7F10.2) is used but if more than NF = 7 is used then more than one card will be needed for each of the input variables. Here we will list the variable arrays as if only one card will be required for the input.
ALL FOLLOWING CARDS, FORMAT(7F10.2)

F(I) array of frequency values (HZ)
CORR(I) an arbitrary spectral shaping factor, normally set equal to 1 (--)
XLL(I) correlation length in the stream direction, based upon the longitudinal component of turbulence (CM)
YLL(I) correlation length in the direction across the wake, based upon the longitudinal component of turbulence (CM)
ZLL(I) correlation length in the span direction, based upon the longitudinal component of turbulence (CM)
XLT(I) correlation length in the stream direction, based upon the transverse component of turbulence (CM)
YLT(I) correlation length in the direction across the wake, based upon the transverse component of turbulence (CM)
ZLT(I) correlation length in the span direction, based upon the transverse component of turbulence (CM)

The following variables, U1U1, U1U2, U2U1, and U2U2, are spectral levels given in dB relative to the RMS levels for the component. The result of this procedure will be: if these turbulence quantities are given in dB down from RMS on a 1/3 octave spectrum then the radiated sound will also be 1/3 octave. If 6% spectra are used then the radiated sound will be 6%, also.

U1U1(I) longitudinal component of turbulence (dB)
U1U2(I) shear stress component (dB)
U2U1(I) shear stress component (dB)
U2U2(I) transverse component of turbulence (dB)
All input data are printed out in the physical units used in the computations.

3.2 Subroutine WAKE

This subroutine computes the wake related sound generation by the rotor. The model used to relate the force fluctuations on the rotor blading to aerodynamic variables is the single airfoil model. The expression which results and is here computed is

\[
|p(x, \omega)|^2 = \frac{1}{16\pi^2} \frac{\omega}{r^2} \sum_{n=-\infty}^{\infty} \sum_{k=1}^{B} \left( \frac{\omega}{a_o} \right)^2 \left( \frac{-\omega R \sin \phi}{s} \right).
\]

For the present case, the force fluctuations are

\[
d_r(\theta_k, f-n\Omega) \cdot d_r^*(\theta_k, f-n\Omega) = S \cdot \delta_w \cdot (\omega-2mn\Omega)^2 \cdot \rho_o \cdot \frac{1}{r} \sum_{l=1}^{3} \sum_{m=1}^{3} \frac{\alpha_f \cdot \alpha_m}{L_i(u_k, u_m, \omega)} \cdot L_2(u_k, u_m, \omega) \cdot L_3(u_k, u_m, \omega) \cdot \frac{u_k u_m(\omega)}{s}.
\]

where: 
- \( S = \text{span} \), \( \delta_w = \text{wake thickness} \), \( L_i = \text{correlation lengths} (i = 1,3) \),
- \( u_k u_m = \text{spectral level of turbulent stress} \), \( \omega = \text{rad\'an frequency} \), \( \Omega = \text{rotor speed} \), and \( f = \text{frequency in Hz} \). \( J_n \) is a Bessel function of the first kind of integer order.

The output from this subroutine is the radiated sound pressure level expressed in dB relative to a reference pressure of 20 \( \mu N/m^2 \).

3.3 Subroutine ORTH1

This subroutine computes the components of the position vector of the sound observer in the coordinate system relative to each of the rotor blades.
The product of these components with the force components on the blades yields the force in the direction of the observer. To do this the position vector must first be expressed in terms of the rotor coordinate system. It must then be rotated by the blade stagger angle to be in the blade coordinate system.

The observer position vector components for a typical blade may be written:

\[
\begin{align*}
    r_1 &= (r \sin \phi - R_s \cos \theta) / [r(1 - \frac{R_s}{r} \sin \phi \cos \theta)] \\
    r_2 &= -R_s \sin \theta / [r(1 - \frac{R_s}{r} \sin \phi \cos \theta)] \\
    r_3 &= \cos \phi / (1 - \frac{R_s}{r} \sin \phi \cos \theta)
\end{align*}
\]

The change from the observer coordinates to those of the rotor blade can be expressed in the rotation

\[
\begin{pmatrix}
-\sin \theta & \cos \theta & 0 \\
0 & 0 & 1 \\
\cos \theta & \sin \theta & 0
\end{pmatrix}
\]

and the further rotation by the stagger angle, \( \lambda \),

\[
\begin{pmatrix}
\sin \lambda & \cos \lambda & 0 \\
-\cos \lambda & \sin \lambda & 0 \\
0 & 0 & 1
\end{pmatrix}
\]

The stagger angle, \( \lambda \), is the angle between the airfoil chord and a radial plane passing through the axis of the rotor.
3.4 Subroutine TONE

Subroutine TONE as currently set up computes the sound generation related to the steady state blade forces. This is the "Gutin" mechanism. The program has been developed for a rotating steady state stress term also but as yet it is not known how to model this in terms of aerodynamic design parameters.

The expression which is computed for the radiated sound pressure is

$$\left| p(\theta, \omega) \right|^2 = \frac{1}{16 \pi^2 r^2} \left( \frac{B}{R_s} \right)^2 \sum_{k=1}^{B} \sum_{m=-\infty}^{\infty} m^2 \int_{2}^{r} \left( a_k, \omega \right) J^2 \left( \frac{\omega R_s \sin \phi}{a_0} \right)$$

where:

- $B$ = number of blades in the rotor
- $F_r$ = blade force in the direction of the observer
- $R_s$ = source of radius
- $\phi$ = observer angle to rotor axis
- $r$ = distance to the observer
- $\omega$ = radian frequency

3.5 Subroutine ORTH2

ORTH2 does exactly the same computation to the blade force as ORTH1 did for the random blade forces. The procedures are parallel.

This model was set up in a computer program so that direct numerical computations of the time series described by the equation for the radiated sound could be made. This direct approach of calculating the actual time series is the difference between the present approach and those of other rotor models. Typically the analytical results for the rotor are Fourier transformed and reduced to a closed form (such as program ROTOR described herein). This approach normally requires that simplifications be made so that the closed form can be obtained. The advantage of the present approach is no simplifications in the analysis need be made.

The time series is computed for a sufficient number of values so that a good statistical sample will result. The time series is then Fourier transformed using a Fast Fourier Transform algorithm to yield the spectrum of the radiated sound. In other words, the model is used to generate a time series which is handled exactly as one would handle experimental data. Very complex source histories can be studied with no more effort than the very simple steady force case. For example, rotor wobble can be simulated in order to study how it affects the generation of sound; the individual blades can be allowed to vibrate as might occur in flutter cases; or each blade can be assigned a different value of force to determine the effect of such blade to blade differences as might be caused by manufacturing imperfections.

Of most importance, is that complex random effects can be included in this model, also. Such mechanisms as force fluctuations related to wake turbulence, inflow turbulence, or even rotating stalls can be studied. The
way this must be done is to express the force fluctuation in a time
series that has the required statistical nature. If the spectrum of the
force fluctuation relative to the blade is known, then it is possible to
generate a random time series which will give the same statistics as the
known result. The methods for generating an auto-regression analysis can be
used to simulate the spectrum of the force on the blades. Once the time
series are known, the results from the different blades may be combined in
different ways to simulate different mechanisms of sound generation. For
example, the effect of large scale turbulence can be simulated by allowing
several of the blades to experience the same force fluctuation, or allow all
of them to experience it. The case where there is no blade to blade corre-
lation would model the wake related sound generation.

The idea of the model is to provide a tool where the various mechanisms
which might produce appreciable sound generation can be evaluated. In addi-
tion, it is sought to set up the model in such a way that its usage will
be reasonably simple and straightforward. As an example, if one wants to
study the effect of different forces on each of the blades, he merely reads
in the array of steady loads he wishes to rotor to have, and that is all.
Rotor wobble is accounted for by replacing the velocity of the source,
the rotor velocity, with a time dependent function describing the wobble
characteristics.

4.1 Tone Noise Generation Model

The generation of pure tone sound due to the steady state forces on the
rotor blading is studied in the model. In addition, an auto-regression
method is used to write a time series which approximates a random force dis-
tribution resulting in broad band noise generation.
The model is based upon M.V. Lowson's development for rotating point forces*. The development is done for a force per unit volume. In this representation only the point force case will be considered. Extension to the distributed case can be treated as an array of point forces where the array is distributed along the span as well as circumferentially. This has been done by the author and the mechanics are straightforward but the expense in computer time is correspondingly increased.

For a point force, the radiated sound in the far field can be written:

\[ p(\vec{x}, t) = \left[ \frac{x_i y_j}{4\pi a_0 r^2 (1-M_e^2)} \left( \frac{\partial F_i}{\partial t} + \frac{F_i}{1-M_e^2} \frac{\partial x_j}{\partial t} \right) \right]_{t_R} \]

where the evaluation of the source terms of the retarded time

\[ t_R = t - \frac{\lvert \vec{x} - \vec{y} \rvert}{a_0} \]

\[ t_R = \text{time of sound generation} \]
\[ t = \text{time of observation}, \text{ and } \lvert \vec{x} - \vec{y} \rvert/a_0 = \text{propagation time}. \]

The position vector \( \vec{r} = \vec{x} - \vec{y} \) can be written in the form

\[ \vec{r} = \sum_{i=1}^{3} (x_i - y_i) \hat{e}_i \]

in rectangular cartesian coordinates.

The Mach number \( M_r \) is the component of the source Mach number in the direction of the observer. It may be written

\[ M_r = \frac{M_s \cdot \hat{r}}{\lvert \vec{r} \rvert} \]

or in components as

The components of the blade force $\mathbf{F}$ can be chosen to represent the thrust and torque loads on the individual blades. Using the blade stagger angle, $\xi$, write

\[ F_1 = -F \cos \xi \]
\[ F_2 = -F \sin \xi \sin \theta \]
\[ F_3 = F \sin \xi \cos \theta. \]

Take the time derivatives of these force components:

\[ \frac{\partial F_1}{\partial t} = 0 \]
\[ \frac{\partial F_2}{\partial t} = -F \Omega \sin \xi \cos \theta \]
\[ \frac{\partial F_3}{\partial t} = -F \Omega \sin \xi \sin \theta. \]

The components of the position of the observer are written in polar form as

\[ x_1 = r \cos \phi \]
\[ x_2 = r \sin \phi \]
\[ x_3 = 0. \]

The location of the source is also written in polar form:

\[ y_1 = 0 \]
\[ y_2 = R_s \cos \theta \]
\[ y_3 = R_s \sin \theta. \]

Finally, the components of the source Mach number are
\[ M_1 = 0 \]
\[ M_2 = -M \sin \theta \]
\[ M_3 = M \cos \theta. \]

The value of the source Mach number is

\[ M_s = \frac{R_s \Omega}{a_0}. \]

The Mach number component \( M_r \) may now be computed:

\[ M_r = \sum_{i=1}^{L} \frac{M_i (x_i - y_i)}{r}. \]

Substitution yields

\[ M_r = \frac{(r_1 \cos \phi)(\phi)/r + (r_1 \sin \phi - R_s \cos \theta)(-M_s \sin \theta)/r}{r} \]

\[ = -(r_1/r) M_s \sin \phi \sin \theta + (R_s/r) M_s \cos \theta \sin \theta, \]

so that to the first order

\[ M_r = -M_s (r_1/r) \sin \phi \sin \theta. \]

The time derivative of the Mach number becomes

\[ \frac{\partial M_r}{\partial t} = -M_s (r_1/r) \Omega \sin \phi \cos \theta. \]

All the terms required for the computation of the pressure radiated are now complete. The radiated sound is
\[ p(x,t) = \frac{F}{4\pi a_0 r^2 (1-M_r)^2} \left( \frac{r_1 \sin \phi - R_s \cos \theta}{r} \right) (-\Omega \sin \xi \cos \phi) \]

\[ -\frac{R_s \sin \theta}{r} \left( -\Omega \sin \xi \sin \theta \right) + \frac{1}{1-M_r} \frac{\partial M}{\partial t} \left[ \frac{r_1 \cos \phi}{r} \right] (-\cos \xi) \]

\[ + \frac{r_1 \sin \phi - R_s \cos \theta}{r} \left( -\sin \xi \sin \theta \right) + \frac{R_s \sin \theta}{r} \left( \sin \xi \cos \phi \right) \]

And, expanding:

\[ p(x,t) = \frac{F}{4\pi a_0 r(1-M_r)^2} \left( \frac{-r_1 \Omega \sin \phi \sin \xi \cos \theta}{r} \right) \]

\[ + \frac{R_s \Omega \sin \xi}{r} \left( \cos^2 \theta + \sin^2 \theta \right) + \frac{1}{1-M_r} \frac{\partial M}{\partial t} \left[ \frac{-r_1 \cos \phi \cos \xi}{r} \right] \]

\[ - \frac{r_1 \sin \xi \sin \phi \sin \theta}{r} \}

The solution reduces to the form

\[ p(x,t) = \frac{F}{4\pi a_0 r^2 (1-M_r)^2} \left[ \Omega \sin \xi \left( R_s - r_1 \sin \phi \cos \theta \right) \right. \]

\[ - \frac{1}{1-M_r} \frac{\partial M}{\partial t} \left( r_1 \cos \phi \cos \xi + r_1 \sin \xi \sin \phi \sin \theta \right) \]

This will give the radiated sound from each of the blades. The above expression is to be evaluated at the retarded time. This will require some further manipulations.

\[ t_R = t \cdot \frac{r}{a_0} \quad \text{where} \quad r = \sqrt{x^2 + y^2} \]

square the distance \( r \)
\[
\begin{align*}
\alpha^2 &= (\mathbf{r}_1 - \mathbf{y}_1)^2 = (r_1 \cos \phi)^2 + (r_1 \sin \phi - R_s \cos \theta)^2 + (R_s \sin \theta)^2 \\
&= \alpha^2_1 - 2 r_1 R_s \sin \phi \cos \theta + R_s^2.
\end{align*}
\]

Now, \( r_1 \gg R_s \), so it will be sufficient for the far field solution to write

\[
\alpha^2 = \alpha^2_1 - 2 r_1 R_s \sin \phi \cos \theta
\]

or, equivalently,

\[
\alpha^2 = (r_1 - R_s \sin \phi \cos \theta)^2 - R_s^2 \sin^2 \phi \cos^2 \theta.
\]

For the far field solution we can therefore use

\[
\alpha = r_1 - R_s \sin \phi \cos \theta.
\]

The retarded time can be written as

\[
\alpha^R = \alpha - r_1/a_o + R_s/a_o \sin \phi \cos \theta [\theta],
\]

where the \([\theta]\) is the retarded value of the blade location.

This source position may be written as

\[
[\theta] = \Omega_{\alpha} (\alpha^R + \theta_{\alpha} = 0) = \Omega (\alpha - r_1/a_o + \frac{\Omega R_s}{a_o} \sin \phi \cos \theta + \theta_{\alpha} = 0).
\]

Now in the solution for the radiated sound substitute \(\alpha^R\) for \(\alpha\) and \([\theta]\) for \(\theta\), the radiated sound pressure becomes

\[
p_K(\mathbf{r}, \alpha, \theta) = \frac{F}{4\pi a_o r^2 (1 - [M_{\alpha}])^2} \left( \Omega \sin \xi (R_s - r_1 \sin \phi \cos \theta) \right)
\]

\[
- \frac{r_1}{(1 - [M_{\alpha}])^2} \left[ \frac{3M}{\xi} \right] \xi \left( \cos \xi \cos \phi \sin \xi \sin \phi \sin \theta \right).
\]
where: \[ r = r_1 - R_s \sin \phi \cos [\theta]_k \]

\[ [M_x]_k = -M_s \sin \phi \cos [\theta]_k \]

\[ [\partial M_x/\partial t]_k = -M_s \Omega \sin \phi \cos [\theta]_k, \]

with:

\[ \Theta_k = \Omega(t - r_1/a_o) = (\Omega R_s/a_o) \sin \phi \cos [\theta]_k + \Theta_k, t_R=0 \]

\[ \Theta_k, t = 0 = \text{location of kth source at } t_R = 0. \]

The total sound from all the rotor blades becomes

\[ p(\Omega, t) = \sum_{k=1}^{B} p_k(\Omega, t). \]

### 4.2 How to Use Program TONE

As was seen in the previous section, the model used to predict the sound radiation generates a discrete time history using the solution for a rotating array of forces, then treats that history in the same way one would treat experimental data.

We previously mentioned the flexibility of this approach. This flexibility is achieved in the program by changing the program listing. A multiple option approach could have been taken but this is wasteful of computer time and assumes one knows all the options which will be needed. The reason for this approach was to provide a flexible tool; however, it does depend upon the operator's ability to change the Fortran statements used to generate the time series. This is easily done since the equations are short and the program is straightforward. The part of the program actually used to generate the time series is about 20 cards long.
The form of the program set up here is for the case where the force on each of the blades is the following function of time

\[ F(t) = F_B (1 + C_d x(t)) \]

where \( F_B \) is the steady state blade force, \( C_d \) is a dynamic loading coefficient, and \( x(t) \) is a time series simulating the unsteady force fluctuations on the blade. Depending upon the particular mechanism, \( x(t) \) can be chosen to simulate either wake related force fluctuations or the fluctuations caused by inflow turbulence interacting with the airfoil. Processes of this type can be represented using autoregressive processes. This will be discussed in section 4.5 below.

### 4.3 Program Inputs

Input to the program is done using cards. Four cards are required to run the program in its present form.

**CARD 1, FORMAT(115)**

- **NOPT** = 0, no plots
- = 1, plot the time history
- = 2, plot the sound spectrum
- = 3, plot both the history and the spectrum

**NOPT** controls the type of output desired. Two CALCOMP subroutines are contained in the program so that the time history for the process can be examined and/or the spectrum of the radiated sound can be plotted. If neither plot is desired then listings of the time history and the spectrum will be the only output.
CARD 2, FORMAT(7F10.2)

BE   bandwidth desired in the spectrum (Hz)
FMAX maximum frequency in the spectrum (Hz)

See Section 4.4 for the implications of these selections.

CARD 3, FORMAT(7F10.2)

ZR number of rotor blades (--)
XI blade stagger angle, measured from blade chord to radial plane passing through rotor axis (DEG)
PHI radiation angle, measured from inlet rotor axis (DEG)
RPM rotor speed (RPM)
RS radial distance to source (M)
R1 radial distance to observer (M)
F magnitude of force on each blade (KG)

CARD 4, FORMAT(7F10.2)

CDYN dynamic force coefficient (--)
A1 autoregression coefficient (--)
A2 autoregression coefficient (--)

See Section 4.5 for a discussion of the selection of the autoregression coefficients.

4.4 Time Sampling

The setting of FMAX and BE determines the sampling rate and the total number of required samples. Letting

\[ f_{\text{max}} = \text{FMAX} \]
\[ B_e = \text{BE} \]
we can illustrate how this is done. First, estimate the number of samples required as

\[ N = 2 \frac{f_{\text{max}}}{B_e} . \]

Since we will use a Fast Fourier Transform to find the spectrum, the number of samples must be of the form \( N' = 2^m \) where \( m \) is an integer. We choose \( m \) such that

\[ 2^{m-1} < N < 2^m. \]

Then compute \( N' = 2^m \) samples of the time series. The new bandwidth becomes

\[ B'_e = 2 \frac{f_{\text{max}}}{N'} . \]

The sampling rate for the time series is

\[ H = \frac{1}{2f_{\text{max}}} . \]

4.5 Use of Autoregression Processes

A second order autoregression process is used in the current form of the program to represent the force fluctuations. This process may be written

\[ x(t) = a_1 x(t-1) + a_2 x(t-2) + Z(t) \]

where \( a_1 \) and \( a_2 \) are the autoregression coefficients (A1 and A2 in the program. \( Z(t) \) is a random number selected using a random number generator.

A time series is generated separately for each blade. If there is to be no correlation between different blades (\( a_0 \) for wake related forces) then
Z will be taken from a different random series for each blade. If correlation is desired between blades then the time series can be selected to reflect the correlation. Correlation would be expected to exist between blades for the mechanism of inflow turbulence.

The main idea is to fit the time series to represent what is desired, then let the program compute the resulting sound radiation.

The spectrum for the second order process above can be solved directly. The spectrum is

\[ G_{xx}(f) = \frac{H u^2}{z} / (1 + a_1^2 + a_2^2 - 2a_1(1-a_2) \cos 3\pi fH - 2a_2 \cos 4\pi fH) \]

\[-1/2H < f < 1/2H.\]

Selection of \(a_1\) and \(a_2\) gives the spectral shape to be expected from \(x(t)\).

A plot of \(a_1\) and \(a_2\) for different spectral shapes is shown below to give an idea of the values of the coefficients needed for particular shapes.
A peaked spectrum is what we would expect for a wake related sound generation mechanism. A low frequency spectrum would be expected for the cases of inflow turbulence. The frequency where the peak will occur is given by

$$\cos 2\pi f_0 M = -a_1 (1 - a_1^2)/4a_2.$$ 

As may be expected, some experimentation will be required to fit the process to an actual experimental spectrum.

To obtain more complicated power spectral shapes higher order processes may be needed. These can be handled as easily as the above on the computer, but the preliminary efforts to get a particular spectrum increase.

For a good general discussion of the above method the reader is referred to SPECTRAL ANALYSIS AND ITS APPLICATIONS by G.M. Jenkins and D.G. Watts (1969).

If more simply definable fluctuations are needed these can be used for \(x(t)\). For example, inlet distortion or the effect of another blade row can be simulated by a Fourier series representation of the force fluctuation resulting from the distortion. A simple cosine with period equal to the stator spacing will give a good qualitative model of blade row interaction noise.

The model can also be extended to account for span distributions of the blade force. This is straightforward but the computer time required does increase substantially.

5.0 PROGRAM SDATA

Program SDATA is used to perform correlation and spectral analysis on discrete time series. The particular operations carried out on two given time series are:

1) Autocovariance function for each sample and cross covariance between the two samples
2) Autocorrelation function for each sample and cross correlation between the two samples
3) Autospectrum for each sample
4) Magnitude and phase representation of cross spectrum between the two samples
5) Squared coherency function

The analysis used as the basis for the program is that presented in SPECTRAL ANALYSIS AND ITS APPLICATIONS, by G.M. Jenkins and D.G. Watts. The method used is exactly that recommended in this reference.

Two input possibilities exist. The first is to input two time series of arbitrary length. For this case the program will compute all the above covariances, correlations, and spectral quantities. The second possibility is to input two covariance functions. In this case the program will only carry out the spectral analysis. Some electronic instruments have become available recently which quickly compute correlation functions. This program can be used in conjunction with these instruments to obtain the spectral representation of the data.

A classical Fourier transform was used in the program. For this reason long samples, in terms of correlation lags, will require substantial computer time. Therefore, a Fast Fourier Transform program should be used for large samples.
5.1 Outline of Computations

This outline is substantially the same as that presented by Jenkins and Watts (pages 382 and 383).

Two time series of data, \( x_{t1} \) and \( x_{t2} \), sampled at increments of \( H \) sec for a total of \( N \) points. For convenience \( H \) is assumed equal to one. The frequency range is then \( 0 \leq f \leq 1/2 \) Hz. For non-unity values of \( H \) the frequency range is \( 0 \leq f \leq 1/2H \). The actual spectral levels are also to be multiplied by \( H \) to obtain quantitatively correct values.

The computations are:

(1) For the \( x_{t1} \) data:

(a) the autocovariance estimate is

\[
\hat{c}_{11}(k) = \frac{1}{N} \sum_{t=1}^{N-k} (x_{1t} - \bar{x}_{1} )(x_{1t+k} - \bar{x}_{1}) \quad 0 \leq k \leq M-1
\]

where \( M \) is the number of time lags in the estimate and the mean value is

\[
\bar{x}_{1} = \frac{1}{N} \sum_{t=1}^{N} x_{1t}
\]

(b) the smoothed spectral estimate using a Tukey window

\[
\overline{c}_{11}(j) = 2 \left\{ \hat{c}_{11}(0) + 2 \sum_{k=1}^{N-1} \hat{c}_{11}(k) w(k) \cos \frac{\pi kj}{F} \right\} \quad 0 \leq j \leq F
\]

\( F \) is a measure of the spacing of the frequency points. The smoothed spectral estimates are to be computed at \( 0, 1/2, ..., 1/2 \)

where \( F \) is of the order 2 to 3 times \( H \). The Tukey window \( w(k) \) is defined by
\[ w(k) = \frac{1}{2} \left( 1 + \cos \frac{\pi k}{M} \right) \quad |k| \leq M \]
\[ = 0 \quad |k| > M . \]

(2) For the \( x_{t2} \) data:

(a) the autocovariance function estimate

\[ c_{22}(k) = \frac{1}{N} \sum_{t=1}^{N-k} (x_{2t} - \bar{x}_{2}) (x_{2t+k} - \bar{x}_{2}) \quad 0 \leq k \leq M-1 \]

with the mean value

\[ \bar{x}_{2} = \frac{1}{N} \sum_{t=1}^{N} x_{2t} \cdot \]

(b) the smoothed spectral estimate

\[ \overline{c}_{22}(j) = 2 \{ c_{22}(0) + 2 \sum_{k=1}^{M-1} c_{22}(k) w(k) \cos \frac{\pi k}{F} \} \quad 0 \leq j \leq F \]

where the same window is used (Tukey) for \( w(k) \).

(3) For the \( x_{t1} \) and the \( x_{t2} \) data:

(a) the cross covariance estimate

\[ c_{12}(k) = \frac{1}{N} \sum_{t=1}^{N-k} (x_{1t} - \bar{x}_{1})(x_{2t+k} - \bar{x}_{2}) \quad 0 \leq k \leq M-1 \]

\[ c_{21}(k) = c_{12}(-k) = \frac{1}{N} \sum_{t=1}^{N-k} (x_{1t+k} - \bar{x}_{1})(x_{2t} - \bar{x}_{2}) \quad 0 \leq k \leq M-1 \]

(b) the even and odd cross covariance estimates

\[ z_{12}(k) = \frac{1}{2} \{ c_{12}(k) + c_{12}(-k) \} \quad 0 \leq k \leq M-1 \]

\[ q_{12}(k) = \frac{1}{2} \{ c_{12}(k) - c_{12}(-k) \} \quad 0 \leq k \leq M-1 \]
(c) the smoothed co- and quadrature spectral estimates

\[ L_{12}(j) = 2 \{ \omega_{12}(0) + 2 \sum_{k=1}^{M-1} \omega_{12}(k) w(k) \cos \frac{\pi j k}{F} \} \quad 0 \leq j \leq F \]

\[ Q_{12}(j) = 4 \sum_{k=1}^{M-1} \omega_{12}(k) w(k) \sin \frac{\pi j k}{F} \quad 1 \leq j \leq F-1 \]

Note that \( q_{12}(0) = 0 \) and that \( Q_{12}(0) = Q_{12}(F) = 0. \)

(d) the smoothed cross amplitude spectral estimate

\[ A_{12}(j) = \sqrt{L_{12}^2(j) + Q_{12}^2(j)} \quad 0 \leq j \leq F \]

(e) the smoothed phase spectral estimate

\[ \Phi_{12}(j) = \arctan \left\{ -\frac{Q_{12}(j)}{L_{12}(j)} \right\} \quad 0 \leq j \leq F \]

(f) the smoothed squared coherency spectral estimate

\[ K_{12}(j) = \frac{A_{12}^2(j)}{E_{11}(j) E_{22}(j)} \quad 0 \leq j \leq F \]

5.2 Correction for Bias Error Reduction

When there is a large delay in the correlation a large error can result in the coherency and phase spectrum. This bias error can be reduced by shifting the cross covariance function so that the maximum correlation occurs at zero time lag.

The way this correction is made in the present program is to search for the time lag corresponding to the largest absolute value of covariance. A new covariance function is then generated such that the peak occurs at the
zero time lag. This function is Fourier transformed and the phase shift introduced by the time shift is applied to the spectral estimate to correct it back. A consequence of the generation of a new covariance function is that it necessarily will contain fewer terms than the original. This results in a wider frequency bandwidth in the spectral estimate. This is why the program will seem to generate different bandwidths for different batches of data even when the same number of lags are called out in the input.

5.3 Input to Program

Two possibilities exist for input to this program. The first is to read in two time series of variables for which correlation and spectral computations are required. This is obtained from data card one by setting the variable OPTION = 1, FORMAT(1I5). If OPTION is not set equal to one the program will read in the data as if it were covariance functions. Input for OPTION = 1 is described in Section 5.3.1 and for OPTION ≠ 1 in Section 5.3.2.

CARD 1, FORMAT(1I5)

<table>
<thead>
<tr>
<th>OPTION</th>
<th>= 1 read in time series</th>
</tr>
</thead>
<tbody>
<tr>
<td>≠ 1 read in covariance functions</td>
<td></td>
</tr>
</tbody>
</table>

5.3.1 OPTION = 1

CARD 2, FORMAT(2I5)

<table>
<thead>
<tr>
<th>NSAMP</th>
<th>number of points in the time sample</th>
</tr>
</thead>
<tbody>
<tr>
<td>MLAG</td>
<td>number of time lags desired in the covariance functions</td>
</tr>
</tbody>
</table>

typically MLAG is chosen to be approximately one tenth as large as NSAMP.

CARD 3, FORMAT(1F10.2)

| DELT | time increment in samples (Sec) |
The remaining inputs under this option are the actual values of the variable in the time series. They are read 7 values to each card in the FORMAT(7F10.2). The number of cards required depends upon the size of the sample. The computer call is

```
DO 10 I = 1,2
10 READ(5,2) (X(J,I), I = 1,NSAMP)
```

This is the total input required for this option.

**5.3.2 OPTION # 1**

CARD 2, FORMAT(2F10.2)

<table>
<thead>
<tr>
<th>XLAG</th>
<th>number of values in the covariance function samples</th>
</tr>
</thead>
<tbody>
<tr>
<td>DELT</td>
<td>time increment in the functions (Sec)</td>
</tr>
</tbody>
</table>

The remaining cards are used to read in the covariance functions. In the present format the functions are read in as follows.

```
DO 10 I = 1,2
DO 10 J = 1,2
10 READ(5,2) (COV(K,I,J), K = 1,M1)
```

where M1 = XLAG + 1 and the indices I,J mean the following:

- \( COV(K,1,1) = C_{11}(k) \) = autocovariance function for series 1, \( k = 0,M \)
- \( COV(K,2,2) = C_{22}(k) \) = autocovariance function for series 2, \( k = 0,M \)
- \( COV(K,1,2) = C_{12}(k) \) = cross covariance function for positive time lags, \( k = 0,M \)
- \( COV(K,2,1) = C_{21}(k) \) = cross covariance function for negative time lags, \( k = 0,M \)

The format used to read in these functions is FORMAT(7F10.2). This completes the input requirements for this option.
5.4 Program Input

The output of the present form of this program is simply a listing of each of the functions computed. The list of functions computed was presented in Section 1.0.
