## ADHESION OF A BIMETALLIC INTERFACE

Abstract

by

John Ferrante

The Hohenberg-Kohn and Kohn-Sham formalisms are used to examine adhesive binding (binding energy as a function of separation) between combinations of simple metals in contact. The metals examined are Al (111), Zn (0001), Mg (0001), and Na (110). The adhesion of dissimilar metal contacts of Al, Zn, Mg are examined using a simple overlap model with the Hohenberg-Kohn formalism along with Smith's parameterized density. The adhesion of similar metal contacts between Al, Zn, Mg, and Na are examined completely self-consistently in an entirely ab initio calculation using the Kohn-Sham formalism. Crystallinity is included using the Ashcroft pseudopotential via first order perturbation theory for the electron-ion interaction; and the ion-ion interaction is included exactly via a lattice sum. The adhesive binding energy was determined both in the local-density approximation and including gradient corrections to the exchange and correlation energy using the gradient corrections of Rasolt and Geldart. Binding was found in all cases. In dissimilar metal contacts the interfacial bonding energy was greater than that in the weaker material predicting the experimentally observed possibility

of metallic transfer. The nonzero position of the binding energy minimum in like metal contacts is explained in terms of consistency between the Ashcroft pseudopotential and the bulk charge density. Good agreement with experimental surface energies is obtained in the self-consistent calculation when nonlocal terms in the exchange and correlation energies are included. Good agreement is also obtained with experimental elastic stiffness constants as compared with values obtained from the curvature of the binding energy curves near the minimum. The range of the strong chemical bonding force was found to be of the order of 0.2 nanometers. Strong similarities with molecular binding are found when examining the kinetic and potential energy contributions to the binding energy as compared with the Ruedenberg and Feinberg examination of molecular binding in hydrogen. Excellent agreement is obtained with the Budd-Vannemenus sum rule as compared with the jellium force at zero separation indicating a high degree of self-consistency.

DEDICATION

I would like to dedicate this work to my dear wife, Patrica,  
for her support and confidence.

### ACKNOWLEDGEMENTS

I would like to thank Prof. P. L. Taylor for his support and his patience which would make Job seem hyperactive, Dr. John R. Smith for years of collaboration and friendship, Dr. Steven V. Pepper for many helpful discussions, friendship, and encouragement, and Dr. Donald H. Buckley for creating a working atmosphere where venturing into untried areas is supported.

## BACKGROUND

Friction and wear are of great technological importance. Adhesion, the mutual attractive force between similar or dissimilar materials when brought into contact is of fundamental importance to friction and wear [1,2,3]. In spite of the importance of metallic adhesion, little work has been done to describe the nature of the strong attractive force between metals in contact or at small separations. This has been due in part to the lack of theoretical techniques for modeling metal surfaces, the lack of experimental data on clean metals and the complexities involved in friction, wear, and adhesion experiments. The experimental data available in the literature is at best only statistically repeatable, i.e., a sufficient number of experiments will give a most probable value. The eruption of surface oxides during rubbing which results in strong adhesion and thus the generation of wear particles is at best a random process. A number of difficulties exist even in adhesion experiments carefully performed in ultrahigh vacuum systems with characterized clean metal surfaces [4,5]. The first difficulty is the fact that real surfaces are not ideally flat, there is a hill and valley structure which makes the true contact area unknown. Second, there are mechanical effects such as recovery of elastically stored energy or bulk defect structures [4] which affect the breaking strength of the bond. Consequently, in order to tackle the complicated problems involved in

metallic adhesion it is necessary to separate its various parts, i.e., binding force, mechanical effects, true surface area, etc. The hope is therefore that an understanding of these isolated phenomena will result in the ability to put the results together and gain a general understanding. In this spirit the present work attempts to understand one phase of the problem, the nature of the clean metal-metal binding force.

Another aspect of the present work is that in previous surface energy calculations only energies at zero and infinite separation were computed. There is a further check which must be performed to verify these results and that is that the binding energy curve must have the correct behavior at zero separation, i.e., zero slope. Therefore, the present work is also a necessary check upon surface energy calculations [6,7]. In addition, a further comparison with experiment can be made in that elastic constants can be estimated from the curvature of the binding energy at the minimum. This study therefore consists of several parts. The adhesive energy (binding energy for two metals versus separation) is calculated for a simple overlap model where the electron gas is held fixed at its bare surface distribution for all combinations of Al, Zn, and Mg. The adhesive energy is then calculated for the more difficult situation allowing relaxation of the electron gas with separation for the like metal pairs Al, Zn, Mg, and Na. Crystallinity is included in both cases. Finally, the constituents of the binding energy are examined for analogies between adhesive and molecular binding.

## I - SELF-CONSISTENT CALCULATIONS OF THE ELECTRON NUMBER DENSITY

## A. Hohenberg-Kohn-Sham Formalism

The present calculation relies on recent advances in surface theory based on the work of Hohenberg, Kohn, and Sham [8,9] who extended the Thomas-Fermi-Dirac Theory. The Hohenberg-Kohn-Sham Theory is an exact formal variational principle for the total energy of an interacting inhomogeneous electron gas in which the total electron density is the functional variable. A number of excellent reviews of this theory are available in the literature [10,11,12]. In this section we will summarize the highlights of the Hohenberg-Kohn-Sham Formalism.

Hohenberg and Kohn (HK), [8] formulate the total energy of a system of interacting particles as a functional of the electron number density  $n(\underline{r})$  for an external potential  $v(\underline{r})$ . They write

$$E_T[n(\underline{r})] = \int d\underline{r} V(\underline{r}) n(\underline{r}) + F[n(\underline{r})] \quad (1)$$

where

$$F[n(\underline{r})] = T_S[n(\underline{r})] + \frac{1}{2} \iint d\underline{r} d\underline{r}' \frac{n(\underline{r})n(\underline{r}')}{|\underline{r}-\underline{r}'|} + E_{xc}[n(\underline{r})] \quad (2)$$

The functional  $T_S[n(\underline{r})]$  is the kinetic energy of the noninteracting electron gas, the second term is the classical Coulomb energy and  $E_{xc}[n(\underline{r})]$  is the exchange and correlation energy which accounts for the remainder.

HK then proceed to argue that for a given external potential

$v(\underline{r})$  the energy functional  $E_v[n]$  acquires its minimum value for the correct density  $n(\underline{r})$  subject to the constraint  $\int n(\underline{r}) d\underline{r} = N$  that states the conservation of the total number of particles. HK then define a new functional  $G[n]$  which omits the classical coulomb energy and for a slow variation (though possibly large) in the density  $n(\underline{r})$ ,  $G[n]$  is expanded in terms of the gradient of  $n$ .

$$G[n(\underline{r})] = \int d\underline{r} [g_0(n(\underline{r})) + g_2(n(\underline{r})) |\nabla n(\underline{r})|^2 + \dots] \quad (3)$$

Where  $G[n] = T_s[n] + E_{xc}[n]$ . The term  $g_0(n)$  represents the energy density of a gas of uniform density,  $n_+$ , and is referred to as the local density approximation (LDA). The LDA has been to date the approximation most frequently used in surface energy calculations [12]. More recent surface energy calculations [13,14,15] have been extended beyond the LDA to include the gradient terms represented by  $g_2(n(\underline{r}))$ . Once an approximation is selected for the exchange and correlation energies, nonlocal energy, and a potential is specified, then the variational principle

$$\delta(E_v[n(\underline{r})] - \mu \int d\underline{r} n(\underline{r})) = 0 \quad (4)$$

is applied where  $\mu$  is a Lagrange multiplier. A differential equation for  $n(\underline{r})$  can then be derived and solved self-consistently with Poisson's equation enabling the calculation of the electron number density, the electrostatic potential, and the total energy of the system.

Kohn and Sham (KS), [9] have extended the principles in the HK Formalism by considering the variational equations

$$\int \delta n(\underline{r}) \left\{ \phi(\underline{r}) + \frac{\delta T_s[n]}{\delta n} + \mu_{xc}[n] \right\} d\underline{r} = 0 \quad (5a)$$

$$\int \delta n(\underline{r}) d\underline{r} = 0 \quad (5b)$$

where

$$\phi(\underline{r}) = V(\underline{r}) + \int d\underline{r}' \frac{n(\underline{r}')}{|\underline{r} - \underline{r}'|} \quad (6)$$

and

$$\mu_{xc} = \frac{d}{dn} (n \epsilon_{xc}(n)) \quad (7)$$

where  $\epsilon_{xc}$  is the exchange and correlation energy/particle of the uniform electron-gas of density  $n$ . Therefore for a given  $\phi(\underline{r})$  one obtains a result that is identical to the HK formalism for a system of noninteracting electrons moving in a potential  $\phi(\underline{r}) + \mu_{xc}(n(\underline{r}))$ . As a consequence they establish a set of one-particle Schroedinger equations (atomic units used throughout  $\hbar = m = e = c = 1$ )

$$\left\{ -\frac{1}{2} \nabla^2 + [\phi(\underline{r}) + \mu_{xc}(n(\underline{r}))] \right\} \psi_i = \epsilon_i \psi_i \quad (8)$$

with a self-consistent potential  $\phi(\underline{r}) + \mu_{xc}(n(\underline{r}))$  where

$$n(\underline{r}) = \sum_i |\psi_i(\underline{r})|^2 \quad (9)$$

$\psi_i(\underline{r})$  are the N-lowest lying orthonormal solutions of equation (8). The only approximation in the procedure is that  $\epsilon_{xc}(\underline{r})$  is an adequate representation of exchange and correlation effects. Inclusion of nonlocal terms will be considered later.

## B. Lang-Kohn Surface Energy Calculations [7]

### 1. Formulation of the Kohn-Sham Equations

The papers most relevant to the present results are the surface energy calculations of Lang and Kohn (LK) ([7] and references cited therein) and Smith [6]. The LK approach work will be summarized here. The application of Smith's results is discussed in the theory section. LK used the Kohn-Sham Formalism to calculate the surface energy of metals ranging from  $r_s = 2$  to  $r_s = 6$  where  $r_s$  is the radius of the Wigner-Seitz sphere. The surface energy is the energy per unit area required to form a free surface. Alternatively it may be thought of as the energy per unit area required to separate a slab of metal into two pieces along a plane to infinite separation.

LK solved the Kohn-Sham equations for a bare metal surface using the jellium model. In this model the external potential  $v(\underline{r})$  is that obtained from the jellium positive charge density  $n_+(\underline{r})$ . Where

$$n_+(\underline{r}) = \begin{cases} 0 & x > 0 \\ n_+ & x \leq 0 \end{cases} \quad (10)$$

where  $x$  is the dimension perpendicular to the surface and  $n_+$  is the magnitude of the bulk electron density. For this model the electrostatic potential is given by Eq. (6) and is modified to the form

$$\phi(\underline{r}) = \int d\underline{r}' \frac{n(\underline{r}') - n_+(\underline{r}')}{|\underline{r} - \underline{r}'|} \quad (11)$$

therefore  $\phi(\underline{r})$  can be determined by Poisson's equation

$$\nabla^2 \phi = -4\pi (n(\underline{r}) - n_+(\underline{r})) \quad (12)$$

The constraint on the total number of particles can be incorporated into the expression via a Lagrange multiplier

$$\delta [E_N[M] - \mu \int n(\underline{r}) d\underline{r}] = 0 \quad (13)$$

therefore for the correct density

$$\mu = \frac{\delta E_N[M]}{\delta n(\underline{r})} = \phi(\underline{r}) + \frac{\delta G[M]}{\delta n(\underline{r})} \quad (14)$$

for large  $N$ ,  $\mu$  is equal to the chemical potential. Performing a volume average over the metal gives

$$\mu = \bar{\phi} + \bar{\mu} \quad (15)$$

where  $\bar{\mu}$  is the bulk chemical potential relative to the mean interior electrostatic potential (in an infinite metal jellium model  $\bar{\phi} = 0$ ). From Eqs. (3) and (13)

$$\bar{\mu} = +\frac{1}{2} k_F^2 + \left. \frac{\delta E_{xc}[M]}{\delta n} \right|_{n=n_+} \quad (16)$$

LK defined

$$V_{\text{eff}}(\underline{r}) = \phi(\underline{r}) + M_{xc}(n(\underline{r})) \quad (17)$$

in Eq. (8) and labeled the states by the quantum numbers  $k, k_y, k_z$  with the following meaning

$$\Psi_{k, k_y, k_z}(r) = \Psi_k(x) \exp(ik_y y + ik_z z) \quad (18)$$

where for  $x \rightarrow -\infty$

$$\Psi_k(x) = \sin(kx - \gamma(k)) \quad (19)$$

where  $\gamma(k)$  is the phase shift introduced by the presence of the surface. The choice of  $\mu = 0$  to define the zero of energy gives finally  $v_{\text{eff}}(x) \xrightarrow{x \rightarrow -\infty} -1/2 k_F^2$  from Eqs. (15), (16), and (17) and

$$-\frac{1}{2} \left( \frac{d^2}{dx^2} + v_{\text{eff}}(m, x) \right) \Psi_k(x) = \frac{1}{2} (k^2 - k_F^2) \Psi_k(x) \quad (20)$$

Picking the Kohn-Sham form for the exchange energy per particle and the Wigner interpolation formula for the correlation energy per particle of the uniform gas they have

$$\epsilon_{xc} = -\frac{0.458}{r_s} - \frac{0.44}{r_s + 7.8} \quad (21)$$

where

$$m_+^{-1} = \left( \frac{4\pi}{3} \right) r_s^3 \quad (22)$$

Finally converting the sum in Eq. (9) to an integral, they find

$$n(x) = \frac{1}{\pi^2} \int_0^{k_F} dk (k_F^2 - k^2) |\Psi_k(x)|^2 \quad (23)$$

to order  $L^{-1}$  where  $L$  is the slab length in the  $x$  direction normal to the surface. Equations (12), (17), (22), and (23) establish

a self-consistent set of equations that could be used to obtain a solution within the LDA. These equations form the bases for part of the present paper.

## 2. Surface Energy Calculation

LK used the calculation of the bare surface electron density within the jellium model to calculate the surface energy of the solid. The surface energy was defined as

$$\sigma = \frac{1}{2A} [2(G[M] + E_{es}[M]) - (G[M'] - E_{es}[M'])] \quad (24)$$

where  $n(\underline{r})$  is the distribution for the bare surface and  $n'(\underline{r})$  is the distribution for the uncleaved solid,  $A$  is the cross-sectional area of the sample, and  $E_{es}$  is the electrostatic contribution to the total energy. The surface energy in the jellium model is

$$\sigma_U = \sigma_S + \sigma_{xc} + \sigma_{es} \quad (25)$$

where

$$\sigma_S = \frac{1}{2\pi^2} \int_0^{k_F} dk k \left( \frac{\hbar^2 k^2}{2m} - \gamma(k) \right) - \int_{-\infty}^{\infty} dx n(x) [V_{eff}(M, x) - V_{eff}(M, -\infty)] \quad (26)$$

This is the equation for the kinetic energy from an expression derived by Huntington [16].

$$\sigma_{xc} = \int_{-\infty}^{\infty} dx n(x) (E_{xc}(M, x) - E_{xc}(M, +)) \quad (27)$$

is the exchange and correlation contribution to the surface energy and

$$\sigma_{es} = \int_{-\infty}^{\infty} dx \phi(n, x) (n(x) - n_+(x)) \quad (28)$$

is the total electron-jellium contribution to the electrostatic energy.

The result of this calculation was that the system was unbound in the jellium model for  $r_s < 4.0$ . Consequently, LK introduced two corrections to the jellium energy which include crystallinity. The first which will be discussed in greater detail later was to include the effects of the ion-ion interaction exactly by performing a lattice sum. In this sum the jellium-jellium interaction is subtracted and consequently acts like a background electron gas for the lattice of point positive ions. LK refer to this term as  $\delta\sigma_{cl}$ . The second correction includes the electron-ion interaction via first order perturbation theory. In this the Ashcroft pseudopotential

$$V_{ps}(r) = \begin{cases} 0 & r \leq r_c \\ -\frac{Z}{r} & r > r_c \end{cases} \quad (29)$$

which has been used successfully to calculate bulk properties of simple metals is used to model the electron-ion interaction. The contribution due to the electron-ion interaction for split minus unsplit crystal is given by

$$\overline{\delta\sigma_{PS}} = \int_{-\infty}^{\infty} dx [M(x) - M_+(x)] \overline{\delta V(x)} \quad (30)$$

where  $\overline{\delta v(x)}$  is the average over the  $y$ - $z$  plane of the sum of the ionic pseudopotentials of the half lattice minus the potential due to the semi-infinite charge background. Details and criticisms of this result will be presented later. The general approach in the Lang-Kohn calculation is similar to that used in the present study for determining the binding energy versus separation.

## II. OTHER SURFACE ENERGY CALCULATIONS

After the initial calculations of Lang and Kohn, an alternate model to explain surface energies was proposed by Schmit and Lucas [17] and Craig [18]. The result of the model was that the dependence of the surface energy on  $r_s$  could be explained by the assumption that correlation was dominant. An excellent summary of this model and its implications is presented by Brown and March [12] and references cited therein. The theory expresses the surface energy in terms of the change in the zero point energy of the plasmons and points out that this could be a large contribution. The surface plasmon model has been criticized from a number of standpoints and now has become passé as a criticism of the Lang and Kohn Calculations. The criticisms involved the cutoff wave number selected for surface plasmons, inclusion of dispersion, effects of particle-hole excitations and changes in bulk-plasmon energy. Griffin and Kranz [19] have recently performed a model calculation determining the bulk and surface changes in the plasmons using an infinite-barrier, random-

phase approximation which they argue reflects the situation of a real metal. They conclude that the surface plasmon contribution to the surface energy and the bulk plasmon contribution to the surface energy are of comparable magnitude but of opposite sign thus giving a small net contribution and supporting the work of Lang and Kohn. The Lang-Kohn calculations and related calculations such as the present work are applicable for simple bulk metals where the s-p character of the conduction band is well separated from d-states. Cyrot-Lackmann [20] has successfully predicted trends in surface energies using a tight-binding approximation and an expansion of the density of states in terms of moments for transition metals. Brown and March [12] also give an excellent summary of these calculations.

### III. NONLOCAL TERMS IN THE GRADIENT EXPANSION

As indicated in Eq. (3), Kohn and Sham suggested a form for the gradient expansion.

$$E_{xc}[M] = \int dr (A_{xc}[M] + B_{xc}[M] |\nabla n|^2) \quad (31)$$

Smith and others [21] have pointed out the importance of the gradient terms to surface theory. Until recently an expression for  $B_{xc}$  was not available in the range of metallic densities. Because of the importance of these terms there have been a number of recent attempts to include them in surface calculations. Rasolt and Geldart have determined  $B_{xc}$  numerically within the random phase approximation [22]. Lau and Kohn [13] have obtained an approximate expression for  $B_{xc}$  by requiring that the surface energy for two adjacent

metal films of nearly equal density be the same as that obtained from the electronic polarizability of Vashista and Singwi, [23]. Rasolt, Wang, and Kahn [24] have examined the convergence of the exchange energy by calculating the exchange energy exactly for a Yukawa potential with a finite barrier potential with a barrier height chosen to reproduce the LK density profile. The model potential approach was used since a calculation for real systems would be prohibitively difficult, if not impossible. The results indicate that the gradient term models the exact energy very closely over the entire range of Yukawa screening length  $\lambda$ , whereas the local term is ~15% too high for  $\lambda < 0.4 \lambda_{TF}$  ( $\lambda_{TF}$  = Thomas-Fermi screening length). The agreement is excellent for  $r_s = 3$  and is slightly worse for  $r_s = 4$ . An argument is given for the correlation energy which would be difficult to calculate having the same behavior. Therefore, they conclude that the gradient expansion is an adequate representation of the exact energy.

Rose, et al. [14] have included the gradient expansion self-consistently into the surface energy calculation. Lau and Kohn [13] have included it through perturbation theory. Both found an approximately 50% increase in the energy for aluminum. Rose found only a small change in the electron density by including this term and a small change in the work function. This discrepancy was attributed to the perturbation approach and the fact that small changes in the density can produce large changes in the dipole layer.

Rose, et al. and Lau and Kohn disagree about this correction with regard to how well they represent experimental surface energies.

This results from a conflict in the experimental literature. This will be discussed later in the paper.

Gupta and Singwi [25] have also estimated this term using the gradient expansion and the work of Bvashista and Singwi, and obtained results which are somewhat smaller but agree to within 30%. Perdew, Langreth, and Sahni [26] have used a wave vector analysis rather than a gradient expansion to extend the results beyond the LDA. They again obtain a result which is ~50% smaller using a wave vector analysis. In general, the calculation of this term is quite difficult. The degree of agreement ~50% and that all calculations are in the direction of increasing the surface energy can be taken as confirming the general magnitude and direction of this term. (The Rasolt-Geldert gradient term is included in the present calculation.)

#### IV. METALLIC INTERFACE CALCULATIONS

The first attempt to calculate interfacial densities and potentials using the Kohn-Sham Formalism was performed by Bennet and Duke [27]. They used a parameterized form for the number density and potential and solved the Kohn-Sham Equations self-consistently by varying parameters. The first attempt to calculate the adhesive energy for a metallic interface was performed by Ferrante and Smith [28,29]. They used the HK Formalism and Smith's [6] parameterization of the electron number density but did not allow relaxation of the electron gas. This work was the first to calculate binding energy versus separation for Al, Zn, Mg, and all possible combinations. Details of this calculation are presented herein. Ferrante and Smith

[30] were the first to obtain a completely self-consistent numerical solution of the Kohn-Sham equations for the case of similar metals in contact versus separation and to include higher order terms in the gradient-expansion self-consistently [31] for the like metal combinations Al, Zn, Mg, and Na. No detailed account of this work is in the literature and will be presented herein. Nieminen [32] solved the Kohn-Sham Equations for the force versus separation for metals ranging from  $r_s = 2$  to 6 self-consistently. Vannemenus and Budd [33] solved the HK Equations self-consistently for two jelliums in contact. Rouhani and Schuttler [34] and Mehrotra, Pant and Das [35] and references cited therein calculated the adhesive energy for alkali-metals in contact comparing zero and infinite separation using the HK Formalism and Smith's parameterized density. Finally, Allan, Lannoo, and Dobrzynski [37] estimated the adhesive energy for zero and infinite separation for dissimilar metals in contact using the techniques of Cyrot-Lackmann.

A more detailed discussion of these papers will be presented later in comparison with the present results. The paper will now proceed by application of the Kohn-Sham Formalism to the calculation of binding energy as a function of separation for bimetallic contacts.

## THEORY

### I - SIMPLE OVERLAP MODEL

#### A. Model

In this section are described the procedures of Ferrante and Smith [28] for calculating binding energy as a function of separation for similar and dissimilar metal combinations of Al, Zn, and Mg. In this calculation the contribution of electron overlap to the binding energy is presented. The electron density distribution is held fixed for each metal at the distribution for the bare metal case and therefore relaxation of the electron gas is not permitted. It will be shown that this simple approach has some appealing features and gives some surprisingly accurate results. The model is shown schematically in Figure 1 where

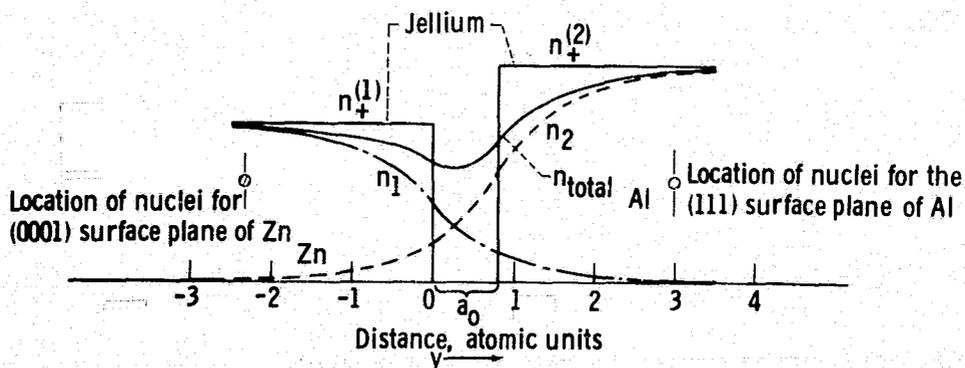

Fig. 1. - Jellium charge density to scale for Al-Zn,  $n_1$  and  $n_2$  denote the metal vacuum electron number densities for Al and Zn, respectively.

where

$$n_1(x) = \left[ n_+^{(1)} - \frac{1}{2} n_+^{(1)} \exp(\beta_1 x) \right] \theta(x) + \frac{1}{2} n_+^{(1)} \exp(-\beta_1 x) \theta(x) \quad (32)$$

$$n_2(x) = \left[ n_+^{(2)} - \frac{1}{2} n_+^{(2)} \exp(-\beta_2(x-a)) \right] \theta(x-a) + \frac{1}{2} n_+^{(2)} \exp(\beta_2(x-a)) \theta(a-x)$$

$$n(x) = n_1(x) + n_2(x) \quad \text{and} \quad \theta(x) = \begin{cases} \theta(x) = 1, & x > 0 \\ \theta(x) = 0, & x < 0 \end{cases} \quad \text{is the Heaviside}$$

function [37]. The electron density  $n(x)$  is the parameterized form used by Smith and  $\beta$  is the exponential decay constant determined by Smith for the bare metal surface. The most densely packed planes are assumed in modeling the density. This assumption is used to minimize the effect of density variations in the  $y$ - $z$  plane which are assumed to be uniform.

#### B. Definition of the Energy

Following the Hohenberg-Kohn Formalism we first define the adhesive binding energy by

$$E_{AD} = \frac{E(\infty) - E(a)}{2A} \quad (33)$$

where

$$E(m) = \int dr N(r) m(r) + \frac{1}{2} \sum_{i,j} \frac{Z_i Z_j}{R_{ij}} + F(m) \quad (34)$$

$$\text{and } F(m) = \frac{3}{10} (3\pi^2)^{2/3} \int dr m^{5/3}(r) - \frac{3}{4} \left( \frac{3}{\pi} \right)^{1/3} \int dr m^{4/3}(r)$$

$$- 0.056 \int dr \frac{m^{4/3}(r)}{0.079 + m(r)} + \frac{1}{72} \int dr \frac{|\nabla m|^2}{m(r)} + \frac{1}{2} \iint \frac{dr dr' m(r) m(r')}{|r - r'|}$$

The first two terms in  $E[n]$  are the electron-ion and ion-ion interaction energies and  $R_{ij}$  is the distance between ion cores. The first three terms in  $F[n]$  are the kinetic and exchange energies and Wigner's interpolation formula for the correlation energy, each for the uniform electron gas. The next term is the next order term in the gradient expansion for the kinetic energy, which is large compared to the correlation energy, and the last term is the classical electrostatic electron-electron interaction energy.

### C. Calculation Procedures

The calculation proceeds by first evaluating the energy for jellium and then introducing crystallinity exactly for the ion-ion interaction, and approximately for the electron-ion interaction via perturbation theory following Lang and Kohn. In evaluating the jellium part of the electrostatic energy it is convenient to combine a part of the first term in Eq. (34) with the last term, the classical electron electrostatic energy giving

$$E_{es} = -\frac{1}{2} \int dx \rho(x,a) \phi(x,a) \quad (35)$$

where  $\phi(x,a)$  is given by

$$\frac{d^2\phi}{dx^2} = 4\pi\rho(x,a) = 4\pi [M_+^{(1)}\theta(-x) + M_+^{(2)}\theta(x-a) - \rho(x,a)]. \quad (36)$$

Once the jellium adhesive binding energies were obtained these energies were modified to correct the jellium electron binding energy to include the effects of the actual ion core potentials via first

order perturbation theory. The Ashcroft pseudopotential is used to give the energy

$$E_{ps} = A \int dx \delta v(x, a) n(x, a) \quad (37)$$

where  $\delta v(x, a)$  is an average over planes parallel to the surface of the difference in potential between an array of pseudopotentials and the jellium and thus is treated as a perturbation in the jellium potential. Details of this calculation are given in Appendix I. In addition, the ion-ion contribution to the total energy is included exactly by a lattice sum.

#### D. Classical Interaction Energy

The ion-ion interaction energy is then included exactly via a lattice sum using a technique developed by Rao and Kohn [38]. In this sum the interaction energy between the two half spaces for arrays of positive ions having the correct geometrical positions for the planes chosen minus the jellium-jellium interaction energy is calculated. The subtracted jellium-jellium term serves the role of a negative background, thus gives a convergent result.

Formally, the interaction energy is written as

$$W_{int}(a) = \iint dr dr' \frac{\rho_1(r) \rho_2(r')}{|r - r'|} \quad (38)$$

where

$$\rho_1(r) = Z \sum_m \delta(x - x_m) \sum_{l, h} \delta(y - y_l) \delta(z - z_h) - \sigma \sum_m \delta(x - x_m)$$

the subscripts 1 and 2 refer to the two half spaces,  $z$  is the

ionic valence,  $\sigma$  is the ionic charge per unit area representing the jellium background. The net density  $\rho(\underline{r})$  can then be expanded in a Fourier series in the  $y$ - $z$  plane, so that

$$\rho(\underline{r}) = \sigma \sum_{m=1}^{\infty} \delta(x-x_m) \sum_{l=-\infty}^{\infty} \sum_{h=-\infty}^{\infty} C_{m\ell h} \exp(i g_l y) \exp(i g_h z) \quad (39)$$

the primes in the  $l$  and  $h$  summations indicate that the term  $g_l = g_h = 0$  which cancels the jellium background has been omitted from the summation.  $W_{\text{int}}$  is evaluated for the fcc[111] direction, the hcp[0001] direction and the bcc[110] direction. A sample calculation for the fcc[111] direction, the most difficult of the three, is presented in Appendix II.  $W_{\text{int}}/A$  is given by:

fcc[111]

$$\begin{aligned} \frac{W_{\text{int}}(a)}{A} = & \frac{2\sqrt{6}}{3} Z M_+ \sum_{m=1}^{\infty} \sum_{h=1}^{\infty} \frac{(1 + \cos \pi h)}{h} (m-1) X^{-3\alpha m} X^{-\frac{aah}{d}} \left\{ \cos \frac{\pi h}{3} X^{5ah} \right. \\ & + \left( \cos \frac{2\pi h}{3} + \frac{\cos \pi h}{3} \right) X^{4ah} + 3X^{ah} + \left( \cos \frac{\pi h}{3} + \cos \frac{2\pi h}{3} \right) X^{2ah} + \left. \cos \frac{\pi h}{3} X^{ah} \right\} \\ & + \frac{2\sqrt{2}}{3} Z M_+ \sum_{m=1}^{\infty} \sum_{l=1}^{\infty} (m-1) \frac{(1 + \cos \pi l)}{l} X^{-3ml} X^{-\frac{al}{d}} \left\{ \cos \pi l X^{5l} \right. \\ & + (1 + \cos \pi l) X^{4l} + 3X^{l} + (1 + \cos \pi l) X^{2l} + \left. \cos \pi l X^{l} \right\} \\ & + \frac{4\sqrt{2}}{3} Z M_+ \sum_{m=1}^{\infty} \sum_{l=1}^{\infty} \sum_{h=1}^{\infty} (m-1) \frac{(1 + \cos \pi(h+l))}{D} X^{-3Dm} X^{-\frac{aD}{d}} \left\{ \cos \frac{\pi h}{3} \right. \\ & \cdot \left( \cos \pi l X^{5D} + \left[ \cos \frac{2\pi h}{3} + \cos \frac{\pi h}{3} \cos \pi l \right] X^{4D} + 3X^{3D} \right. \\ & \left. \left. + \left[ \cos \frac{\pi h}{3} \cos \pi l + \cos \frac{2\pi h}{3} \right] X^{2D} + \cos \pi l X^{D} \right\} \right. \end{aligned} \quad (40a)$$

where  $d$  is the interplanar spacing,  $c$  is the nearest neighbor distance

$$x = \exp(-2\pi d/c), \quad D = \sqrt{l^2 + h^2/3}, \quad \alpha = \sqrt{3}/3;$$

hcp [0001]

$$\begin{aligned} \frac{W_{int}(a)}{A} &= 4\beta ZM + \sum_{m=1}^{\infty} \sum_{h=1}^{\infty} (m-1) X^{-2\alpha mh} X^{-\frac{\alpha h}{d}} \\ &\cdot \left\{ \cos \frac{2\pi h}{3} + 2X^{2\alpha h} + \cos \frac{2\pi h}{3} X^{\alpha h} \right\} \\ &+ 4\beta ZM + \sum_{m=1}^{\infty} \sum_{l=1}^{\infty} (m-1) \frac{(1 + \cos \pi l)}{l} X^{-2ml} X^{-\frac{\alpha l}{d}} \{X^{3l} + 2X^l + X^l\} \\ &+ 8\beta ZM + \sum_{m=1}^{\infty} \sum_{l=1}^{\infty} \sum_{h=1}^{\infty} (m-1) \frac{(1 + \cos \pi (h+l))}{D} X^{-2mD} X^{-\frac{\alpha D}{d}} \\ &\cdot \left\{ \cos \frac{2\pi h}{3} X^{3D} + 2X^{2D} + \cos \frac{2\pi h}{3} X^D \right\} \end{aligned}$$

(40b)

where  $\beta = (\sqrt{3}d)/(45c)$ ;

bcc [110]

$$\begin{aligned} \frac{W_{int}(a)}{A} &= \frac{\sqrt{2}}{2} ZM + \sum_{m=1}^{\infty} \sum_{h=1}^{\infty} (m-1) \frac{(1 + \cos \pi h)}{h} \cos \pi h X^{-2mh} X^{-\frac{\alpha h}{d}} \\ &\cdot \left\{ X^{3\alpha h} + 2 \cos \pi h X^{2\alpha h} + X^{\alpha h} \right\} + \frac{ZM}{2} + \sum_{m=1}^{\infty} \sum_{l=1}^{\infty} (m-1) \frac{(1 + \cos \pi l)}{l} \\ &\cdot X^{-2ml} X^{-\frac{\alpha l}{d}} \{X^{3l} + 2X^{2l} + X^l\} + ZM + \sum_{m=1}^{\infty} \sum_{l=1}^{\infty} \sum_{h=1}^{\infty} (m-1) \frac{(1 + \cos \pi (h+l))}{D} \\ &\cdot X^{-2mD} X^{-\frac{\alpha D}{d}} \cos \pi h \{X^{3D} + 2 \cos \pi h X^{2D} + X^D\} \end{aligned}$$

(40c)

where  $D = \sqrt{l^2 + h^2/2}$ ,  $\alpha = \sqrt{2}/2$ . For the hcp and fcc cases a simplifying approximation which agrees to the exact value (summed to six significant figures) to 1.0 percent is now presented as

$$\frac{W_{int}(a)}{A} = -\frac{2\sqrt{3}Z^2}{c^3} \exp\left(-\frac{4\pi\sqrt{3}}{3c}(d+a)\right) \quad (41)$$

The exact values for the sums are tabulated in Appendix II along with a comparison of the exact values with Eq. (41).

### E. The Order of the Error

This simple overlap model might be expected to give reasonably accurate results for  $[n_+^{(2)}]/[n_+^{(1)}] \approx 1$ . It is exact for  $a = 0$  and  $n_+^{(1)} = n_+^{(2)}$  since expanding  $E[n(\underline{r})]$  we have

$$\begin{aligned} E[M(\underline{r}, a)] &= E[n] + \int d\underline{r} \delta n(\underline{r}) (\delta E[n]/\delta n(\underline{r})) \\ &+ \frac{1}{2} \iint d\underline{r} d\underline{r}' \delta n(\underline{r}) \delta n(\underline{r}') (\delta^2 E[n]/\delta n(\underline{r}) \delta n(\underline{r}')) + \dots \end{aligned} \quad (42)$$

where  $\delta n$  is the variation of the electron number density. Since  $\int d\underline{r} \delta n(\underline{r}) (\delta E[n]/\delta n) = 0$  by the variational principle,  $E[n(x, a)]$  is accurate to second order in  $\delta n$ . As will be seen for the case of like metal pairs, the simple overlap model predicts all of the principle physical features of the binding energy.

## II - SELF-CONSISTENT CALCULATION

### A. Background

In establishing the theory for the like metal calculation, the presentation will proceed with a more general discussion of dissimilar metals in contact. Then these results will be applied to the

specific case of like metal couples. The case of two dissimilar metals in contact can be represented schematically in an energy diagram as in Figure 2.

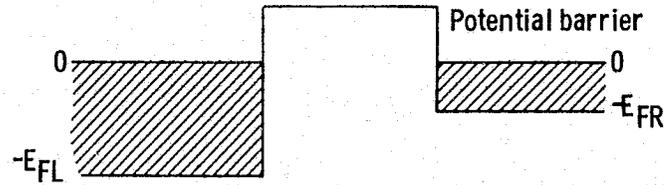

Fig. 2. - Schematic energy diagram for dissimilar metals in contact.

where the shaded areas are the conduction bands, the zero of energy (after equilibration) is taken at the Fermi Level and  $E_{FL}$  and  $E_{FR}$  are the Fermi energies of the left and right hand metals. We would have for the Schrodinger equation  $(-1/2) \nabla^2 \psi + v_{eff} \psi = E\psi$ . The details of  $v_{eff}$  will be discussed later but at present we can see that it has a general form that can be represented by Figure 3.

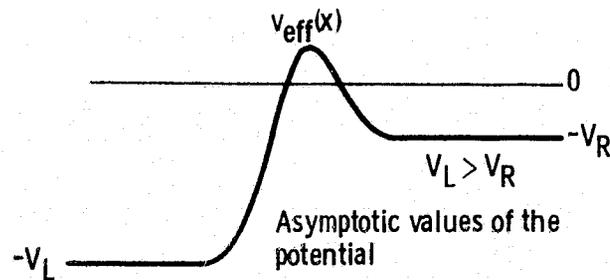

Fig. 3. - General bimetallic potential.

$$v_{\text{eff}}(x) = \begin{cases} -V_L & x \rightarrow -\infty \\ -V_R & x \rightarrow \infty \end{cases} \quad \text{which is the condition we would have for two dis-}$$

similar metals in contact, taking  $V_R$  and  $V_L$  to be positive.

In the asymptotic regions there are two types of degenerate solutions

$$\begin{aligned} \psi_L &\sim e^{ik_L x} + R_L e^{-ik_L x} & x \rightarrow -\infty & \quad 0 > -E > -V_R \\ &\sim T_L e^{ik_R x} & x \rightarrow \infty & \end{aligned} \quad (43)$$

$$\begin{aligned} \psi_R &\sim T_R e^{-ik_L x} & x \rightarrow -\infty \\ &\sim e^{-ik_R x} + R_R e^{-ik_L x} & x \rightarrow \infty \end{aligned} \quad (44)$$

where  $k_R^L = \sqrt{2(V_R^L - E)}$ , taking  $E$  to be positive, and  $R$  and  $T$  are complex constants. For  $-V_R > -E > -V_L$

$$\begin{aligned} \psi_L &\sim e^{ik_L x} + R_L e^{-ik_L x} & x \rightarrow -\infty \\ &\sim T_L e^{-ik_R x} & x \rightarrow \infty \end{aligned} \quad (45)$$

where now  $|R_L| = 1$  since there can be no net flux into the classically forbidden region and  $q_R = \sqrt{2(E - V_R)}$  for  $-E < -V_R$  and using the property of the Wronskian that if two solutions correspond to the same energy then the Wronskian of those solutions is independent of  $X$  [39]. It can easily be shown that using the asymptotic solutions will give

$$k_L (1 - |R_L|^2) = k_R |T_L|^2 \quad (46a)$$

$$k_L |T_R|^2 = k_R (1 - |R_R|^2) \quad (46b)$$

$$k_R T_L = k_L T_R \quad (46c)$$

With this frame work we can now examine the asymptotic form of the electron number density in each solid. Starting with Eq. (9) we

have  $n(\underline{r}) = \sum_{i=1}^N |\psi_i(\underline{r})|^2$ . Converting the sum to an integral we

have  $n(\underline{r}) = \frac{2}{(2\pi)^3} \sum_{j=1}^2 \int d^3 \underline{k} |\psi_k^j|^2$  where the summation index  $j$

is over the two degenerate solutions. Using cylindrical coordinates we have

$$n(\underline{r}) = \frac{2}{(2\pi)^3} \sum_{j=1}^2 \int_0^{2\pi} \int_0^{k_F} \int_0^{\sqrt{k_F^2 - k^2}} d\phi k_{||} dk_{||} dk |\psi_k^j|^2. \quad (47)$$

Integrating gives

$$n(\underline{r}) = \frac{1}{4\pi^2} \sum_{j=1}^2 \int_0^{k_F} dk (k_F^2 - k^2) |\psi_k^j|^2.$$

Taking the left hand metal, using the asymptotic form for the wave function, Eq. (46) and the definition of the bulk density in terms of  $k_F$  we get

$$M(X) = \frac{1}{2\pi^2} \int_0^{k_{FL}} dk_L (k_{FL}^2 - k_L^2)^2 \text{Re}(R_L(k_L) e^{2ik_L X}) \quad (48)$$

Adawi [40] has shown that the integral has a leading term

$$\Delta M \sim \frac{k_{FL}^2}{2\pi^2 X^2} \text{Re}(R_L(k_{FL}) e^{2ik_{FL} X}); \quad \Delta M = M(X) - M+L \quad (49)$$

The result for the right hand metal is similar. Therefore the electron number density in the bulk of either metal is represented by the bulk density plus terms with decaying oscillations whose wavelength is half the Fermi wavelength and whose amplitude depends on the reflection coefficient evaluated at the Fermi momentum. This result is similar to that obtained by Lang and Kohn [7] as would be expected. The result shows that the wave function normalization consistent with Eq. (47) is an incident wave of unit amplitude. Obviously, for the same metal couples the problem simplifies greatly since we have symmetry about the midpoint between the two metals. It is interesting to note that this formulation can be viewed as a scattering problem in terms of Jost functions [41] where the eigenfunctions can be represented as a linear combination of the two linearly independent solutions  $\phi(\underline{k}, \underline{r})$  and  $\phi(-\underline{k}, \underline{r})$  whose asymptotic limits are  $\phi(\underline{k}, X) \sim e^{ikX}$   $\phi(-\underline{k}, X) \sim e^{-ikX}$ .

## B. Working Equations

The next step in the present work is to establish the working equations for the calculation. A model for the jellium and electron density for Al is shown in Figure 4. As presented previously the effective potential can be expressed in general as

$$V_{\text{eff}}(\underline{r}) = V(\underline{r}) + \int d\underline{r}' \frac{n(\underline{r}')}{|\underline{r} - \underline{r}'|} + V_{\text{xc}}(n, \underline{r})$$

where  $v(\underline{r})$  is an external potential, e.g., from the jellium background  $\int d\underline{r}' \frac{n(\underline{r}')}{|\underline{r} - \underline{r}'|}$  is the classical electrostatic potential and  $v_{\text{xc}}$  is the exchange and correlation potential (Eq. (6), (7), and (11)). For the jellium model the first two terms can be lumped together to give the total electrostatic potential. We now want to develop explicit expressions for these terms in order to determine the self consistent potential and electron number density.

Since we are dealing with a variational problem we use a standard calculus of variations approached in order to obtain the working equations. Thus the symbolic notation  $\delta E[n]/\delta n$  becomes the operational equation  $\frac{\partial E}{\partial n} - \frac{d}{dx} \frac{\partial E}{\partial n'}$  where  $n' = dn/dx$ .

### 1. Electrostatic Potential

Starting with the electrostatic terms in the total energy with the jellium giving the external potential, we get the same result as Lang and Kohn for the total electrostatic potential previously given in Eq. (11) as

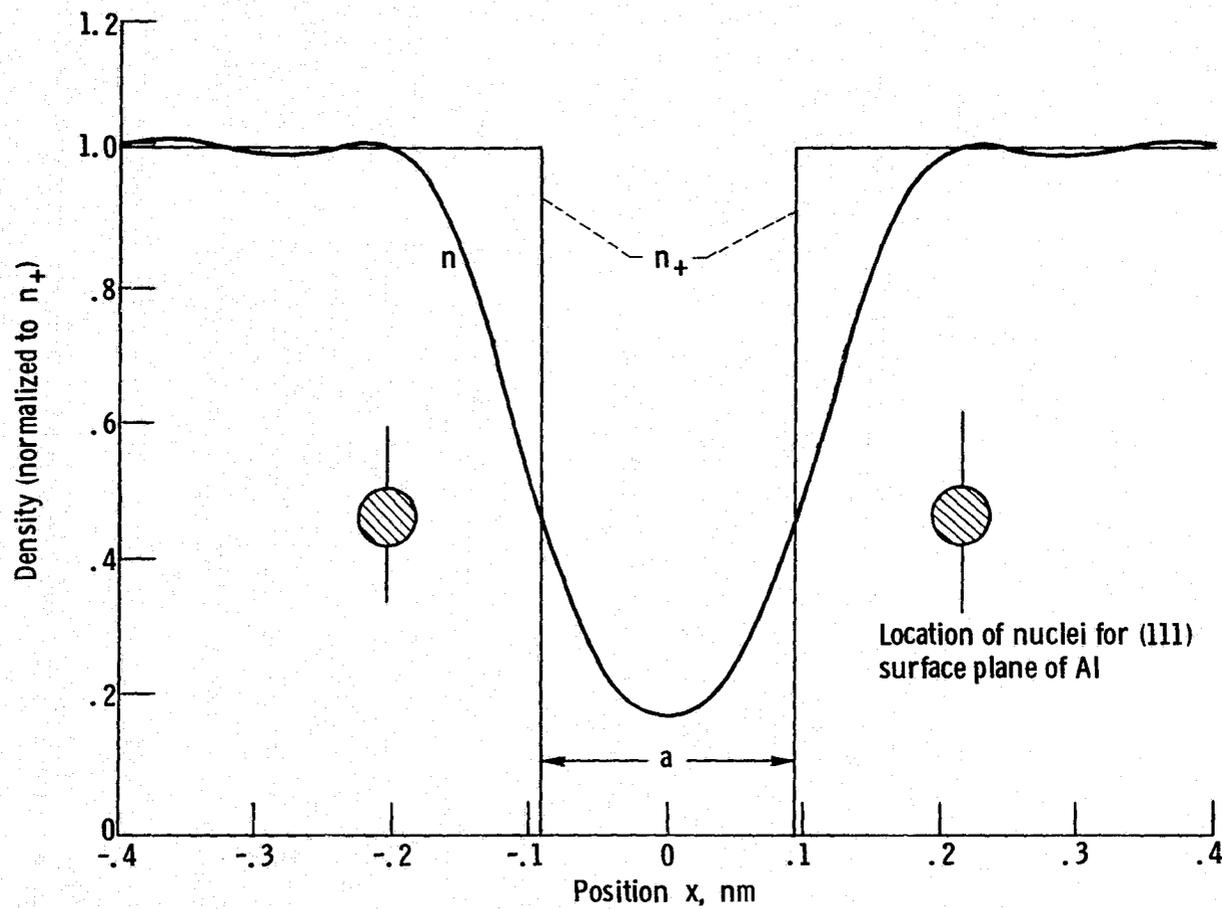

Fig. 4. - Electron number density  $n$  and jellium ion charge density,  $n_+$ , for an Al-Al contact normalized to unit density.

$$\phi(r) = \int dr' \frac{n(r) - n_+(r)}{|r - r'|}$$

This equation can be simply restated in terms of Poisson's equation which for one dimension is  $d^2\phi/dx^2 = -4\pi(n(x) - n_+(x))$ . Boundary conditions will be discussed later in this section and numerical methods will be discussed in the calculations procedures section.

## 2. Exchange and Correlation Potential

### a. Local density approximation

The total exchange and correlation energy is given by the expression  $E_{xc}[n(r)] = \int dr n(r) \epsilon_{xc}(n(r))$  where  $\epsilon_{xc}$  is the exchange and correlation energy per particle. Therefore, the exchange and correlation contribution to the potential is  $\mu_{xc} = (d/dn)(n\epsilon_{xc})$ . Using the Kohn-Sham exchange and the Wigner interpolation formula for the correlation energy (Eq. (21)) as did Lang and Kohn [7], we get

$$\begin{aligned} \mu_{xc}(n(x)) = & -0.458 \left(\frac{4}{3}\right) \left(\frac{4\pi}{3}\right)^{1/3} n^{1/3} - \frac{0.44 \left(\frac{4}{3}\right) \left(\frac{4\pi}{3}\right)^{1/3} n^{1/3}}{(1 + 7.8 \left(\frac{4\pi}{3}\right)^{1/3} n^{1/3})} \\ & + \frac{0.44 \left(\frac{1}{3}\right) \left(\frac{4\pi}{3}\right)^{2/3} (7.8) n^{2/3}}{(1 + 7.8 \left(\frac{4\pi}{3}\right)^{1/3} n^{1/3})^2} \end{aligned} \quad (50)$$

### b. Nonlocal Terms (Higher Order in the Gradient Expansion)

As pointed out in the background section, inclusion of the next higher order terms in the gradient expansion should be considered in surface energy calculations since there is a substantial change in the electron number density and thus the gradient of the density is large near the jellium surface. The difficulty with including these

terms from the recent work of Geldart and Rasolt [22] arises from the fact that an analytic expression for the coefficient in the gradient expansion is not available. Therefore, in order to interpolate and extrapolate the numerical values, the coefficient as a function of  $r_s$  (kindly provided by Dr. Rasolt) was curve fit to an expression which was found to fit the values well.

The expression for the energy per particle is given by

$$f = \frac{C_{xc}(m)}{m^{4/3}} |\nabla m|^2 \quad (51)$$

where  $C_{xc}$  has been approximated by

$$C_{xc}(m) = A m^c e^{-B m^{-3/3}} \quad (52)$$

where

$$A = 2.69413 \times 10^{-3}$$

$$B = 2.61294 \times 10^{-3}$$

$$C = 3.44333 \times 10^{-2}$$

The term chosen for  $C_{xc}$  prevents a divergence [41] in the potential which would otherwise occur for small number density. The limitations of this procedure will be discussed later. A plot of the curve fit along with the values of Rasolt and Geldart are presented in Figure 5. Applying the variational principle to Eq. (51) gives

$$\mu'_{xc}(m) = - \frac{C_{xc}(m)}{m^{4/3}} \left( 2 \frac{d^2 m}{dx^2} + S(m) \left( \frac{dm}{dx} \right)^2 \right) \quad (53)$$

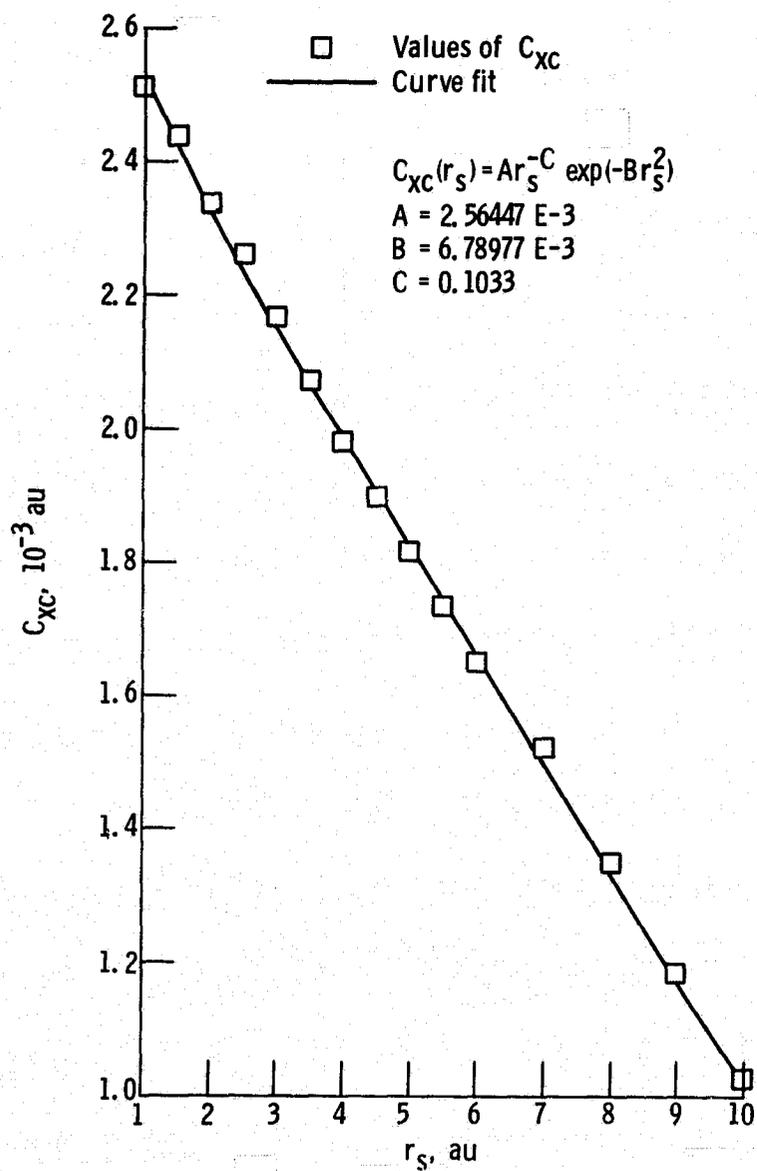

Fig. 5. - Curve fit to the Rasolt and Geldart [22] gradient coefficient,  $C_{XC}$  as a function of  $r_S$ .

where

$$S(m) = \frac{1}{3m} (3C - 4 + 2B m^{-2/3}) \quad (54)$$

### 3. Boundary Conditions

#### a. Potential

The jellium potential is of the form

$$V_{\text{eff}}(x) = \phi(n(x)) - \mu_{xc}(n(x)) + D \quad (55)$$

where  $D$  is a constant and where we now are considering the LDA. We must take the numerically derived  $\phi$  and  $\mu$  and include the correct asymptotic values for  $v_{\text{eff}}$ . As stated previously

$$v_{\text{eff}}(x) = \begin{cases} -1/2 k_{\text{FL}}^2 & x \rightarrow -\infty \\ -1/2 k_{\text{FR}}^2 & x \rightarrow \infty \end{cases} \quad \text{for the zero of energy chosen. Therefore,}$$

$$\begin{aligned} -\frac{1}{2} k_{\text{FL}}^2 &= \phi(-\infty) + \mu_{xc}(n_{+L}) + D \\ V_{\text{eff}}(x) &= \phi(x) + \mu_{xc}(x) - \phi(-\infty) - \mu_{xc}(n_{+L}) - \frac{1}{2} k_{\text{FL}}^2 \end{aligned} \quad (56)$$

At the right limit we have

$$-\frac{1}{2} k_{\text{FR}}^2 = \phi(\infty) + \mu_{xc}(n_{+R}) - \phi(-\infty) - \mu_{xc}(n_{+L}) - \frac{1}{2} k_{\text{FL}}^2$$

Therefore

$$\Delta\phi = \phi(\infty) - \phi(-\infty) = \frac{1}{2}(k_{\text{FL}}^2 - k_{\text{FR}}^2) + \mu_{xc}(n_{+L}) - \mu_{xc}(n_{+R}) \quad (57)$$

and we have a restriction on the electrostatic potential. In

addition the electrostatic potential must satisfy the conditions

$$\frac{d\phi}{dx} \xrightarrow{x \rightarrow \pm\infty} 0 \quad ; \quad \frac{dV_{eff}}{dx} \xrightarrow{x \rightarrow \pm\infty} 0 \quad (58)$$

in order to satisfy charge neutrality in the bulk of the materials. A similar result applies to the nonlocal case. However, we note that  $\mu'_{xc} \xrightarrow{x \rightarrow \pm\infty} 0$  since  $\nabla n = 0$  in the bulk. The situation for the symmetric like metal problem is obviously simpler and we can in this case use the condition that  $d\phi/dx = 0$  at the symmetry point thus requiring less computational effort. This condition on the electrostatic potential is used to solve Poisson's equation.

In the present and other numerical calculations, the boundary conditions as  $x \rightarrow \pm\infty$  cannot be satisfied directly because of the finite computational space. This problem has been approached from a number of different standpoints [7,32]. In general, in this work the numerical solutions were forced to match the bulk conditions at the computational space (slab) boundaries selecting them so that they are large enough not to cause serious perturbations in the solutions. The charge neutrality condition was handled differently in that initially charge neutrality was imposed in the computational space to promote convergence. Then this restriction was removed when the solution was sufficiently convergent and allowed to relax to the final solution. The assumption was that since the self-consistent solution for the semi-infinite film is charge neutral, the final solution would be driven towards this condition. An evaluation and comparison with other results of the success of these

calculations will be presented later. They will be presented in the DISCUSSION section.

### b. Wave functions

The form of the wave functions in the asymptotic region is given in Eqs. (43) to (45). In this calculation the potential at the slab (computational space boundaries) is assumed to be sufficiently flat that the asymptotic forms of the wave functions apply and therefore the numerical solutions are matched to these values at the slab boundary. The details of this matching are given in the section devoted to describing the calculational procedures.

### C. Self-Consistent Equations

In summary, we have the following self-consistent equations

$$-\frac{1}{2} \frac{d^2 Y_k^i}{dx^2} + N_{\text{eff}}(x) Y_k^i = \frac{1}{2} (k^2 - k_F^2) Y_k^i \quad (58a)$$

$$M(x) = \frac{1}{4\pi^2} \sum_{i=1}^2 \int_0^{k_F} dk (k_F^2 - k^2) |Y_k^i|^2 \quad (58b)$$

$$\frac{d^2 \phi}{dx^2} = 4\pi (M(x) - M_+(x)) \quad (58c)$$

$$\mu_{xc} = \frac{C_{xc}}{M^{4/3}} \left( 2 \frac{d^2 M}{dx^2} + S(M) \left( \frac{dM}{dx} \right)^2 \right) \quad (58d)$$

and/or

$$\begin{aligned} \mu_{xc} = & -0.984390 M^{1/3} - \frac{0.945702 M^{1/3}}{(1 + 12.5735 M^{1/3})} \\ & + \frac{2.97271 M^{2/3}}{(1 + 12.5735 M^{1/3})^2} \end{aligned} \quad (58e)$$

The procedure then is (a) to solve for the wave functions; (b) calculate the number density from the wave functions; (c) solve Poisson's Equation for the electrostatic potential; (d) calculate the second order contribution to the potential evaluated locally (first order = 0) for the gradient expansion for the nonlocal case and/or (e) calculate the 0th order exchange and correlation contribution to the potential evaluated locally (for the LDA only this term is included). Equations (58c), (58d), and (58e) give a new potential,  $V_{\text{eff}}(\mathbf{x})$ , which can be used to repeat the process.

#### D. Calculation of the Binding Energy

The adhesive energy is defined in this calculation as

$$E_{\text{Ad}} = \frac{E(a) - E(\infty)}{2A} \quad \text{where } a \text{ is the separation between materials and}$$

$A$  is the sectional area. The reason for this particular form for the definition of the energy is that it emphasizes the similarity to molecular binding. The difference in energy is given by

$$E(n(x,a)) = \frac{A}{2} \int dx \phi(k,a) (n(x,a) - n_+(x,a)) + W_{\text{int}}(a) + T_s(n(x,a)) + E_{\text{xc}}(n(x,a)) + E'_{\text{xc}}(n(x,a)) + A \int dx S_V(x,a) n(x,a) \quad (59)$$

where  $n_+(x,a)$  represents the total jellium density for both materials. The kinetic energy difference is given by

$$T_S = (2S+1) \int_{-x_0}^{x_0} dx \left\{ \sum_{occ, i} \psi_k^{i*} (-\frac{1}{2} \nabla^2) \psi_k^i - \frac{3}{10} (3\pi^2)^{2/3} (n_{+L})^{5/3} \theta(-(x+\frac{a}{2})) + n_{+R}^{5/3} \theta(x-\frac{a}{2}) \right\} \quad (60)$$

where  $n_{+L}$  and  $n_{+R}$  are the bulk densities in each material,  $\theta$  is the Heaviside function, and  $s$  is the spin.

The energy in Eqs. (59) and (60) is referenced to zero separation for each bulk material for computational convenience. Infinite separation is chosen for the referencing when the results are plotted because it emphasizes the similarity to molecular binding. The finite limits on the integral indicates that the slab is sufficiently large that the deviation from bulk conditions past the slab boundaries is not significant. This can be tested by the form in which the integral is written by increasing the slab length in a test case and then estimating convergence on the basis of the form of the density in the bulk. Equation (10) is modified by use of the Schroedinger equation to the form

$$T_S = (2S+1) A \int_{-x_0}^{x_0} dx \left\{ \sum_{occ, i} |\psi_k^i|^2 \frac{(k^2 + k_{||}^2)}{2} - \frac{3}{10} (3\pi^2)^{2/3} (n_{+L})^{5/3} \theta(-(x+\frac{a}{2})) + n_{+R}^{5/3} \theta(x-\frac{a}{2}) \right\} + A \int_{-x_0}^{x_0} dx \left\{ V_{eff}(n_{L,R}, \pm \infty) - V_{eff}(x, a) \right\} n(x, a) \quad (61)$$

where the  $\pm$  and L,R are chosen to suit the proper half-space.

The first term can be evaluated to order  $L^{-1}$  (appendix IV) in a

manner similar to that used in calculating the electron number density. Changing the sum to an integral and using cylindrical coordinates we get for the integration over k-space

$$\frac{1}{8\pi^2} \sum_{i=1}^2 \int_0^{k_F} dk |Y_k^i|^2 k^2 (k_F^2 - k^2) + \frac{1}{16\pi^2} \sum_{i=1}^2 \int_0^{k_F} dk |Y_k^i|^2 (k_F^2 - k^2)^2 \quad (62)$$

Substituting these expressions for the first term in expression (61) gives the Kinetic Energy Contribution to the total energy. The difference in electrostatic energy difference is given by

$$E_{es} = \frac{A}{2} \int_{-x_0}^{x_0} dx \phi(x, a) (n(x, a) - n_+(x, a)) + W_{int}(a). \quad (63)$$

Expressions for  $W_{int}(a)$  are given in the previous section.

$$n_+(x, a) = n_{+L} \Theta(-(x+a/2)) + n_{+R} \Theta(x-a/2) \quad (64)$$

The exchange and correlation energy (LDA) difference is given by

$$E_x = \frac{3}{4} \left(\frac{3}{\pi}\right)^{1/3} A \int_{-x_0}^{x_0} dx \left\{ n^{4/3}(x, a) - n_{+L}^{4/3} \Theta(-(x+a/2)) + n_{+R}^{4/3} \Theta(x-a/2) \right\} \quad (65)$$

$$E_c = 0.056A \int_{-x_0}^{x_0} dx \left\{ \frac{n^{4/3}(x, a)}{0.079 + n^{1/3}(x, a)} - \frac{n_{+L}^{4/3} \Theta(-(x+a/2))}{0.079 + n_{+L}^{1/3}} - \frac{n_{+R}^{4/3} \Theta(x-a/2)}{0.079 + n_{+R}^{1/3}} \right\}. \quad (66)$$

For the nonlocal contributions

$$E'_{xc} = A \int_{-x_0}^{x_0} dx \frac{C_{xc}(m(x,a))}{m^{4/3}(x,a)} \left( \frac{dm(x,a)}{dx} \right)^2. \quad (67)$$

The pseudopotential contribution to the energy requires a somewhat more detailed discussion. These details taken from Lang and Kohn [7] are repeated here for completeness. In addition, some derivations not given by Lang and Kohn are presented in Appendix I. The general expression for the pseudopotential contribution to the energy is

$$E_{ps} = A \int_{-x_0}^{x_0} dx \delta V(x,a) m(x,a) \quad (68)$$

(The presentation here will be for one half-space since the extension to both is simple.) Where

$$\delta V(x,a) = \left\langle \sum_{y(x<0)} V_{ps}^{(y)} \right\rangle - \phi_+(x) \quad (69)$$

and where the brackets indicate an average over the  $y$ - $z$  directions and the summation is over planes passing through the centers of the lattice planes perpendicular to the  $x$ -direction. The second term is the potential due to the semi-infinite jellium. The general purpose of expression (68) therefore is to add in the proper electron-ion interaction and subtract off the electron-jellium interaction which is already included in expression (63). As can be seen, the additional term is introduced through first order perturbation theory on the assumption that this term is small compared to the total

potential. This point has been in contention but recent work which will be presented in the DISCUSSION section will show that this is a good approximation for the simple metals. LK now break up this term into two terms

$$\delta V(x) = \delta V_1(x) + \delta V_2(x) \quad (70)$$

where

$$\delta V_1(x) = \left\langle \sum_{r(x<0)} -Z/|r-r_0|^{-1} \right\rangle - \phi_+(x) \quad (70a)$$

$$\delta V_2(x) = \sum_{r(x<0)} \left\langle V_{PS}^{(0)} + Z/|r-r_0|^{-1} \right\rangle \quad (70b)$$

The average in (70a) treats the charges as though they are smeared out over a lattice plane. From the previous definition (Eq. (29)) of the Ashcroft pseudopotential we see that the term (70b) is zero outside the ion core and has a  $1/r$  dependence inside the core which is averaged over the  $y$ - $z$  planes. Working through the electrostatics for these terms (details of which are presented in Appendix I) gives

$$\delta V_1(x) = -2\pi m_+ [x + ld \theta(-x - (2l-1)d/2)]^2 \quad (71a)$$

and

$$\delta V_2(x) = 2\pi d m_+ (r_c - |x + (2l-1)d/2|) \theta(r_c - |x + (2l-1)d/2|) \quad (71b)$$

where  $l$  is an integer designating the lattice plane and these results apply if there is no core overlap, as is obvious from the method used to do the averaging.

#### E. Checks on Self-Consistency

Fortunately there is now a method to examine the degree of self-consistency for the jellium part of the calculation. Budd and Van-nemenus [42] have derived an expression for the force at zero separation using the Hellman-Feynman Theorem. The force per unit area is given by

$$F/A = -n_+ \Delta\phi(a) \quad (72)$$

where  $a$  is the separation between the two jellium slabs and  $\Delta\phi$  is the difference in electron electrostatic potential energy between the jellium surface at a separation  $a$  and the jellium surface at infinite separation.  $F/A$  is also given by  $\partial E/\partial\Omega$  where  $E$  is the total energy and  $\Omega$  is the total volume.

$$\frac{\partial E_0}{\partial\Omega} = n^2 \frac{\partial f}{\partial n} \quad (73)$$

where  $f$  is the energy per electron for the uniform electron gas and where the subscript 0 indicates  $a = 0$ . Since we have an expression for the energy per particle for the uniform electron gas a comparison of Eqs. (72) and (73) gives a check on the degree of self-consistency for the numerical calculations. Heinrichs and Kumar [43] derive a similar expression for dissimilar metal contacts and this

result will be used to evaluate the validity of the simple-overlap model. Equation (72) also enables evaluation of the force versus separation for the jellium and thus the total force when the lattice sum and pseudopotential contributions are included in the total energy by taking the derivative of these terms. Equation (73) expressed in terms of  $r_s$  the Wigner-Seitz radius is

$$\frac{\partial E_0}{\partial \Omega} = 0.439646 r_s^{-5} (0.4 - 0.0829 r_s - \frac{0.796 r_s^3}{(r_s + 7.8)^2}) \quad (74)$$

The Heinrichs-Kumar expression for the jellium force between dissimilar metals is

$$F_{12}(0) = P_i + P_i \Delta V(0) \quad i = 1, 2 \quad (75)$$

where

$$P_i = \frac{0.175858}{r_s^5} - \frac{0.0364466}{r_s^4} - \frac{0.0350142}{(r_s^2 + 7.8 r_s)^2} \quad (75a)$$

$$\Delta V_2(0) = \frac{1}{M_+^{(1)} - M_+^{(2)}} [M_+^{(1)} (M_1 - M_2) - (P_1 - P_2)] \quad (75b)$$

$$\mu_i = \frac{1.84158}{r_s^2} - \frac{0.610667}{r_s} - \frac{0.44}{(r_s + 7.8)} - \frac{0.146667 r_s}{(r_s + 7.8)^2} \quad (75c)$$

$\Delta V_1(0)$  is obtained from  $\Delta V_2(0)$  by interchanging subscripts 1 and 2. In evaluating the simple overlap model the results of Eq. (75) will be compared with  $(dE_{\text{jellium}}/da)_{a=0}$  the derivative of the jellium portion of the binding energy evaluated at  $a = 0$ .

### F. Other Checks on Results

There are a number of checks that the results of these calculations must meet. The first is that the binding energy and its component energies must agree with the bare metal results at large separation. Another comparison of practical importance would be to predict experimental surface energies. These two conditions essentially only examine one point on the binding energy curves. An additional comparison which can be made with experiment is to obtain the elastic constants for a given direction from the curvature of the binding energy curve at equilibrium. This comparison has the additional feature of not simply depending on the energy at a single point but on the behavior of the binding energy curves at small separations. Since for small separations from equilibrium Hooke's Law will apply (Fig. 6)

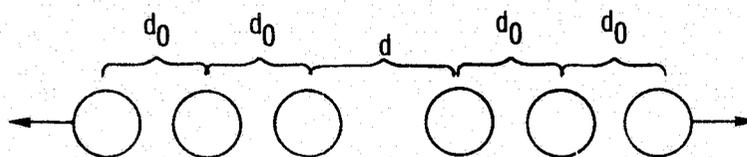

Fig. 6. - Change in interplanar spacing upon forming a surface.

$$F = C\epsilon = ka \tag{76}$$

where  $F$  is the force unit area,  $C$  is the elastic constant,  $\epsilon$  is the strain,  $k$  is the spring constant and  $a$  is the change in distance between lattice planes from pulling the metals apart, however,

$$\epsilon = \frac{d - d_0}{d_0} \text{ and } a = d - d_0, \text{ therefore,}$$

$$C = kd_0 \tag{77}$$

In this we assume a nonuniform strain between the two planes forming the surfaces with the other planes undisturbed [44,45]. In addition, we assume no distortion in the  $y$  or  $z$  directions.

## CALCULATIONAL PROCEDURES

Obtaining a numerical self-consistent solution to the surface problem has proven to be quite difficult. L-K [7] found that they couldn't get a solution using convergence factor techniques, therefore, they resorted to a functional equivalent of the Newton-Raphson method [46]. Rose and Shore [47] took a different approach in which a parameterized trial potential was used as input in which the parameters were varied by a simplex method [48] in order to minimize the total energy. The trial potential obtained in this manner reproduced the LK number densities and surface energies. Aldrege and Kleinman [49] and Appelbaum and Hamman [50] were able to obtain self-consistent solutions to three-dimensional problems by using convergent factor methods. Both found that the zeroth order ( $k_{||} = 0$ ) term was the most unstable part of the calculation and the higher order terms in the Fourier expansion converged rapidly. It is this unstable term that is evaluated in the present study.

In this section the techniques used to obtain a solution for the like-metal bimetallic Kohn-Sham equations with varying separation between the half-spaces are described. An IBM 360-67 time sharing system was used for the computations.

## I - SOLUTION OF SCHROEDINGER EQUATION AND POISSON'S EQUATION

The Numerov method [46] is used to obtain a solution for the Schroedinger Equation (Eq. (58a)). The Numerov method is a predictor corrector technique for second order differential equations in which the first derivative does not appear and has a remainder of the order of  $y^{(6)}h^5/240$  where  $y^{(6)}$  is the sixth derivative of the function and  $h$  is the mesh size in configuration space.

Quadrature is used for the solution of Poisson's equation (Eq. (58d)). Therefore, the potential is found by integrating the net charge twice. The Adams' method [51] with error of order  $h^6$  is used to perform the integrations since Simpson's rule [49] with an interpolation proved to be unstable. The instability arose from the fact that the integral of the net charge density was a decreasing rather than increasing function of position in the bulk of the solid; therefore, in the asymptotic region errors of the order of the charge density fluctuations arose from the need to interpolate to obtain alternate mesh points with Simpson's rule curve fit to the number density. A spline fit (Appendix V) followed by integration was also adequate but required substantially greater computer time and storage. The jellium net charge and potential were determined analytically and then combined with the numerical integration of the electron density. The solution of Poisson's Equation was checked by constructing a trial density similar to Smith's [6] with a small sinusoidal form in the bulk to simulate Friedel oscillations. The results agreed to 1-2 parts in  $10^6$ . In the calculation of the electrostatic potential the integration proceeded from the symmetry point

where the slope or the field was taken to be equal to zero. The integration proceeded into the bulk to the end of the slab where the entire potential, electrostatic plus exchange and correlation was required to equal the bulk potential.

A different test was applied to the solution of Schroedinger's equation. The solution was checked by comparing the wave function and number densities obtained from the solution of the Schroedinger equation for a triangular potential, the details of which are presented in Appendix III. It was found that the slope discontinuities for a square barrier created large errors in the solution obtained from the Numerov method.

Once the wave functions were determined both analytically and numerically the electron number density was calculated using Eq. (58b) by performing the k-space integrations. The results for the calculated and analytic densities are shown in Figure 7. The agreement was again good. The final self-consistent solution was probably superior to even these since small errors were introduced into the wave functions at the discontinuities in the slope of the triangular potential. The k-space integrations for the number density were performed by Simpson's rule since it required keeping only three wave functions in computer storage. The configuration space and k-space mesh sizes were selected by determining the maximum values that were necessary for accurate solutions. These were found to be 0.25 au and  $0.02 k_F$ .

The solution of Schroedinger's equation for a given potential proceeded by assuming the form of the wave function for the trans-

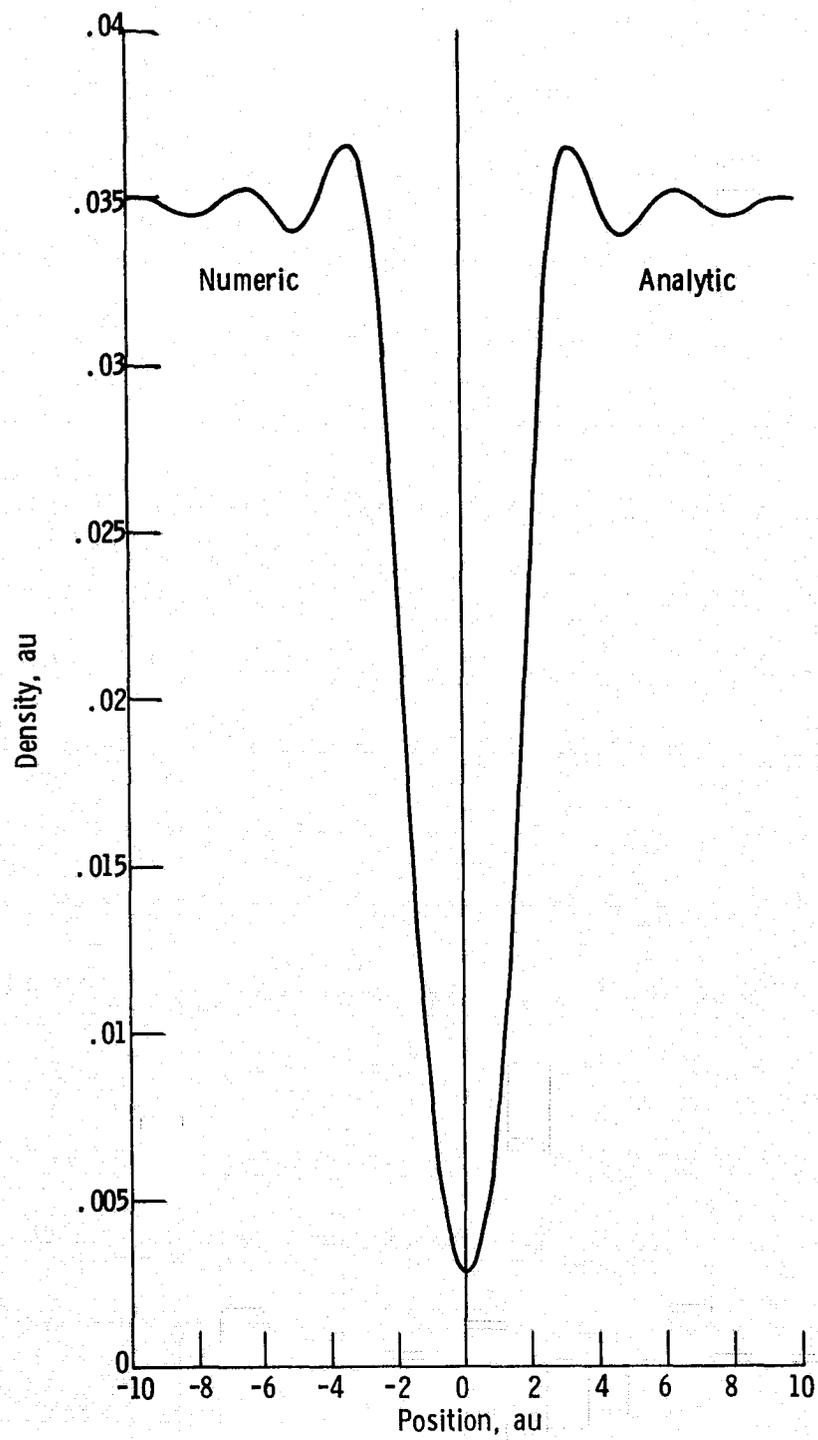

Fig. 7. - Electron density for a triangular potential for a barrier height  $k_F^2$  with a Fermi wave number,  $k_F = 1$  au and barrier width of 2 au.

mitted wave for an electron incident from the left half space to be  $e^{ik_R L_R}$  deep in the bulk of the second half space where

$k_R = \{2[\epsilon(k) - V(L_R)]\}^{1/2}$  where  $V(L_R)$  is the value of the total potential at the right hand boundary  $L_R$ . The Numerov Method uses two points to start the calculation rather than the slope and function, therefore, the same value of  $k$  was used for the second point which has an  $x$  value one mesh point from the right hand extreme which is equivalent to assuming the potential is constant at this point. The integration proceeded into the bulk of the second material where the numerical solutions were matched to

$$\Psi_k(x) = A(e^{ik_L L_L} + R_L e^{-ik_L L_L}) \quad (78)$$

where the coefficients were chosen as described in the THEORY section. The same assumption holds in this form of the wave function as for the starting values, i.e., the potential is essentially flat. The matching was performed by requiring the slope and function to be equal at  $x = L_L$ . Numerical derivatives were obtained with an I.B.M. computer routine called DET5 (Appendix VI). The wave functions were then renormalized by division by the constant  $A$  as outlined in the THEORY section. These wave functions are then used to calculate the electron number density (Eq. (58b)).

## II - TRIAL SOLUTIONS AND SELF-CONSISTENCY PROCEDURE

### A. Trial Solutions

The calculation proceeded by first constructing a trial

potential at the smallest separation between half-spaces used, 0.25 au, on the assumption that the system would deviate least from the uniform density at zero separation. A trial density of the Smith type as discussed in Chapter 2 was used in constructing a trial potential, but this proved to be unstable. The criterion used for judging the sufficiency of the trial potential was that the differences between input and output potential between the second and third iterative loops should decrease. The potential derived from the simple exponential density was insufficient to satisfy this criterion, by varying the exponential decay constant  $\beta$ . A successful trial potential was obtained by using the previous trial potential with a Gaussian well which simulated the first Friedel oscillation in the potential and whose position and strength could be varied along with  $\beta$ . This potential proved to be an adequate starting point to obtain a self-consistent solution at a separation of 0.25 au. For the subsequent separations a trial potential was obtained from the potential at the previous separation. First the potential at the previous separation was fixed relative to the jellium surface, then the points needed to complete the potential between the two metals were obtained by a linear extrapolation. At larger separations it was necessary also to increase the jellium slab length because of the increase in amplitude and range of the Friedel Oscillations near the jellium surface. In these cases the potential for large  $x$  was extrapolated by using the bulk value of the potential. It was later found that trial solutions for intermediate separations could be obtained starting from a solution at a larger separation by fixing the

potential relative to the jellium and reflecting those values through the symmetry point, thus omitting the need for extrapolation. Trial solutions could also be obtained at intermediate separations by interpolation of the potential between to previously obtained solutions, e.g., a solution at a separation of 2.5 au could be obtained from the solutions at 2 and 3 au.

This procedure was used to obtain a complete set of solutions for  $r_s = 2$ . Trial potentials were then generated for other values of  $r_s$  by multiplying the previously obtained self-consistent potential of the  $r_s$  value nearest to the desired value by  $k_{F2}^2/k_{F1}^2$ , the ratio of the bulk potentials squared. Trial potentials were also needed for the calculations including nonlocal terms in the exchange and correlation energies. The self-consistent solutions for the local density approximation were sufficient trial solutions.

## B. Self-Consistency

### 1. Procedure

Before commenting on the procedure used to obtain self-consistency it should be mentioned that in order to obtain convergence it was initially necessary to require charge neutrality in the slab. The technique used to obtain neutrality was simply to renormalize the electron density by multiplying it by the appropriate constant to make the net charge in the slab equal to zero. This technique was also used by Applebaum and Hamman [48] and proved to be adequate. Lang and Kohn [7] obtained neutrality by adding a Gaussian which was centered at the jellium surface to the electronic

charge. The amplitude of the gaussian was adjusted to insure that  $\frac{dv_{\text{eff}}}{dx} \xrightarrow{x \rightarrow -\infty} 0$ . The converged number density obtained from requiring neutrality was in general nonneutral. Requiring neutrality in the slab was needed for the comparisons of input and output potentials. Once convergence was obtained with the charge neutrality restriction, it was removed and the self-consistency procedure was continued. These converged solutions proved to give adequate trial potentials for other values of  $r_s$  by the simple ratio technique without first requiring charge neutrality.

As stated earlier a convergence factor method was used to obtain self-consistency rather than the Lang-Kohn method which would have been cumbersome for this calculation. The convergence factor involves using a linear combination of the output and input potentials as the trial potential for the next loop of the iteration

$$(V_{in})_{i+1} = (V_{in})_i + \alpha((V_{out})_i - (V_{in})_i) \quad (79)$$

In the early stages of the calculation starting from the invented trial potential it was necessary to use a very small convergence factor  $\alpha = 0.002$ , to promote convergence due to the extreme instability of the system. This could be increased to 0.025 as convergence occurred. Larger convergence factors resulted in divergence. However, even with  $\alpha = 0.025$  the rate of convergence proved to be quite slow. At this stage it was found that more rapid convergence could be promoted by using a large convergence factor, typ-

ically 0.25 to 0.5 depending on the separation between slabs in order to promote the establishment of features present in the final solution followed by a small convergence factor for a number of iterations in order to damp out instabilities introduced by the large convergence factor. The same procedure could be used for the solutions where the charge neutrality constraint was removed, but a much smaller convergence factor typically, 0.005, was necessary for convergence in subsequent loops since the lack of requiring charge neutrality in the slab during the iterations caused a much more severe instability. It was found that this procedure could be repeated to obtain any degree of self-consistency. The criterion for stopping the calculation will be discussed later.

The calculation of the wave functions and thus the number density consumed the greatest amount of computer time. In order to minimize computer time it was found that k-space intervals of  $0.05 k_F$  were sufficient to obtain convergence in the initial stages of iteration. In the final stages the k-space intervals were reduced to  $0.02 k_F$ . This procedure was only used when the nonlocal terms were included in the potential but very likely would have been adequate in all cases.

## 2. Condition for Self-Consistency

In similar previous calculations the condition for self-consistency was based simply upon the difference between input and output potential presented as a fraction of the bulk value. However, in the present calculation a more reasonable criterion is to

base the maximum fractional difference as a percentage of the barrier height. This is comparable to previous bare surface calculations for large separations and a much more stringent condition for small separations. It should be mentioned that using the potential rather than the density to judge self-consistency is also much more stringent since the potential depends very strongly on the density. The highest deviation (3.5%) between input and output potentials was for sodium at a separation of 0.25 au. The deviations were as low as a fraction of a percent. The largest deviations were for the smallest separations since considerably more iterations were needed to obtain convergence at these separations. It was found that the binding energy which is the result of this study was not a strong function of the degree of self-consistency for deviations of less than 100 meV. For example, for aluminum a difference between 60 and 2 meV only made a difference of 2% in the binding energy for aluminum, nonlocal, at a separation of 15 au. An additional test was used to determine convergence. The final output potential was used as an input with a convergence factor of 1.0 to determine whether deviations between input and output would remain of the same order. However, continued iterations at large convergence factors would cause a divergence because of small deviations from neutrality.

It is possible to attain a higher degree of self-consistency for any separation. The potentials and densities are available on punched cards, if a higher degree of self-consistency is required.

## III - BINDING ENERGIES

The binding energy were evaluated by performing quadrature with the exception of Wint as outlined in the THEORY section. These integrations were performed using QSF (Appendix VII). Since all of the functions were well behaved no problem arose in using this procedure.

## IV - ELASTIC CONSTANTS

The procedure for transforming the elastic constants for a given crystal direction from experimental data are given in reference [52]. The calculated elastic constants were obtained by taking the second derivative of the binding energy curves by fitting them with a spline curve fit (Appendix V). This procedure allows a nonuniform spacing for the separations when fitting a function.

## RESULTS

Presentation of the results will be in a form that reflects the order in which they are produced in the self-consistent calculations. Since the binding energy versus separation is the principle result of the calculation it will be presented last. Also included will be checks of the results, tables of self-consistent densities and potentials, force curves, tables of components of the binding energies, a comparison of experimentally and theoretically determined elastic constants, and a listing of the computer program. The tables of number densities and potential energies (Appendix X), energy breakdowns (Appendix IX) include a complete listing of all results obtained at each separation in the hope that this will serve as a comprehensive document. For results obtained from the simple overlap model only the binding energy curves will be presented for purposes of comparison. The number densities can be obtained simply by use of Smith's [6] bare-metal calculations, and the potential energy and components of the binding energy can be obtained using quadrature of the expressions presented in Section I of the THEORY section. The tabular results will be organized by presenting them in increasing order of  $r_s$  for the materials considered. A listing of the computer program is presented in Appendix VIII.

### I - NUMBER DENSITIES AND POTENTIAL ENERGY

Figures 8 and 9 show some typical plots of the electron number

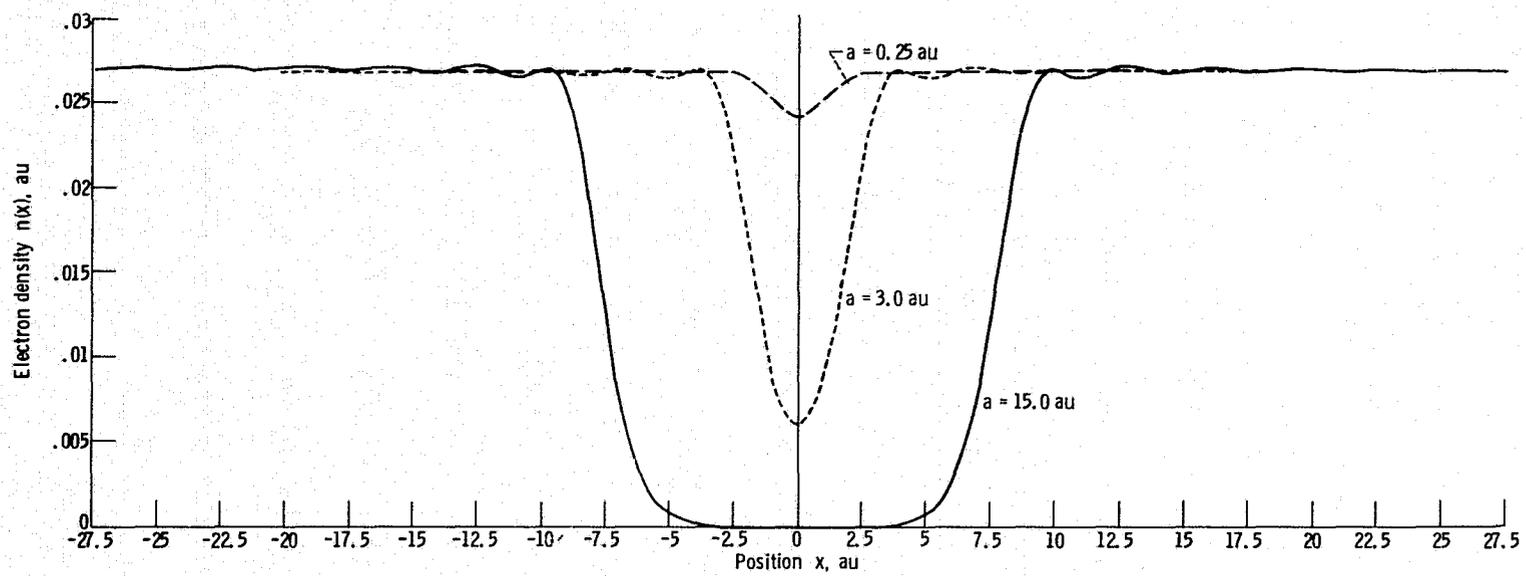

Fig. 8. - Electron density versus position for an Al(111)-Al(111) contact for separations of 0.25, 3.0, and 15 au.

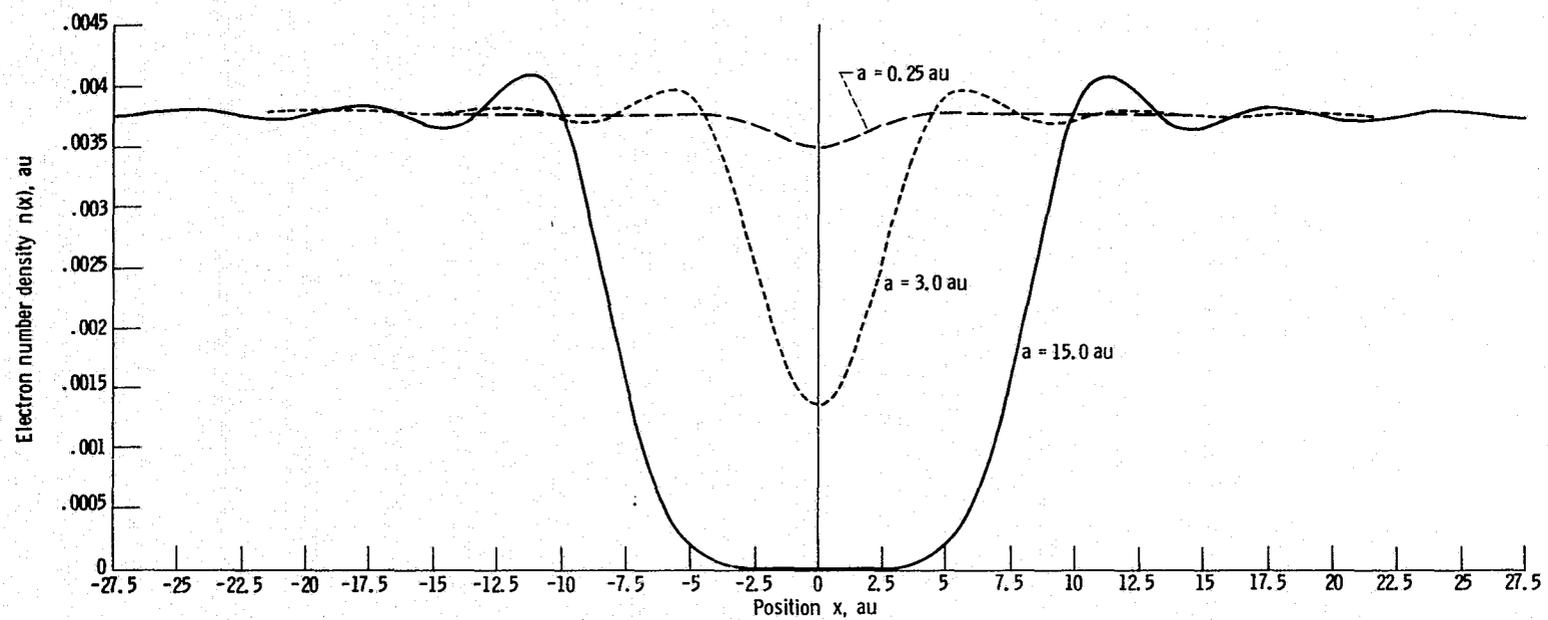

Fig. 9. - Electron density versus position for a Na(011)-Na(011) contact for separations of 0.25, 3.0, and 15.0 au.

density for Na and Al at 0.25, 3.0, and 15 atomic units. We can see two main features; the electron number density falls off rapidly as the separation increases, the oscillations in the density increase as the separation increases and the magnitude of the oscillations are larger for sodium than aluminum. Figures 10 and 11 shows similar plots for the potential energy  $V_{\text{eff}}(x)$ , as a function of separation for Al and Na. Here we see the barrier height increasing with separation and in addition again the oscillations are increasing with separation and likewise increase from Al to Na. Figure 12 is a plot showing the increase in barrier height versus separation for aluminum for both the local and nonlocal approximation. It can be seen that the barrier height versus separation differs for small separations which is typical of each element examined but the difference disappears at larger separations. In addition, at separations of 15 au the "work function," the difference between the barrier height and the top of the conduction band has not as yet saturated to the bare-metal value. The barrier height varies much more slowly than the number density with separation which changed little between a separation of 10 and a separation of 15 au.

Figure 13 shows a plot of the potential energy for Al at a separation of 15 au including the nonlocal terms in the potential. It is apparent that some anomaly has appeared at this separation. There is a dip in the potential energy on either side of the symmetry point. The question arises concerning whether this is an actual physical effect or a breakdown in the numerical techniques used. This point will be addressed in the DISCUSSION section. A listing

of the computer program for the self-consistent calculation is in Appendix VII. The complete self-consistent densities and potential energy tables for the local and nonlocal gradient expansion are presented in Appendix X.

## II - SIMPLE OVERLAP BINDING ENERGIES

Figure 14 shows a plot of binding energy as a function of separation for the densest packed planes of Al, Zn, and Mg for each possible combination of contacts between any pair of these elements. They also include the possibility of having the lattices in registry or lack of registry for the like-metal contacts which means that  $W_{int}$  is included or omitted from the total binding energy. The primary features of these curves are that the minimum was at a non-zero separation, the range of the strong binding force is 4.0 atomic units and that the dissimilar metal contacts had stronger binding than the weaker of the two similar metal contacts for nonregistry ( $W_{int} = 0$ ) which would be the situation which has been observed in bimetallic contacts [4]. A list of the binding energies are presented in Table I. A check of the Budd-Vanemenus Sum Rule [42] for

the jellium as altered by Heinrichs and Kumar [43] is presented in Table II.

### III - SELF-CONSISTENT BINDING ENERGIES

The binding energy versus separation for the self-consistent like-metal contacts in registry are given in Figure 15. The two curves give the binding energies for the LDA and nonlocal approximation for the densest packed planes of Al, Mn, Mg, and Na. Infinite separation was taken at 15 au since the binding energy saturated at this value as can be seen by comparing to its value at 10 au. Figure 16 presents the binding energy for the metals obtained from finding the bulk density which minimizes the cohesive energy to first order holding the Ashcroft ion-core radius fixed. The self-consistent binding energies are qualitatively quite similar to the simple overlap results. There is a nonzero minimum and the attractive forces are quite short range as can be seen by comparing Figures 14 and 15. Quantitatively the binding energies are larger in magnitude and are slightly shorter in range than for simple overlap. A comparison of analytical (taken at the minimum in

				688	[56]
Na	---	240	275	273	[58]

differ from those using the experimental bulk density by the fact that the minima are at zero separation thus identifying the reason for the nonphysical, nonzero minima. Actually, the bulk density could have been held fixed and the ion-core radius could have been varied but since the primary objective was to identify the reason for the nonzero minimum and both  $n_+$  and  $r_c$  are experimentally determined quantities the choice is somewhat arbitrary. This approach can be easily taken for those who are interested. Checks on the degree of self-consistency by calculating the jellium force at zero separation using the Budd-Vannemenus theorem [42] are presented in Table IV. A typical total force versus separation curve for magnesium including local and nonlocal effects is shown in Figure 17. These were obtained by numerical differentiation of the total energy curves using a spline fit.

The constituents of the binding energy at each separation and for all cases considered are presented in Appendix IX. Figure 18

Zn	$1.365 \times 10^{-3}$	$1.368 \times 10^{-3}$	$1.363 \times 10^{-3}$
Mg	$5.612 \times 10^{-4}$	$5.615 \times 10^{-4}$	$5.628 \times 10^{-4}$
Na	$1.437 \times 10^{-5}$	$1.452 \times 10^{-5}$	$1.447 \times 10^{-5}$

presents a typical plot of these energies for the specific case of a Mg(0001)-Mg(0001) contact. There are two interesting features in these curves; the kinetic energy is negative and the potential energy is positive at intermediate separations relative to infinite separation. Thus, the kinetic energy is responsible for bonding in these regions.

Finally, the elastic constants for each element are estimated by numerically taking the second derivative of the binding energy curves near the minimum. This calculation gives an additional comparison with experiment which tests some details of the curves near the minimum. The surface energy only gives a comparison with experiment of one point. These results and their comparison with experiment are presented in Table V.

## DISCUSSION

Having now presented the results of the metallic adhesion calculations, the implications and explanation of the results in terms of adhesion and their relationship to other similar surface calculations currently being conducted will be discussed. The format will follow that presented in the RESULTS section including general comments on certain aspects of the calculation. We should point out that the present work is an ab initio calculation which depends on no fitting parameters.

### I - ELECTRON NUMBER DENSITY AND POTENTIAL ENERGIES

#### A. Electron Density

Figures 8 and 9 show some of the typical electron density profiles as a function of separation for aluminum and sodium. As we can see there are a number of features readily observable in these plots namely, that as the metals separate the electron number density in the intermediate region falls off rapidly and that the oscillations in the density increase with separation. The other interesting feature is that at a given separation the oscillations in the number density are larger for sodium than for aluminum. These oscillations are similar to the familiar Friedel oscillations [61] occurring with an impurity atom in a solid. They arise from the perturbations introduced into the potential by creating the surfaces. As would be expected the amplitude of the oscillations should in-

crease with the strength of the disturbance as is observed in Figures 8 and 9 corresponding to Figures 10 and 11 which show the increase of the potential barrier between the surfaces as a function of separation. For all separations the oscillations will have the general form given by Adawi as shown in the THEORY section and for large or infinite separation the number density should approach the form given by LK

$$n(x) \xrightarrow{X \rightarrow \pm\infty} n_{\pm} \left[ 1 + \frac{S}{(k_F X)^2} \cos(2k_F X - 2\gamma_F) + O\left(\frac{1}{X^3}\right) \right] \quad (80)$$

where  $\gamma_F$  is the phase shift at the Fermi momentum. A similar result is obtained for the infinite or square barrier model. If we examine this we see that  $\frac{\Delta n}{n_{\pm}} \sim \frac{1}{k_F^2} \sim n_{\pm}^{-2/3}$ , therefore, the amplitude of the oscillations should increase with decreasing  $n_{\pm}$ , the bulk electron density or conversely, increase with increasing  $r_s$ , the Wigner-Seitz radius. This effect is manifested in the larger oscillations for sodium and serves as a check on the results. Another perspective in explaining the oscillations is given in terms of the discontinuity in the slope of the dielectric function [61] which is due to the sharp cut off at the Fermi surface and produces oscillations in the potential of wave number  $2k_F$ . The wavelength of the Friedel oscillations was checked by examining  $x^2(n(x) - n_{\pm})$  near the slab boundary. In all cases it was found that near the boundary the oscillations had wavelengths very close to  $\pi/k_F$  ( $\sim 1-2\%$ ).

Plots of the densities obtained from including gradient corrections to the potential were not included, because differences between these and the LDA densities were not perceptible with the scale used. Complete listings of these densities, however, are presented in Appendix V. This result is in agreement with that obtained by Rose, et al. [14] in their bare metal calculations who also used the Rasolt and Geldart gradient correction and also obtained only small differences in the electron number density.

### B. Potential Energy

Figures 10 and 11 show the potential energy  $v_{\text{eff}}(x)$  for separations of 0.25, 3, and 15 atomic units for both Al and Na. We see that the barrier increases in both height and range with separation as would be expected. In addition, we can again see that the oscillations in the potential display the same behavior as with the density, the oscillations increase with separation and with  $r_s$ .

Figure 13 shows a similar plot but for the gradient correction term included in the potential for aluminum at 15 au. In this figure, however, the potential is plotted from the end of the slab to the symmetry point. It can be seen that an anomalous depression appears in the potential. A similar behavior occurs in the potential for every value of  $r_s$  calculated. However, the potential is well behaved at 10 au. The behavior at 15 au is a result of the extrapolation of the Rasolt and Geldart [22] coefficient breaking down at these separations. Rasolt and Geldart have suggested that this coefficient is not accurate for values of  $r_s$  much greater

than six since the random phase approximation is used. At a separation of 15 au for aluminum the equivalent density falls to a minimum value equivalent to  $r_s = 14.5$  whereas for a separation of 10 au the equivalent  $r_s$  value is 4.5. The comparison is similar for sodium. The behavior of  $a = 15$  is therefore attributed to a breakdown of the expression. An examination of Equations (53) and (54) shows that the term multiplying  $C_{xc}(n)$  is divergent as  $n \rightarrow 0$  for an exponential fall-off in the density. This fact is well known and the general procedure in atomic calculations, Herman, Van Dyke, and Otenburger [41], has been to multiply the potential by a function which prevents this divergence. We can see for an exponential fall-off that although the potential is divergent, the contribution to the total energy (Eq. (67)) is convergent. The argument used is that although the potential is divergent or incorrect, the density is small in this region and thus gives a small contribution to the energy (Eq. (67)). Rose, et al. (private communication) experienced a similar problem in that they approximated  $C_{xc}(n)$  by a linear fit. However, an additional function was also used to prevent divergence in their trial potential. This was the reason, in addition to the excellent curve fit, that a gaussian was chosen in the present work to fit  $C_{xc}(n)$ . As a test we see that in examining the binding energy curves (Fig. 15) that the binding energy has essentially saturated at a separation of 10 au and there is no strong effect at a separation of 15 au. This can be verified by the fact that the LDA binding energies which do not contain this term have similar behavior.

Figure 12 shows the increase in the barrier height versus separation in aluminum for the LDA and including the gradient terms. We can see that the two differ at small separations and approach one another at large separations. In addition, the work function has not saturated and is smaller than the Lang-Kohn (private communication) value for the jellium at a separation of 15 au. Although the differences in density are small between LDA and nonlocal and the binding energy has essentially saturated, this is not a surprising result. The electrostatic potential as determined from Poisson's Equation (Eq. (58c)) depends on differences between large numbers and thus small differences in density can be transformed to large differences in potential. Whereas, small differences in density will not be reflected as large differences in binding energy due to the variational principle as pointed out in Equation (42).

At this point some difficulties in determining the electrostatic potential should be mentioned. The self-consistent solution to the Kohn-Sham equations should require charge neutrality which is equivalent to requiring that  $\frac{d\phi}{dx} \xrightarrow{x \rightarrow -\infty} 0$ . Although this condition is imposed explicitly in the H-K formalism it does not arise as readily in the Kohn-Sham formalism and results in serious convergence problems in the self-consistent calculations because of the long-range nature of the coulomb interaction. Lang and Kohn used a variational technique which avoided this difficulty by starting with a neutralized trial density and then expanding the density in the surface region in terms of derivatives of harmonic oscillator wave

functions which preserved charge neutrality and then determining the expansion coefficients of these terms in such a way that self-consistency was required. The present author used this technique successfully on the bare-metal problem, but found it cumbersome for the bimetallic problem. Therefore, the approach described in the calculation section was attempted. First, neutrality in the slab was required, then this restriction was removed and the iterations were continued to convergence in the potential. Examination of the electrostatic potential energy near the slab bulk boundary demonstrated that  $x^2\phi(x)$  had the correct behavior in this region for charge neutrality, i.e., sinusoidal oscillations. A further check of these results is obtained from the Budd-Vannemenus Theorem since the forces calculated in Table IV depend on the difference in electrostatic potential in the bulk and at the jellium surface. As can be seen the agreement is excellent. The result is not surprising since the self-consistent solution should be neutral over all space. Any solution which is not neutral would diverge. Another approach has been used in surface calculations to handle these problems by Perdew and Monnier [82] and Nieminen [32]. They modify Poisson's equation by addition a term which guarantees that the electrostatic potential satisfies the correct asymptotic boundary conditions. The Perdew-Monnier Results for the bare metal agree well with the present calculation at large separations, and therefore, both approaches serve as a mutual confirmation of each other.

## II - BINDING ENERGIES FOR THE SIMPLE OVERLAP MODEL

The binding energies versus separation for the simple-overlap model are shown in Figure 14. The binding energies are given in Table III along with experimentally determined surface energies. This calculation was the first successful attempt to examine the adhesive interaction between two dissimilar clean metals. A number of interesting results are apparent; the range of the strong binding energy is approximately 4 au; the dissimilar metal nonregistry contacts ( $W_{int} = 0$ ) were stronger than the weaker of the two metals; the minimum occurs at nonzero separation, and the binding energies are within reasonable agreement with experimental surface energies. The agreement with the qualitative and quantitative features of the self-consistent calculations (Fig. 15) is quite remarkable for such a crude approximation. In addition to reasonable values for the surface energies, the calculation gives good values for the range of the strong binding chemical forces and predicts that transfer of material from the lower surface energy to the higher surface energy can occur which is observed experimentally [4].

The simple overlap model is also important from two other theoretical aspects; in evaluating the success of Smith's surface energy calculations and in evaluating the importance of charge transfer to binding. Examination of Figure 14, curve II, shows that the simple surface energy calculation comparing zero and infinite separation which is the self-consistent Smith solution for

like metal pairs gives a poor result for the surface energy. Examining the binding energy versus separation in the spirit of cohesive energy calculations in which both energy and lattice constant are examined gives a different perspective on Smith's work in that it shows that the procedure can give better surface energies than expected. The present result shows that reasonable surface energies for similar metal contacts but poor lattice constants are obtained. Including the correct ion-ion interaction into the calculation (curve I) in effect improves the lattice constant and somewhat improves the binding energy. The question of the location of the minimum will be examined in detail later. The second result of importance especially to the dissimilar metal contacts is that binding is obtained without charge transfer and that indeed binding is obtained simply from electron-sharing. This will be important in evaluating self-consistent dissimilar metal contacts and helps separate the physical contribution necessary for binding.

A check of this calculation can be performed by a comparison with Heinrich and Kumar's [43] modification of the Budd-Vannemenus Theorem as presented in Eq. (75). This comparison is presented in Table II. As can be seen the results are remarkably good for dissimilar metals. Since the similar metal result is self-consistent at infinite separation the result for this case is not surprising. The good agreement is possibly a result of the argument in Eq. (42) concerning the effects of errors in the number density on the energy. Recently, Raykov [63] derived an expression for the difference in

electrostatic potential for the jellium model between dissimilar metal contacts as a function of separation from Heinrich's and Kumar's work. Raykov concluded that simple overlap did not correctly predict the difference in potential at the jellium surfaces for the simple overlap model in contraction to the good agreement with forces. This result is to be expected, since the calculation was not done self-consistently. Although the approach in this calculation is somewhat simple, it, in general, has produced some interesting and important results in metallic adhesion and have been used by other researchers in the field [14, 64, 65].

### III - SELF-CONSISTENT BINDING ENERGIES

In this section of the paper there are a number of topics to be discussed such as comparisons with experiments for the binding energy, the location of the minimum in the binding energy curve, forces, and others. Each topic will, therefore, be discussed in a separate section for clarity.

#### A. Local and Nonlocal Contributions to the Binding Energy

Figure 15 shows the binding energy versus separation for Al, Zn, Mg, and Na both in the local density approximation and including the next higher order contribution to the exchange and correlation energy in the gradient expansion as determined by Rasolt and Geldart. We can see that the general features in these curves are quite similar to the simple overlap model. Quantitatively, however, the results are improved with regard to agreement with experiment and location of the minimum. The range of the strong bonding force

is still of the order of 4.0 au (defined as  $\sim 10\%$  of the binding energy).

As can be seen in Table III, including the Rasolt-Geldart non-local contributions improves the agreement of the calculated surface energies with experiment (taken at the minimum in the binding energy curves). This result is in agreement with attempts by others to include such terms as discussed in the BACKGROUND section. In fact, the problem is not in the scatter in theoretical values for the surface energy, but rather the scatter in experimental values [51] for the surface energies. The experiments are usually performed of necessity at elevated temperatures and on liquid metals and the concomitant surface contamination problems often make the results of these difficult experiments questionable. An excellent review of these experiments is presented by Hondros [66]. In addition, the present and the other surface energy calculations are truly brittle fracture at 0 K models. Consequently, it is necessary to obtain surface energy measurements for solids of which there are few or to extrapolate from liquid metal values. The latter is the approach taken by Lang and Kohn, however, in performing the extrapolation they extrapolated through a phase change. In this paper, we choose instead the values published by Wawra [53], who derived the surface energies indirectly from solids at close to 0 K via ultrasonic attenuation. Wawra's method suffers from the same experimental uncertainty as other studies ( $\sim \pm 20\%$ ) because it depends on the fact that the surface energy is proportional to the bulk modulus [67]. He uses this principle and the surface energy data of others in

order to determine the proportionality constants. His experiments are performed under the correct experimental conditions, i.e., solids at low temperature and thus require no extrapolation. Unfortunately, for Mg we could not find values for solids and have used the extrapolated values of Bohdansky and Shins [55] and compare to those of Tyson and Miller [56].

Evaluating these results in terms of adhesion experiments is quite difficult. Clean real surfaces in contact do not have well defined surface areas because of the asperity problem and consequently quantitative comparisons may be questionable. In addition, elastic recovery, ductile fracture in metals, and defects may make comparisons even more difficult. The practical importance of the present work is in setting bounds for studies of both breaking force and contact areas. When evaluating real surfaces the question must also be asked whether the strong short range is the dominant force in contacts, since the "true" contact is just over a fraction of the apparent area. In between it is not obvious whether the strong short range or the weaker long range Van der Waals forces dominate. Inglesfield [65] directed himself to this question using the results of Ferrante and Smith [28] and his own Van der Waals calculation and concludes that the long range forces make a negligible contribution in mechanical adhesion for aluminum based on estimates of the true contact area and an estimate of the average separation between asperities. In conclusion, it should be pointed out that the strong bonding forces are important in adhesive wear [4] where wear particles are generated because of adhesion and in brittle fracture of

metals at low temperatures [44].

### B. Location of the Minimum in the Binding Energy

As stated previously the location of the minimum in surface energy calculations is analogous to examining the accuracy of the lattice constant in cohesive energy calculations. Therefore, the present work is a further check on surface energy calculations which evaluates the accuracy of how well it predicts the lattice constant. As we can see in Fig. 15 for Al, Zn, and Mg we overestimate the interplanar spacing at the surface whereas for Na the calculation underestimates the surface lattice constants. It was speculated that the reason for nonzero minimum was that the bulk lattice constant (or  $n_+$ ) must be chosen such that the cohesive energy is a minimum for the Ashcroft pseudopotential. The Ashcroft pseudopotential did not minimize the observed equilibrium bulk density for most bulk metals [62]. In order to accomplish this we use the expression for the ground state energy per atom for the solid obtained by Heine and Weaire [68].

$$\begin{aligned}
 U_0 = & \frac{1.105Z^{5/3}}{r_a^2} - \frac{0.458Z^{4/3}}{r_a} - \frac{0.44Z^{4/3}}{r_a + 7.0Z^{1/3}} - \frac{0.9Z^2}{r_a} \\
 & + \frac{3Z^2}{2r_a} \left(\frac{r_m}{r_a}\right)^2 - A_0 \left(\frac{r_m}{r_a}\right)^3 + (\alpha - 1.8) \frac{Z^2}{2r_a}
 \end{aligned} \tag{81}$$

Where  $r_a = Z^{1/3} r_s$  and  $Z$  is the valence of the ion. The first term is the kinetic energy per electron. The second and third terms are the exchange and Wigner form for the correlation energy per particle. The next three terms are a combination of the poten-

tial for a uniform electron gas and the ionic pseudopotential which is averaged over the ion-core sphere. These terms correspond to the pseudopotential corrections presented earlier. The last term corrects for Ewald energy for point ions in a uniform electron gas and is similar to what we have previously called Wint. Therefore, it is a point ion correction where the constant  $\alpha$  is given for a number of crystal structures in Reference [69]. The form for the energy presented in Eq. (81) is written in terms of the Abarenkov, Animalu, and Heine pseudopotential. In order to use the Ashcroft pseudopotential we set  $A_0$ , the value of the potential in the ion core, equal to zero and  $r_m = r_c$ . We proceed by finding the value of  $r_a$  and thus  $r_s$  which minimized  $U_0$  by differentiating and finding the zeroes of  $dU_0/dr_a$ . In the subsequent calculation for the hcp metals the value of the axial ratio which minimized the Ewald energy is used, however, the difference between this and the ideal ratio is negligible in the present calculation. Having determined the  $r_s$  which minimized  $U_0$  for the Ashcroft pseudopotential for each metal we repeat the self-consistent calculations for the binding energies. The results are shown in Figure 16. These can be compared with the results obtained for the experimental  $r_s$  values (Fig. 15) for both the LDA and with gradient corrections. We see that the minimum has moved and occurs at zero separation. This is somewhat difficult to judge for Al, Zn, and Mg because if we look at the binding energies for experimental  $r_s$  values we see that there is a very rapid rise from the minimum. Curve fitting the new binding energies in the region of the minimum and extrapolating to

$a < 0$  indicated that there was indeed a minimum. Also using the binding energy curves in Figure 15 near the minimum for comparison is convincing that there is indeed a minimum at these points. The results are most obvious with Na where the minimum for experimental values occur for  $a < 0$  and the shift in the position of the minimum is toward the right. Therefore, it is apparent that a large portion of the discrepancy in the location of the minimum can be accounted for by the consistency between  $r_c$  and  $n_+$  with regard to the cohesive energy.

### C. Components of the Binding Energy and Forces

Appendix V gives the components of the binding energy for each material combination. The kinetic, exchange, and correlation total electrostatic (jellium + Wint), pseudopotential, nonlocal, and jellium components of the binding energy are presented for each separation referenced to a separation of 15 au. Since only the bare metal values for these quantities are available in the literature [7,14,62] we compare our values for the components of the surface energy with these values. The present results do not compare well with Lang and Kohn but agree extremely well with those of Perdew and Monnier [62]. The reason for the disagreement with Lang and Kohn and the agreement with Perdew and Monnier is that Lang and Kohn interpolated to obtain densities for nonintegral  $r_s$  values whereas Perdew and Monnier and the present author used the experimental values of  $r_s$  for each material. Perdew and Monnier had also come to the same conclusion. The fact that the surface energy

agreed well between the three even though the components did not is attributable to the argument given in Eq. (42) for the accuracy of simple overlap. That is, that the errors in the energy are second order in the number density. There is a disagreement with Perdew and Monnier's energies for zinc. The authors have checked their calculation (private communication) and now agree well with these results. As was mentioned, there was somewhat of a discrepancy with the results of Rose and Shore [14] concerning the nonlocal contributions to the energy, but these have also been resolved to be related to interpolation to obtain densities and a less accurate technique for obtaining numerical derivatives (private communication). It should be pointed out, therefore, that we get the correct separated solid limit for not only the surface energy but also the components of the surface energy.

A second point that should be addressed is the validity of using perturbation theory in order to evaluate the electron-ion contribution to the energy. This contribution is large and is needed for binding since the jellium is unbound. It is small compared to the kinetic energy. Perdew and Monnier found the perturbation theory to be fairly accurate (~10% error in surface energy for Al ranging to little effect of Na) but poor for lead by including the electron-ion pseudopotential self-consistently in their surface energies. That fact that it is poor for lead is not surprising since it is the only tetravalent metal tested, has more than one value for the ion core radius depending upon the property that is fit and and has by far the highest atomic num-

C2

ber of the elements examined. This was first pointed out by Lang and Kohn [7].

Figure 18 is a plot showing the breakdown of component energy versus separation for Mg relative to infinite separation ( $a = 15$  au). Some interesting features appear in this figure, namely, that over a portion of the curve the kinetic energy is negative relative to infinite separation whereas the potential energy is positive. The total energy shows none of these interesting features as might be expected. Therefore, at large separations the change in kinetic energy is responsible for the binding. Before entering into a discussion of this behavior at this point a more general discussion concerning the details of the calculation is of interest.

It is interesting to examine the present calculation from the standpoint of the variational principle and of chemical binding to which the present work bears strong analogies. In order to have bonding it is necessary to have the energy lower at a finite separation than at the separated solid limit as is the case in chemical bonding. Also by analogy to the chemical bond the bonding apparently arises from sharing electrons in the bond region. In chemical binding the energy lowers to a minimum value at the equilibrium separation and then rises beyond this point due to nuclear repulsion. Examining the binding energy curves simply from their qualitative aspects reveals that it would be difficult to distinguish them from those that would be expected for binding in a diatomic molecule. In a sense bimetallic adhesion can be looked upon in terms of the binding of two large molecules when brought into con-

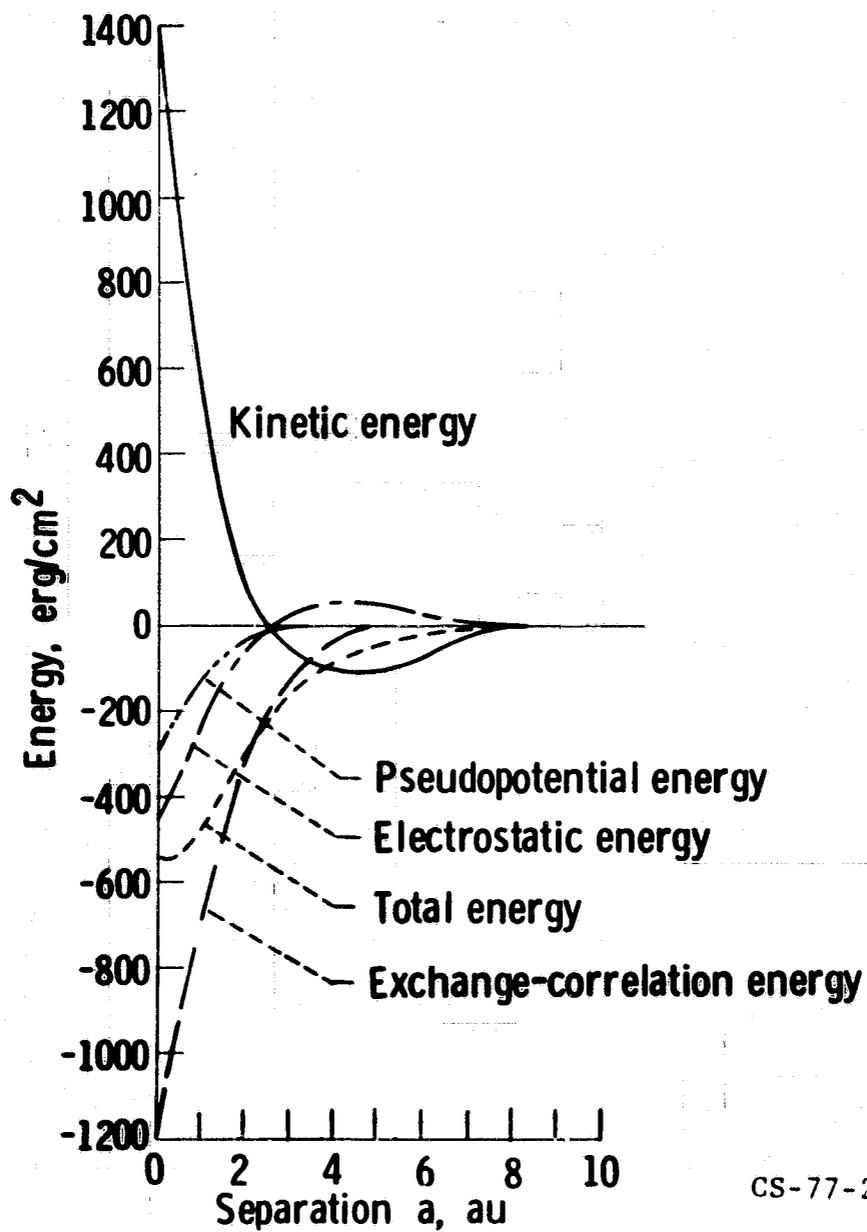

Fig. 18. - Self-consistent energy components of the binding energy for a Mg(0001)-Mg(0001) contact.

tact with one another and examining the effect of varying the charge density on the total energy. It is interesting to see how far the analogy will carry over. If we compare the components of the binding for simple overlap (Fig. 19) and for the self-consistent case we find that the kinetic and potential energies change monotonically. Thus, the behavior observed in the self-consistent case is not necessary for bonding and is a result of charge rearrangement. The fact that bonding occurs for simple overlap is sufficient to say that bonding will occur for dissimilar metals by the variational principle.

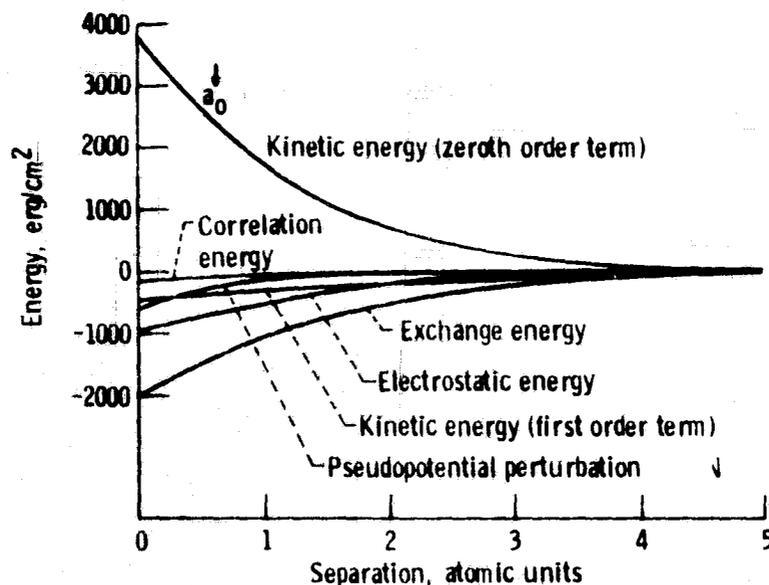

Fig. 19. - Energy components for the typical case of Al-Zn.  $a_0$  is the location of the energy minimum.

In seeking an explanation for the behavior of the potential and kinetic energy we again find a direct analogy in the work of Feinberg and Ruedenberg (FR) [70] on the formation of a hydrogen molecule,  $H_2$ . FR solve the hydrogen molecule problem variationally

by use of trial wave functions. They then in a manner similar to the present calculation determine the kinetic, potential, and total energy as a function of separation. The same behavior for the kinetic and potential energy is observed in the hydrogen molecule as in the self-consistent, like-metal, bimetallic case. FR have an explanation of this behavior both in terms of the wave functions and the electronic charge density. The drop in the kinetic energy is a result of the symmetric wave functions in the bond region. The overlapping orbitals produces a smoothing of the wave functions in the bond region effectively destroying  $d\psi/dx$  in this region. The  $T_{||}$  component of the kinetic energy is reduced relative to the separated atom limit. The behavior of the potential energy is caused by charge transfer into the bonding region. In this case charge is transferred from a region where potential energy is low near the nuclei to a region where potential energy is higher in the bond. Since the kinetic energy effect dominates, kinetic energy is responsible for incipient bonding. It is this kinetic energy term which is also responsible for bonding at the equilibrium separation where the virial equation  $T = -(1/2)V$  must be satisfied. The lowering of the kinetic energy pressure results in a charge contraction towards the nuclei thus lowering the potential energy and near equilibrium a subsequent increase in the kinetic energy because of the contraction. As a result of the combined effect the energy minimum is reached at a higher value of the kinetic energy. FR point out that in viewing the effects in terms of the density that the smoothing of the density in the bond region gives a decreased ki-

netic energy by virtue of the uncertainty principle.

The situation in the adhesion problem is similar to that in molecular bonding and gives the same qualitative behavior. Unfortunately, it is not possible to do a complete examination for adhesion, because of the self-consistent calculation. In molecular bonding with trial wave functions it is simple to fix certain properties such as spacing and examine the effects on the energy of others such as charge distribution. FR conclude that the difference in kinetic energy pressure in the molecule as opposed to the atom is essential to the formation of the covalent bond. This is not the case in adhesive bonding. The simple overlap model demonstrates that electron sharing is sufficient for bonding without the paradoxical effects in the kinetic and potential energies. The rate of loss in potential energy is simply greater than the rate increase in kinetic energy. Similar effects to molecular bonding occur in the self-consistent calculations but these must be a result of charge rearrangement analogous to those presented by FR for molecular bonding.

Finally, we show a plot of the adhesive force versus separation for the LDA and gradient expansion for Mg (0001) vs Mg (0001). This result is typical for all other materials. We can see that the force rises rapidly with separation to a maximum value which gives the force for brittle fracture. The nonlocal approximation gives a higher breaking force than the LDA in agreement with binding energy curves. The force achieves its maximum value at approximately 0.1 nanometers. Also included is Table IV which shows the jellium force at zero separation calculated for present results using

Eq. (72) and using the Budd-Vannemenus theorem (Eq. (74)). This table is actually a check on the self-consistency of the present calculation.

#### IV - ELASTIC STIFFNESS CONSTANTS

The elastic stiffness constants can be estimated from the binding energy curves by taking the second derivative as pointed out in the THEORY section. Comparing elastic constants with experiment is an important check on the Kohn-Sham formalism, since the only previous comparisons were with surface energies which only examines one point on the binding energy curves. The elastic constants check the behavior of the solution in the vicinity of the minimum. In addition, unlike surface energies, elastic constants can be determined very accurately experimentally. The results of the calculation as determined by a spline fit are presented in Table V along with experimental values [57,58,59,60], as can be seen the agreement is quite remarkable and is of the same order of accuracy as obtained from cohesive energy calculations [71,72]. The nonlocal values are better than the local with the exception of zinc which also deviates for the surface energy. Monnier and Perdew [62] point out that the Ashcroft pseudopotential may be in error for zinc and consequently this may account for the poorer agreement. The agreement for Na is quantitatively poor and probably is worse than the others since points are not available near the minimum for the spline fit. The trends in elastic constants are also predicted correctly.

The degree of agreement may have been somewhat fortuitous since there are not many values of binding energy available near the minimum. Obtaining binding energies for more separations near the minimum is difficult since it would require a variable mesh size with smaller intervals in the gap between the surfaces or a small uniform mesh size which would require large computer storage and long computation times. The spline fit is convenient since it is smooth, provides an analytic form, and can handle a variable spacing. In spite of the questionable accuracy the results are sufficiently good to encourage more sophisticated numerical techniques to obtain self-consistent solutions for small gap sizes.

### CONCLUDING REMARKS

The adhesion of simple metals in contact (Al, Zn, Mg, and Na) has been examined by use of the Hohenberg and Kohn formalism and the Kohn and Sham formalism with and without gradient terms in the exchange and correlation energy. The spirit of this calculation is similar to cohesive energy calculations in which both the energy and lattice constant are investigated by examining binding energy versus separation. Strong analogies to molecular binding are also observed when examining both the binding energy curves and the component energies versus separation.

The results of the Hohenberg and Kohn simple overlap calculations (no relaxation or self-consistency), give reasonable quantitative and qualitative results. The surface energies are of the right order of magnitude, give the correct relative trends, and the range of strong chemical bonding forces is given. The model predicts transfer in dissimilar metal contacts in that interfacial energies are greater than binding energies in the weaker of the two materials. The possibility of incorrect lattice constants (nonzero minimum) is predicted as is observed in self-consistent calculations. In addition, the model demonstrates that charge transfer (relaxation is not necessary for bonding).

The self-consistent Kohn-Sham calculations for similar metal contacts are quite quantitative. Good agreement with experiment for

both surface energies and elastic stiffness constants are obtained when nonlocal terms in the exchange and correlation energy are included. The range of the strong chemical bonding forces is found to be 0.2 nanometers. Corrections to the lattice constant (nonzero minimum) are obtained by determining the bulk density which minimizes the cohesive energy for the Ashcroft pseudopotential. Excellent degrees of self-consistency are obtained as can be verified by comparison with the Budd-Vannemenus theorem. Strong analogies to molecular binding are observed when comparing the behavior of the kinetic and potential energies versus separation to similar results obtained for  $H_2$  molecules by Feinberg and Ruedenberg. Crystallinity included in perturbation theory for the pseudopotential and a lattice sum for ionic potentials is found to be necessary for binding and agreement with experiment.

## APPENDIX I

### PSEUDOPOTENTIAL CORRECTION

We here present the derivations of Eqs. (70a) and (70b) for completeness since these derivations do not appear in the literature. The first term Eq. (69a) has a simple geometrical interpretation. The first term is the potential due to an array of sheets of charge with a surface density given by the proper planes of interest (e.g., fcc(111)). The second term is the potential due to the jellium charge density extending half an interplanar spacing on each side of a lattice plane. Thus the geometrical model for this term is a series of sheets of charge imbedded in the uniform distribution of charge with the jellium surface extending half an interplanar spacing beyond the first lattice plane. Let us first consider the first lattice plane since the extension to other planes is elementary. From elementary electrostatics and simple geometrical considerations the field due to the first sheet of charge is

$$E_1 = \pm 4\pi \frac{n_+ d}{2} \begin{cases} x > -d/2 \\ x < -d/2 \end{cases} \quad (11)$$

where  $d$  is the interplanar spacing and we are defining the electronic charge as positive. The field due to an element of jellium for  $x > -d/2$ .

$$E_2 = 4\pi M_+ \int_{-d/2}^x dx = 4\pi M_+ (x + d/2) \quad (12)$$

The total field is

$$E = E_1 + E_2 = 4\pi M_+ x = -dV_1/dx \quad (13)$$

For  $V = 0$  at  $x = 0$  we have

$$V_1 = -2\pi M_+ x^2 \quad 0 > x > -d/2 \quad (14)$$

for  $-d < x < -d/2$ , we again have

$$E_2 = 4\pi M_+ (x + d/2)$$

$$E = E_1 + E_2 = 4\pi M_+ (x + d) = -dV_2/dx \quad (15)$$

Requiring continuity of the potential at  $x = -d/2$  we get

$$V_2 = -2\pi M_+ (x + d)^2 \quad (16)$$

Eq. (70a) follows simply by extending this results to other lattice planes.

The second term in the pseudopotential (Eq. (69b)) is a plane-wise average of the difference between the coulomb potential and Ashcroft pseudopotential [73]. Thus the term is zero outside the ion-cores and the plane wise average of the coulomb potential within the ion cores. Considering only the left-half and the first plane of pseudo-ions as an example we can evaluate this term. The integral we wish to evaluate is thus

$$\delta V_z = \sum_v \int \frac{-Z dA}{[(x'-x_0)^2 + (y'-y_0)^2 + (z'-z_0)^2]^{3/2}} \quad (17)$$

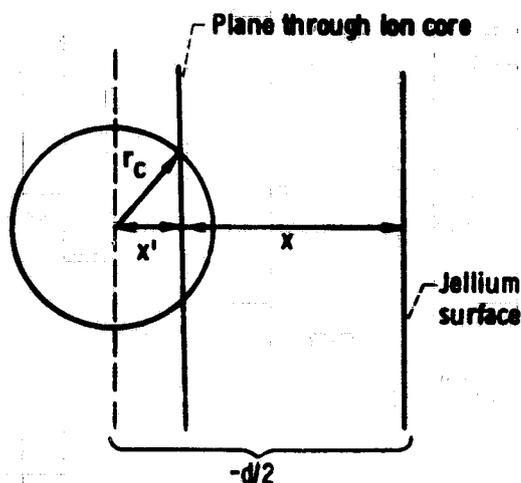

where  $A$  is the cross-sectional area and  $v$  is a summation index that locates the centers of the ions. Since the integrals over each ion core are identical choosing now a single plane and atom we can write

$$\delta V_z = -\frac{ZN_d}{A_d} \int \frac{dy'dz'}{[x'^2 + y'^2 + z'^2]^{3/2}} \quad (18)$$

where  $N$  is the total number of ion cores in the plane,  $A$  is the cross-sectional area and we are now integrating over a single ion core

$$m+d = \frac{ZN_d}{A_d} \quad (19)$$

We can now show the integration schematically with the following diagram

I.1. - Geometrical construction for the pseudo-potential contribution from the ion-core.

Transforming to cylindrical coordinates in the  $y$ - $z$  plane we have

$$\delta V_2 = -M+d \int_0^{\sqrt{r_c^2 - (x+d/2)^2}} \int_0^{2\pi} \frac{r dr d\phi}{[r^2 + (x+d/2)^2]^{1/2}} \quad (\text{I10})$$

integrating we get

$$\delta V_2 = 2\pi m+d (r_c - |x + \frac{1}{2}d|) \theta(r_c - |x + \frac{1}{2}d|) \quad (\text{I11})$$

where the Heaviside function restricts the contribution to within the ion core. Again the extension to the whole lattice in order to obtain Eq. (73b) follows easily.

## APPENDIX II

### LATTICE SUM

In this Appendix a more detailed presentation of the techniques used to derive the expression for the lattice sums in Eqs. (40a), (40b), and (40c) is presented. This again is included for completeness since Ferrante and Smith [28] outlined the procedure in their initial adhesion calculations. The evaluation of these terms will be presented for the specific case of an fcc(111) versus fcc(111) interaction as an example.

As stated in Eq. (38) the interaction energy is given by

$$W_{int}(a) = \int \frac{\rho_1(r) \rho_2(r')}{|r-r'|} dr dr' \quad (III)$$

where the subscripts 1 and 2 refer to the half space and  $\rho_i(r)$  is the net charge density ion minus jellium. The principle involved here is similar to the pseudopotential correction for the electron-ion interaction. The jellium-jellium interaction is subtracted out and the ion-ion interaction is added in. The difference in this case is that the result is exact. Thus we have a situation where calculationally we are evaluating the equivalent of the interaction energies of two periodic arrays of positive ions in a uniform distribution of negative charge. The primary contribution of this calculation is that it has extended the evalu-

ation of interaction energy to nonzero separation between the slabs which has been put to use in other calculations [32].

The charge density is given by

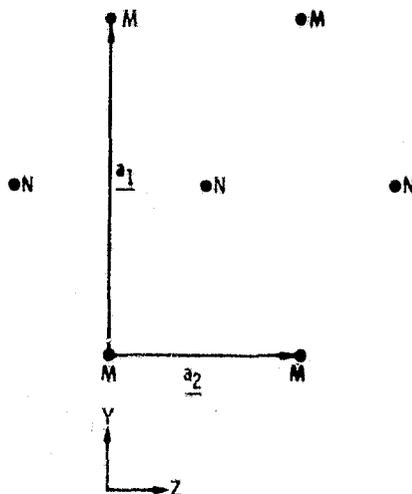

$$\rho(\underline{r}) = Z \sum_m \delta(x-x_m) \sum_l \sum_h \delta(y-y_l) \delta(z-z_h) - \sigma_1 \sum_m \delta(x-x_m) \quad (\text{II2})$$

where  $Z$  is the valence of the ions, the  $\delta$ 's are Dirac  $\delta$ -functions and  $\sigma_1$  is the charge per unit area of the jellium. The procedure applies only to the case in which the jellium from the two half-spaces do not overlap. The general procedure is to expand the density in a Fourier series giving

$$\rho(\underline{r}) = \sigma_1 \sum_m \delta(x-x_m) \sum_{l=-\infty}^{\infty} \sum_{h=-\infty}^{\infty} C_{m lh} e^{i g_l y} e^{i g_h z}$$

where  $g_l$  and  $g_h$  are components of reciprocal lattice vectors,  $C_{m lh}$  is a structure factor and the prime indicates that the terms  $g_l = g_h = 0$  has been omitted. This term cancels out the jellium background and gives a convergent series.

We now proceed with an example calculation to demonstrate the procedure used. Taking an fcc(111) surface we choose an orthogonal coordinate system as shown.

II.1. - Breakdown of fcc(111) or hcp(001) planes into two sublattices.

where  $\underline{a}_1$  and  $\underline{a}_2$  are basis vectors for the M mesh which has a unit cell area  $A_1$  where  $\underline{a}_1 = c_1 \sqrt{3} \hat{j}$ ;  $\underline{a}_2 = c_1 \hat{k}$  where  $\hat{j}$  and  $\hat{k}$  are unit vectors in the y and z directions and  $c_1$  is the nearest neighbor distance. The N sublattice can be located with respect to the M using the translation vector  $(\sqrt{3}/2)c_1 \hat{j} + (1/2)c_1 \hat{k}$ , thus we have a two-dimensional lattice with a basis. The fcc structure has ABC stacking. Let  $\rho^{(1A)}$  be the difference between the discrete charge density and the jellium charge density for the A-planes

$$\begin{aligned}
 \rho^{(1A)} &= -\sigma_1 \underbrace{\sum_{m_i} \delta(x' - x_{m_i}^{(A)})}_{\text{jellium}} \\
 &+ \underbrace{Z_2 \sum_{m_i} \sum_{h_i'} \sum_{l_i'} \delta(x - x_{m_i}^{(A)}) \delta(y' - \sqrt{3} c_1 h_i') \delta(z' - c_1 l_i')}_{\text{M-mesh}} \\
 &+ \underbrace{Z_1 \sum_{m_i} \sum_{h_i'} \sum_{l_i'} \delta(x - x_{m_i}^{(A)}) \delta(y - \sqrt{3} c_1 (h_i' + 1/2)) \delta(z' - c_1 l_i')}_{\text{N-mesh}}
 \end{aligned}
 \tag{II.3}$$

where the summation indices  $h_1'$  and  $l_1'$  locate points in the direct lattice.

This can then be expanded in a Fourier series with reciprocal lattice vectors determined by the standard procedures given by

$\underline{b}_1 = (\sqrt{3}/3c_1)\hat{j}$ ;  $\underline{b}_2 = (1/c_1)\hat{k}$  for the A planes giving

$$\begin{aligned} \rho^{(A)}(x', y', z') = & -\sigma_1 \sum_{m_1} \delta(x-x_{m_1}^{(A)}) + \frac{\sigma_1}{2} \sum_{m_1} \sum_{l_1} \sum_{h_1} \delta(x-x_{m_1}^{(A)}) \\ & \cdot \exp[(i2\pi/3c_1)h_1 y'] \exp[(i2\pi/c_1)l_1 z'] \\ & + \sigma_1/2 \sum_{m_1} \sum_{l_1} \sum_{h_1} \delta(x-x_{m_1}) \exp[(i2\pi/3c_1)\sqrt{3}h_1 y'] \\ & \cdot \exp[(i2\pi/c_1)l_1 z'] \exp[i\pi(h_1 + l_1)] \end{aligned}$$

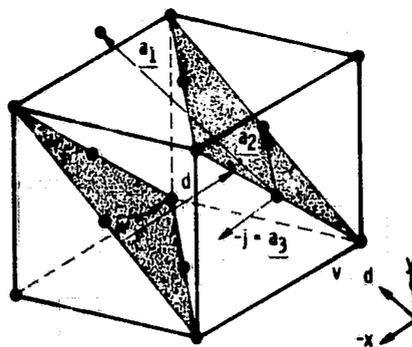

(II4)

where the  $h_1$  and  $l_1$  summations locate points in the planar reciprocal lattice.

The B set of planes can be located with respect to the A by the direct lattice vector  $(\sqrt{3}/3)c_1\hat{j}$  and the C set of planes by adding  $(\sqrt{3}/6)c_1\hat{j} + (1/2)c_1\hat{k}$ . For the total charge density which will be used in the potential we have

$$\rho^{(V)} = \rho^{(A)} + \rho^{(B)} + \rho^{(C)} \quad \text{(II5)}$$

An example of the three-dimensional lattice is shown in Figure II-2.

11.2. - Three-dimensional drawing showing coordinate axes and basis vectors for fcc(111) planes.

The potential at a point outside of the metallic half space is given by

$$\delta\phi^{(1)} = \int d\mathbf{r}' \frac{\rho^{(1)}(\mathbf{r}')}{|\mathbf{r} - \mathbf{r}'|} \quad (\text{II.6})$$

evaluating this integral we get

$$\begin{aligned} \delta\phi^{(1)} = & \frac{\sigma_1 c_1}{2} \sum_{m_i} \sum_{h_i, l_i} \left\{ \frac{1 + \exp[i\pi(h_i + l_i)]}{(l_i^2 + h_i^2/3)^{1/2}} \exp\left(i \frac{2\pi}{3c_1} \sqrt{3} h_i y\right) \right. \\ & \cdot \exp\left[i \frac{2\pi}{c_1} h_i z\right] \exp\left[-\frac{2\pi}{c_1} (x - x_{m_i}^{(A)}) (l_i^2 + h_i^2/3)^{1/2}\right] \\ & + \exp\left[\frac{i 2\pi}{c_1} h_i z\right] \exp\left[-\frac{2\pi}{c_1} (x - x_{m_i}^{(B)}) (l_i^2 + h_i^2/3)^{1/2}\right] \\ & \left. + \exp[i\pi(h_i/3 + l_i)] \exp\left[-\frac{2\pi}{c_1} (x - x_{m_i}^{(C)}) (l_i^2 + h_i^2/3)^{1/2}\right] \right\} \end{aligned}$$

(II.7)

In performing these integrals the following relationships have been used

$$\int_0^{\infty} dx \frac{\cos(\alpha x)}{(\beta^2 + x^2)^{1/2}} = K_0(\alpha\beta) \quad \alpha, \beta > 0$$

$$\int_0^{\infty} dx K_0(\alpha^2(x^2 + \beta^2)) \cos(\gamma x) = \frac{\pi}{2} \frac{\exp[-\beta(\alpha^2 + \gamma^2)^{1/2}]}{(\alpha^2 + \beta^2)^{1/2}}$$

for  $\text{Re}\alpha > 0$ ;  $\text{Re}\beta > 0$ , and  $\gamma > 0$  where  $K_0$  is the modified Bessel function of the second kind of order zero.

In order to calculate the interaction energy we perform the integral

$$W_{int}(a) = \int dr \rho^{(2)}(r) \delta\phi^{(1)} \quad (\text{II8})$$

where  $\rho^{(2)}(r)$  is the charge density in the second slab.

$W_{int}/A$  is composed of terms of the following form

$$\begin{aligned} & \frac{\sigma c_1^2}{4} \sum_{m_2, m_1} \sum_{l_1, h_1} \sum_{l_2, h_2} \frac{(1 + \exp[i\pi(h_2 + l_2)])(1 + \exp[i\pi(h_1 + l_1)])}{(l_1^2 + h_1^2/3)} \\ & \cdot \exp\left[-\frac{2\pi}{c_1}(x_{m_2}^{(A)} - x_{m_1}^{(A)})(l_1^2 + h_1^2/3)\right] \exp[i\pi(h_2/3 + l_2)] \\ & \cdot \iint \frac{dy dz}{A} \exp\left[\frac{2\pi i}{c_1}\left(\frac{h_1}{c_1} + \frac{h_2}{c_2}\right)\right] \exp\left[2\pi i\left(\frac{l_1}{c_1} + \frac{l_2}{c_2}\right)\right] \end{aligned} \quad (\text{II9})$$

where  $x_{m_1}^{(A)} = -3d(m_1 - 1) - (1/2)d$ ,  $x_{m_2}^{(A)} = 3d(m_2 - 1) + (1/2)d$  + a similar expressions can be derived for B and C planes [28]. We can see that the y-Z integrations give respectively Kronecker deltas in  $h_1, -h_2$  and  $l_1, -l_2$ , respectively. Finally since the sums extend from  $-\infty$  to  $\infty$  the terms can be simplified by com-

binning positive and negative terms to give trigonometric functions

and using the identity  $\sum_{m_1=1}^{\infty} \sum_{m_2=1}^{\infty} g(m_1 + m_2) = \sum_{m=1}^{\infty} mg(m)$  for the

planewise summations in the  $x$ -directions and considerable algebra we get Eq. (40a) for the fcc(111) lattice sum. The sums for the hcp(0001) and bcc(001) surfaces follow the same procedures with only the geometrical specifications of the lattice vectors and basis differing for these planes.

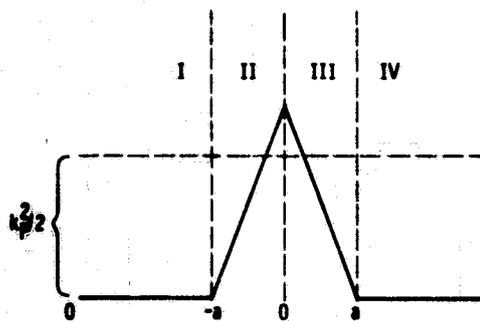

Another interesting aspect to this calculation is a consideration of what occurs in the lattice sum in the case that two dissimilar metals in contact. In this case we get nonregistry between the half spaces facing one another. This is equivalent to having  $h_2/c_2$  and  $l_2/c_2$  in the integrations shown in Eq. (II9), consequently instead of getting Kronecker  $\delta$ 's in the integers  $h$  and  $l$  we could only get a nonzero result for the lowest integer ratios  $\frac{l_1}{l_2} = -\frac{c_1}{c_2} = \frac{h_1}{h_2}$  (a more general discussion of this point is presented by Ferrante and Smith [28].) Since for most dissimilar materials this would be quite a large number the contribution to  $W_{int}$  for dissimilar materials would be quite small because of the exponential fall off in  $W_{int}$ . Consequently, we have two extremes for the inclusion of the ion-ion interaction registry which applies to the case of separating a perfect solid to nonregistry which applies to dissimilar metals in contact and for which the principle ionic con-

tribution is the jellium-jellium interaction of the leading term in the lattice sum.

### APPENDIX III

#### SOLUTION FOR THE TRIANGULAR POTENTIAL

There has been considerable interest in a linear ramp potential for simulation of the bare metal problem. Sahni and Grunebaum [74] have found the slope and barrier height which minimized the total Kohn-Sham energy and got good agreement with the self-consistent Lang-Kohn densities and energies. Although the solution for the triangular potential (Fig. III.1) was simply chosen to check the numerics in the present calculation inclusion of details of techniques used to solve the symmetric triangular potential are presented since they may be useful for metal-metal contact calculations.

III.1. - Triangular potential barrier.

The potential energy for this calculation is defined as follows.

$$V(x) = \begin{cases} 0 & x \leq -a \\ \alpha(x+a) & -a < x < 0 \\ \alpha(-x+a) & 0 \leq x \leq a \\ 0 & x > a \end{cases} \quad (\text{III1})$$

We have therefore for the Schroedinger equation in each region

$$\begin{aligned} \text{I} - & -\frac{1}{2} \frac{d^2\psi}{dx^2} = (k^2/2) \psi \\ \text{II} - & -\frac{1}{2} \frac{d^2\psi}{dx^2} + \alpha(x+a)\psi = (k^2/2) \psi \\ \text{III} - & -\frac{1}{2} \frac{d^2\psi}{dx^2} + \alpha(-x+a)\psi = (k^2/2) \psi \\ \text{IV} - & -\frac{1}{2} \frac{d^2\psi}{dx^2} = (k^2/2) \psi \end{aligned} \quad (\text{III2})$$

Considering Eqs. II and III we see that these can readily be cast in the form of Airy's equation [75] starting with region II we have

$$\frac{d^2\psi}{dx^2} - \gamma(x+a-E')\psi = 0 \quad (\text{III3})$$

where  $\gamma = 2\alpha$  and  $E' = k^2/2\alpha$ . We next make a variable transformation  $Z_1 = \gamma^{1/3}(x+a-E')$  giving

$$\frac{d^2\psi}{dZ_1^2} - Z_1\psi = 0 \quad (\text{III4})$$

which is Airy's equation. Using a similar procedure for region III

we obtain

$$\frac{d^2\psi}{dz_2^2} - z_2\psi = 0 \quad (\text{III5})$$

where  $z_2 = \gamma^{1/3}(-x + \alpha - E')$  following the procedure outlined in the THEORY section we have as one of the independent sets of solutions for a plane wave incident from the left

$$\psi_{kI} = A e^{ikx} + B e^{-ikx} \quad (\text{a.})$$

$$\psi_{kII} = C A_{ik}(z_1) + D B_{ik}(z_1) \quad (\text{b.})$$

$$\psi_{kIII} = E A_{ik}(z_2) + F B_{ik}(z_2) \quad (\text{c.})$$

$$\psi_{kIV} = e^{ikx} \quad (\text{d.})$$

(III6)

The particular normalization chosen is to facilitate mathematical simplicity of the solution. The wave functions must be renormalized by dividing by  $A$  at the end to satisfy the requirements of unit incident flux.  $A_1(z)$  and  $B_1(z)$  are the two independent solutions to Airy's equation and some useful identities used in the calculation are presented:

$$A_i(z) = \frac{1}{3} \sqrt{z} [I_{-1/3}(\rho) - I_{1/3}(\rho)] \quad (a.)$$

$$A_i(-z) = \frac{1}{3} \sqrt{z} [J_{-1/3}(\rho) + J_{1/3}(\rho)] \quad (b.)$$

$$B_i(z) = \sqrt{z/3} [I_{-1/3}(\rho) + I_{1/3}(\rho)] \quad (c.)$$

$$B_i(-z) = \sqrt{z/3} [J_{1/3}(\rho) - J_{-1/3}(\rho)] \quad (d.)$$

$$A_i'(z) = -\frac{1}{3} z [I_{-2/3}(\rho) - I_{2/3}(\rho)] \quad (e.)$$

$$A_i'(-z) = -\frac{1}{3} z [J_{-2/3}(\rho) - J_{2/3}(\rho)] \quad (f.)$$

$$B_i'(z) = (z/\sqrt{3}) [I_{-2/3}(\rho) + I_{2/3}(\rho)] \quad (g.)$$

$$B_i'(-z) = (z/\sqrt{3}) [J_{-2/3}(\rho) + J_{2/3}(\rho)] \quad (h.)$$

$$W \{ A_i(z), B_i(z) \} = 1/\pi \quad (i.)$$

(III7)

Where  $J$  and  $I$  are Bessel function and modified Bessel functions of the first kind,  $W$  is the Wronskian,  $\zeta = (2/3)z^{3/2}$  and the prime denotes the derivative.

We now proceed to obtain a solution by requiring continuity of the slope and function at each boundary.

At  $x = -a$

$$A e^{ika} + B e^{-ika} = C A_{ik}(z, x=-a) + D B_{ik}(z, x=-a) \quad (a.)$$

$$ikA e^{-ika} - ikB e^{ika} = \gamma^{1/3} C A_{ik}'(z, x=-a) + \gamma^{1/3} D B_{ik}'(z, x=-a) \quad (b.)$$

at  $x = 0$

$$C A_{ik}(z, x=0) + D B_{ik}(z, x=0) = E A_{ik}(z_2=0) + F B_{ik}(z_2=0) \quad (c.)$$

$$C A_{ik}'(z, x=0) + D B_{ik}'(z, x=0) = E A_{ik}'(z_2=0) + F B_{ik}'(z_2=0) \quad (d.)$$

(III8)

at  $x = a$

$$E A_{ik}(z_2=a) + F B_{ik}(z_2(x=a)) = e^{ika}$$

$$\gamma^{1/3} A'_{ik}(z_2(x=a)) + \delta^{1/3} F B'_{ik}(z_2(x=a)) = ik e^{ika}$$

Solving Eq. (III8) we get

$$E = \pi [e^{ika} B'_{ik}(z_2(x=a)) - ik \delta^{1/3} B_{ik}(z_2(x=a))] \equiv v_1 \quad (a)$$

$$F = \pi [ik \delta^{-1/3} A_{ik}(z_2(x=a)) - e^{ika} A'_{ik}(z_2(x=a))] \equiv v_2 \quad (b)$$

$$v_3 \equiv v_1 A_{ik}(z_2(x=0)) + v_2 B_{ik}(z_2(x=0)) \quad (c)$$

$$v_4 \equiv v_1 A'_{ik}(z_2(x=0)) + v_2 B'_{ik}(z_2(x=0)) \quad (d)$$

$$C = \pi [v_3 B'_{ik}(z_1(x=0)) - v_4 B_{ik}(z_1(x=0))] \quad (e)$$

$$D = \pi [v_3 A_{ik}(z_1(x=0)) - v_4 A'_{ik}(z_1(x=0))] \quad (f)$$

$$v_7 \equiv v_5 A_{ik}(z_1(x=-a)) + v_6 B_{ik}(z_1(x=-a)) \quad (g)$$

$$v_8 \equiv \gamma^{1/3} [v_5 A'_{ik}(z_1(x=-a)) + v_6 B'_{ik}(z_1(x=-a))] \quad (h)$$

$$A = (e^{ika}/ik) (ik v_7 + v_8) \quad (i)$$

$$B = (e^{-ika}/ik) (ik v_7 - v_8) \quad (j)$$

(III9)

The results are then inserted into Eq. (58b) in order to calculate the number density. The resulting density is then compared with the number density obtained numerically (Fig. 7) for the same potential for  $k_F = 1$  and  $a = 1$  au. As can be seen the results are quite good.

## APPENDIX IV

### KINETIC ENERGY INTEGRALS

In this Appendix we will justify the approach used for calculation of the kinetic energy (Eq. (62)) and point out the differences with the Lang-Kohn [7] (Eq. (26)) approach which is a generalization of the Huntington [16] approach. An excellent discussion of the latter is given by Sugiyama [76]. The starting point for the two expressions is basically the same, namely, using the Schroedinger equation to define the single particle kinetic energy as the difference between the eigenvalue  $\epsilon_i$  and the potential energy per particle. The approach, however, in obtaining the sums over the states is quite different in that the L-K approach is basically macroscopic and ours is basically microscopic. In the L-K expression the sum over eigenvalues is examined before and after creating the surface. Starting with particles in a box creating a surface in the middle of the box causes a shift in the density of states in k-space because the k-values undergo a shift in value  $k \rightarrow k + \Delta k$ . Therefore, for a crystal of length  $2L$  the new values of  $k$  are given by

$$k = \frac{n\pi}{L} - \frac{\gamma(\frac{n\pi}{2L})}{L}$$

or

$$k = k' - \frac{\gamma(k')}{L}$$

(IV1)

where  $n$  is an integer and  $\gamma(k)$  is the phase shift in the wave function deep in the bulk caused by scattering from the surface potential (Eq. (19)) and the  $k'$  are the  $k$ -values before creation of the surface. The term  $\gamma(k)/L$  is of order  $1/L$ . We can think of the change in terms of the infinite potential barrier as a change in the size of the box of the order of a lattice spacing. With a real potential, however, the phase shift depends on  $k$ , unlike the infinite potential barrier. L-K proceed to derive an expression for the kinetic energy in terms of the change in the sum over eigenvalues.

$$\sum_{\substack{k, k_y, k_z \\ \text{occ.}}} \frac{(k^2 + k_y^2 + k_z^2)}{2} \quad (\text{IV2})$$

between the split and unsplit crystal and in terms of the phase shift  $\gamma(k)$ . For the bare metal calculation  $\gamma(k)$  can be easily determined.

In this work the kinetic energy is determined in terms of a twofold integration in  $k$  and configuration space in terms of the exact wave functions (Eq. (60)). Proceeding in general for the  $k$ -space integration we have

$$\sum_{\substack{k, k_y, k_z \\ \text{occ.}}} f(k, x) \quad (\text{IV3})$$

where  $f(k, x)$  is some function of  $k$  such as the arguments of the integrals presented in Eq. (60). In converting the sum to an integral using the Euler-McClaurin formula [75] we get

$\int_0^{n_m} dn f(k, x)$  ignoring higher order terms (referring now only to the x-direction) where  $n_m$  is the highest occupied state. The density of states in k-space  $A_k(n)$  has shifted from the profile in a box value to

$$\frac{dn}{dk} = \frac{2L}{\pi} \left( 1 + \frac{1}{L} \frac{d\delta}{dk} \right) = \frac{2L}{\pi} \left( 1 + \frac{\delta'}{L} \right) = D_m(k) \quad (\text{IV4})$$

where  $\delta'$  is the derivative with respect to  $k$ . In converting to a k-space integration we get

$$\frac{2L}{\pi} \int_0^{k_F} dk f(k, x) + \frac{2L}{\pi} \left\{ \frac{1}{L} \int_0^{k_F} dk \delta'(k) f(k, x) \right\} \quad (\text{IV5})$$

therefore, in using the particle in a box density of states we are ignoring terms of order  $1/L$  (the second term in (IV5)). We must next consider the errors in the x-integration. We can assume  $C = (x_0/L)$  is constant where  $x_0$  is the length of the jellium in the computational space in order to neglect the effects of slab length on integrating the second term in configuration space (x-integration in Eq. (60)). The next consideration is selecting  $x_0$  such that the deviation of the density from bulk conditions (Eq. (80)) is sufficiently small. This was checked by comparing the result of using Eq. (60) to the Lang-Kohn values of the kinetic energy for the bare metal case with integral values of  $r_s$ .

## APPENDIX V

## Spline Curve

AUTHOR:

R. Bruce Conright, Jr.

PURPOSE:To provide a function  $y = f(x)$  which interpolates for a given table of data points  $(x_i, y_i)$ USAGE:

To fit data, the call

**CALL SPLINI(X, Y, NPTS, BO, BN, J)**

where

- X - the array of points  $x_i$  in ascending order
- Y - the array of corresponding  $y_i$
- NPTS - the number of these points
- BO - the boundary condition at lower  $x$  boundary
- BN - the boundary condition at upper  $x$  boundary
- J = -1, the boundary conditions are the slopes  $dy/dx$
- = 2, the boundary conditions are  $d^2y/dx^2$

is required. After this, the spline fit is available through two entry points in SPLINI:

YY = F(XX) where

XX independent variable, within the range of the  $x_i$ .

YY resultant interpolated Y value at XX.

and

DY = DF(XX) where

XX as above

DY approximate slope  $dy/dx$  at XX.RESTRICTIONS:

- 1)  $3 < NPTS \leq 50$
- 2)  $X(1) \leq XX \leq X(NPTS)$

ERROR MESSAGES:

When the input X is out of the range specified, a warning message is printed. The return is normal, but the answer is generally meaningless.

METHOD:

The curve-fit is a set of cubic equations passed piece-wise through each pair of data points, constrained to match the derivatives at the data points. The fit is therefore very "smooth", excellent for interpolation or plotting. It is not to be used for extrapolation. Further this spline fit is not intended for large batches of data with scatter, noise, etc., because the fit passes exactly through every data point.

The method requires the boundary conditions to specify completely the solutions to the interpolation equations (reference). It is usually sufficient to say that the  $d^2y/dx^2$  at the boundary are zero, whenever the boundary conditions are not known.

ACCURACY:

Dependent on the input data. DF is about one s.f. less accurate than F.

SUBPROGRAMS USED:

None

## APPENDIX VI

# PROGRAMMERS MANUAL

## LEWIS RESEARCH CENTER

11/70

QSF/DQSF

## NUMERICAL INTEGRATION

IDENTIFICATION:

IBM Scientific Subroutine Package

PURPOSE:

To compute the vector of integral values for a given equidistant table of function values.

USAGE:

CALL QSF(H, Y, Z, NDIM) for single precision, or

CALL DQSF(H, Y, Z, NDIM) for double precision.

where

- H - The increment of argument values.
- Y - The input vector of function values.
- Z - The resulting vector of integral values.  
Z may be identical with Y.
- NDIM - The dimension of vectors Y and Z.

**DOUBLE PRECISION:** H, Y, and Z must be declared double precision in the calling program if the call is to DQSF.

RESTRICTIONS:

NDIM must be 3 or greater.

METHOD:

To compute the vector of integral values:

$$z_i = z(x_i) = \int_a^{x_i} y(x) dx \quad \left. \vphantom{\int_a^{x_i} y(x) dx} \right\} (i = 1, 2, \dots, n)$$

with  $x_i = a + (i-1)h$

for a table of function values  $y_i (i = 1, 2, \dots, n)$ , given at equidistant points  $x_i = a + (i-1)h (i = 1, 2, \dots, n)$ , Simpson's rule together with Newton's 3/8 rule or a combination of these two rules is used. Local truncation error is of the order  $h^5$  in all cases with more than three points in the given table. No action takes place if the table consists of less than three sample points.

The function to be integrated is assumed to be continuous and differentiable (three or four times, depending on the rule used).

Formulas used in this subroutine ( $z_j$  are integral values,  $y_j$  function values) are:

$$z_j = z_{j-1} + \frac{h}{3} (1.25 y_{j-1} + 2y_j - 0.25 y_{j+1}) \quad (1)$$

$$z_j = z_{j-2} + \frac{h}{3} (y_{j-2} + 4y_{j-1} + y_j) \quad \text{(Simpson's rule)} \quad (2)$$

$$z_j = z_{j-3} + \frac{3}{8} h (y_{j-3} + 3y_{j-2} + 3y_{j-1} + y_j) \quad \text{(Newton's 3/8 rule)} \quad (3)$$

# PROGRAMMERS MANUAL

## LEWIS RESEARCH CENTER

11/70

$$z_j = z_{j-5} + \frac{h}{3} (y_{j-5} + 3.875 y_{j-4} + 2.625 y_{j-3} + 2.625 y_{j-2} + 3.875 y_{j-1} + y_j) \quad (4)$$

[combination of (2) and (3)]

Sometimes formula (2) is used in the following form:

$$z_j = z_{j+2} - \frac{h}{3} (y_j + 4 y_{j+1} + y_{j+2}) \quad (5)$$

ERROR MESSAGES: NoneACCURACY: Local truncation error is of the order  $h^5$  in all cases with more than three points in the given table.SUBPROGRAMS USED: NoneREFERENCES: Hildebrand, F. B. Introduction to Numerical Analysis. McGraw-Hill, New York, 1956.

DET5/DDET5

## NUMERICAL DIFFERENTIATION

ORIGINAL PAGE IS  
OF POOR QUALITY

**IDENTIFICATION:**

IBM Scientific Subroutine Package

**PURPOSE:**

To compute a vector of derivative values given a vector of function values whose entries correspond to equidistantly spaced argument values.

**USAGE:**

CALL DET5 (H, Y, Z, NDIM, IER) for single precision, or

CALL DDET5 (H, Y, Z, NDIM, IER) for double precision.

where

- H - Constant difference between successive argument values. H is positive for increasing argument values and negative otherwise.
- Y - Given vector of function values (dimension NDIM).
- Z - Resulting vector of derivative values (dimension NDIM).
- NDIM - Dimension of vectors Y and Z.
- IER - Resulting error parameter.

If IER = -1, NDIM is less than 5 and there is no computation.

If IER = 0, there is no error.

If IER = 1, H is equal to 0 and there is no computation.

**DOUBLE PRECISION:** H, Y, and Z must be declared double precision in the calling program if the call is to DDET5.

**NOTE:** Z can have the same storage location as Y. If Y is distinct from Z then it is not destroyed.

**RESTRICTIONS:**

H must be greater than zero, and NDIM must be greater than 5.

**METHOD:**

If X is the suppressed vector of argument values, then except at the points  $X(1)$ ,  $X(2)$ ,  $X(NDIM-1)$ , and  $X(NDIM)$ ,  $Z(I)$  is the derivative at  $X(I)$  of the Lagrangian interpolation polynomial of degree 4. The polynomial is relevant to the 5 successive points  $(X(I+K), Y(I+K))$  with  $K = -2, -1, 0, 1, 2$ .

**ERROR MESSAGES:**

None

**ACCURACY:**

Dependent upon the characteristics of the input data.

**SUBPROGRAMS USED:**

None

APPENDIX IX

COMPONENTS OF BINDING ENERGY

This Appendix contains tables of the components of the binding energies for each material and each separation used. All energies are references to the 15 atomic units separation values at which point the adhesive energy had essentially saturated. The following defines the symbols.

$\alpha$	Separation between slabs in atomic units
$\sigma_s$	The kinetic energy in ergs/cm <sup>2</sup>
$\sigma_{xc}$	The sum of the exchange and correlation energies in ergs/cm <sup>2</sup>
$\sigma_{es}$	The sum of the electrostatic energy and Wint in ergs/cm <sup>2</sup>
$\sigma_{ps}$	The pseudopotential contribution to the energy in ergs/cm <sup>2</sup>
$\sigma_{NL}$	The nonlocal contribution to the energy in ergs/cm <sup>2</sup>
$\sigma_u = \sigma_s + \sigma_{xc} + \sigma_{es} - Wint$	The jellium contribution to the energy in ergs/cm <sup>2</sup>
$\sigma_T$	The total adhesive bonding energy in ergs/cm <sup>2</sup>

## APPENDIX X

### SELF-CONSISTENT POTENTIALS AND DENSITIES

In this Appendix the self-consistent potentials and densities are listed in order of increasing  $r_s$  values. Each element is treated as a section. The ordering is LDA followed by nonlocal values. The superscript + indicates self-consistent densities obtained by minimizing the cohesive energy. Each element is presented in order of increasing separation. The first entry is the first point at the computational space-bulk boundary. The  $x$ -values are readily obtained knowing the  $x$ -value of the first entry and the mesh spacing which are included in the following table. The symmetry point is readily recognized as the minimum in the density or the maximum in the potential. Each listing contains a few entries past the symmetry point. The maximum number of separations were calculated for Mg in order to Separate Force Curves.

Separation, au	x-value of first entry, au	Mesh size, au	Entry of sym- metry point
0.25	-15.0	0.125	121
.50	-15.0	.25	61
