Produced by the NASA Center for Aerospace Information (CASI)
On May 20, 1976, by memorandum LC-5-363 from this office, you were requested to process document release authorizations for documents generated by the Space Shuttle Engineering and Operations Support Contract NAS 9-14960 according to the following criteria:

a. "May be announced in STAR (or CSTAR if classified)."

b. "May be made publicly available, except (1) classified material which should be released to security qualified requestors only, and (2) documents which may be released overseas that come under the jurisdiction of the Federal Early Domestic Dissemination Program."

The above referenced contract has been superseded by NAS 9-15550, but the processing of document release authorizations should continue to be guided by the same criteria. If any additional clarification of this criteria is needed, such requests should be addressed to LC/R. B. Merrifield, ext. 2091.
SUBJECT: TRANSMITTAL OF WORKING PAPER 1.4-7-245
ENCL: Remote Manipulator System Flexibility Analysis Program

To: NASA/LYNDON B. JOHNSON SPACE CENTER
2101 NASA ROAD 1
HOUSTON, TEXAS 77058

ATTN: Use Brief Informal Language

REMARKS:

Two programs 'A' and 'B' have been developed on the Hewlett Packard-9825.

Program 'A' calculates the flexibility coefficients for the Remote Manipulator System (RMS) modeled as five beams with each beam composed of an arbitrary number of segments.

Program 'B' calculates the end-effector arm flexibility and the joint flexibility terms for the torque motor model for any arbitrary arm configuration.

1.0 SUMMARY

The 'Payload Deployment and Retrieval System Simulation' (PDRSS) program, which is currently in use for simulating the Remote Manipulator System (RMS) does not have the capability to update the flexibility coefficients as the arm design changes. Any standard structural program can be used to calculate these coefficients. However, most of these structural programs require large computers and the associated turn-around time and expense make them unattractive for calculating just the flexibility coefficients. A program (called 'Program A' in this report) has been developed on the Hewlett Packard-9825 to calculate these flexibility coefficients.

Another program (called 'Program B') has been developed to cut down the number of PDRSS runs required to simulate various RMS maneuvers. This program calculates the end-effector flexibility and the joint flexibility terms for the torque motor model of each joint for any arbitrary arm configuration. Instead of making expensive PDRSS runs for all the required arm operations, program 'B' can be used to select those which involve stiffest arm configurations. Figure 2 shows the use of programs 'A' and 'B' in conjunction with the PDRSS program. Flexibility coefficients calculated by 'A' are required as input to 'B'.

Section 2.0 describes the purpose of this task in greater detail. Equations used in 'A' and 'B' are presented in Section 3.0.

Appendix A discusses the mathematical basis for the equations used in 'A' and 'B'.

Appendix B familiarizes the user with the procedure required to access the programs 'A' and 'B', the input parameters required and the output obtained.

Appendix C presents the results which are obtained through the use of programs 'A' and 'B' for two example problems and compares them with the PDRSS results. Appendix D contains the listing of programs 'A' and 'B'.
2.0 INTRODUCTION

The 'Payload Deployment and Retrieval System Simulation' (PDRSS) program, which is currently in use for simulating the RMS, uses a five beam model to represent the arm. In this model, flexibility coefficients for each of the five beams are required to simulate the arm motion and the loads generated during any commanded arm operation. At present, the flexibility coefficients built-into the PDRSS program, have been calculated by assuming beam one is between the attach point and the shoulder pitch joint and is composed of three different segments. Similarly, beam two is between the shoulder pitch joint and the elbow pitch joint and is composed of three segments; beam three is between the elbow pitch joint and the wrist pitch joint and consists of three segments; beam four is between the wrist pitch joint and yaw joint and consists of two segments; beam five is between the wrist yaw joint and the end effector and consists of three segments. The above model is shown in Figure 1.

The PDRSS program does not have the capability to update the flexibility coefficients as the arm design changes. Any standard structural program can be used to calculate these flexibility coefficients but most of these programs use large computers and the turn-around time and expense involved make them unattractive. Therefore, it was recognized that a program is needed, which could be run on a desk-type computer, to calculate the flexibility coefficients for the arm modeled by any given number of beams each consisting of an arbitrary number of segments. This led to the first objective of this task, i.e., to develop a program on the Hewlett-Packard 9825 to calculate the flexibility coefficients. The second objective of this task was to develop the capability to determine the arm flexibility in any given configuration, i.e., deflection at the end-effector due to unit loads at the end effector for any arbitrary arm configuration. This information would be useful in making a judgement regarding the arm stiffness and thereby anticipating its natural frequency and loads in a given configuration.
For example, to assure that design loads are not exceeded during arm operation, instead of making expensive PDRSS runs for all the required arm operations we can select those which involve arm configurations with higher stiffnesses. To this end another H. P. program has been developed which determines end-effector arm flexibility, when given the individual beam flexibility coefficients and the arm configuration (characterized by specifying six joint angles). This program has been further extended to determine the flexibility coefficients for the torque motor model at each joint. When studying simplified simulation techniques which could be used instead of PDRSS, flexibility for the torque motor model can be calculated with the above program. The use of programs 'A' and 'B' in conjunction with the PDRSS program to simulate the arm is shown in Figure 2.

NOTE: ARM FLEXIBILITY IS CALCULATED IN THE WRIST-PITCH SYSTEM

Figure 1
Figure 2
3.0 ANALYSIS

Equations used in programs 'A' and 'B' are presented below. Program 'A' uses the standard load/deflection relationship for a beam to calculate the flexibility coefficients. Three rotational and two displacement degrees of freedom are assumed for each beam. In the RMS simulation it is assumed that the displacement along the beam axis is negligible; therefore, the flexibility coefficient in the axial direction is taken to be zero. Program 'B' uses the flexibility coefficients of each beam to calculate the combined arm flexibility at the end-effector. Program 'B' takes into account the effect of arm configuration by using transformation matrices to transform all the flexibility coefficients into the wrist-pitch system. Through the use of the Jacobian matrix, program 'B' uses the end-effector flexibility coefficients to calculate the flexibility at each of the six RMS joints. It further calculates, the joint flexibility terms for the torque motor model at each joint. Appendix A presents the derivation which leads to the equations used in program 'A' and 'B'.

3.1 PROGRAM 'A'

For a beam consisting of n segments, the load/deflection relationship is given by

\[
\begin{align*}
\{ E_R^n \} & = \begin{bmatrix} L_n & \alpha & \ldots & \alpha & \ldots & \alpha \end{bmatrix} \begin{bmatrix} L_{n-1} & \alpha & \ldots & \alpha & \ldots & \alpha \\ 0 & L_n & \ldots & 0 & \ldots & 0 \\ 0 & 0 & \ldots & L_{n-1} \end{bmatrix} \{ \varepsilon_L^1 \} \\
\{ P_R^n \} & = \begin{bmatrix} L_1 & 0 & \ldots & 0 \end{bmatrix} \begin{bmatrix} \alpha \end{bmatrix} \{ \varepsilon_L^1 \} \\
\end{align*}
\]

(1)
where

\[
L^n = \begin{pmatrix} 1 & z_n \\ 0 & 1 \end{pmatrix}, \quad \alpha^n = \begin{pmatrix} \frac{z^2_n}{2EI_2} & \frac{z^3_n}{6EI_2} \\ \frac{z_n}{EI_2} & \frac{z^2_n}{2EI_2} \end{pmatrix}
\]

\[
E_R^n = \begin{pmatrix} \gamma_{RN} \\ \phi_{RN} \end{pmatrix}, \quad P_R^n = \begin{pmatrix} M_{RN} \\ F_{RN} \end{pmatrix}, \quad G = \begin{pmatrix} 0 & 0 \\ 0 & 0 \end{pmatrix}
\]

Superscript \( n \) = Number of Segment  
Subscript \( L \) = L.H.S. of Segment  
Subscript \( R \) = R.H.S. of Segment  
\( z_n \) = Length of \( n \)th Segment  
\( E \) = Young's Modulus, \( n \)th Segment  
\( I_2 \) = Moment of Inertia About the Z-Axis, \( n \)th Segment  
\( Y_{RN} \) = Displacement at R.H.S. of \( n \)th Segment in the Y-Direction.  
\( \phi_{RN} \) = Rotation at R.H.S. of \( n \)th Segment About the Z-Axis  
\( M_{RN} \) = Bending Moment Applied at R.H.S. of \( n \)th Segment About the Z-Axis  
\( F_{RN} \) = Force Applied at R.H.S. of \( n \)th Segment in the Y-Direction

Another Equation, Similar to (1) can be written for bending about the Y-Axis. The only difference would be the moment of inertia about the Y-Axis, \( I_1 \), instead of \( I_2 \). For torsional flexibility, the torque/rotation relationship is given by

\[
\Theta_R^n = \sum_{K=1}^{n} \frac{\tau_K}{G_K J_K} \tau_R^n \quad (2)
\]
where \( \Phi_R^n = \) Rotation at R.H.S. of nth Segment About the Beam Axis

\( \tau_R^n = \) Applied Torque at R.H.S. of nth Segment About the Beam Axis

\( G_n = \) Shear Modulus of nth Segment

\( J_n = \) Polar Moment of Inertia of nth Segment

In Program 'A' Equations (1) and (2) have been programmed to calculate flexibility coefficients of a beam consisting of arbitrary number of segments \( n \).

3.2 PROGRAM 'B'

For the RMS consisting of five beams, end-effector flexibility \((\gamma_E)\) in the Wrist-Pitch System is given by

\[
\{\gamma_E\} = \sum_{i=1}^{5} \begin{pmatrix} I & 0 \\ -r_{i5} & I \end{pmatrix} \begin{pmatrix} T_{i1} & 0 & Y_{11} & Y_{12} \\ 0 & T_{i1} & Y_{12} & Y_{22} \end{pmatrix} \begin{pmatrix} T_{iW} & 0 \\ 0 & T_{iW} \end{pmatrix} \begin{pmatrix} I & r_{i5} \end{pmatrix} \tag{3}
\]

where \(-r_{i5} = -\sum_{k=1}^{4} r_K\)

\( r_K = \begin{pmatrix} 0 & -r_K^3 & r_K^2 \\ r_K^3 & 0 & -r_K^1 \\ -r_K^2 & r_K^1 & 0 \end{pmatrix} \)

where \( r_K^j = \) Length of \((K + 1)\)th Beam in jth Direction, \( K = 1, 2, 3, 4 \)

\( j = 1, 2, 3 \)

Superscripts \( j = 1, 2, 3 \) Represent \( X, Y, Z \) Axes of the Orbiter Coordinate System, Respectively.
$T_{Wi}$, $i = 1, 2, 3, 4, 5$ are the transformation matrices from the beam $i$ system to the $W$. Pitch system. $Y_{11}^i$, $Y_{12}^i$, $Y_{22}^i$, $i = 1, 2, 3, 4, 5$ are the matrices of flexibility coefficients of beam $i$.

The joint flexibility matrix is given by

$$\{Y_J\} = \{J^{-1}\} \{Y_E\} \{J^{-T}\}$$

(4)

and the flexibility term for the torque motor model at each joint is:

$$Y_i^e = Y_{iiJ} - \{Y_{iJ}^{21}\}^T \{Y_{iJ}^{22}\}^{-1} \{Y_{iJ}^{21}\} i = 1, 2, 3, 4,$$

(5)

$\{Y_{iJ}^{22}\}$ is a 5x5 matrix derived from $\{Y_J\}$ by deleting the $i$th row and column. $i$ being the number of the joint. $\{Y_{iJ}^{21}\}$ is a 5x1 matrix derived from $\{Y_J\}$ by taking the $i$th column and deleting the $i$th element.

Equations (3), (4) and (5) are used in Program 'B' to calculate the end-effector flexibility, joint flexibility and the flexibility terms for the torque motor model.
4.0 CONCLUSIONS AND RECOMMENDATIONS

Two computer programs, 'A' and 'B', on the Hewlett-Packard 9825 have been developed incorporating the computations described in the previous section. The input and output data formats of these programs are described in Appendix B, sample results are in Appendix C and Program Listings are in Appendix D. Conclusions and recommendations related to the use of these programs are summarized below.

Program 'A' is used to calculate flexibility coefficients for the example problem 1 in Appendix C-1. Flexibility coefficients for beams 2 and 3 as calculated by Program 'A' are presented in Appendix C-3.1 along with corresponding flexibility coefficients currently used in the PDRSS. Comparing the two we conclude that they match closely. The difference in 2nd and 3rd decimal place: (8 and 9 significant figures) is attributed to different number of significant figures in the two machines.

Program 'B' is used to calculate the end-effector arm flexibility for the example problem 2 in Appendix C-2. For comparison, end-effector arm flexibility calculated by Program 'B' is presented in Appendix C.3-2 along with end-effector flexibility calculated by PDRSS. We again conclude that these flexibility coefficients match almost exactly. Again, the insignificant difference is attributed to the different machines used to compute these coefficients.

We have concluded from the execution of the sample problems that the formulation and implementation of the programs is correct. The programs are available for use. Further information may be obtained by contacting the author, Lalit Kumar, at McDonnell Douglas Technical Services Company, 488-5660, Extension 216.
5.0 REFERENCES

For a cantilever beam of length \( L \) shown in Figure A-1, the deflection due to end load \( F \) is given by

\[
\gamma_F = \frac{L^3}{3EI_2} F \tag{A-1}
\]

The deflection due to moment \( M \) is:

\[
\gamma_M = \frac{L^2}{2EI_2} M \tag{A-2}
\]

The total deflection is:

\[
\gamma = \gamma_F + \gamma_M = -\frac{L^3}{3EI_2} F + \frac{L^2}{2EI_2} M \tag{A-3}
\]

Similarly, Total Rotation/Slope is given by:

\[
\phi = \frac{L^2}{2EI_2} F + \frac{L}{EI_2} M \tag{A-4}
\]

where \( E \) = Young's Modulus

\( I_2 \) = Moment of Inertia of the Beam Crosssection About the Z-Axis

\( I_1 \) = Moment of Inertia of the Beam Crosssection About the Y-Axis
For an arbitrary uniform beam segment loaded as shown in Figure A-2:

\[ \phi_R = \phi_L + \frac{\ell}{E_2} M_R - \frac{\ell^2}{2E_2} F_R \quad \text{(A-5)} \]

\[ Y_R = Y_L + \ell \phi_L + \frac{\ell^2}{2E_2} M_R - \frac{\ell^3}{3E_2} F_R \quad \text{(A-6)} \]

\[ M_L = M_R - \ell F_L \quad \text{(A-7)} \]

\[ F_L = F_R \quad \text{(A-8)} \]

Rearranging Equations A-5, --- A-8 and writing in matrix form:

\[
\begin{bmatrix}
Y_R \\
\phi_R \\
M_R \\
F_R
\end{bmatrix} =
\begin{bmatrix}
1 & \ell & \ell^2/2E_2 & \ell^3/6E_2 \\
0 & 1 & \ell/E_2 & \ell^2/2E_2 \\
0 & 0 & 1 & \ell \\
0 & 0 & 0 & 1
\end{bmatrix}
\begin{bmatrix}
Y_L \\
\phi_L \\
M_L \\
F_L
\end{bmatrix}
\quad \text{(A-9)}
\]

In partitioned form:

\[
\begin{bmatrix}
\xi_R \\
P_R
\end{bmatrix} =
\begin{bmatrix}
L & \alpha \\
0 & L
\end{bmatrix}
\begin{bmatrix}
\xi_L \\
P_L
\end{bmatrix}
\quad \text{(A-10)}
\]
where \( L = \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} \), \( \alpha = \begin{bmatrix} 2^2/2Ei_2 & 3^3/6Ei_2 \\ 2^2/Ei_2 & 2^2/2Ei_2 \end{bmatrix} \), \( 0 = \begin{bmatrix} 0 & 0 \\ 0 & 0 \end{bmatrix} \)

Similarly for two consecutive segments

\[
\begin{bmatrix} \xi_R^1 \\ \xi_L^1 \end{bmatrix} = \begin{bmatrix} L^1 & \alpha^1 \\ 0 & L^1 \end{bmatrix} \begin{bmatrix} \xi_R^1 \\ \xi_L^1 \end{bmatrix}
\]

\[
\begin{bmatrix} P_R^1 \\ P_L^1 \end{bmatrix} = \begin{bmatrix} 0 & L^1 \\ 0 & 0 \end{bmatrix} \begin{bmatrix} P_R^1 \\ P_L^1 \end{bmatrix}
\]

\[\text{(A-11)}\]

and

\[
\begin{bmatrix} \xi_R^2 \\ \xi_L^2 \end{bmatrix} = \begin{bmatrix} L^2 & \alpha^2 \\ 0 & L^2 \end{bmatrix} \begin{bmatrix} \xi_R^2 \\ \xi_L^2 \end{bmatrix}
\]

\[\text{(A-12)}\]

but

\[
\begin{bmatrix} \xi_R^1 \\ \xi_L^2 \end{bmatrix} = \begin{bmatrix} \xi_R^1 \\ P_L^2 \end{bmatrix}
\]

\[\text{(A-13)}\]

Therefore by substitution

\[
\begin{bmatrix} \xi_R^2 \\ \xi_L^1 \end{bmatrix} = \begin{bmatrix} L^2 & \alpha^2 \\ 0 & L^2 \end{bmatrix} \begin{bmatrix} L^1 & \alpha^1 \\ 0 & L^1 \end{bmatrix} \begin{bmatrix} \xi_R^1 \\ \xi_L^1 \end{bmatrix}
\]

\[\text{(A-14)}\]

For \( n \) consecutive segments

\[
\begin{bmatrix} \xi_R^n \\ \xi_L^n \end{bmatrix} = \begin{bmatrix} L^n & \alpha^n \\ 0 & L^n \end{bmatrix} \begin{bmatrix} L^{n-1} & \alpha^{n-1} \\ 0 & L^{n-1} \end{bmatrix} \begin{bmatrix} L^1 & \alpha^1 \\ 0 & L^1 \end{bmatrix} \begin{bmatrix} \xi_R^1 \\ \xi_L^1 \end{bmatrix}
\]

\[\text{(A-15)}\]

Subscript Refers to the Segment Number

Subscript \( L \) = L.H.S. of Beam

Subscript \( R \) = R.H.S. of Beam
By Definition

\[ \{\delta\} = \{A\} \begin{bmatrix} F \end{bmatrix} \]

6x1  6x6  6x1

Where \( \delta \) is the deflection due to load \( F \) and \( A \) is a 6x6 matrix of flexibility coefficients. Writing \( A \) in expanded form

\[
\begin{pmatrix}
\delta_{\theta_x} \\
\delta_{\theta_y} \\
\delta_{\theta_z} \\
\delta_x \\
\delta_y \\
\delta_z
\end{pmatrix} = \begin{pmatrix}
A_{11} & A_{12} & A_{13} & A_{14} & A_{15} & A_{16} \\
A_{21} & A_{22} & A_{23} & A_{24} & A_{25} & A_{26} \\
A_{31} & A_{32} & A_{33} & A_{34} & A_{35} & A_{36} \\
A_{41} & A_{42} & A_{43} & A_{44} & A_{45} & A_{46} \\
A_{51} & A_{52} & A_{53} & A_{54} & A_{55} & A_{56} \\
A_{61} & A_{62} & A_{63} & A_{64} & A_{65} & A_{66}
\end{pmatrix} \begin{pmatrix}
M_x \\
M_y \\
M_z \\
F_x \\
F_y \\
F_z
\end{pmatrix}
\]

(A-17)

In our model we assume zero flexibility along the beam longitudinal axis, say, X-axis. \( A_{4i} = 0, \ i = 1, 2, 3, 4, 5, 6 \)

Since, by definition \( A \) is symmetric, \( A_{i4} = A_{4i} = 0, \ i = 1, 2, 3, 4, 5, 6 \)

Also, for a beam \( A_{12} = A_{13} = A_{14} = A_{15} = A_{16} = 0 \)

\( A_{23} = A_{24} = A_{25} = 0 \)

\( A_{34} = A_{36} = 0 \)

\( A_{56} = 0 \)

And due to symmetry \( A_{21} = A_{31} = A_{41} = A_{51} = A_{61} = A_{32} = A_{42} = A_{52} = A_{43} = A_{63} = A_{65} = 0 \)
Therefore the flexibility matrix $A$ reduces to

$$
\begin{pmatrix}
A_{11} & 0 & 0 & 0 & 0 & 0 \\
0 & A_{22} & 0 & 0 & 0 & A_{26} \\
0 & 0 & A_{33} & 0 & A_{35} & 0 \\
0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & A_{35} & 0 & A_{55} & 0 \\
0 & A_{26} & 0 & 0 & 0 & A_{66}
\end{pmatrix}
$$

(A-18)

i.e., seven non-zero flexibility coefficients need to be determined. For a single beam segment, using equations A-5 and A-6

$$
A_{22} = \frac{\ell}{E_{11}}, \quad A_{33} = \frac{\ell}{E_{12}}, \quad A_{55} = \frac{\ell^3}{3E_{12}}
$$

$$
A_{66} = -\frac{\ell^3}{3E_{11}}, \quad A_{26} = \frac{\ell^2}{2E_{11}}, \quad A_{35} = -\frac{\ell^2}{2E_{12}}
$$

$$
A_{11} = \text{Torsional Flexibility} = \frac{\ell}{GJ}
$$

For a beam consisting of more than one segment, $A_{22}, A_{33}, A_{55}, A_{66}, A_{35}, A_{26}$ are calculated using equation A-15 and rewriting it in the form of equations A-5, A-6, A-7, A-8

$$
\text{And } A_{11} = \frac{\ell_1}{G_{1}J_{1}} + \frac{\ell_2}{G_{2}J_{2}} + \cdots + \frac{\ell_n}{G_{n}J_{n}}
$$

(A-20)

The above equations have been programmed to calculate the flexibility coefficients of beams given the lengths, Young's modulus, moment of inertias about the two bending axes, shear modulus (G) and polar moment of inertia (J) of each segment.
The flexibility matrix, \( A \) for a beam can be written in the following form
\[
A = \begin{pmatrix}
Y_{11} & Y_{12} \\
Y_{12} & Y_{22}
\end{pmatrix}
\quad (A-21)
\]
where
\[
Y_{11} = \begin{pmatrix}
A_{11} & 0 & 0 \\
0 & A_{22} & 0 \\
0 & 0 & A_{33}
\end{pmatrix}, \quad Y_{12} = \begin{pmatrix}
0 & 0 & 0 \\
0 & 0 & A_{26} \\
0 & A_{35} & 0
\end{pmatrix}
\]
and
\[
Y_{22} = \begin{pmatrix}
0 & 0 & 0 \\
0 & A_{55} & 0 \\
0 & 0 & A_{65}
\end{pmatrix}
\]

From Reference 1, Page 14, the End-Effector Flexibility \( \{Y_E\} \) is given by
\[
\{Y_E\} = \sum_{i=1}^{n-1} \begin{pmatrix}
1 & 0 \\
-r_{i5} & 1
\end{pmatrix} \begin{pmatrix} T_{W1} & 0 & \{Y_{11} \_ i}^{T} \_ T_{iW} & 0 \\
0 & T_{W1} & \{Y_{12} \_ i}^{T} \_ T_{iW} & 0 \\
\end{pmatrix} \begin{pmatrix}
1 & r_{i5} \\
0 & 1
\end{pmatrix}
\quad (A-22)
\]
where
\[
-r_{i5} = \sum_{K=i}^{4} r_{K}^{J}
\]
\[
r_{K} = \begin{pmatrix}
0 & -r_{K}^{3} & r_{K}^{2} \\
r_{K}^{3} & 0 & -r_{K}^{1} \\
-r_{K}^{2} & r_{K}^{1} & 0
\end{pmatrix}
\]
\( r_{K}^{J} \) = length of \( K+1 \) beam in \( j \)th direction
Superscripts 1, 2, 3 Represent \( X, Y, Z \) Axes of Orbiter Coordinate System, Respectively.
\( T_{Bi} \), \( i = 1, 2, 3, 4, 5 \)
is the transformation matrix from beam \( i \) system to N. Pitch system.

\( Y_{11}^i, Y_{12}^i, Y_{22}^i \), \( i = 1, 2, 3, 4, 5 \)
Are the matrices of flexibility coefficients of beam \( i \).

Equation A-22 has been programmed to determine the End-Effector flexibility
given the length of each beam, orientation of the arm (characterized by 6
joint angles) and the seven flexibility coefficients for each beam.

The joint flexibility matrix \( \{Y\}_{j} \) is derived as follows:
The End-Effector flexibility relationship can be expressed as

\[
\begin{bmatrix}
\delta_e
\end{bmatrix} = \begin{bmatrix}
Y_e
\end{bmatrix} \begin{bmatrix}
F_e
\end{bmatrix}
\]
\tag{A-23}

Where \( \{\delta_e\} \) is a 6x1 matrix containing three rotations and three deflections,
\( \{F_e\} \) is a 6x1 force matrix containing three moments and three forces;
\( \{Y_e\} \) is a 6x6 flexibility matrix.

End-Effector deflections can be related uniquely to joint rotations using the
rate law (valid only for 6 joint system), Reference 2.

\[
\begin{bmatrix}
J
\end{bmatrix} \begin{bmatrix}
\delta\theta
\end{bmatrix} = \begin{bmatrix}
\delta_e
\end{bmatrix}
\]
\tag{A-24}

\( \{J\} \) = 6x6 Jacobian matrix for the given arm (6 Joints) configuration.
\( \{\delta\theta\} \) = 6x1 matrix of rotations at each of the 6 Joints

Similarly End-Effector loads can be related to joint torques

\[
\{\tau_F\} = \{J\}^T \{F_e\}, \quad \{\tau_F\} = 6x1 \text{ Matrix of Joint Torques}
\]
\tag{A-25}

Or \( \{J\}^{-1} \{\tau_F\} = \{F_e\} \)
\tag{A-26}

Substituting for \( F_e \) and \( \delta_e \) in Equation A-23, we get
\[
\begin{align*}
\{J\} \{\delta \theta\} &= \{\gamma e\} \{J\}^T \{\tau_F\} \\
\text{Or} \quad \{\delta \theta\} &= \{J\}^{-1} \{\gamma e\} \{J\}^T \{\tau_F\} \\
\text{From A-27} \quad \{\gamma J\} &= \{J\} \{\gamma e\} \{J\}^T \{\tau_F\} \\
\text{Equation A-28 has been used to calculate the joint flexibility.}
\end{align*}
\]

Flexibility terms for the torque motor model at each joint are calculated from \{\gamma J\} matrix as follows:

\[
\gamma_i = \gamma_{iJ} - \left( \gamma_{iJ}^{21} \right)^T \left( \gamma_{iJ}^{22} \right)^{-1} \left( \gamma_{iJ}^{21} \right) \quad i = 1, 2, 3, 4, 5, 6 \quad (A-29)
\]

Where \(\gamma_{iJ}^{22}\) is the 5x5 matrix derived from \(\gamma_{iJ}\) by deleting the \(i\)th row and column, \(i\) being the number of joint. \(\gamma_{iJ}^{21}\) is the 5x1 matrix derived from \(\gamma_{iJ}\) by taking the \(i\)th column and deleting the \(i\)th element.
APPENDIX B

PROGRAM USAGE

The following programs may be obtained from L. Kumar, 488-5660, Ext. 217.

B.1 CALCULATION OF FLEXIBILITY COEFFICIENTS - PROGRAM A

To access the program and run it, the following procedure is required:

Step 1  Load the tape on HP-9825, labeled side of the tape toward the back of HP-9825.

Step 2  Turn on the calculator and the printer.

Step 3  Access the appropriate track number by typing trk \ 1 and pressing the EXECUTE key. \ indicates a blank space.

Step 4  Load the appropriate file by typing ldf \ 3 and pressing the EXECUTE key.

Step 5  Run the program by pressing the RUN key.
## Input Parameters

Once the program is running several self-explanatory messages are displayed. The following explains the displays and inputs required sequentially.

<table>
<thead>
<tr>
<th>HP-9825 Display</th>
<th>Display Duration</th>
<th>Response Required From User</th>
</tr>
</thead>
<tbody>
<tr>
<td>(1) Beam One, First Cross Axis</td>
<td>2 Secs</td>
<td>No Response Required, Info only</td>
</tr>
<tr>
<td>(2) No. of segments</td>
<td></td>
<td>Input the number of segments in beam 1 and press &quot;Continue&quot; key</td>
</tr>
<tr>
<td>(3) Notation used for segment K</td>
<td>2 Secs</td>
<td>No resp. req., Info only</td>
</tr>
<tr>
<td>(4) L [K] = Length, Inches</td>
<td>2 Secs</td>
<td>No resp. req., Info only</td>
</tr>
<tr>

</tr>
<tr>
<td>(18) Beam two, first cross axis</td>
<td>2 Secs</td>
<td>No resp. req., Info. only</td>
</tr>
</tbody>
</table>

Display will start again from Line (2). Input parameters for Beam 2 from Line (2) to (17).

| (19) Beam three, first cross axis | 2 Secs | No Resp. req. Info. only |
| (20) Beam four, first cross axis | 2 Secs | No Resp. req. Info. only |
| (21) Beam Five, First Cross Axis | 2 Secs | No Resp. req. Info. only |

Start again from line (2). Input Beam 3 parameters from Line (2) to (17).

(22) End

NOTE: Currently the program has been set-up for five beams but it can easily be extended to any number of beams by simply changing the beam counter variable YO.
Program Output

Referring to Eqn. A-15, for any beam consisting of several segments we can write

\[
\begin{pmatrix}
Y_R \\
\phi_R \\
M_R \\
F_R
\end{pmatrix}
= \begin{pmatrix}
L & \alpha \\
0 & L
\end{pmatrix}
\begin{pmatrix}
Y_L \\
\phi_L \\
M_L \\
F_L
\end{pmatrix}
\]

where \( L \) is a 2x2 matrix given by \( \begin{pmatrix} L_K | L_K^{-1} | \ldots | L_1 \end{pmatrix} \)

\( K = \text{No. of segments}, \quad \begin{pmatrix} L_K \\
0 \end{pmatrix} = \begin{pmatrix} 1 & L_K \\
0 & 1 \end{pmatrix} \)

\( \alpha \) is a 2x2 matrix given by

\( \alpha' = \begin{pmatrix} L_K | L_K^{-1} | \ldots | L_2 | \alpha_2 \end{pmatrix} + \begin{pmatrix} L_K | L_K^{-1} | \ldots | \alpha_1 | L_1 \end{pmatrix} + \ldots + \begin{pmatrix} \alpha_K | L_K^{-1} | \ldots | L_1 \end{pmatrix} \)

The program outputs matrix \( L \) and \( \alpha \) in each cross-axis for beam 1 to beam 5, followed by flexibility coefficients Gamma [1]... Gamma [7].
Interpretation of Gamma $i$, $i = 1, 2, 3, 4, 5, 6, 7$

Numerical values of Gamma $i$, $i = 1, 2, 3, 4, 5, 6, 7$ as calculated by the program are correct but the signs for some of the Gammas might be reversed due to loading direction chosen in Equations A-3 and A-4. The following signs are associated with each of the Gammas.

Gamma $i$, $i = 1, 2, 3$ are the rotations in radians about axes $x$, $y$, $z$ or $x$, $z$, $y$ (depending upon whether first cross axis is the Y-Axis or Z-Axis) for unit loads in Ft-Lb applied about axes $x$, $y$, $z$ or $x$, $z$, $y$ respectively. These three Gammas are always positive.

If first cross axis is the Y-Axis

Gamma 5 = Disp. in Z-Dir. For Unit Force in Z-Dir. (FT/LB) Always Positive.
Gamma 4 = Disp. in Y-Dir. For Unit Force in Y-Dir. (FT/LB) Always Positive.
Gamma 6 = Rot. About Y-Axis For Unit Force in Z-Dir. (Rad/LB.) Always Negative.
Gamma 7 = Rot. About Z-Axis For Unit Force in Y-Dir. (Rad/LB.) Always Positive.

If first cross axis is the Z-Axis

Gamma 5 = Disp. in Y-Dir. For Unit Force in Y-Dir. (FT/LB) Always Positive.
Gamma 4 = Disp. in Z-Dir. For Unit Force in Z-Dir. (FT/LB) Always Positive.
Gamma 7 = Rot. About Y-Axis For Unit Force in Z-Dir. (Rad/LB.) Always Negative.

End of the program
PROGRAM OUTPUT DESCRIPTION

Output obtained depends upon the user's choice. The following data (except the components of beam lengths in the wrist-pitch system and the joint flexibility terms for the torque motor model which is always printed) is optional and can be printed or not printed.

(i) Transformation matrices - from beam coordinate systems to orbiter system.

(ii) End-Effector arm flexibility in W-pitch system i.e., if

\{\delta e\} is a 6x1 deflection matrix at the E.E. due to \{P_e\} loads at the E.E. then \{\delta e\} = \{Y\} \{P_e\}. And \{Y\} is the 6x6 E.E. flexibility matrix.

(iii) Jacobian 6x6 matrix for the given arm configuration

(iv) Joint flexibility matrix. For a six joint system, six rotations (one rotation at each joint) can be related to torques at each joint thru joint flexibility matrix.

\{\delta \theta\} = \{Y_J\} \{\tau_f\}, \{Y_J\} = Jt. Flex. Matrix.
### Example 1

Calculate the flexibility coefficients of an arm composed of five beams with the following number of segments, section and material properties.

**Beam 1**

Number of segments = 3

<table>
<thead>

C.2 Example 2

Calculate end effector arm flexibility in the wrist-pitch system for a five beam arm defined by the following beam lengths and orientation. Use the built-in flexibility coefficients for each beam.

Outboard Roll Angle = 19.2°
Shoulder Yaw Angle = 0.0°
Shoulder Pitch Angle = 90.0°
Elbow Pitch Angle = -30.0°
Wrist Pitch Angle = 30.0°
Wrist Yaw Angle = 0.0°
Hand Roll Angle = 0.0°
Beam 1 Length, FT = 2.874083
Beam 2 Length, FT = 20.920833
Beam 3 Length, FT = 23.1625
Beam 4 Length, FT = 1.5
Beam 5 Length, FT = 4.416667
Output From Program B

The following output is obtained by answering "Yes" to all the print options available.

OUTBOARD ROLL ANGLE=r0
SHOULDER YAW ANGLE=r1
SHOULDER PITCH ANGLE=r2
ELBOW PITCH ANGLE=r3
WRIST PITCH ANGLE=r4
WRIST YAW ANGLE=r5
HAND ROLL ANGLE=r6
ATTACH PT. TO SHOULDER PITCH LENGTH=r7
SHOULDER PITCH TO ELBOW PITCH LENGTH=r8
ELBOW PITCH TO WRIST PITCH LENGTH=r9
WRIST PITCH TO WRIST YAW LENGTH=r10
WRIST YAW TO END EFFECTOR LENGTH=r11
