The combination of a “C” mode scan electronics in a portable, battery powered biomedical ultrasonoscope having “A” and “M” mode scan electronics, the latter including a clock generator for generating clock pulses, a cathode ray tube having X, Y and Z axis inputs, a sweep generator connected between the clock generator and the X axis input of the cathode ray tube for generating a cathode ray sweep signal synchronized by the clock pulses, and a receiver adapted to be connected to the Z axis input of the cathode ray tube. The “C” mode scan electronics comprises a plurality of transducer elements arranged in a row and adapted to be positioned on the skin of the patient’s body for converting a pulsed electrical signal to a pulsed ultrasonic signal, radiating the ultrasonic signal into the patient’s body, picking up the echoes reflected from interfaces in the patient’s body and converting the echoes to electrical signals; a plurality of transmitters, each transmitter being coupled to a respective transducer for transmitting a pulsed electrical signal thereto and for transmitting the converted electrical echo signals directly to the receiver, a sequencer connected between the clock generator and the plurality of transmitters and responsive to the clock pulses for firing the transmitters in cyclic order; and a staircase voltage generator connected between the clock generator and the Y axis input of the cathode ray tube for generating a staircase voltage having steps synchronized by the clock pulses.

BIOMEDICAL ULTRASONOSCOPE
ORIGIN OF THE INVENTION

The invention described herein was made by an employee of the United States Government and may be manufactured and used by or for the Government for governmental purposes without the payment of any royalties thereon or therefor.

BACKGROUND OF THE INVENTION

1. Field of the Invention

The present invention relates generally to ultrasonic devices of the pulse-echo type, and more particularly to such devices which are suited for examination of the interior of a patient's body for non-invasive medical diagnosis.

2. Description of the Prior Art

Ultrasonic pulse-echo systems have heretofore been proposed for the examination of the interior of a patient's body. The present echocardiograph, echocardiograph, echocarriograph, or ultrasonoscope displays inter-bio-organs with a single ultrasonic element transducer by non-invasive techniques and with the aid of mechanical and/or electrical devices to provide several different types of displays. These include mechanical linear, arc hand held sector, compound scans, and their respective types of displays. The most common ultrasonic diagnostic instrument in use is the echocardiograph which utilizes a hand-held single ultrasonic element transducer for non-invasive examination of heart patients. The single ultrasonic element transducer echocardiograph provides "A" mode and "M" mode oscilloscope (CRT) visual displays.

None of the known biomedical ultrasonoscopes is capable of a selection of visual displays including "C" mode scan as well as the common "A" and "M" modes. Furthermore, conventional biomedical ultrasonoscopes are large and bulky, and incapable of portable, battery powered operation.

BRIEF SUMMARY OF THE INVENTION

It is therefore one object of the present invention to provide an improved biomedical ultrasonoscope.

It is another object to provide an improved biomedical ultrasonoscope which permits a thorough diagnostic examination while being as simple and as compact as possible.

It is yet another object to provide an improved biomedical ultrasonoscope incorporating "C" mode, "A" mode, and "M" mode scans while being as simple and as compact as possible.

The objects of the present invention are achieved by the combination of "C" mode scan means in a biomedical ultrasonoscope having "A" and "M" mode scan means, the latter including a clock generator for generating clock pulses, a cathode ray tube having X, Y, and Z axis inputs, a sweep generator connected between the clock generator and the Y axis input of the cathode ray tube for generating a cathode ray sweep signal synchronized by the clock pulses, and a receiver adapted to be connected to the Z axis input of the cathode ray tube. The "C" mode scan means comprises transducer means including a plurality of transducer elements arranged in a row and adapted to be positioned on the skin of the patient's body for converting a pulsed electrical signal to a pulsed ultrasonic signal, radiating the ultrasonic signal into the patient's body, picking up the echoes reflected from interfaces in the patient's body and converting the echoes to electrical signals; a plurality of transmitters, each transmitter being coupled to a respective transducer for transmitting a pulsed electrical signal thereto and for transmitting the converted electrical echo signals directly to the receiver; sequencer means connected between the clock generator and the plurality of transmitters and responsive to the clock pulses for firing the transmitters in cyclic order; and a staircase voltage generator connected between the clock generator and the Y axis input of the cathode ray tube for generating a staircase voltage having steps synchronized by the clock pulses.

An important feature of the invention is the use of a single or common receiver, whereas some "C" mode display instruments utilize separate receivers for each transducer in the array.

Another important feature of the invention is that it permits the use of COS/MOS integrated logic circuit components so as to minimize power consumption.

The foregoing as well as other objects, features, and advantages of the present invention will become more apparent from the following detailed description taken in conjunction with the appended drawings.

BRIEF DESCRIPTION OF THE DRAWINGS

FIG. 1 is an isometric view of the exterior structure of the ultrasonoscope of this invention.
FIG. 2 is a block diagram of a preferred embodiment of the ultrasonoscope of this invention.
FIG. 3 shows the representation obtained by display of the echo signals on the screen of the cathode ray tube with "A" mode scan.
FIG. 4 shows the representation obtained by display of the echo signals on the screen of the cathode ray tube with "M" mode scan.
FIG. 5 shows the representation obtained by display of the echo signals on the screen of the cathode ray tube with "C" mode scan.
FIGS. 6 and 7 collectively show a schematic circuit diagram of the "C" mode scan means of the preferred embodiment of the ultrasonoscope of this invention.
FIGS. 8(a) to (h) is a first series of waveforms produced at various points in the schematic circuit diagram of FIG. 6 and 7.
FIGS. 9(a) to (e) is a second series of waveforms produced at various points in the schematic circuit diagram of FIG. 6 and 7.

DESCRIPTION OF THE PREFERRED EMBODIMENT

FIG. 1 illustrates, in isometric view, the exterior structure of the portable, battery powered ultrasonoscope of the invention which is provided for the examination of the interior of a patient's body. FIG. 2 illustrates the invention in block form. A master clock generator generates a repetitive clock pulse which is fed as a trigger pulse to a transmitter. The transmitter transmits an electrical pulse to an ultrasonic transducer which is positioned on the skin of the patient's body. The transducer converts the electrical signal to an ultrasonic pulse which it radiates into the patient's body from the end of the transducer. Echoes are reflected from the surface of the body and from interfaces in the body. The echoes are picked up by the transducer and converted to electrical echo signals. The electrical echo signals are applied to a receiver. The receiver receives the electrical echo signals and feeds...
them to a cathode ray tube 21. The signal generated by
the master clock generator 13 is also fed as a trigger pulse to a time-base sweep generator 23. The time-base
sweep generator 23 generates a sawtooth time-base
signal. The time-base sweep signal is applied to
the X axis input of the cathode ray tube 21 to horizon-
tally deflect a spot of light produced on the screen of
the cathode ray tube synchronously with the pulsing of the transducer 17. "A" mode scan and "M" mode scan
are combined in the ultrasonoscope. In "A" mode, the
signal from the receiver 19 is applied to the Y axis input
of the cathode ray tube 21. In "M" mode the signal from the receiver 19 is applied to the Z axis input of
the cathode ray tube 21.

FIG. 3 illustrates "A" mode scan wherein the echoes are presented as vertical deflections of the trace or
"pips" on the screen, and since the time delay between a transmitted pulse and the received echo depends on
the distance between the transducer to the reflecting interface, the depth of the reflecting interface from the
top of the cathode ray is represented along the X axis. The signal generated by the master clock generator 13
is also fed to a depth marker generator 25. The depth
marker generator 25 generates repetitive pulses which are fed to the Y axis input of the cathode ray tube 21 to provide depth markers along the base line of the display. In FIGS. 3 and 4, depth markers are denoted by the numeral 53.

In accordance with the present invention, the ul-
trasonoscope is further provided with "C" mode scan
means outlined by the broken line 27.

In "C" mode, the repetitive clock pulses generated by
the master clock generator 13 are fed as trigger pulses to a staircase voltage generator 29 over connections repre-
sented by lead 31. The staircase voltage generator 29 generates a staircase voltage signal whose steps are in
sync with the clock pulses. The staircase signal is ap-
plicated over connections represented by lead 33 to the Y axis input of the cathode ray tube 21. The signal gener-
ated by the master clock generator 13 is also fed to a sequencer 35 over lead 37. The sequencer 35 is provided
with a plurality of output terminals whose number
(N + 4) where N is a positive integer, is determined by
the desired resolution of the display, and may amount to
24 for example. The sequencer 35 is set by the clock pulse to initiate a trigger pulse at each one of its out-put
terminals in time sequence. The second output terminal
and the second-from-last output terminal are connected to the depth marker generator 25 over connections represented by lead 39. The second and second-from-
last trigger pulses in the sequence cause display of the
depth markers at the bottom and top of the screen of the
cathode ray tube. A plurality 41 of transmitters, N in number, are connected respectively to the third
through third-from-last output terminals of the se-
quencer 35. Each of the next trigger pulses after the first two in the sequence fire the transmitters 41 in cyc-
ic order. Each transmitter transmits an electrical pulse over connections represented by lead 43 to a respective
one of an array of N ultrasonic transducers 45 arranged
in a row and positioned on the skin of the patient's body.

The respective transducer converts electrical signal to an ultrasonic pulse which is radiated into the patient's body from the end of the transducer. The echoes are
picked up by the transducer and converted to electrical
echo signals. The electrical echo signals are applied to
the receiver 19 over connections represented by lead 47. The last output terminal of the sequencer is con-
ected to a bias voltage generator 49. The last trigger
pulse in the sequence causes the bias voltage generator 49 to generate a bias voltage for offsetting the vertical
position of the staircase voltage half a raster line from
that of the previous frame on the screen of the cathode ray tube 21. The bias voltage signal is applied over connections represented by lead 51 to the Y axis input of
the cathode ray tube.

In "C" mode, the receiver signal is applied to the Z
axis input of the cathode ray tube 21.

FIG. 5 illustrates "C" mode scan wherein the echoes are represented as a brightening or intensity modulation
of the cathode ray. The vertical position of the cathode ray corresponds at any time with the position of the active transducer in the array. The depth of the reflect-
ing interface from the plane of the transducer is repre-
sented along the X axis. The number of horizontal lines in the frame is selected as twice the number of transduc-
ers plus two extra lines at the top and bottom for depth
markers. The bias voltage applied to the Y axis input produces the visual effect of having twice the number of ultrasonic transducers in the array, thereby enhanc-
ing the display. Depth markers are denoted by the num-
eral 53. The representation obtained on the screen of the cathode ray tube provides a two dimensional or cross-sectional image of anatomical organs or structures or the like, in which all displacements, for instance, of the heart wall, can be observed.

The prime embodiment of this invention is more par-
ticularly described with reference to FIG. 6 and 7
which collectively show a schematic circuit diagram of
the "C" mode scan means of the ultrasonoscope of this
invention. The circuits outlined in FIG. 6 and 7 by broken lines carry the same reference numbers as the blocks in FIG. 2.

Enclosed by a broken line 29 is the staircase voltage
generator. A non-inverting amplifier 55 is connected to input lead 31. The output of the amplifier 55 is connected to the first input of the positive logic NOR gate 57 whose output forms the input of the positive logic NOR gate 59. The output of the amplifier 55 is also connected to the clock input CL of the 7-stage binary counter 63 and the set output Q of the D-type flip-flop 61 is connected to the reset input R of the binary counter 63. The outputs of the stages of the binary counter 63 are connected to an analog-to-digital conversion resistor ladder network 65 whose output is coupled through source follower 67 to lead 33. When each clock pulse appears on lead 31, the output of the NOR gate 57 goes low in opposition to a high at its inputs. The output of the NOR gate 59 is thereby caused to go high and the binary counter 63 is energized causing a voltage waveform to appear across the ladder network 65 and to be coupled through the source follower 67 to the Y-axis input of the cathode ray tube 21.

Enclosed by the broken line 35 is the sequencer. The output of the non-inverting amplifier 55 is connected.
by lead 68 to the clock input CL of the units decade counter 69 to start a count of units and the set output P of the D-type flip-flop 61 is connected by lead 70 to the reset input R of the units decade counter 69. A tens decade counter 71 is cascaded with the units decade counter 69 and driven thereby to indicate tens. The outputs of the stages of the units decade counter 69 are connected to the data inputs IN of the bilateral pulse switches PSN-2 through PSN+2, the output of the first stage being connected to every tenth pulse switch starting with PSN-2, the output of the second stage being connected to every tenth pulse switch starting with PSN-1, and so forth. The outputs of the stages of the tens decade counter 71 are connected to the control inputs VC of the bilateral pulse switches PSN-2 through PSN+2, the output of the first stage being connected to the first ten pulse switches, the output of the second stage being connected to the second ten pulse switches and so forth. The outputs OUT of the bilateral pulse switches PSN-2 through PSN+2 are connected to ground through the resistors R and the second bilateral switch PSN-1 and the second from last bilateral pulse switch PSN+1 are connected through the diodes 73 and 75 to the pulse amplifier driver 77 whose output is connected by lead 39 to the depth marker generator 25. The outputs of the third through third from last pulse switches PS3 through PSN are connected to the pulse amplifiers A1 through AN. The operation of the sequence 35 will now be described in conjunction with FIG. 7 and the waveforms illustrated in the timing diagrams of FIG. 8. The clock pulses have a waveform as illustrated in FIG. 8(a). Let it be assumed that the units decade counter 69 and the tens decade counter 71 have been reset by a positive going pulse at their reset inputs R. When the first clock pulse appears on lead 31 the clock input CL of the units decade counter 69 goes high in response to a high at the output of the amplifier 35. A voltage pulse Pn-2 with a waveform as shown in FIG. 8(c) then appears at the output of the first stage of the units decade counter 69 and also at the data inputs IN of every tenth bilateral pulse switch starting with the first switch PSN-2. In order for the pulse Pn-2 to pass through the switches to their outputs OUT, a positive voltage is required at the switch control inputs VC. This voltage is derived from the output of the first stage of the tens decade counter 71 and appears only for the first ten pulses switches PSN-9 through PS9. Thus only the pulse switch PSN-9 is turned on, allowing the pulse Pn-2 to pass through to its output OUT and across the resistor R. In the meantime, the step S11-2 of the staircase voltage waveform shown in FIG. 8(b) is generated and the staircase voltage is allowed time to settle during retrace. When the second clock pulse appears on lead 31, the clock input CL of the units decade counter 71 goes high and a voltage pulse Pn-1 with a waveform as shown in FIG. 8(d) appears at the output of the second stage of the units decade counter 69. This clock pulse also initiates step S18-1 of the staircase voltage waveform shown in FIG. 8(b). With a positive voltage at the control input VC of the bilateral pulse switch PSN-1 from the output of the first stage of the tens decade counter 71 pulse switch PSN-1 is turned on next. The pulse Pn-1 passes through the switch, appears across the resistor R and is coupled through the diode 73 to the pulse amplifier driver 77. When the third clock pulse appears on lead 31, the staircase voltage is advanced another step to step S1 as shown in FIG. 8(b) and a voltage pulse P1 with a waveform as shown in FIG. 8(e) is caused to appear at the output of the third stage of the units decade counter 69 and at the input of pulse switch P5 and every tenth pulse switch thereafter. Only pulse switch PS1 is turned on because only its control input VC voltage is high and the pulse P1 passes through the pulse switch PS1 to the first pulse amplifier A1. The sequence of events described for pulse P1 is then repeated for each of the pulses P2 through P9. The voltage pulse P10 is the tenth pulse event for the units decade counter 69. The next clock pulse initiates two events. The first event is that the units decade counter 69 recycles producing pulse P0 at the output of its first stage. The second event is that a positive going pulse from the output CO of the units decade counter 69 is coupled to the input CL of the tens decade counter 71. This latter pulse turns off the positive voltage at the output of the first stage of the tens decade counter 71 and replaces it with a positive voltage at the output of the second stage so that the control inputs VC of the pulse switches PS9 through PS10 now are caused to go high. Pulse switch PS9 is turned on and the pulse P9 passes through to the ninth pulse amplifier A9. The succeeding clock pulses cause the pulses P10 through P9 to be passed through the pulse amplifiers PS10 through PS9. The waveform of the voltage pulse PS9 is shown in FIG. 8(f), and the corresponding step S9 of the staircase voltage waveform is illustrated in FIG. 8(b). When the (N+1)th clock pulse appears on lead 31, the staircase voltage is advanced to step S1+1 as shown in FIG. 8(b) and a voltage pulse P1+1 with a waveform as shown in FIG. 8(g) is caused to appear at the output of the corresponding stage of the units decade counter 69 and at the data input IN of the pulse switch PSN+1. The pulse P1+1 passes through the pulse switch PSN+1, appears across the resistor R and is coupled through the diode 75 to the pulse amplifier driver 77. Finally, when the (N+2)th clock pulse appears on lead 31, a voltage pulse P1+2 with a waveform as shown in FIG. 8(h) occurs at the data input IN of the pulse switch PSN+2. The pulse P1+2 passes through the pulse switch PSN+2 to the direct set input S of the D-type flip-flop 79 causing its set output Q to go high, thereby resetting the binary counter 63, the units decade counter 69, and the tens decade counter 71 for a new cycle of operations. Enclosed by a broken line 41 in FIG. 2 are the ultra-sonic transmitters TX1-TXN and analog switches S1-SN. Only pulse -ASN. Only the details of the first transmitter TX1 have been illustrated since each of the N transmitters is identical. The output of the pulse amplifier A1 is connected to the junction of the control input VC of the analog switch AS1 and the resistor R1. The resistor R1 is connected by a parallel combination of the resistor R2 and the capacitor C1 to ground. Resistor R1 is also connected to ground through the capacitor C2 and the parallel combination of the diode CR1 and the primary winding of the transformer T1. A silicon controlled rectifier SCR1, shunted by the resistor R5, is connected at its gate through the resistor R3 to one of the secondary windings of the transformer T1, and at its cathode to ground through the diode CR2. A silicon controlled rectifier SCR2, shunted by the resistor R6, is connected at its gate through the resistor R4 to another secondary winding of the transformer T1, at its cathode to the anode of the silicon controlled rectifier SCR1 through the diode CR3 and at its anode to the high voltage HV through the series circuit of the coil L1, the decoupling diode CR9 and the resistor R9, and to ground through the capacitor C3 and the diode CR4. The junction of
the diode CR9 and the resistor R9 is connected to
ground through the capacitor C5. The junction of the
capacitor C3 and the diode CR4 is connected through the
diode CR5 to the junction of the first ultrasonic
transducer, the resistor RD and the capacitor C4. The
capacitor C4 is connected to ground through the parallel
combination of diodes CR7 and CR8 and the resistor
R8, and also to the data input IN of the analog switch
AS1. Referring to FIGS. 7 and 9, the operation of the first transmitter will now be described, as illustrative of the operation of the N ultrasonic transmitters. The transmitter relies on capacitive discharge to fire the ultrasonic transducer. When the pulse Pi with a waveform as shown in FIG. 9(a) appears at the output of the pulse amplifier A1, resistors R1 and R2 provide isolation and divide the pulse amplitude. The capacitor C1 filters out high frequency noise and the capacitor C2 differentiates the pulse. The negative portion of the differentiated pulse is clipped by the diode CR1 and the positive portion of the pulse with a waveform shown in FIG. 9(b) passes to transformer T1 causing a current to flow in its secondary windings and the silicon controlled rectifiers can be added in cascade depending upon the magnitude of the high voltage. Capacitor C3 is charged from the high voltage HV through a charging circuit comprising the resistor R9, the diode CR9, the coil L1, the capacitor C3, and the diode CR4. When the leading edge of the pulse P1 fires the silicon controlled rectifiers, while only two silicon controlled rectifiers are shown, it is to be understood that additional silicon controlled rectifiers can be added in cascade depending upon the magnitude of the high voltage. Capacitor C3 is charged from the high voltage HV through a charging circuit comprising the resistor R9, the diode CR9, the coil L1, the capacitor C3, and the diode CR4. When the leading edge of the pulse P1 fires the silicon controlled rectifiers, the charge on the capacitor C3 is discharged through SCR1 and SCR2 via the diode CR5 and the resistor R7 in parallel with the first ultrasonic transducer. The discharge current impulse with a waveform shown in FIG. 9(c) causes the first ultrasonic transducer to radiate an ultrasonic pulse into the patient's body from the end of the transducer. The echoes picked up by the transducer are converted to electrical echo signals appearing across the resistor R7 with a waveform shown in FIG. 9(d). The electrical echo signals are capacitively coupled through the capacitor C4 to the data input IN of the analog switch AS1. The diodes CR7 and CR8 are provided for clipping large signals and the resistor R8 is the input load for the analog switch. The analog switch AS1 is turned on by the appearance of the pulse P1 at the control input VC and the electrical echo signals are passed through the switch to a common signal bus 81 and to the base of the transistor Q3 whose output is coupled to the receiver 19 by lead 47, as intensity modulating signals with a waveform shown in FIG. 9(e).

Enclosed by the broken line 49 is the bias voltage generator. The output OUT of the pulse switch PSN+2 is connected by lead 84 to the clock input CL of the D-type flip-flop 79 whose set output Q comprises the input of the pulse amplifier 85. At the output of the pulse amplifier 85 are connected two potentiometers 87 and a source follower 89 which is connected by lead 51 to the Y input of the cathode ray tube. At the last clock pulse appearing on lead 31, the voltage pulse PXY+2 sets the D-type flip-flop 79 causing its set output Q to go high and providing an input voltage to the source follower 89. A bias voltage is thereby supplied to offset the staircase voltage at the Y input of the cathode ray tube 21.

Obviously, numerous modifications and variations of the present invention are possible in light of the above teachings. It is therefore to be understood that within the scope of the appended claims, the invention may be practiced otherwise than as specifically described herein.

What is claimed as new and desired to be secured by Letters Patent of the United States is:

1. In a biomedical ultrasonoscope for examination of the interior of a patient's body and having "A", "M", and "C" mode scan electronic circuits whereby "A" and "M" or "C" mode scan displays can be selected, the plurality of analog switches equal in number to the number of ultrasonic transducer elements, each analog switch having an input and an output, each analog switch input being coupled to a respective transducer element, said analog switch outputs all being coupled to said receiver; and a plurality of transmitters, each transmitter being coupled to a respective ultrasonic transducer element for transmitting a pulsed electrical signal thereto;
a staircase voltage generator connected between the clock generator and the Y axis input of the cathode ray tube for generating a staircase voltage at said Y axis input with voltage steps synchronized by the clock pulses; sequencer means connected to the clock generator, transmitters, analog switches, and staircase voltage generator and responsive to the clock pulses for sequentially actuating the transmitters, sequentially closing said analog switches for a predetermined gate period, and recycling said staircase voltage generator after each frame;
said sequencer means including a first counter connected to the clock generator for counting clock pulses, a second counter connected to the first counter for counting multiples of clock pulses, and a plurality of pulse switches, each pulse switch having a data input connected to the first counter, a control input connected to the second counter, and an output connected to a respective one of the plurality of transmitters.

2. The biomedical ultrasonoscope recited in claim 1 wherein each of the plurality of transmitters includes: a capacitor having one electrode connected to a respective ultrasonic transducer; capacitor charging means for charging the capacitor; and
4,156,304

9 capacitor charging means for discharging the capacitor to transmit a pulsed electrical signal to the respective ultrasonic transducer; said capacitor charging means including means for connecting the other electrode of the capacitor to an external high voltage source; and the capacitor discharging means including at least one silicon-controlled rectifier connected between the other electrode of the capacitor and ground, and means coupled between said silicon-controlled rectifier and one of said pulse switches for cyclically trig-

gering said silicon-controlled rectifier and dis-
charging said capacitor.

3. The biomedical ultrasonoscope recited in claim 1 wherein the staircase voltage generator includes: a binary counter connected to the clock generator and; an analog-to-digital conversion resistor ladder net-
work connected between the binary counter and the Y input of the cathode ray tube.
