Aerodynamic characteristics obtained in a rotational flow environment utilizing a rotary balance located in the Langley spin tunnel are presented in plotted form for a 1/6.5-scale, single-engine, high-wing, general aviation airplane model. The configurations tested included the basic airplane, various wing leading-edge devices, tail designs, and rudder control settings as well as airplane components. Data are presented without analysis for an angle-of-attack range of 8° to 90° and clockwise and counter-clockwise rotations covering an $\frac{\alpha_b}{V}$ range from 0 to 0.85.

INTRODUCTION

The NASA Langley Research Center has initiated a broad general aviation stall/spin research program which includes spin-tunnel and free-flight radio control model tests, as well as full-scale flight tests for a number of configurations typical of light, general aviation airplanes. To support this effort, rotary balance wind tunnel force tests covering these same configurations will be conducted to establish a data base for analysis of model and full-scale flight results, and to develop design charts for desirable stall/spin characteristics.

A 1/6.5-scale, single-engine, general aviation airplane model, referred to as model B, having a high-wing location was tested in a rotational flow environment utilizing a rotary balance located in the Langley spin tunnel. This report presents the data obtained for the basic configuration, various wing leading-edge devices, tail designs and rudder control settings as well as airplane components. Data for model B having a low-wing location are presented in reference 1.
SYMBOLS

The units for physical quantities used herein are presented in the International System of Units (SI) and U.S. Customary Units. The measurements were made in the U.S. Customary Units; equivalent dimensions were determined by using the conversion factors given in reference 2.

- \( b \): wing span, m (ft)
- \( c \): mean aerodynamic chord, cm (in.)
- \( C_L \): lift-force coefficient, \( \frac{\text{Lift force}}{qS} \)
- \( C_N \): normal-force coefficient, \( \frac{\text{Normal force}}{qS} \)
- \( C_A \): axial-force coefficient, \( \frac{\text{Axial force}}{qS} \)
- \( C_Y \): side-force coefficient, \( \frac{\text{Side force}}{qS} \)
- \( C_\ell \): rolling moment coefficient, \( \frac{\text{Rolling moment}}{qSb} \)
- \( C_m \): pitching-moment coefficient, \( \frac{\text{Pitching moment}}{qSb} \)
- \( C_n \): yawing-moment coefficient, \( \frac{\text{Yawing moment}}{qSb} \)
- \( q \): free-stream dynamic pressure, N/m² (lb/ft²)
- \( S \): wing area, m² (ft²)
- \( V \): free-stream velocity, m/sec (ft/sec)
- \( \alpha \): angle of attack, deg
- \( \beta \): angle of sideslip, deg
- \( \Omega \): angular velocity about spin axis, rad/sec
- \( \Omega_b \): spin coefficient, positive for clockwise spin
- \( \frac{\Omega}{\sqrt{V}} \): aileron deflection, positive when right aileron is down
- \( \delta_a \): (\( \delta_{\text{right}} - \delta_{\text{left}} \))/2, deg
- \( \delta_e \): elevator deflection, positive when trailing edge is down, deg
δ_r rudder deflection, positive when trailing edge is to left, deg

Abbreviations:
cg center of gravity
LE leading edge
SR spin radius
TE trailing edge

TEST EQUIPMENT

A rotary balance measures the forces and moments acting on an airplane while subjected to rotational flow conditions; the background for this apparatus is discussed in reference 3. A photograph and sketch of the rotary balance apparatus installed in the Langley spin tunnel are shown in figures 1 and 2, respectively. The rotating portion of the balance system, mounted on a horizontal supporting boom which is hinged at the wall, is moved from the wall to the center of the tunnel by cables. The rotary arm of the balance system, which rotates about a vertical axis, is attached to the outer end of the horizontal supporting boom and is driven by a drive shaft through couplings and gears.

A test model is mounted on a strain gauge balance which is affixed to the bottom of the rotary balance apparatus. Controls located outside the tunnel are used to activate motors on the rig which position the model to the desired attitude. The angle-of-attack range of the rig is 8 to 90 degrees and the sideslip angle range is ±15 degrees. The spin radius and the lateral displacement motors allow the operator to position the moment center of
the balance on the spin axis or at a specific distance from the spin axis. This is done for each combination of angle of attack and sideslip angle. The general practice is to mount the moment center of the balance at the cg location about which the aerodynamic moments are desired. Electrical current from the balance, and to the motors on the rig, is conducted through slip-rings located at the rig head. Examples of how the rig is positioned for different angle of attack and sideslip angles are shown in figures 2a and 2b, respectively.

The model can be rotated up to 90 rpm in either direction. By using different rotational speeds and a specific airflow in the tunnel, the motions of a steady spinning airplane can be simulated. The aerodynamic forces and moments can then be measured for values of $\frac{\Omega_b}{2V}$, including the case of $\frac{\Omega_b}{2V} = 0$, where static aerodynamic forces and moments can be obtained.

A NASA six-component strain gauge balance is mounted inside the model and measures the normal, lateral and longitudinal forces and the yawing, rolling and pitching moments acting about the mode body axis. The interactions that exist between the six components are available from balance calibration tests and are accounted for after the balance voltages are converted to forces and moments.

The data acquisition, reduction and presentation system for the rotary balance set-up is composed of a 12-channel scanner/voltmeter, a mini-computer and a plotter. With this equipment,
on-line digital print-out and/or graphical plots of data are possible.

TEST PROCEDURES

Rotary aerodynamic data are obtained in two steps. The first step is to record the inertial forces and moments (tares) acting on the model at different attitudes and rotational speeds. To accomplish this, a covered bird-cage-like structure is mounted to the upper rig which encloses the model without touching it. In this manner, the air immediately surrounding the model is rotated with it. As the rig is rotated at the desired attitude and rate, the inertial forces and moments generated by the model are measured and stored on magnetic tape for later use.

The second step in the data-gathering process is to measure aerodynamic and inertial forces at different attitudes and rotational speeds for a selected tunnel velocity with, of course, the cage structure removed. The tares are subtracted from these values, and the remaining aerodynamic forces and moments are then converted to coefficient form and stored on magnetic tape.

MODEL

A 1/6.5-scale fiberglass/aluminum model of a configuration considered to be a typical high-wing, single-engine, light general aviation airplane was tested in the present study. A three-view drawing of this model is shown in figure 3, dimensional characteristics of the model are presented in Table I, and a photograph of the model installed on the rotary balance located in the Langley spin tunnel is presented in figure 1.
The model was fabricated such that various airplane components were removable for component build-up tests and for testing alternate wing leading edges and tail configurations. In addition, allowance was made for attaching various fuselage modifications.

The four tail configurations tested involved different locations of the horizontal tail as shown in figure 4. The fuselage shape and wing leading-edge modifications tested are shown in figures 5 and 6, respectively.

The model control surfaces could be set at any position prior to the test. The maximum deflections for the control surfaces were:

- Elevator, deg 28 up, 23 down
- Rudder, deg 25 right, 25 left
- Aileron, deg 20 up, 15 down

**TEST CONDITIONS**

The tests were conducted in the spin tunnel at a tunnel velocity of 7.62 m/sec (25 ft/sec) which corresponds to a Reynolds number of 119,378 based on the model mean aerodynamic chord. Unless noted otherwise in Table II, all the configurations were tested through an angle-of-attack range of 8 to 90° at a zero sideslip angle with the spin axis passing through the full-scale airplane cg location of .25c for angles of attack above 30°. For angles of attack below 35°, the spin axis was set 99 cm (39 in.) forward of the cg. Consequently, data was obtained for both a 0 and 99 cm (39 in.) spin radius at angles of attack of 30 and 35°. At each spin attitude, measurements
were obtained for nominal $\frac{\Omega b}{2V}$ values of .1, .2, .3, .4, .45, .55, .65, .75 and .85 in both clockwise and counter-clockwise directions, as well as for $\frac{\Omega b}{2V} = 0$ (static value).

DATA PRESENTATION

Table II identifies the configurations tested and the corresponding appendix figure numbers which present the aerodynamic data. The aerodynamic coefficients vs. $\frac{\Omega b}{2V}$ are presented for each configuration in six sequentially numbered figures in the following order: $C_n$, $C_\alpha$, $C_m$, $C_N$, $C_Y$ and $C_A$. Each figure, in turn, consists of four pages which present the subject aerodynamic coefficient vs. $\frac{\Omega b}{2V}$ for the following angles of attack and spin radii, unless noted otherwise in Table II.

a) $\alpha = 8, 10, 12, 14, 16$ deg  \hspace{1cm} SR = 99 cm (39 in.)
b) $\alpha = 18, 20, 25, 30, 35$ deg  \hspace{1cm} SR = 99 cm (39 in.)
c) $\alpha = 30, 35, 40, 45, 50$ deg  \hspace{1cm} SR = 0
d) $\alpha = 55, 60, 70, 80, 90$ deg  \hspace{1cm} SR = 0

All the moment data are presented for a cg position of 0.25\(c\).

Lift coefficient as a function of angle of attack for zero rotation rate is presented at the end of the Appendix for several configurations cited in Table II.

\( b/2V \)

(b) \( \alpha = 15 \text{ to } 35 \text{deg}, SR = 99 \text{cm (39 in)} \).

Figure A1.19. Concluded.
Figure A119. Effect of rotation rate and angle of attack on side force coefficient for configuration having outboard LE wing droop extended inboard 42.7 cm (16.8 in). $\delta_e = 0^\circ$, $\delta_a = 0^\circ$, $\delta_r = 0^\circ$, $\beta = 0^\circ$. $\alpha = 8$ to 16 deg, $SR = 99$ cm (39 in).
(b) \( \alpha = 18 \text{ to 35 deg}, SR = 99 \text{ cm (39 in).} \)

Figure A119. Concluded.
Figure A120: Effect of rotation rate and angle of attack on axial force coefficient for configuration having outboard LE wing droop extended inboard 42.7 cm (16.8 in). $\alpha = 0^\circ$, $\alpha = 0^\circ$, $\delta r = 0^\circ$, $\beta = 0^\circ$. 

(a) $\alpha = 8^\circ$ to $16^\circ$, $SR = 99$ cm (39 in).
(b) $\alpha = 18$ to $35 \text{deg}$, $SR = 39 \text{cm (3.9 in)}$.

Figure A120. Concluded.
Figure A121: Effect of rotation rate and angle of attack on yawing moment coefficient for configuration having outboard LE wing droop extended inboard 45.2 cm (17.8 in). $\alpha = 15$ to 30 deg, $\delta R = 99$ cm (39 in).
Figure A122. Effect of rotation rate and angle of attack on rolling-moment coefficient for configuration having outboard LE wing droop extended inboard 45.2 cm (17.8 in): $\alpha = 16^\circ$ to $30^\circ$, $SR = 89$ cm (35 in).
Figure A123: Effect of rotation rate and angle of attack on pitching-moment coefficient for configuration having outboard LE wing droop extended inboard 45.2 cm (17.8 in). $\delta_n = 0^\circ$, $\delta_l = 0^\circ$, $\delta_r = 0^\circ$, $\beta = 0^\circ$. 

$C_m$ vs $\Omega b / 2V$ for $\alpha = 15$ to $30^\circ$, $SR = 99$ cm (39 in).
Figure A1.24: Effect of rotation rate and angle of attack on normal force coefficient for configuration having outboard LE wing droop extended inboard 45.2cm (17.8 in), $\alpha = 0^\circ$, $\phi = 50^\circ$, $\delta = 0^\circ$, $\beta = 0^\circ$. $\sigma = 15^\circ$ to $30^\circ$, SR = 99 cm (39 in).
Figure A125. Effect of rotation rate and angle of attack on side force coefficient for configuration having outboard LE wing droop extended inboard 45.2 cm (17.8 in). \( \alpha = 0^\circ, \phi = 0^\circ, \delta_r = 0^\circ, B = 0^\circ \).
Figure A126. Effect of rotation rate and angle of attack on axial force coefficient for configuration having outboard LE wing droop extended inboard 45.2cm (17.8in). $\phi_r = 0^\circ$, $\phi_t = 0^\circ$, $\phi_c = 0^\circ$, $\beta = 0^\circ$. $\alpha = 16\,^\circ$ to $30\,^\circ$, SR = 99cm (39in).
Figure A127. Effect of rotation rate and angle of attack on yawing-moment coefficient for configuration having outboard LE wing droop extended inboard 47.8 cm (18.8 in). $\alpha = 16$ to 30 deg, $\delta R = 99$ cm (39 in).
Figure A126. Effect of rotation rate and angle of attack on rolling moment coefficient for configuration having outboard LE wing droop extended, inboard 47.8cm (18.8in). δp = 0°, δr = 0°, δr = 0°, 90°.
Figure A129. Effect of rotation rate and angle of attack on pitching-moment coefficient for configuration having outboard LE wing droop extended inboard 47.8 cm (18.8 in). $\alpha = 0^\circ$, $\delta_s = 0^\circ$, $\delta_r = 0^\circ$, $\beta = 0^\circ$.
Figure A130. Effect of rotation rate and angle of attack on normal force coefficient for configuration having outboard LE wing droop extended and inboard 7.8cm (18.5in). $\alpha=0^\circ$, $\delta_x=0^\circ$, $\delta_y=0^\circ$. $B=10^\circ$. 

$\Gamma_b/2V$

$\alpha=15^\circ$ to $30^\circ$, $SR=49\text{cm}(19\text{in})$.

Figure A132. Effect of rotation rate and angle of attack on axial force coefficient for configuration having outboard LE wing droop extended inboard 47.8 cm (18.8 in), α = 0°, α = 0°, δ = 0°, θ = 0°.
Figure A133. Effect of rotation rate and angle of attack on yawing-moment coefficient for configuration having outboard LE wing droop extended inboard 42.7cm (16.8in) with moderate nose radius. $\beta = 0^\circ$, $\delta_x = 0^\circ$, $\delta_r = 0^\circ$, $\delta = 0^\circ$. $\alpha = 16\text{ to }30\text{deg}, SR = 99\text{cm (39in)}.$
Figure A135. Effect of rotation rate and angle of attack on pitching moment coefficient for configuration having outboard LE wing droop extended inboard 42.7cm (16.8in) with moderate nose radius. $\alpha = 15^\circ$ to $30^\circ$, $SR = 99\text{cm (39in)}$. 
Figure A136. Effect of rotation rate and angle of attack on normal force coefficient for configuration having outboard LE wing droop extended inboard 42.7 cm (16.8 in) with moderate nose radius. $\delta_a = 0^\circ$, $\delta_k = 0^\circ$, $\delta_r = 0^\circ$, $E = 0^\circ$. "$\alpha$ = 16 to 30 deg, $\delta R$ = 99 cm (39 in).
Figure A187. Effect of rotation rate and angle of attack on side-force coefficient for configuration having outboard LE wing droop extended inboard 42.7cm (16.8in) with moderate nose radius. \( \phi_e = 0^\circ; \text{\( \phi_s \)} = 0^\circ; \text{\( \phi_r \)} = 0^\circ; \beta = 0^\circ \).
Figure A108. Effect of rotation rate and angle of attack on axial-force coefficient for configuration having outboard LE wing droop extended inboard 42.7 cm (16.8 in) with moderate nose radius. \( \delta_m = 0^\circ, \delta_a = 0^\circ, \delta_e = 0^\circ, \beta = 0^\circ. \)
Figure A1.38. Lift coefficient as a function of angle of attack for various wing flap devices.
Figure A142: Lift coefficients as a function of angle of attack for various span LE outboard wing drops.
Aerodynamic characteristics obtained in a rotational flow environment utilizing a rotary balance located in the Langley spin tunnel are presented in plotted form for a 1/6.5-scale, single-engine, high-wing, general aviation airplane model. The configurations tested included the basic airplane, various wing leading-edge devices, tail designs, and rudder control settings as well as airplane components. Data are presented without analysis for an angle-of-attack range of 8° to 90° and clockwise and counter-clockwise rotations covering an \( \frac{5\pi}{2} \) range from 0 to 0.85.
