GRAPHIC CONSTRUCTION OF JOUKOWSKI WINGS.*

By E. Trefftz.

In plotting the cross-sectional outline (or profile) of a Joukowski wing, we proceed as follows (Fig. 6).

We first plot an \( \text{xy} \) system of coordinates with the origin \( O \) such that the \( x \) axis forms the angle \( \beta \) with the horizontal direction of the wing and mark on the \( x \) axis the point \( L \), for which \( x = -l \), and on the \( y \) axis the point \( F \), for which \( y = f \).

We now describe two circles and label them \( K_1 \) and \( K_2 \). The center \( M_1 \) of the first circle is situated on the straight line \( LF \) at a distance \( 26 \) from the point \( F \) (beyond the section \( LF \)). The circle, moreover, passes through the point \( L \). The second circle likewise passes through the point \( L \) and its center \( M_2 \) is likewise on \( LF \), the position of \( M \) on \( LF \) being determined by the following condition. If \( OV_1 \) is the portion of the positive \( x \) axis cut off by the circle \( K_1 \) and \( OV_2 \) the portion cut off by the circle \( K_2 \), then \( OV_1 \times OV_2 = l^2 \).

We now draw, from the point \( O \), the two lines \( OA_1 \) and \( OA_2 \), so as to form equal angles with the \( x \) axis, \( A_1 \) being the point of intersection of the first line with the circle \( K_1 \) and \( A_2 \) the intersection of the second line with the circle

* From "Zeitschrift für Flugtechnik und Motorluftschifffahrt," May 31, 1913, pp. 130 and 151.
Then the center $P$ of the line $A_1 A_2$ is the point sought on the Joukowski wing profile.

In plotting the preceding figures, 34 points were found in this manner for each one, by shifting the first line from the point $L$ $15^\circ$ each time and drawing the second line symmetrically with reference to the $x$ axis.

In order to determine the pressure on each point of the profile, when the wing is exposed to a horizontal wind having the velocity $V$, we must know the velocity $q$ at which the air flows by each point of the profile. The pressure on each unit area of the wing surface is then proportional to $q^2$.

We can now find the values of $q$ in a very simple manner. For this purpose, we draw a horizontal line through the point $L$. If we designate by $h$ the distance of the point $A_1$ (of the circle $K_1$) from this horizontal line, we obtain, for any desired point $P$ of the figure, the corresponding value of $q$ in the following manner. We take from the diagram the distance between the points $A_1$ and $A_2$, at the middle of which we had found the point $P$, and also the distances of the point $A_1$ from the origin $O$, from the center $M_1$ of the circle $K_1$, and from the horizontal line passing through $L$. We then have

$$q = V \frac{O A_1}{A_1 A_2} - \frac{2 h}{M_1 A_1}$$

The mathematical proof for the given constructions is simple. As already mentioned, the profile of a Joukowski wing
can be constructed by describing on the $z$ plane, with the aid of the formula $z = \zeta + \frac{p}{4\zeta}$, the circle $K$, determined by the camber and radii difference. This circle passes through the point $\zeta = -\frac{b}{c}$.

The systems of coordinates are plotted both in the $\zeta$ plane and in the $z$ plane in such manner that the $\zeta$ axis and the $x$ axis form the angle $\beta$ with the horizontal wind direction.

If we now describe, in the $z$ plane, both circles, which we obtain from the given circle $K$ in the $\zeta$ plane by employing the two conversion formulas

$$z_1 = 2\zeta \quad \text{and} \quad z_2 = \frac{p}{2\zeta}$$

then these are the same two circles we designated above by $K_1$ and $K_2$.

The point $A_1$ has the coordinate $z_1$ and the point $A_2$ has the coordinate $z_2$, hence the center of $A_1 A_2$ has the coordinate $z = \frac{1}{2}(z_1 + z_2) = \zeta + \frac{p}{4\zeta}$, as desired. $P$ is therefore an actual point on the Joukowski curve.

The following formula holds good for the velocity $q$ at which the air flows by every point on the Joukowski figure.

$$q = \frac{\kappa(\zeta,m)}{\left|\frac{d\zeta}{dz}\right|}$$

From $z = \zeta + \frac{p}{4\zeta}$ it follows that
\[ \frac{dz}{d\zeta} = 1 - \frac{1}{4} \zeta \frac{d^2}{d\zeta^2} = \frac{1}{2\zeta} \left( 3\zeta - \frac{1}{2} \right) = \frac{z_1 - z_2}{z_1} \]

whence we obtain

\[ \left| \frac{dz}{d\zeta} \right| = \frac{A_1}{A_2} \frac{4}{A_1 A_2} \]

since the absolute value of \( z_1 - z_2 \) equals the distance \( A_1 A_2 \) and the absolute value of \( z_1 \) equals the distance \( OA_1 \).

For \( \kappa(\xi, \eta) \), we obtain, from formula 2 of the preceding article, \( \kappa = \frac{2\sqrt{h}}{M_1 A_1} \), in which \( h \) is the distance of the point \( A_1 \) from the horizontal line passing through \( L \). In the expression there given for the numerator, it is equal to \( h \) and the denominator is equal to \( \frac{1}{2}(L_1 A_1) \), as may be easily verified. We thus obtain

\[ q = \sqrt{\frac{2h}{L_1 A_1}} \frac{4}{A_1 A_2} \]

which is just the formula given above for \( q \).
