(JPL PUBLICATION 81-94)
Prepared by the Jet Propulsion Laboratory, California Institute of Technology, for the Department of Energy through an agreement with the National Aeronautics and Space Administration.

The JPL Low-Cost Solar Array Project is sponsored by the Department of Energy (DOE) and forms part of the Photovoltaic Energy Systems Program to initiate a major effort toward the development of low-cost solar arrays.

This report was prepared as an account of work sponsored by the United States Government. Neither the United States nor the United States Department of Energy, nor any of their employees, nor any of their contractors, subcontractors, or their employees, makes any warranty, express or implied, or assumes any legal liability or responsibility for the accuracy, completeness or usefulness of any information, apparatus, product or process disclosed, or represents that its use would not infringe privately owned rights.
ABSTRACT

This report describes progress made by the Low-Cost Solar Array Project during the period February to July 1981. It includes reports on project analysis and integration; technology development in silicon material, large-area silicon sheet and encapsulation; process development; engineering, and operations. It includes a report on, and copies of visual presentations made at, the Project Integration Meeting held at Pasadena, California, on July 15 and 16, 1981.

INTRODUCTION

This report describes the activities of the Low-Cost Solar Array Project from February to July, 1981, including the 18th LSA Project Integration Meeting (PIM) held July 15 and 16, 1981.

The LSA Project is assigned the responsibility for advancing solar array technology while encouraging industry to reduce the price of arrays to a level at which photovoltaic electric power systems will be competitive with more conventional power sources. Set forth here are the goals and plans by which the Project intends to accomplish this, and the progress that has been made during the period.

SUMMARY OF PROGRESS

Checkout of the Hemlock Semiconductor Corp. process development unit (PDU) for making silicon by a dichlorosilane process was completed and integrated operations of the PDU and an intermediate-sized silicon-deposition reactor were started.

Fabrication of equipment for the Union Carbide Corp. silane-to-silicon experimental process system development unit (EPSDU) was completed, but the start of mechanical and electrical installation was delayed because of FY81 budget revisions. The silicon shutter was assembled and initial tests with chunk silicon demonstrated that silicon shot formation was acceptable. The use of up to 21% silane in H2 feedstock was successfully demonstrated in the FBR to give dense polysilicon deposition on seed particles.

Westinghouse Electric Corp. has successfully demonstrated and can routinely achieve constant width control for its silicon dendritic web crystal-growth process. Ribbons nearly 5 meters in length have been produced with width held uniform to within 0.1 mm.

Experiments at Mobil Tyco Solar Energy Corp. with their existing edge-defined film-fed growth ribbon growers are investigating design factors that limit growth speed and influence ribbon quality, for use in the design of a new four-ribbon (10-cm-wide) grower.

A Project-sponsored Wafering Workshop was held in Phoenix, Arizona. More than 80 persons attended; some 30 papers on wafering were presented. Empirical and theoretical experts exchanged information freely during exhaustive and comprehensive discussions.

All technical features for advanced wafering have been demonstrated individually. Future efforts will be directed toward combining these features into a practical wafering system.
PROJECT SUMMARY

The final 35-kg heat-exchange method (HEM) ingot required under the current contract with Crystal Systems, Inc., has been grown. The solidification time for the ingot was 40 h and the total cycle time was 70 h.

Based on Project activities in the identification and development of encapsulation material, Du Pont has indicated that the potential market for ethylene vinyl acetate (EVA) lamination film warrants their direct involvement. Du Pont has identified and worked with a custom extrusion vendor to develop a commercial source of rolls of standard EVA lamination film, 18 mils thick and up to 30 inches wide, that is non-blocking.

A preliminary draft copy of the Encapsulation Design and Material Specification Report for Industry Use was exhibited at the 18th Project Integration Meeting. The report was well received by the industrial participants at the conference.

An automated cell-stringing and soldering machine and an automated lamination system have been completed by Arco Solar, Inc., under a Project contract. Two hundred eighty eight modules were assembled using the automated equipment, 56 of which will undergo environmental testing at JPL.

Preliminary design reviews were held on the Westinghouse Electric Corp. and Solarex NEPSDU contracts. These contracts were revised to extend the period of performance in order to accommodate FY81 budget revisions.

Numerous reports covering module and array design technology were published. Subjects included standards for safety, module design and test specifications, low-cost structures for large ground mounted arrays, module and array circuit design optimization, module hot-spot durability design, fracture mechanics of silicon solar cells and module and array reliability.

Seven contractors were notified of their selection for negotiations in the Block V preliminary design procurement action. ARCO Solar, RCA Corp., Solar Power Corp. and Solarex were selected for their proposed designs of intermediate-load modules and General Electric Co., Mobil Tyco and Spire Corp. were selected for their residential module designs.
Area Reports

PROJECT ANALYSIS AND INTEGRATION AREA

INTRODUCTION

The objective of the Project Analysis and Integration (PA&I) Area is to support the planning, analysis, integration, and decision-making activities of the Project. This is done by developing and documenting Project plans, and by contributing to the generation and development of alternative Project plans through the assessment of technology options; by establishing standards for economic comparison of options under Project study and developing the analytical capabilities to perform the trade-offs required; by supporting the integration of the tasks within the Project and between the Project and other elements of the National Photovoltaics Program, and by providing coordinated assessment of, and progress toward achievement of, Project goals by the various areas of the Project working with the solar-array manufacturing industry and the National Photovoltaics Program.

PROGRESS

The metallization-grid-pattern optimization effort, in cooperation with the Process Development Area, is progressing. Two different designs have been metallized: the present conventional design, which is optimized using only two variables, and an improved design using four variables in the optimization. Results are being evaluated.

A revised power model, based on the series-parallel methodology developed by the Engineering Area, has been coded and initial test cases have been run. Model extensions, which include varying cell failure rates over time and replacing modules during system operation, are being incorporated.

Revisions and improvements in the SAMICS methodology are in progress. Release 4 of SAMIS (October 1) will have year-by-year financial reports. Revisions of Format C have been completed and are now available at stationery stores. A revised Format A will be ready for printing soon.

A first draft of an Engineer's Guide to SAMIS has been completed. The Guide is designed for the first-time or occasional user and contains explicit instructions for the use of SAMIS. Users of SAMIS will also benefit from a short course to be offered by JPL. A two-day course is planned to coincide with the 19th PIM.

A major effort to improve effluent control algorithms and to update control equipment and process costs has resulted in revision of the SAMICS Cost Catalog dealing with process waste disposal and pollution control. The revisions were based on input from process designers on control levels and methods now applicable or expected soon, and on cost input from control-equipment suppliers. Improvements in the approach to estimating environmental effluent costs were described at the 18th PIM and are contained in the PA&I Technology Session portion of the Proceedings.
Silicon Material Task

INTRODUCTION

The objective of the Silicon Material Task is to establish the practicability of processes capable of producing silicon (Si) in a form suitable for use in the manufacture of terrestrial solar cells, at a price less than $14/kg (1980 $) by 1986. The program formulated to meet this objective provides for development of processes for producing either semiconductor-grade Si or a less pure, but utilizable (i.e., a solar-cell-grade) Si material.

TECHNICAL GOALS, ORGANIZATION AND COORDINATION

Solar cells are now fabricated from semiconductor-grade Si, which has a market price of about $65/kg. A drastic reduction in cost of material is necessary to meet the technology feasibility objectives of the LSA Project. Efforts are now under way to develop processes that will meet the Task objective in producing semiconductor-grade Si. Another means of meeting this requirement is to devise a process for producing a less-pure, so-called solar-cell-grade Si material. The allowance for the cost of Si material in the over-all economics of the solar arrays for LSA is dependent on optimization trade-offs, which concomitantly treat the price of Si material and the effects of material properties on the performance of solar cells. Accordingly, the program of the Silicon Material Task is structured to provide information for these tradeoffs concurrently with the development of high-volume, low-cost processes for producing Si. This structure has been described in detail in previous LSA Progress Reports. The program also includes economic analyses of silicon-producing processes and supporting efforts, both contracted and in-house at JPL, to respond to problem-solving needs.

Thirteen contracts in progress are listed in Table 1.

</table>
Four contracts in this category were active. Battelle Columbus Laboratories completed the draft of the final report on investigating the production of Si by the zinc reduction of silicon tetrachloride; the report will be released soon.

Energy Materials Corp. completed the draft of its final report on an Si melt-replenishment system for Czochralski crystal growth using trichlorosilane (SiHCl₃), under a near-term cost-reduction contract, and this report also will be released soon.

Hemlock Semiconductor Corp. is developing a process for making Si from dichlorosilane (SiH₂Cl₂) using Siemens-type deposition reactors. A one-year extension of the contract was executed in late June. A system for feeding cylinder-supplied SiH₂Cl₂ to reactors was constructed, and an intermediate-scale deposition reactor, modified for use with SiH₂Cl₂, was successfully tested with this reactant. The data indicate that the Si deposition rate is about double that obtained with the conventional reactant, SiHCl₃, an increase that is consistent with the rate increase required to meet program objectives.

Construction of the process development unit (PDU) for investigating the rearrangement of SiHCl₃ to SiH₂Cl₂ was completed, the PDU was integrated with the intermediate-scale reactor, and testing was begun. Operations proceeded very smoothly; 17 tests were completed by the end of June. Two problems have surfaced: the amount of Si being deposited on the bell jar walls, about 2% of the total amount being deposited, is excessive, and the power consumption of the deposition reactor is higher than desired.

Process flow diagrams for a 1000-MT/yr plant using the Hemlock process were updated, including safety-related changes that were made in the PDU design as a result of previous testing conducted as part of this program, such as elimination of SiH₂Cl₂ storage and dilution of the SiH₂Cl₂ immediately as it leaves the distillation column on its way to the deposition reactor.

Union Carbide Corp. continued construction of the 100-MT-Si/yr experimental process system development unit (EPSDU) at East Chicago, Indiana. All civil and structural work was completed. Most of the equipment has been delivered to the site, and most major equipment pieces have been inspected and placed in position.

Bids for the mechanical installation were received from five bidders, and these responses are being evaluated. The electrical-installation bid package is being prepared. Awarding of these installation subcontracts will probably be delayed because of an FY81 funding recision.

In the UCC R&D program, the Si powder melter subcontract work at Kayex continued, with assembly of the shotter and completion of several tests in which Si chunk material was melted and converted to product containing some free-flowing shot.

The fluidized-bed silane (SiH₄)-pyrolysis PDU was assembled and operated successfully with SiH₄ feed concentrations ranging from 10% to 21%.
SILICON MATERIAL TASK

Particle morphology appears to be excellent, and little undesirable Si powder was produced. The effort was stopped in mid-May because of budget contraints.

Development of Processes for Producing Solar-Cell-Grade Silicon

Final reports were issued by SRI International on the process for producing Si by the sodium reduction of silicon tetrafluoride, and by Westinghouse Electric Corp. on the arc-heater process, in which silicon tetrachloride is reduced by sodium.

Impurity Studies

C. T. Sah Associates is developing a computer model based on the fundamental parameters of solar cells and applying it to the determination of the effects of impurities and defects of Si on solar cell performance. The effect of cell thickness on the performance of Si cells containing impurity recombination centers was analyzed using a transmission-line-circuit model and zinc (Zn) impurity as the model recombination center. Results show that the AM1 efficiency has a broad maximum (less than 0.1% variation from 20 to 70 μm) in back-surface-field n+/p/n+ and p+/n/n+ cells of 17% efficiency with 5 x 10¹⁴ atoms/cm³ base doping and 10¹² atoms Zn/cm³. Back-surface reflection in cells of optimum thicknesses increases the efficiency by less than 1% through increase of Jsc.

Comparison of the theory with measurements on impurity-containing thin cells made on web using Zn-vapor-reduced silicon was attempted. The base resistivity is about 0.3 ohm-cm or 6 x 10¹⁶ holes/cm³. The cells have large excess dark current that varies as exp (qV/1.63kT) up to and including Voc and is independent of cell area (one mm² to one cm²). Uniform Zn concentration theory predicts the normal current behavior, exp (qV/kT). Capacitance-voltage measurements suggest that there is a boundary that may account for the large excess current due to recombination in the space charge layer.

In the program by Westinghouse R&D Center to determine the effects of impurities on the performance of solar cells, the Phase IV program has been completed and a final report is being prepared. The effort included: evaluation of experimental Si materials, investigation of impurity effects in polycrystalline devices, identification of impurity thresholds for high-efficiency cells, assessment of process effects such as ion implanting on impurity-doped devices, and an extension of studies to identify long-term impurity effects. Some of the major results during this period follow:

The threshold impurity concentration for breakdown of a smooth crystal-liquid interface, Cθ⁺, is 2 to 10 times smaller for polycrystalline than for single-crystal ingots.

Using a model relating the measured value of Cθ⁺ to experimental growth parameters, the values of the liquid impurity diffusion constants were calculated for gadolinium, zirconium, molybdenum, tungsten, vanadium, titanium, iron, cobalt, palladium, silver, and copper in Si. The parameter Dθ ranged from 1.5 to 4.2 x 10⁻⁴ cm²/sec for these elements; the values are similar to those reported for other metals in liquid Si.
Of the various gettering treatments investigated, the most effective for titanium appears to be high-temperature reaction in hydrogen chloride (HCl) alone or phosphorus oxychloride (POCl₃) alone. For copper-doped cells, none of the gettering treatments (implant damage plus HCl or POCl₃ implant damage plus heat treatment, or HCl/POCl₃ alone) raises cell efficiency to that of the baseline devices.

Extensions of the experimentally supported impurity performance model to high-efficiency devices indicate that impurity tolerance is less in high-efficiency than conventional n⁺p devices and that this impurity sensitivity can be reduced by using thinner high-efficiency cells.

Supporting Studies

AeroChem Research Laboratories completed its experimental program in the investigation of the formation and growth of Si particles from the decomposition of silane (SiH₄) at high temperatures. Experiments on the SiH₄-to-particle formation process were conducted, in which the extent of SiH₄ decomposition, particle size, particle concentration, and particle growth rate were measured as functions of residence time, temperature, pressure, and SiH₄ concentration. Experiments were also made with particle seeding. The final report on the program was prepared and issued.

The report by Lamar University on its process feasibility study, covering all efforts since contract inception in 1975, was issued. The contract follow-on was initiated; it will be conducted by the Texas Research and Engineering Institute with the same principal investigator, C. Yaws, who was in charge of the effort at Lamar. The initial work will be a chemical-engineering analysis of the Hemlock Semiconductor Corp. process for producing Si from SiH₂Cl₂.

The Massachusetts Institute of Technology (MIT) completed a two-year contract to investigate the hydrochlorination of metallurgical-grade Si and SiCl₄ to form SiHCl₃, in support of the Union Carbide program. Experiments indicated that the fines that are elutriated from the reactor during operation contain a high proportion of the metallic impurities in metallurgical-grade Si. Fines elutriation can therefore be employed as part of the purification process. Experiments also showed that in the presence of cuprous chloride catalyst, the silicon mass in the fluidized bed reactor has a long reaction life under the expected conditions of operation. The final report on the contract was issued.

The follow-on contract to the MIT work was initiated. The effort will be conducted at Solarelectronics under the same principal investigator who directed the MIT program, J. Mui.

The JPL in-house program included effort on the fluidized-bed reactor (FBR), conversion of SiH₄ to molten Si, and impurity investigations.

The design of a 6-in.-dia FBR for the investigation of SiH₄ pyrolysis was completed, and fabrication was started. Experiments in a 2-in.-dia FBR at high SiH₄ concentration, including 100% SiH₄, were conducted successfully without bed agglomeration and with less than 10% fines. These results are significant in that they may aid considerably in achieving lower silicon costs by means of increased throughput, since FBR operation with 10 mole % SiH₄ in hydrogen has
SILICON MATERIAL TASK

already been shown analytically to be economically attractive. The Si deposits were dense and coherent.

The silane-to-molten-silicon (SMS) converter offers the potential of a one-stage conversion process. The unit was modified to allow rapid experimentation at high temperatures (1500 to 1750°C). Preliminary short-duration experiments were then conducted to examine the effects of configuration, flow, and temperature on the conversion of SiH₄ to molten Si. Two problems have been encountered: plugging of the SiH₄ injector by Si that rapidly forms as the SiH₄ is introduced into the hot reactor, and formation of Si powder that is swept out of the reactor without melting. The experiments are providing information for design changes to circumvent these problems.

In the analysis of electrically active impurities using thermally stimulated capacitance (TSCAP) measurements, an evaluation indicated that very consistent equipment operation was required to obtain the necessary measurement accuracy. As a result, the TSCAP system was automated by use of a calculator-controlled system. The system measures three parameters: characteristic temperature of a trap, trap concentration, and trap energy level. Initial tests were made on a sample containing gold. The results indicate that small errors in measuring temperature may be causing errors in trap energy level. Improvements are being made to eliminate this source of error.

A Zeeman atomic absorption spectrometer to be used for impurity analysis was procured and put into operation. The spectrometer uses the Zeeman effect on a resonant transition to correct automatically for background interference, making it possible to measure the concentrations of trace elements in a host material directly without chemical pretreatment. Sensitivity is in parts-per-billion for elements such as iron, copper, chromium, and manganese. Elements that form carbides, such as boron, or those that are extremely refractory, such as tungsten, are difficult to measure. The instrument is being calibrated.

In the effort on consolidation of sub-μm Si powder, the powder compactor-extruder, which feeds the material to the melter, was modified and successfully operated.
Large-Area Silicon Sheet Task

Present solar-cell technology is based on the use of silicon wafers obtained by slicing Czochralski (Cz) or float-zone ingots (up to 10 cm in diameter), using single-blade inner-diameter (ID) diamond saws. This method of obtaining single-crystal silicon wafers is tailored to the needs of large-volume semiconductor device production (e.g., integrated circuits, discrete power and control devices other than solar cells). The small market offered by present solar-cell users does not justify industry’s development of the high-volume silicon production techniques that would result in low-cost photovoltaic electrical energy.

The improvement of the standard Czochralski ingot growth process by reduction of expendable material costs and improvement of ingot growth rate together with improved slicing techniques will produce large areas of silicon at costs meeting the goals of the LSA Project. Growth of large ingots by casting techniques, such as the heat exchanger method (HEM) growth, and the ubiquitous crystallization process (UCP) can reduce sheet costs further.

The objective of the Large-Area Silicon Sheet Task is to develop and demonstrate the feasibility of several processes for producing large areas of silicon-sheet material suitable for low-cost, high-efficiency solar photovoltaic energy conversion. To meet the objective of the LSA Project, sufficient research and development must be performed on a number of processes to determine the capability of each of producing large areas of crystallized silicon at a low cost. The final sheet-growth configurations must be suitable for direct incorporation into an automated solar-array processing scheme.

Growth of crystalline silicon material in a geometry that does not require cutting to achieve proper thickness is an obvious way to eliminate costly processing and material waste. Growth techniques such as edge-defined film-fed growth (EFG) and dendritic growth (web), are possible candidates for the growing of solar-cell material.

Research and development of ribbon and ingot growth, and of multiple-blade, multiple-wire, and inner-diameter (ID) blade cutting, initiated in 1975-76, are in progress.

ORGANIZATION AND COORDINATION

When the LSA Project was initiated (January 1975) a number of methods potentially suitable for growing silicon crystals for solar-cell manufacture were known. Some of these were under development; others existed only in concept. Development work on the most promising methods is continuing. After a period of accelerated development, these methods will be evaluated and the best will be selected for advanced development. As the growth methods are refined, integrated process schemes will be developed by which the most cost-effective solar cells can be manufactured.

The Large-Area Silicon Sheet Task effort is organized into four phases: research and development of sheet growth methods (1975-77); advanced development of selected growth methods (1977-80); prototype development (1981-82); development, fabrication, and operation of pilot production growth plants (1983-86).

INGOT TECHNOLOGY

Crystal Systems, Inc.: The Schmid-Viechnicki technique (heat-exchanger method or HEM) was developed to grow large single-crystal sapphire. Heat is removed from the crystal by means of a high-temperature heat exchanger. The heat removal is controlled by the flow of helium gas (the cooling medium) through the heat exchanger. This obviates motion of the crystal, crucible, or heat zone. In essence, this method involves directional solidification from the melt where the temperature gradient in the solid is controlled by the heat exchanger and the gradient in the liquid is controlled by the furnace temperature. The overall goal of this program is to determine whether the heat-exchanger ingot casting method can be applied to the growth of large shaped-silicon crystals of 30-cm-cube dimensions of a quality suitable for the fabrication of solar cells. This goal is to be accomplished by the transfer of sapphire-growth technology (50-lb ingots have already been grown), and theoretical considerations of seeding, crystallization kinetics, fluid dynamics, and heat flow for silicon.

Kayex Corp.: In the advanced Cz contracts, efforts are geared to developing equipment and a process to achieve the cost goals and demonstrate the feasibility of continuous-Cz solar-grade crystal production. Kayex has already demonstrated the growth of 150 kg of single-crystal material, using only one crucible, by periodic melt replenishment.

Semix: The semicrystalline casting process is a Semix proprietary process yielding a polycrystalline silicon "brick" capable of being processed into cells of up to 16% efficiency at AM1.

Crystal Systems, Inc., P. R. Hoffman Co. and Silicon Technology Corp.: Today most silicon is sliced into wafers with an inner-diameter saw, one wafer at a time. Advanced efforts in this area are continuing. The multiwire slicing operation uses reciprocating blade-head motion with a workpiece fed from below. Multiwire slicing uses 5-mil steel wires surrounded by a 1.5-mil copper sheath that is impregnated with diamond as an abrasive.
The multiblade slurry technique is similar to the multiwire slicing technique, except that low-carbon steel blades (typically 1 cm in height and 6 to 8 mils thick) are used in conjunction with an abrasive slurry mixture of SiC and oil.

**MATERIAL EVALUATION**

Applied Solar Energy Corp. (ASEC): Proper assessment of potential low-cost silicon sheet materials requires the fabrication and testing of solar cells using reproducible and reliable processes and standardized measurement techniques. Wide variations exist, however, in the capability of sheet-growth organizations to fabricate and evaluate photovoltaic devices. It is therefore logical and essential that the various forms of low-cost silicon sheet be evaluated impartially in solar cell manufacturing environments with well-established techniques and standards. ASEC has been retained to meet this need.

Materials Research, Inc.: The current MRI sheet defect-structure assessment effort includes a correlation of impurity distributions with defect structures in various sheet materials obtained from the ingot and shaped-sheet manufacturers.

**SHAPED-SHEET TECHNOLOGY**

Mobil Tyco Solar Energy Corp.: The EFG technique is based on feeding molten silicon through a slotted die. In this technique, the shape of the ribbon is determined by the contact of molten silicon with the outer edge of the die. The die is constructed from material that is wetted by molten silicon (e.g., graphite). Efforts under this contract are directed toward extending the capacity of the EFG process to a speed of 4.5 cm/min and a width of 10.0 cm. In addition to the development of EFG machines and the growing of ribbons, the program includes economic and theoretical analysis of ribbon thermal and stress conditions.

Westinghouse: Dendritic web is a thin, wide ribbon form of single-crystal silicon produced directly from the silicon melt. "Dendritic" refers to the two wirelike dendrites on each side of the ribbon, and "web" refers to the silicon sheet that results from the freezing of the liquid film supported by the bounding dendrites. Dendritic web is particularly suited for fabrication into solar cells for a number of reasons, including the high efficiency of the cells in arrays and the cost-effective conversion of raw silicon into substrates.
Encapsulation Task

INTRODUCTION

The objective of the Encapsulation Task is to develop and qualify one or more solar-array module encapsulation systems that have demonstrated high reliabilities and 20-year lifetime expectancies in terrestrial environments, and that are compatible with the low-cost objectives of the Project.

The scope of the Encapsulation Task includes developing the total system required to protect the optically and electrically active elements of the array from the degrading effects of terrestrial environments. The most difficult technical problem has been the development of high-transparency materials for the sunlit side that also meet the LSA Project low-cost and 20-year-life objectives. In addition, technical problems have occurred at interfaces between elements of the encapsulation system, between the encapsulation system and the active array elements, and at points where the encapsulation system is penetrated for external electrical connections.

The encapsulation system also serves other functions in addition to providing the essential environmental protection; e.g., structural integrity, electrical resistance to high voltage and dissipation of thermal energy. The approach used to achieve the objective of the Encapsulation Task includes an appropriate combination of contractor and JPL in-house efforts, which can be divided into two technical areas:

(1) **Materials and Process Development.** This effort includes all of the work necessary to develop, demonstrate, and qualify one or more encapsulation systems to meet the LSA Project cost and performance goals. It includes the testing of off-the-shelf materials, formulation and testing of new and modified materials, development of automated processes to handle these materials during fabrication of modules, and systems analysis and testing to develop optimal module designs.

(2) **Life Prediction and Material Degradation.** This work is directed toward the attainment of the LSA Project 20-year-minimum life requirement for modules in 1986. It includes the development of a life-prediction method applicable to terrestrial photovoltaic modules and validation by application of the method to specific photovoltaic demonstration sites. Material degradation studies are being conducted to determine failure modes and mechanisms. This effort supports both the materials and processes development work and the life-prediction method development.

SUMMARY OF PROGRESS

Materials and Process Development

**Pottant Materials**

New material products tailored to the specific requirements defined and publicized by the LSA Project for PV module encapsulation are now available from general suppliers. These products include nonblocking ethylene vinyl acetate (EVA) film in production quantities, laminated EVA-Tedlar sheets, and
ENCAPSULATION TASK

polymethyl methacrylate (PMMA) UV-screening cover films from Du Pont and 3M. Springborn Laboratories, Inc., has also achieved pilot-plant production capability for poly-n-butyl acrylate (PnBA). PnBA and ethylene methylacrylate (EMA) casting syrups are available for industrial evaluation. Springborn is also evaluating other casting liquids, including an aliphatic polyether urethane from Development Associates.

In a survey of edge-seal and gasket materials, Springborn has identified ethylene-propylene-diene monomer (EPDM) as the lowest-cost gasketing material now available. This material, specifically Du Pont Nordel EPDM with a proprietary formulation designed for a long outdoor service life, has been purchased and is being evaluated.

Springborn is also evaluating low-soiling surfacing materials. Preliminary results in this area indicate that glass, Tedlar and acrylic front-cover films having surface treatments containing fluorine remain measurably cleaner than either untreated controls or materials having other anti-soiling surface treatments.

Hygroscopic expansion has been verified as a major cause of cell cracking in modules using woodboard substrates. Various methods of coating and sealing the substrate to prevent initial desiccation during vacuum-bag processing have not been successful. Materials and processing studies in this area are continuing at JPL and Springborn.

A report, "Photovoltaic Module Encapsulation Design and Materials Selection" (JPL Document No. 5101-177, in press), has been written to describe the module encapsulant material requirements for the various functional elements of a complete photovoltaic module encapsulation package. This information is presented in terms of material properties, performance, life and cost requirements. It describes the status and availability of potential material and process candidates with criteria and guidelines for their selection, processing, and optimizing configurations for specific applications. This report is expected to be published and distributed in about three months.

UV Absorbers

Work has continued on the development of chemically bound UV stabilizers for polymer films. O. Vogl's group at the University of Massachusetts has successfully grafted 5-vinyl tinuvin to a wide variety of polymers including EVA, PMMA, polycarbonate, nylon and PnBA. Evaluation of these modified polymers is being conducted at Springborn.

Development of other (more available) UV stabilizers by Vogl has resulted in the synthesis and copolymerization of 2(2-hydroxy-5-isopropenylphenyl) 2H-benzotriazole (2H5P). The compound does not homopolymerize, however, and grafting attempts with 2H5P have not been successful. At the same time, and based on the same intermediates as those used for the synthesis of 2H5P, a new synthesis of 2(2-hydroxy-5-vinylphenyl) 2H-benzotriazole (2H5V) has been carried out that promises to have advantages over 2H5P. Grafting of 2H5V onto a number of common polymers has been accomplished, including atactic polypropylene, polyethylene-co-vinyl acetate, PMMA, polybutyl acrylate and polycarbonate. In preliminary experiments 2H5P does not graft under similar conditions.
ENCAPSULATION TASK

Efforts are continuing in the evaluation of the spectral characteristics of these compounds to establish clearly and beyond any doubt the most effective derivative of 2(2-hydroxyphenyl) 2H-benzotriazole as the prime candidate for polymerizable UV stabilizers for the LSA Project.

Springborn, with JPL, has begun the evaluation of new polymeric and monomeric UV stabilizers and high-performance anti-oxidants. These materials have just become available from American Cyanamid Co. for evaluation as long-life stabilization additives for low-cost encapsulation materials.

Electrostatic Bonding

All of the electrostatically bonded (ESB) minimodules have been received from Spire Corp. This includes five modules with preformed mesh interconnects. All modules are undergoing laboratory and field testing.

Antireflective (AR) Coatings

Both AR coating contracts with Motorola Inc. have been completed. All deliverables (reports and glass samples) have been received. Both AR coatings, acid etch and sodium silicate, have been deployed for outdoor evaluation by JPL.

Module Design

Experimental validation and updating of an optical-performance prediction model is continuing at Spectrolab, Inc. The effects of various module encapsulant design parameters on module thermal response, optical performance, electrical isolation, and solar cell stresses are being evaluated. It was observed that module electrical isolation approaching intrinsic material properties could be achieved with two or more dielectric layers (pottant plus film). Electrical breakdowns finally occurred at sharp corners and edges of solar cell or circuit components. Voids and bubbles in the encapsulant did not significantly contribute to electrical breakdown. Optical evaluation of various module configurations verified the effectiveness of AR coatings, as compared with uncoated designs. It was also observed that power output was independent of EVA thickness for thicknesses between 10 and 35 mils. It was further found that designs employing Craneglas above solar cells were as efficient as, if not more efficient than, modules not having Craneglas above the cells.

A report has been completed on the thermomechanical modeling and optimal stress design of a Solarex minimodule. Results indicate that modules with substrates and adhesives having lower moduli of elasticity and thicker adhesive bond lines have lower maximum thermally induced stresses. Guidelines are presented for evaluating stress levels and adhesive thickness of future designs.

A joint effort between JPL and Spectrolab is under way to develop graphical design analysis curves, i.e., master curves with reduced variables. These curves, when defined and verified, will enable the module designer to optimize the encapsulant-system design parameters such as pottant thickness, pottant modulus, and cover-film properties and to assess which module performance characteristics are most affected by encapsulant configuration and material choices.
ENCAPSULATION TASK

Based on these curves, Spectrolab will fabricate and test a 1.4-m-square module of a design having the most favorable life-cycle energy cost.

Illinois Tool Works (ITW) has demonstrated the capacity to produce operational solar cells having front and back metallization and antireflective coatings deposited by gasless ion plating. The process has repeatedly produced cells equal to or better than comparable commercial cells in performance, at a projected (SAMIS) production cost of 5.6¢/Wp for the metallization plus AR coating.

The problem of ohmic contact of the ion-plated metallization on the p back surface of Spectrolab wafers is continuing to be investigated at ITW.

Bonding and Primers

E. P. Plueddemann of Dow Corning Corp. is continuing his work on encapsulant primer systems. Functional EVA-to-glass and EVA-to-polyester film primers (independently developed) have been identified. These primers appear initially to work also for EMA, although testing is incomplete. Work on primers for bonding fluorocarbon films to EMA, EVA and PnBA is continuing. Progress is also being made on polyurethane coating potting primers. Complete development of these is expected within a year.

Material Degradation and Life Prediction

Photodegradation Model for EVA

The general computer program necessary to simulate the process of photodegradation is now in routine use in the University of Toronto laboratory. The operational facility can generate concentration-time profiles of all of the identifiable species for a given input mechanism and rate data set. A summary of three tentative conclusions produced by computer simulation are: the major products of alkane photodegradation are isomeric alcohols, ketones and water; there is minimal crosslinking at low levels of oxidation in linear alkanes, and the product distribution and overall rate of oxidation is dominated by the fate of the peroxy radicals formed in the propagation cycle after proton abstraction from the alkane.

Experimental studies of photodegradation of n-decane and 2,4-dimethyl pentane (DMP) are being done to improve the initial mechanism proposed for the photodegradation of hydrocarbon segments of EVA. Most of the products of photodegradation of n-decane and DMP, such as isomeric alcohols and ketones, have been identifiable using gas chromatography (GC). Failure to observe speculated results, however, suggests that only primary products associated with the early stage of photodegradation are being formed under the photodegradation experimental setup (medium-pressure Hg lamp with a Pyrex glass UV-filtered vessel and irradiation times of 4 to 48 h). In extended outdoor exposure, slow secondary processes become significant and may even dominate final failure modes associated with embrittlement, permeability, discoloration, etc. If these processes can be identified in the early stage, retardation, monitoring or control of the photodegradative breakdown of these plastic materials may be possible. Further testing to quantify these processes is continuing.
ENCAPSULATION TASK

The automatic viscometer capable of measuring up to 50 or 60 solutions in automatic sequence is now fully operational and has been demonstrated. The laser-GC photolysis apparatus which, by monitoring yields of carbon monoxide, acts as a probe of early photooxidation in polymer films, remains to be demonstrated.

Stress relaxation of EVA at small strains (<10%) is being measured at various temperatures by JPL. The objective of this work is to obtain an understanding of flow behavior and its dependence on photothermal degradation of EVA. The log stresses vs log time curves for data between -50°C and +30°C were found to be superimposable. This indicates that flow behavior of EVA may be similar to that of other elastomers, although X-ray diffraction has shown that EVA is a crystalline copolymer. Measurements at other temperatures are in progress. These data will be used in the development of master curves that are needed for life-prediction modeling.

Corrosion Diagnostics and Modeling

The 1980 Annual Report was received from the Rockwell Science Center. The major conclusions discussed in this report are summarized:

1. Completion of a 13-month field study of atmospheric corrosion at the LSA test site at Mead, Nebraska, verifies the fundamental assumptions of a new atmospheric corrosion model, which predicts that corrosion rate is the product of the moisture condensation probability ($P_c$) and the maximum ionic diffusion current ($I_L$) at the corrosion interface. Encapsulant protection is specifically related to suppression of $I_L$ at the corrosion interface.

2. Alternating-current impedance measurements as a function of frequency combined with impedance spectrum analysis appear to provide a new and versatile nondestructive evaluation (NDE) for solar arrays.

3. A computer model for hydrothermal stress analysis (HTSA) has successfully analyzed and predicted the internal stresses and solar-cell cracking mechanisms in LSA modules using a fiberboard substrates. Diffusion-barrier coatings of EVA or polytrifluoroethylene (KEL-F) delay but do not change the failure process.

The atmospheric corrosion model and corrosion monitors are now being combined in a new laboratory test plan for encapsulant bond evaluation. Both ionic conduction and electromechanical mechanisms of corrosion are being evaluated under laboratory simulation of atmospheric corrosion conditions. The Science Center atmospheric corrosion simulator, which controls UV, moisture, and temperature cycles, is being used in these studies.

Efforts are now concentrated on developing corrosion monitors as NDE tools for module-life prediction and on developing corrosion models and materials selection criteria for environmental corrosion-resistant interfaces. Integrated with the use of atmospheric corrosion monitors (ACM) for encapsulant primer evaluations, ac impedance measurements now provide information on modules undergoing moisture diffusion.
ENCAPSULATION TASK

Experiments aimed at correlating moisture diffusion and ac impedance responses of two Block IV modules show that the effect of small changes in moisture content can be sensed, despite scatter in the measurement resulting from thermal fluctuations. The thermal fluctuations have recently been eliminated through tighter thermostatic control. These baseline tests have been extended to include a study of the temperature response of one of the cells. In these tests the cell was thoroughly dried and stored in a desiccator. Ac impedance of the cell under zero bias and in a dark, thermostatted cabinet provided the shunt resistance ($R_{SH}$) of the cell as a function of temperature. A plot of $1/R_{SH}$ vs. $1/T_{OK}$ was found to be linear. The activation energy resulting from this Arrhenius behavior is 7.23 kcal/mole (0.31 eV). The 7.23 kcal/mole activation energy for the dry cell corresponds to a charge transport other than that controlled by liquid state diffusion and may result from a process internal to the semiconductor.

The delivery of the field-instrument design for the measurement of ac impedance has been postponed until September. It is expected that the design will incorporate slight modifications in available hardware.

An inventory of materials used for module encapsulation has been supplied to the Science Center by JPL. Some of these materials will be screened for their corrosion-protection potential by means of the ACM technique.

Photodegradation of Polymers

Studies are continuing by G. Rogers's group at Case Western Reserve University on the photodegradation of PnBA. The studies use Fourier transform infrared (FTIR) absorbance and difference spectra to characterize changes in unmodified PnBA after weathering in the QUV Accelerated Weathering Tester. Results to date indicate that PnBA degrades by means of chemical crosslinking and chain scission in the presence of oxygen. It was also observed that unmodified PnBA is fairly stable in oxygen-free environments. This leads to a preliminary conclusion that, for PnBA, antioxidant additives may be more important to long-term stability than UV stabilizers.

Fracture and Crack Modeling

An evaluation of commercially available finite-element programs to calculate the crack-tip stress-intensity factors ($K_{IC}$) with temperature gradients has been completed. Several programs were identified including MARC (MARC Analysis Research Co.), ANSYS (Swanson Analysis Systems, Inc.), ADINA (MIT), and TEXGAP (University of Texas, Austin).

The TEXGAP program, a FORTRAN-coded finite-element computer program, was received by JPL. The main feature of the program, not available in other commercial programs, is the availability of a finite-element code that has been developed for the analysis of cracks in structures due to differential temperature loading. To date, the TEXGAP program has not been successfully run at JPL; additional programming and engineering effort would be required to prepare the program for use in test-case calculations. This will not be done; this contract has been terminated due to funding cutbacks. The results of the program were to have been used for solar-array life prediction.
ENCAPSULATION TASK

Module Life Testing

Validation of the Battelle accelerated-test plan at JPL has been discontinued after 120 days (360 cycles) of accumulated test time. Electrical tests at room temperature continue to show that one module has completely failed, and four others exhibit power losses exceeding 10%. Visual inspection continues to show additional stress cracks in the interconnects, and small delaminations are beginning to appear. Electrical continuity tests at +95°C indicate that only one of the 10 modules is still functional at that temperature, and 50% of the modules exhibit open circuits at 60°C. Nearly all of the performance degradation appears to be attributable to interconnect fatigue failure. A final report on the study is being prepared.

Minimodule qualification testing (thermal cycling and humidity-freeze cycling) and measurement of nominal operating cell temperatures (NOCT) are about 50% complete. NOCT values have ranged from 39.8°C to 45.7°C for six module designs. All field-test minimodules have been deployed at the JPL and Goldstone weathering sites. The Point Vicente weathering site will be reactivated in August, when increased module security will be available.

Very little visual degradation of minimodule or two-cell subminimodule encapsulation has been detected, but a great number of cracked cells have been reported in modules with wood-fiber hardboard substrate. This is primarily due to the hygroscopic expansion of the substrate. Various attacks on this problem are being developed.
PROCESS DEVELOPMENT AREA

INTRODUCTION

The Area name has been shortened from the original Production Process and Equipment Development Area to Process Development Area.

Since the start of the Project, the Process Development Area has assessed and monitored the development of those processes that showed promise of reducing processing costs significantly. Four categories of processing were identified as critical: surface preparation, junction formation, metallization, and module completion. More recently, the Process Development Area has begun integrating individual processes into complete processing sequences.

AREA OBJECTIVE

The objective of this area is to identify, assess, and develop processes and process sequences to reduce fabrication costs of reliable solar modules, and to make these processes available to the photovoltaic industrial community through technology transfer.

SUMMARY OF PROGRESS

Process Sequence Development

Two module experimental process system development units (MEPSDU) are under contract, one with Solarex Corp. and one with Westinghouse Electric Corp. These contracts had been scheduled for completion in 1982; they were modified at the beginning of May 1981 to proceed at a reduced funding rate for the remainder of the fiscal year. This reduced rate alters the contract schedules to set completion dates in 1983-1984 with no change of scope of technical duties.

Both Solarex and Westinghouse completed preliminary design reviews, including presentations by major subcontractors, in March. As a result of the review, Westinghouse will go to a frameless module design. Twelve minimodules of this design have been built and are being given environmental tests.

Solar: x has replaced Kulicke & Soffa, Inc., with Tracor MBA as subcontractor for the automated soldering machine, due to cost considerations. Tracor MBA was selected from a group of solicited proposals.

Junction Formation

Work on the use of non-mass-analyzed (NMA) ion implantation has progressed to the point where it is quite clear that this process will be satisfactory for the manufacture of high-efficiency solar cells. Motorola Inc. is developing the process under private funding. Westinghouse and Spire Corp. are cooperating with JPL to establish sufficient knowledge for the development of commercial machines based on NMA ion implantation. Investigation of the source and control of contaminants, including those brought into the process by the silicon wafer itself, are continuing.
PROCESS DEVELOPMENT AREA

Spire has successfully demonstrated a 4-in.-dia capability with its pulsed-electron-beam annealing (PEBA) machine. Work is now concentrating on the development of an MMB ion implanter that is intended to be joined with the PEBA. This will allow ion implanting and annealing without breaking vacuum.

ECA Research Center has reported success in furnace-diffusing a junction into an epitaxial layer grown on a metallurgical-silicon substrate. It had been assumed for some time that the impurities in the metallurgical-grade silicon would penetrate the entire device at diffusion temperatures, forcing a departure from conventional processing.

Bernd Ross Associates have successfully produced experimental solar cells using a copper-based thick-film ink that incorporated a fluorocarbon as the fluxing agent. These cells survived 10 minutes in boiling water and retained good adhesion to the silicon. Studies of chemical reactions (involved in possible ink formulations) lead to concern over voids caused by release of gaseous products. The addition of lead acetate has provided a liquid-phase transport medium during firing that solves the void problem. Experimental data has substantiated the improvement in surface-contact conduction.

Spectrolab, Inc., has essentially completed the Midfilm metallization process contract. Two minimodules and 30 cells, 2.1 x 2.1 in., using the most promising silver-powder-based system, are being given environmental tests. Several experiments using powders based on molybdenum trioxide and tin (a technology from an earlier contract with Sol/Los) produced cells of varying low quality. A MoSn-base metallized cell of high series resistance was silver-electroplated, resulting in a cell of respectable performance. The MoSn system had successfully contacted the silicon but was highly resistive due to the limitation of the Midfilm process’s thickness capability.

A new contract with Photowatt International, Inc., was executed on May 15. Photowatt will evaluate the technical feasibility and cost effectiveness of firing a metallic thick film (Ni) through an AR coat (Si$_3$N$_4$) to make electrical contact with the sun side of a solar cell. Brush-type selective plating of Cu will also be investigated. The advantages are a simplified process sequence and lower material and processing costs.

Module Completion

Tracor MBA has assembled its cell-stringing machine, lamination machine and edge-sealing machine. All discrete functions of the machines have been tested and are operational. Remaining work is focused on a software program to synchronize the operation of the total assembly.

LABORATORY ACTIVITIES

New materials supplied by the Encapsulation Task have been tested in the modified ARCO Solar, Inc., laminator. Tedlar with Du Pont Adhesive No. 68040 adhered very well to the ethylene vinyl acetate (EVA) encapsulant and a new encapsulant, ethylene methyl acrylate (EMA). After 30 minutes in boiling water, the EMA encapsulant had bubbles visible in the bulk material but no delamination or reduction in peel strength. There was no visible or mechanical degradation
PROCESS DEVELOPMENT AREA

of the EVA laminant after 6 hours of boiling. Peel-strength tests broke the samples without peeling failure.

Experiments are being performed with the processes specified in both MEPSDU contracts to verify their performance and to identify as many sensitive elements as possible.
ENGINEERING AREA

INTRODUCTION

The LSA Engineering Area has two primary objectives: to assist in achieving Module Technical Readiness by developing engineering design criteria, test methods, analysis tools, and trade-off data that support the engineering of optimum modules from a least-cost-array point of view, and to achieve, at an early date, technical readiness with respect to the balance of the flat-plate array subsystem exclusive of the modules.

Activities within the Engineering Area emphasized array requirements generation, array subsystem development, module development, and array-performance criteria and test-standards development. An expanded description of the status of each of the Engineering Area contracts was included in the 18th P1M Handout (JPL Document No. 5101-181). Active contracts and referenced papers and documents are listed at the end of this section.

ARRAY REQUIREMENTS

The array-requirements activity addresses the identification and development of detailed design requirements and test methods at the array level. Areas of continuing activity that address improved definition of array requirements include the establishment of module and array electrical safety criteria, the generation of intermediate-load-center building codes as applied to intermediate array design, and the development of array-to-power-conditioner electrical interfaces, coordinated with Sandia National Laboratory and The Massachusetts Institute of Technology Lincoln Laboratory (MIT-LL).

Safety Requirements

A necessary element of module technology readiness, especially for residential and ILC applications, is the early development of safety requirements at the design level. Consistent with this goal, input obtained from the February 3 Workshop on Module and Array Safety and comments from program participants and the PV industry were used to update LSA Document No. 5101-164, "Interim Standard for Safety: Flat-Plate Photovoltaic Modules. Vol. I, Construction Requirements" (Reference 1). After updating, the document was distributed to the PV community and was specified as a supporting document for Block V procurements.

Supporting the development of array safety requirements, the National Electrical Code Ad Hoc Subcommittee on Photovoltaics (NEC AHSC) convened at JPL March 24 to 26 to draft revisions for the 1984 NEC. New articles that address the unique characteristics of a PV system and the changes needed to preclude an unsafe installation were the focus of this meeting. The PV Array working group of the NEC AHSC convened at JPL April 22 and 23 and at MIT-LL June 16 to 18 to draft the special array-related concerns for submittal to the NEC. A draft document now in review has specific areas requiring resolution (module definition, module identification, and maximum system voltage) before an NEC AHSC meeting at Westbrook, Illinois, August 11 to 13. In support of efforts toward residential roof-mounted array safety, additional roof-covering classification
ENGINEERING AREA

and fire-penetration tests are scheduled at Underwriters Laboratories on August 14 to determine a PV module's resistance to severe fire exposures from sources outside a building. Included are shingle and integral-mount residential-module designs.

Progress in array safety was documented in a paper presented at the American Section, International Solar Energy Society (AS ISES) meeting May 26, titled "Code-Related Considerations for Flat-Plate Photovoltaic Arrays" (Reference 2).

Commercial and Industrial Building Codes

In support of the development of intermediate-load array-design guidelines, Burt Hill Kosar Rittelmann Associates completed their assessment of intermediate-load-center building codes and regulations (initial results were presented at the 17th PIM). An executive summary and clarifying points are being added to the final report, which is scheduled for release September 15.

Power-Conditioning Interface

Selection of the optimum input voltage window for power conditioning is influenced by array voltage fluctuations caused by site weather conditions. A JPL in-house analysis, using solar radiation surface meteorological observations (SOLMET) typical-year data tapes, generated input for determining the optimum power-conditioning voltage, current and power levels vs array parameters. The completed data were provided to Sandia National Laboratory for both residential and intermediate-load applications. Tabulated data on array power-conditioner interface optimization will be included in Sandia's Power Conditioning Specification.

ARRAY SUBSYSTEM DEVELOPMENT

Array subsystem development activity is focused on the development of conceptual designs for integrated flat-plate array/module support structures as an important approach to minimizing total array costs. A critical output of array conceptual designs is the definition of specific design requirements addressed to functional performance, interface and maintainability (at the array level).

Integrated Residential Arrays

A number of residential array conceptual designs were evaluated during the reporting period through contracts with the American Institute of Architects Research Corp. (AIA/RC) and General Electric Co. (GE). Design reviews in conjunction with the integrated residential array effort were held February 17 and 18, March 19 and 20, and April 29 and 30.

AIA/RC reviewed the 15 conceptual designs generated by their architect subcontractors. The AIA/RC advisory committee, consisting of Solarex Corp., Heery Energy Consultants, National Association of Home Builders Research

28
Foundation and Energy Design Associates representatives, then selected three concepts for design optimization. Evaluations of these designs were completed and AIA/RC recommended the Burt Hill Kosar Rittelmann Associates design for final design and fabrication.

After evaluating 19 different module/array types, GE optimized three concepts: direct-mounted, overlapped, rectangular shingle; integral mount with plastic tray, and stand-off mount with aluminum frame. Further evaluation of these concepts resulted in approval of GE's optimized "universally mountable" design using a rolled-steel support. Refinement of this concept is in progress, with emphasis on reducing costs of array installation and module production.

JPL Engineering Area in-house efforts on residential module installation methods included the construction of six 4 x 4-ft panel frames (one module each) and a 45° test roof with a 16-ft slant height and a 12-ft width. Preliminary tests have shown a library-type rolling-ladder configuration to be convenient and to provide adequate access for module installation and replacement. Both aluminum and wooden frame module supports are being tested.

Large Ground-Mounted Arrays

In support of optimized large ground-mounted array design, a task report titled "Low-Cost Solar Array Structure Development" (Reference 3) was completed and distributed to the PV community. The report included cost analyses, durability and earthquake loading assessments based on modal testing.

Photovoltaic/Thermal Arrays

In the area of photovoltaic/thermal module development, an economic study that included installation costs showed the PV/T unglazed collector system to be marginally economical (life-cycle savings of $600 over 20 years). The study is being documented and further PV/T work is deemed unjustified.

Module Engineering

Module engineering addresses the development of design methods, analysis tools and design concepts necessary to support significant cost and performance improvements at the array-element level. Activities are conducted to clarify design tradeoffs, to develop analysis tools and test methods and to provide generalized design solutions for the PV community. Specific activities included cell reliability testing, module voltage isolation, interconnect fatigue, hot-spot endurance, cell-fracture mechanics, module soiling and module environmental endurance.

Cell-Reliability Testing

The Clemson University contract, which has been developing reliability and accelerated-stress test data on most of the solar-cell types now being used in LSA module designs, included evaluation of newly developed cells that have
ENGINEERING AREA

low-cost potential (due primarily to the type of metallization system used). Among the new cells received, those that use copper-based metallization systems show evidence of reduced mechanical strength on the lead attachments and low metal-to-silicon adhesion.

Module Voltage Isolation

The voltage isolation task addresses the source and magnitude of leakage currents to ground caused by initial insulation flaws or material aging. The development effort is directed toward predictions of module life and providing for human safety. Activities included:

The high-voltage field-test stand was upgraded to 3000 Vdc for use in continuing central-station module field-exposure insulation studies. In support of these tests, two experimental modules were instrumented with temperature and moisture (vapor) sensors and were calibrated under nine different combinations of temperature and relative humidity while under 3000 V electrification. Data reduction is in progress and the results will identify responses of both room-temperature vulcanized (RTV) and ethylene vinyl acetate (EVA) encapsulants.

The initial cell-string flaw-characterization tests were completed. Solar-cell electrodes used to break down air gaps of various sizes were observed to exhibit deviations from uniform field conditions, both at small gap separations (point-to-plane effects) and at large gap separations (square-edge effects).

Construction of a low-voltage film breakdown apparatus was completed and underwent preliminary testing with single-layer and multilayer polymer films. The data reduction system is being improved to permit higher data rates.

The electrical-insulation environmental-life test chamber for minimodules has been completed, less power and data collection circuitry.

Procurement of minimodules representing recent module designs (Block IV, PRDA and commercial) has been initiated, encompassing approximately 100 modules for environmental and life testing.

This work was documented in the 1981 Institute of Electrical and Electronics Engineers (IEEE) Photovoltaic Specialists Conference paper "Defect Design of Insulation Systems for Photovoltaic Modules" (Reference 4).

Interconnect Fatigue

Examination of the mechanical-fatigue life of cell interconnects is continuing in an effort to obtain a 20-year life-prediction model. Two parts of a report on cell-interconnect fatigue have been drafted: strain prediction and allowable strain analyses, and a cost-optimization algorithm. A nomograph on determining strain from interconnect-shape parameters was developed for presentation at the 18th PIM. In support of this effort, a three-axis micrometer-comparator to measure interconnect geometries in situ has been designed and
ENGINEERING AREA

built. This device will be used on modules undergoing thermal cycling to determine their geometries and their condition (e.g., breakage).

Hot-Spot Endurance

This activity's objective is development of suitable laboratory test procedures for evaluation of the hot-spot endurance of a module under severe hot-spot field conditions. Development activities included the collection of laboratory data from Block III modules for validating the analytical thermal model under development. The thermal model supports the development of module design guidelines for hot-spot endurance capability. Agreement between the model and test data has been generally close for both insulated- and uninsulated-back modules. Limits of model applicability are being developed and additional hot-spot tests are planned to validate the laboratory test procedures. A task report on hot-spot heating design guidelines is scheduled for December release. This effort was also documented in the 1981 IEEE PV Specialists Conference paper "Photovoltaic Module Hot-Spot Durability Design and Test Methods" (Reference 5).

Cell-Fracture Mechanics

Efforts in the fracture mechanics study of Si solar cells centered on the design of a mechanical-strength-testing jig. The prototype testing jig is designed to evaluate the feasibility of a quality-control method for Si wafers and cells, based on testing their mechanical strength. Results were reported in a PV Specialists Conference paper, "Application of Fracture Mechanics to the Failure Analysis of Photovoltaic Solar Modules" (Reference 6).

Module Soiling

Module soiling studies continued with samples measured from 70% of the field-test sites. The trends exhibited after six months in the field this year closely follow those established during the previous year of field exposure. JPL in-house research also included low-cost cleaning methods for arrays, using both water and chemical-cleaner spray washes. A chemical cleaner proved superior to multiple water washes on glass samples with oily films, increasing the relative normal hemispherical transmittance from 87% to 99%. The upper limit was 94% using water washes.

Module Environmental Endurance

Several environmental-endurance development efforts are being addressed to provide the technical base required to achieve reliable modules with 20-year lifetimes. The Illinois Institute of Technology Research Institute (IITRI) is continuing its work in compiling reliability data on all module design technologies vs design technology performance in both field use and field tests. A major input to the IITRI work was initiated when the U.S. Coast Guard Research and Development Center agreed to provide LSA with reliability data obtained from different module designs it has tested.
ENGINEERING AREA

JPL in-house efforts included the development of detailed test methods for salt-spray testing in both outdoor and lab test environments, and a humidity-degradation rate curve based on comparisons of humidity testing cycles and humidity-temperature data from SOLMET weather tapes. To obtain the required temperature-humidity acceleration factors, a contract was initiated with Wyle Laboratories to subject Block I and Block III modules to six-month humidity tests with environments of 40°C, 93% RH and 85°C, 85% RH.

A review of the overall module test program at JPL was presented at the 1981 Institute of Environmental Sciences Conference in a paper, "Outdoor and Laboratory Testing for Photovoltaic Modules" (Reference 7).

PERFORMANCE CRITERIA AND TEST STANDARDS

Active interfaces are maintained between LSA Engineering activities and the Solar Energy Research Institute (SERI) Performance Criteria-Test Standards (PC/TS) project to draft interim performance criteria and standards covering both flat-plate and concentrator arrays.

In support of the SERI project, the Array Subsystem Task Group convened at JPL February 2 and at Motorola Inc., Government Electronics Division (GED) March 18 and 19 to update the "Interim Performance Criteria for Photovoltaic Energy Systems" report distributed by SERI (No. SERI/TR-742-654). Emphasis was placed on the review of new and redrafted criteria and test methods in personal safety, durability and reliability, and concentrator electrical performance. The task group presented 12 criteria statements, three test methods and 18 definitions to SERI, who will publish the second edition (now in review) of the Interim Performance Criteria document (IPC-2) in December.

The Electrical Performance Subgroup of the Array Subsystem Task Group (led by Arizona State University) met at JPL February 3, at Motorola GED March 17 and at Orlando, Florida, May 11 to 15, to determine acceptable test methods for measuring optical performance of reflective concentrators. The lens test methods are being prepared for Task Group submittal.

Also in support of SERI's Performance Criteria and Test Methods Project, JPL formed a Photovoltaic Environmental Subgroup to review and document environmental test methods for array subsystem elements. JPL, Sandia, the U.S. Department of Defense, and foreign organizations are evolving environmental test requirements and methods for photovoltaics that should be examined in detail by a cadre of outdoor and laboratory testing experts. The objective of the subgroup is to develop for flat-plate and concentrator array elements a cost-effective set of environmental qualification test procedures that can provide reasonable assurance of reliable performance in a wide range of climates. The first meeting of this subgroup was held at JPL July 14.

ENGINEERING SUPPORT

Engineering interface activities provide for transfer of array requirements, specifications, conceptual designs, design guidelines, analysis tools and test methods to the photovoltaic community. R. G. Ross Jr., Engineering Area manager, lectured on module and array engineering at a three-day short
course on photovoltaics conducted by Arizona State University. The presenta-
tion was later embodied in two IEEE PV Specialists Conference papers titled
"Design Techniques for Flat-Plate Photovoltaic Arrays" and "Photovoltaic Module
and Array Reliability" (References 8 and 9). Additional past work on the
probability statistics of cloudy days was presented at AS ISES in a paper,
"Techniques for Determining Solar Insolation Deficits" (Reference 10).

A matrix comparing design features of photovoltaic modules in field applica-
tions and LSA procurements was generated. The matrix, intended to facilitate
comparisons of design and test history data, includes module types with mate-
rials of construction; cell types with materials used for inter-connects and
metallization, coatings, etc.; module and system circuit (series-parallel) con-
figurations that identify series blocks, blocks per diode, etc., and specific
problems encountered in both field and laboratory tests. It will be continually
updated.

JPL's Engineering Area staff participated in the MIT-LL Residential PIM
in Cambridge, Massachusetts, on June 24-25, 1981. Presentation topics included
LSA Project Update, Block V Performance Requirements, and Integrated Array
Designs. Presentations made at the Photovoltaic System Definition and Develop-
ment PIM at Sandia April 8 included "Photovoltaic Array Safety Requirements."

Module design specifications were developed, including "Block V Solar Cell
Module Design and Test Specification--Intermediate-Load Applications" and
"Block V Solar Cell Module Design and Test Specification--Residential Applica-
tions." These documents were released February 20 as part of the Block V RFP
(References 11 and 12). A preliminary draft of the Central-Station Module
Design and Test Specification was circulated for LSA in-house review.
REFERENCES

OPERATIONS AREA

INTRODUCTION

The overall objectives of the Operations Area are to stimulate the use by module manufacturers of the latest improvements and innovations in module production and design technology through contracts for development of qualified solar-cell modules; to perform appropriate environmental and stress tests to confirm the adequacy of module design; to operate field-test sites to accumulate the data needed to establish the kinds and levels of environmental stress tests required to qualify modules; to perform failure analysis on modules that have failed either in the field or during qualification testing to provide guidance for proper corrective action, and to provide testing and failure analysis services and facilities as required to support other DOE test and applications experiments.

MODULE DEVELOPMENT

Block IV Design and Qualification

Only small progress has been made toward completing the design and qualification phase of the Block IV effort. In the ARCO Solar, Inc., intermediate-load module, the butyl edge sealant, which had softened and flowed during thermal cycling, was replaced by a new acrylic copolymer sealant. Modules with this sealant successfully completed all of the pertinent qualification tests. Drawings for the ARCO residential modules were approved and modules were delivered to JPL for testing. Before testing could be started, ARCO requested permission to substitute for the delivered modules a new set using a Tedlar front cover of twice the thickness previously used, in an effort to overcome an edge-delamination problem that had appeared on similar modules tested for the Southwest Residential Experiment Station (RES). The Photowatt International, Inc., module that failed the test program has had design changes and new modules are being fabricated. Solarex Corp. modules of both intermediate-load and residential configurations have been submitted for testing, but none has passed.

Block IV Production Contracts

Purchase orders for a few kilowatts of modules designed and qualified under the provisions of the Block IV design contracts have been placed with all of the contractors. A contract for the ARCO intermediate-load module was placed, late in this reporting period, but no order has been placed for the residential module. General Electric Co. and Motorola Inc. have delivered all modules required by purchase orders placed with them. Applied Solar Energy Corp. and Spire Corp. have made partial delivery of the modules ordered from them. All other orders for modules are under a contractually imposed hold until tests are completed and the final design documentation is in order. This hold pertains to the Photowatt modules and both Solarex (residential and intermediate-load) modules. No modules of the Block IV design were produced for sale by Solar Power Corp., but a laminated module of their commercial configuration that had been altered to conform to the Block IV specification passed all the qualification tests.
OPERATIONS AREA

Block V Design

The RFP for the Block V competition was released to 29 potential propos­
ers in February. Fourteen organizations proposed 19 different module designs, which were evaluated and rated. Selections were made and seven contracts were negotiated as follows:

Intermediate-Load Modules:
- ARCO Solar
- RCA
- Solar Power Corp.
- Solarex

Residential-Load Modules:
- General Electric
- Mobil Tyco Solar Energy Corp.
- Spire

MODULE TEST AND EVALUATION

Performance Measurements

New reference cells have been selected, fabricated and calibrated for Block IV modules manufactured by ASEC, GE and Photowatt because latest versions of their modules and original reference cells no longer matched in spectral response. In addition, new reference cells have been selected, fabricated and calibrated for use by Massachusetts Institute of Technology Lincoln Laboratory (MIT-LL) in testing ASEC, ARCO, Solcel International, Solarex, Motorola, Photowatt, and Spire (photovoltaic/thermal) modules. Several Block II and Block III reference cells were recalibrated at JPL for use by DSET Laboratories, Inc., and Wyle Laboratories. Forty-three additional reference cells are being selected, fabricated and calibrated for use by JPL Field Testing, Sandia National Laboratory and Solenergy Corp.

The large-area pulsed solar simulator (LAPSS) No. 2 is continuing to function properly and is being used primarily for Encapsulation Task module evaluation, reference-cell evaluation and selection, and miscellaneous engineer­
ing measurements. LAPSS 1 is presently being integrated with the PDP 11/60 computer. All required hardware has been completed and final system evaluation is nearly complete. Preliminary comparison tests indicate an even closer agreement between the two LAPSS systems than previously reported. The color temperature of LAPSS 2 was found to be somewhat higher than that of LAPSS 1, resulting in an increase in illumination in the blue portion of the LAPSS 2 spectrum.

The PDP software has been modified to allow the storage of parameter tables unique to each type of module under evaluation. This greatly reduces operator error and significantly increases throughput by reducing the time required for the operator to enter or modify a specific module's parameter table. New tables can be added or deleted easily.
OPERATIONS AREA

Environmental Testing

Testing is continuing or has been completed on Block IV, MIT-LL Residential Experiment Station, Program Research and Development Announcement (PRDA)-38 retest, World Bank, Process Development Area, and commercial modules. The results are given in Tables 3, 4, and 5. In addition to the familiar Block IV tests, two hot-spot test stations have been set up in Building 248-2. Hot-spot tests, called out in the Block V Design and Test Specification, have been run on MIT-LL RES, PRDA-38, World Bank, and Block IV types of modules.

Qualification testing is still under way on Block IV modules. Six types are considered to have qualified and four are not. Most module types did not pass the first time and improved designs had to be submitted by the manufacturers. The six qualified types averaged two sets of tests and the still-to-be-qualified types have averaged three sets. Tests run on samples drawn from the lots of modules purchased after qualification indicate that the level of quality of the module has not been maintained. Some significant degradation has occurred, which casts doubt on the ability of the manufacturers to maintain quality of product consistently. All modules given the new hot-spot test passed except two, MIT-LL GR and World Bank UU. Encapsulant bubbles and discoloration are common. Of the failed modules, the common failure mode is a reduction of shunt resistance (partial shorting) of the cells. No catastrophic failures have occurred.

Field Tests

For a combination of fiscal, logistic and technical reasons, a major restructuring of field-test activity was required. Since the 17th Project Integration Meeting in February a plan was formulated and is being implemented. Details of this plan were presented at the 18th PIM.

Most of the effort since the 17th PIM has centered on the restructuring of the test sites. A key feature of the restructuring is that the Blocks I, II, and III modules now deployed at the local sites will either be transported to an enlarged Goldstone site for continued testing (on a time-available basis) or surplussed. On June 19 the last set of routine data was obtained on these modules at the JPL site. An analysis of the electrical performance data for the past eight months indicates that nine additional modules failed since October of 1980 and that 32 of the remaining 211 modules are now degraded. A summary of the electrical performance data is presented in Table 6. Using a new analysis program that factors out the effects of embedded dirt on performance, the mean power decrement of the degraded modules was determined. Table 7 contains a breakdown of this information.

To obtain an update of all the modules at the local sites before their relocation, electrical performance data also was obtained on the Goldstone and Table Mountain modules (the Point Vicente modules were stolen in March of 1981). Of the original 162 modules deployed at the two sites several years ago, 12 failed before October 1980. Four other modules have failed since then. Three of these are Block I Solar Power modules at Goldstone. Of the remaining 146 modules, 10 have degraded.

Other significant accomplishments:

1. The decommissioning of the 12 continental remote sites (in accordance with the restructuring plan) was started and is well under way. Contracts are being let to the resident site managers to remove and ship the test modules to JPL, and to remove the stands from the ground. Completion of the decommissioning is expected by the end of September.

2. Plans are proceeding to establish a hot, humid environmental-test site (in accordance with the restructuring plan). A two-phase contract was let to the Florida Solar Energy Center at Cape Canaveral for the site. The first phase covers the installation of test stands and the establishment of the site at their facility; it should be completed in mid-September. The second phase covers routine monthly inspections of the modules to be deployed at the site.

3. Expansion of the Goldstone site was completed in July. The site was enlarged to accommodate 30 additional 4 x 4-ft test units, which will be used to support the old modules. A security fence will be installed around the site's perimeter. It is expected to be in place by the end of September.
OPERATIONS AREA

4. Removal of the hundreds of feet of wiring for the old modules at the JPL site was started and completed in July. Rewiring of the site for the Block IV modules, in accordance with the restructuring plan, is expected to be done by the middle of October, contingent upon availability of materials.

5. In-house fabrication of a battery-powered array data logger, capable of collecting data and providing diagnostics on 40-A, 400-V arrays, was initiated. Completion of this instrument is expected by the end of September.

Failure Analysis

Problem and failure analysis activity continued to provide failure-analysis support to the test and applications experiments of MIT-LL and Lewis Research Center (LeRC), and also to the JPL field and environmental test activities. Additional failed Block II and III Solarex modules from Bryan, Ohio, and Schuchull, Arizona, were confirmed to have failed because of broken interconnects, as reported previously. MIT-LL submitted two Solarex modules from the Carlisle house because of voltage breakdown. The problem was caused by moisture ingress to voids in the edge seal and the module wire layout. MIT-LL also sent an ARCO module from the Westinghouse Northeast RES that exhibited excessive leakage current to ground. It was determined that the foil vapor barrier was floating, providing a series capacitance and allowing a large voltage to develop between foil and ground. Grounding the foil transfers the voltage stress to the encapsulant and the withstanding voltage could be increased from 800 Vdc to 3500 Vdc without exceeding the allowable leakage current.

Finally, MIT-LL reported concern over leakage currents in ARCO modules used in the Hawaiian residences. This report is under review and study by failure analysis and engineering activities.

Block IV modules continued through qualification testing and suffered some failures. Photowatt modules experienced erratic power measurements and decreases in power after the environment tests. The erratic power measurements were traced to momentary overloading of the bypass diodes by the LAPSS in the process of curve tracing coupled with marginal diode current-carrying capacity. Further analysis showed shorting of the top and bottom surfaces of the cell. A laser scan is used before module testing to confirm cell matching and to discover shorted cells. Solarex modules have undergone extensive analysis effort. The problems encompassed uncured EVA, delamination of Tedlar back surface from EVA, cell back-contact metal not adhering to silicon, shorted diodes, shorted cells, inadequate de-aeration of the laminate and dielectric breakdown between frame and cell strings.

APPLICATIONS INTERFACE

Test and Applications support was provided as follows:

1. Attendance and follow-up support to 12 quarterly and critical-design reviews at Sandia for PRDA applications, and at MIT-LL for residential applications.
OPERATIONS AREA

2. Coordination and follow-up support of module qualification testing for the MIT-LL residential-applications experiments.

3. Coordination and follow-up support of module-failure analysis of field failures at various MIT-LL and LeRC installations.
The Low-Cost Solar Array (LSA) Project convened its 18th Project Integration Meeting (PIM) at the Pasadena Center on July 15-16, 1981.

The theme for this PIM was dual in nature--Perspectives for Progress, and Module and Array Long-Life Performance. This dual theme was believed to be timely in view of technical achievements to date. Viewpoints of the Project, the government, users and manufacturers on the status of photovoltaics development and its future needs were presented.

Emphasis was placed on displays showing the current status of technical advancements.

PERSPECTIVES FOR PROGRESS

JET PROPULSION LABORATORY

W.T. Callaghan

The Work Remaining

• PROJECT WILL FOCUS ON TECHNICAL FEASIBILITY TO:
  • ASSUME TECHNICAL RISKS THAT INDUSTRY WILL NOT ASSUME
  • EFFECT TRANSFER OF TECHNICAL FINDINGS TO INDUSTRY

• MEASURE OF SUCCESS IS
  • DETERMINED BY THE ADOPTION RATE OF INFORMATION AND ITS USEFULNESS TO INDUSTRY
  • PHOTOVOLTAIC POWER BECOMING COMPETITIVE

Specific Work Remaining in the Project

• SILICON MATERIAL REFINEMENT
• SHEET MATERIAL FORMATION
• ENCAPSULATION
• PROCESS RESEARCH AND DEVELOPMENT
Silicon Material

- LOW-COST MATERIAL IS VERY IMPORTANT TO INDUSTRY
- NO LOW-COST MATERIAL SOURCE EXISTS FOR INDUSTRY
- MATERIAL COMES FROM SEMICONDUCTOR INDUSTRY AT SEMICONDUCTOR PRICES: $60 - $80/kg
- LOWER-COST REFINEMENT PROCESSES REQUIRES BOTH LOWER-COST FEEDSTOCK AND DEPOSITION TECHNOLOGY,
- PROJECT, THROUGH INDUSTRY, HAS DEMONSTRATED NEW TECHNOLOGICAL PATHS TOWARD ACHIEVING BOTH REQUIREMENTS

- WHAT REMAINS TO BE DONE:
  - DEMONSTRATE TO INDUSTRY WITH SUFFICIENT CONFIDENCE THAT THE TECHNOLOGY FEASIBILITY IS SHOWN I.E.,
    - REPRODUCIBLE
    - SCALABLE TO INDUSTRIAL PROPORTIONS
    - PROFITABLE
  - THE MEASURE OF SUCCESS IS INDUSTRIAL ADOPTION AND AVAILABILITY OF SILICON TO THE PHOTOVOLTAICS INDUSTRY
Sheet-Material Formation

- INDUSTRY STANDARD IS SEMICONDUCTOR-INDUSTRY INGOT WAFER
  - ERRATIC SUPPLY
  - UNPREDICTABLE PRICE
  - HIGHLY VARIABLE QUALITY

- PROJECT, THROUGH INDUSTRY, HAS DEVELOPED ADVANCED INGOT TECHNOLOGICAL PATHS
  - PRODUCES HIGH-QUALITY SHEET MATERIAL
  - AT LOWER PRICE
  - WITH GREATLY INCREASED THROUGHPUT RATES

- ADVANCED INGOT WORK IS EXPECTED TO BE ADOPTED BY INDUSTRY

- THE LONGER-TERM, TRULY LOW-COST SHEET TECHNOLOGIES ARE MATERIAL-CONSERVATIVE; DRAWN RIBBON IS A PROMISING TECHNICAL APPROACH FOR WIDESPREAD U.S. ENERGY USAGE

- WORK REMAINING:
  - INVESTIGATE PROCESS EFFECTS ON CRYSTALLIZATION LEADING TO IMPROVEMENT IN SHEET QUALITY
  - UNDERSTAND BASIC LIMITATIONS OF SILICON-SHEET MATERIAL QUALITY AND ITS EFFECT ON SOLAR CELL PERFORMANCE
  - INVESTIGATE CRITICAL FACTORS FOR HIGH THROUGHPUT OF MULTIPLE, THIN, FLAT AND WIDE RIBBON
  - STUDY PROCESS PARAMETER LIMITS AND SEQUENCES TO DEVELOP AUTOMATED GROWTH WITH MELT REPLENISHMENT
  - TRANSFER TECHNOLOGICAL INFORMATION FOR INDUSTRY ADOPTION
Encapsulation

- Protective material for terrestrial photovoltaics was:
  - Expensive
  - Short-lived
  - Highly variable in design

- Promising material combinations offer potentially lower cost and longer life such as:
  - Low-iron glass top cover
  - EVA or PVB POTTANT
  - Glass or Mylar/Tedlar back cover

- The work remaining:
  - Identify and control basic degradation mechanisms such as
    - Corrosion effects
    - Interface stability
    - Photothermal effect

- Develop lifetime prediction methodologies for projection of realistic life-cycle cost economics data needed to define competitive photovoltaic systems
Process Development

• PROCESS SEQUENCES TO DEVELOP SHEET MATERIAL INTO PHOTOVOLTAIC CELLS HAVE MANY TECHNOLOGICAL STEPS

• SURFACE PREPARATION, METALLIZATION, ANTIREFLECTIVE COATING AND JUNCTION FORMATION HAVE ALTERNATIVE APPROACHES BUT HAVE BEEN EXPENSIVE FOR COMPETITIVE POWER SYSTEMS

• PROMISING WORK HAS BEEN ACCOMPLISHED IN IMPROVING INTERRELATIONSHIPS OF PROCESS STEPS AND IN REDUCING COSTS

• THE WORK REMAINING IS TO DEFINE PROCESS STEPS THAT ARE:
  • COMPATIBLE WITH DIFFERENT SHEET MATERIALS
  • CONSISTENT WITH COST-COMPETITIVE PV SYSTEMS
  • SCALABLE FROM LABORATORY EXPERIENCE BY INDUSTRY TO LEVELS OF INTEREST TO THEM

• SPECIFIC TASKS OF PRIMARY IMPORTANCE ARE:
  • OHMIC CONTACT
  • DIFFUSION BARRIER IN ADVANCED METALLIZATION SYSTEMS
  • HIGH-EFFICIENCY CELL-JUNCTION FORMATION
  • ADVANCED ANTIREFLECTIVE COATINGS

Summary

• A GREAT DEAL OF WORK REMAINS TO BE DONE

• SUFFICIENT R&D BY THE LSA PROJECT WILL BE NECESSARY TO REDUCE ADOPTION RISKS TO AN ACCEPTABLE LEVEL FOR INDUSTRY TO PROVIDE COMPETITIVE PHOTOVOLTAIC POWER
Module Size vs Installation Cost

- Rack or Standoff or Direct Mount systems show installation cost proportional to number of modules.

- Integral Mount systems show installation cost proportional to a combination of number of modules and total perimeter of modules.

- Systems over 1kW show significant cost impact of module size.

- Ideal module size is limited to approximately 4 ft. x 6 ft., or 10% of system total, whichever is smaller.

- Impact of small (4 ft²) modules on large system installations can be as high as an extra $1 to $2 per watt installation cost.

- Use of several small modules in a pre-assembled frame shifts cost burden to the factory. Pre-assembled water-proof frames (Integral Mounting) can be expensive.

PLENARY SESSION

Module A

Parallel in junction box. Use series diodes only if shadowed.

Use 2-cond. cable

Shorting plugs

ARRAY WIRING

All shunt diodes built into modules.

Module AA

Use 1 conductor cable or 2-cond. in parallel

Parallel at inverter input. Use series diodes only if shadowed

To Inverter
PLENARY SESSION

Wiring Schemes

PANEL A, STANDOFF MOUNT
Use AMP Econo-seal circular plastic waterproof connectors, factory installed.

PANEL A, INTEGRAL MOUNT
Use AMP NM-1 Romex splice hermaphroditic connectors, field or factory installed, same wiring diagram as above.

PANEL AA, STANDOFF MOUNT
Use AMP Photovoltaic connector, factory installed.

PANEL AA, INTEGRAL MOUNT
Use AMP NM-1 connector with all wires in parallel, field or factory installed, same wiring diagram as above.
PLENARY SESSION

Mismatch Losses

Cell to cell mismatch of current ± 10% voltage match better.

Modules with low level paralleling give lower system mismatch losses.

Low V, High I  Low I, High V
Low level paralleling  Many series cells, 2 parallel
(8) within module  within module
Example: Module AA, Example: Module A
System 2  System 1
Series module wiring  Series module wiring

Module current mismatch:
± 3.5%  ± 7%

Similar result can be achieved by paralleling small modules before series connection.

Conclusion: Low level paralleling probably increases performance 3 to 5%.
History of Electric Utility Industry

1882 to 1920's
- Edison Illuminated Co., 100 buildings in Manhattan
- Mostly hydro, some coal
- Competition in some geographic regions, loose regulation

1920's to 1930's
- Large holding companies developed to finance expansion and interconnect
- 15 top holding companies controlled 80% of investor own generation

1930's to 1940's
- 1935 Public Utility Holding Company Act - result of unfavorable public opinion towards holding companies
- Public power projects popularized because of economics of depression, disenchantment with holding companies, and general mood that federal government could solve social and economic problems,
- Public power received government subsidies in low-cost loans, no income taxes, nominal payments for other taxes.

1940's to 1960's
- Growth in investor-own utilities - about 100% for each decade
- Investor-own utilities came to account for about 80% of capacity
- Technological improvements, stable economy, and economy of scale caused reducing utility rates.

1960's to 1980's
- Improvements peaked out, inflation, and environmental fixes reversed reducing rate trend.
- Diminishing oil and natural gas supplies cause switch to coal, nuclear, etc.
- New plants tend to relatively higher capital costs.

Utility Requirements of a Generating Plant

VITAL REQUIREMENTS
"MUST":
- WORK
- BE ECONOMICALLY COMPETITIVE
- BE LICENSABLE
- HAVE ESTABLISHED SUPPLIER BASE
- BE ACCEPTABLY SAFE
- BE OPERABLE
- BE GENERALLY ACCEPTABLE TO PUBLIC
- ACCEPTABLY INTERFACE WITH GRID

FLEXIBLE REQUIREMENTS
"MINIMIZE":
- CAPITAL, O&M, AND FUEL COSTS
- PLANT CONSTRUCTION TIME
- STARTUP POWER REQUIREMENTS
- WASTE PROBLEMS
- LAND REQUIREMENTS
- DECOMMISSIONING EFFORT
- STARTUP TIME
- LOWEST OPERATING LEVEL
- ENVIRONMENTAL IMPACTS AND HAZARDS

"MAXIMIZE":
- AVAILABILITY
- FLEXIBILITY IN UNIT RATING
- CAPACITY CREDIT
- PLANT LIFE
- EFFICIENCY
- PART-LOAD EFFICIENCY
- LOAD FOLLOWING CAPABILITY
- SITING FLEXIBILITY

* MAY BE OF SPECIAL CONCERN IN THE CASE OF PHOTOVOLTAICS.

  - THERMAL CYCLING
  - HUMIDITY
  - ULTRAVIOLET RADIATION

- **CORROSION (CELL METALLIZATION, WIRE, TERMINAL)**
  - HUMIDITY
  - CONTAMINANTS

- **ELECTRICAL INSULATION BREAKDOWN**

- **OPTICAL SURFACE SOILING**
PLENARY SESSION

Failure Mode: Interconnect Fracture

- PERCENTAGE OF P/FR's: 18%
- NUMBER OF MANUFACTURERS INVOLVED: 4
- CAUSE: FATIGUE FAILURE, PRIMARILY INDUCED BY DIFFERENTIAL THERMAL EXPANSION STRESSES DURING DIURNAL TEMPERATURE CYCLING
- EFFECT: INTERMITTENT TO CONTINUOUS OPEN CIRCUIT, SOMETIMES ACCOMPANIED BY ARCING ACROSS FRACTURE
- NOTABLE EXAMPLES: BLOCK II POLYESTER SUBSTRATE MODULES AT UPPER VOLTA AND SCHUCHULI

Failure Mode: Environmental-Stress-Cracked Cells

- PERCENTAGE OF P/FR's: 25%
- NUMBER OF MANUFACTURERS: 4
- CAUSE: MAINLY HAIL AND DIFFERENTIAL THERMAL EXPANSION STRESS ON CELLS DAMAGED IN MANUFACTURE
- EFFECT: 2-4% OF VISIBLY CRACKED CELLS HAVE LED TO OPEN CIRCUIT IN FIELD
- NOTABLE EXAMPLES: HAIL DAMAGE EXISTS AT MOST SITES WITH BLOCK I-III MODULES
PLENARY SESSION

Failure Mode: Reverse-Bias-Cracked Cells

- **PERCENTAGE OF P/FR's:** 9%
- **NUMBER OF MANUFACTURERS:** 2
- **CAUSE:** CELL HEATING FROM REVERSE VOLTAGE BIAS
  GAS GENERATION UNDER CELL CRACKED CELL
  OPEN/SHORTED CELL
- **EFFECT:** POWER DEGRADATION OR LOSS
- **NOTABLE EXAMPLES:** MOUNT LAGUNA

Degradation Mode: Encapsulation Delamination

- **PERCENTAGE OF P/FR's:** 22%
- **NUMBER OF MANUFACTURERS:** 4
- **CAUSE:** SILICONE RUBBER TO SUBSTRATE ADHESIVE
  BOND FAILURES UNDER MOISTURE, THERMAL,
  UV, AND WIND STRESSES
- **EFFECT:** EXPOSURE OF CELLS AND INTERCONNECTS;
  MOISTURE ENTRAPMENT. NO IMMEDIATE
  FUNCTIONAL EFFECT
- **NOTABLE EXAMPLES:** MOST INSTALLATIONS
PLENARY SESSION

Failure Mode: Grounded Cell String

- PERCENTAGE OF P/FR's: 9%
- NUMBER OF MANUFACTURERS: 4
- CAUSE: DESIGN/WORKMANSHIP
- EFFECT: POWER LOSS; POTENTIAL FOR ARcing; MAINTENANCE PROBLEM
- NOTABLE EXAMPLES: NATURAL BRIDGES

Conclusions

- FAILURE MECHANISMS ARE COMPLEX
- POOR PREDICTION CAPABILITY PLACES HIGH RELIANCE ON QUALIFICATION TESTS AND SYSTEM EXPERIMENTS
- LESSONS
  - IMPORTANCE OF MATERIAL CHOICES REEMPHASIZED
  - INTERCONNECT DESIGN REDUNDANCY, CONFIGURATION
  - HAIL PROTECTION
  - REVERSE BIAS PROTECTION
  - INCREASE DESIGN MARGINS
  - EMPHASIS ON QA/QC
What Have We Learned?

I. THE SOLAR CELL IS A HIGHLY SOPHISTICATED DEVICE, PRODUCED IN A PROCESS WITH MANY SEQUENTIAL STEPS.

II. ITS DESIGN AND ITS PRODUCTION HAVE REACHED A HIGH TECHNOLOGY LEVEL, BUT THERE IS GREAT POTENTIAL FOR FUTURE TECHNOLOGY ADVANCES, IN A MULTITUDE OF APPROACHES.

III. THE PRESENT LEVEL OF TECHNOLOGY HAS BEEN REACHED THROUGH A LARGE NUMBER OF RELATIVELY SMALL ADVANCES, USUALLY BUILDING ON EACH OTHER. SUCCESSFUL "BREAKTHROUGHS" ARE HARD TO FIND.

IV. IN DEVICE DESIGN AND IN PROCESS METHODS, THE EARLY PROGRESS HAS GENERALLY BEEN EMPIRICAL, FOLLOWED BY SUCCESSIVELY DEEPENED UNDERSTANDING OF THE UNDERLYING PRINCIPLES, AND BY TECHNOLOGY ADVANCES BASED ON THIS UNDERSTANDING.

This progress has involved significant R&D by diverse contributors. A substantial part of the advances has been based on new findings made outside of the field.

Example 1: "FIELD-FREE" SOLAR CELL + CELL WITH FIELD THROUGHOUT BASE REGION + CELL WITH FIELD NEAR BACK CONTACT (BSF CELL) + CELL WITH HIGH-LOW JUNCTION NEAR BACK CONTACT + CELL WITH HIGH-LOW JUNCTION AND "THICK" THIRD LAYER NEAR CONTACT.

Example 2: CZOCHRALSKI CRYSTAL GROWING:
1956: 150G INGOTS ~ 3/4" DIAMETER, 1 QUARTZ CRUCIBLE PER INGOT, COMPLETELY MANUAL CONTROL, 1 OPERATOR/FURNACE.

GRADUAL TECHNOLOGY ADVANCEMENT TO:
1981: 150KG PER QUARTZ CRUCIBLE, 6" DIAMETER INGOTS, FULLY AUTOMATIC GROWTH CONTROL, 1 OPERATOR FOR 3-4 FURNACES.

![Graph showing module efficiency vs. cost per unit area and value per unit area.](image-url)

- **90€/m² AREA RELATED B.O.S. COSTS**
- **60€/m² AREA RELATED B.O.S. COSTS**
- **30€/m² AREA RELATED B.O.S. COSTS**
- **5€/m² AREA RELATED B.O.S. COSTS**
- **ZERO SOLAR CELL VALUE**

**VALUE PER UNIT AREA (€/m²)**

**VALUE PER UNIT PEAK POWER OUTPUT**
The Four Areas Needing Technology Progress

1. **Increased Efficiency**
   - Cell/Module/System level

2. **Advanced Process Technologies**
   - Range from resource to product
   - Cost reduction commensurate with efficiency goals
   - Selection considering resource limitations

3. **Increased Reliability**
   - Lower energy cost through reduced maintenance, extended system life

   - Installation
   - Power conditioning
   - Energy storage

Assumption: Area-related BOS cost $60/m². Encaps’n and Mod. Ass’y: $28/m².
How to Get Higher Efficiency in Si Solar Cells

GOAL: Higher voltages simultaneous with the best currents already achieved. (V_{oc} approaching 0.7V recently reported.)

DESIGN: "Narrow" base and front layer structures, high-low junctions, "wide" third base layers, optical back surface reflection, front surface treatment (MIS?), no heavy doping (> ~ 10^{18} cm^{-3}) in active layers, relatively long diffusion lengths in all active layers, low series resistance, careful resistivity/diffusion length/layer thickness trade-offs, highly effective AR treatment (texture or 2-layer AR), metallization with minimum shading.

CONSTRUCTION: Highly controlled process to attain all design parameters within given tolerances, while achieving high yield.

NOTE: Design and construction need to be optimized for all parameters. One flaw can limit performance, overriding all other efforts at performance gain.

Increased Module-System Efficiency

Higher packing factors
Higher cover transmission
Less wiring loss
Higher power conditioning efficiency
Better storage subsystems, especially higher efficiency, longer life.
PLENARY SESSION

Two Schools of Thought

Premises: High performance has a high economic value. It requires a highly perfect device structure, down to the atomic level. Low-cost approaches will be found for processes which yield high performance.

Consequences: Eliminate potentially damaging impurities. Avoid crystal defects, including dislocations, grain boundaries, etc. Construct device according to high performance design. Enhance competitiveness by high reliability, long life.

Approach: Use high-purity semiconductor. Use single crystal or semi-crystalline material. Process to maintain (enhance?) properties of semiconductor (anneal, getter). Apply low-loss processes ("BSF", fine line metallization, high performance AR). Closely control process to achieve high yield. Place large emphasis on process cost reduction while maintaining above attributes.

Low-cost materials and processes are more important than higher performance.

Select low-cost materials, even of inadequate purity. Use low-cost deposition processes, leading to (fine)-polycrystalline or amorphous semiconductors. Apply low-cost device manufacturing processes, even if they yield reduced performance. Long life less important than cheap replacement.

Reduce damaging impurities by "upgrading" (leaching, remelting, etc.). Improve crystal structure by post-treatments (heating, re-melting, etc.). Passivate crystal defects, incl. boundaries (etching, junction formation, etc.). Set standards low to get high yield.

To Concentrate, or Not to Concentrate?

PV systems with Optical Concentration

- Give more output than flat-plate systems (same area) in arid climates
- Can utilize expensive very high efficiency PV converters
- Can deliver heat besides electricity - at a cost
- May operate more satisfactorily in attended operation (central station)

Consequently

- There should be a significant specialty market for concentrator - PV systems
- The general market may be flat-plate PV systems
PLENARY SESSION

Approach to Cost Reduction

- Reduce Number of Process Steps
- Reduce Number of Pieces Handled
- Design Simplified Device Structure
- Develop Continuous Flow Process (not Batch)
- Select High Speed Processes
- Slow Process Steps Have to be Simple, (e.g., Heat Treating)
- Reduce Use of Indirect Materials
- Simplify Process:
  - Eliminate Masking
  - Eliminate Wet Processes
  - Eliminate Critical Tolerances
  - Select Processes for Compatibility
- Select Processes for High Controllability and High Yield
- Integrate Array Assembly with Device Fabrication
- Reduce Energy Use

Example: Si Slicing

Technology in Use: ~ 40 years
Experience: Tremendous advancement, can slice 15 cm dia., up to 25 wafers/cm, up to 50 cm²/min
Problems: Work damage to wafers, blade life, (slurry usage)
Status: Essentially empirical, do not understand cutting process
Need: Research into interaction of cutting tool (abrasive particle) and Si, is ductile cutting possible? Role of lubricants? How is work damage caused, how can it be reduced?
Potential Result: Order of magnitude increase in cutting speed
PLENARY SESSION

Example: Si Ribbon Growing

Technology in Development: ~ 20 years

Experience: Width up to 15 cm; thickness as low as 50 μm. Growth speed up to ~ 4 cm/min.

Problems: Stresses, crystal defects, limited diffusion length, limited growth speed (web-dendrite possibly excluded)

Need: Research to understand thermal environment at growth zone and in cool-down region, and its relation to stresses in ribbon, defect generation, and limitation of growth speed. How can this thermal environment be improved? What are the limits?

Potential Result: High quality ribbons. Increased growth speed?

Example: Electroless Plating (Ni)

Technology in Use: Many decades in metal plating

Experience: ~ 25 years intermittent in Si contact formation

Problems: Process not reliable, contact degradation and metal separation intermittently experienced.

Need: Research into interface of Si and metal. What causes a strong Si/metal bond? What is the role of O? How can thickness of SiO$_x$ layer before plating be controlled? Can thickness of this layer be measured and plating time be adjusted according to thickness? Are other materials responsible for problems? What is the role of cleaning baths prior to plating?

Potential Result: A high-yield, low-cost metallization process.
Approximate Present Efficiency Distribution

Why so wide?
Why yield so low?

13.0% ave

20% rejects

The Options to Process Cost Reduction

1a MG Si — Purification (SemI-Grade ≤ $10/kg, Likely '82)
   SINGLE X-TAL
   → "Cz" (G/Quality?)
   → HEM
   "Sl/IING (C/ost?)
   → HEM-GERMITE (C/ost '83)
   → RTR (G/Quality? C/ost?)
   → CELL FAB — MODULE FAB (G/radual C/ost RED', AUTOM')
   → INTEGRAL MODULE FAB (C/ONCEPT)

   SEMI X-TAL
   → VARIOUS CASTING (G/Quality? C/ost?)
   → EFG "Sl/IING (C/ost?)
   → RTR (G/Quality? C/ost?)
   → CELL FAB — MODULE FAB
   → INTEGRAL MODULE FAB

   POLY X-TAL
   → CVD (SUBSTRATE?)
   → CASTING
   → SKIN COATING (G/DIC)
   → REHEAT
   → CELL FAB — MODULE FAB
   → INTEGRAL MODULE FAB

   AMORPHOUS
   → SPIN CASTING
   → DISCHARGE DEPOS.
   → FLUORIDE CVD
   → CELL FAB — MODULE FAB

1b LP Si — Partial Purification (+ $10/kg possible; Quality?)
   SEMI X-TAL
   → FAST Cz HEM
   → "Sl/IING
   → POLY X-TAL
   → VARIOUS CASTING
   → CASTING (SUBSTRATE, INCL. GaAs CELLS)
   → SKIN COATING
   → SPIN CASTING
   → CVD
   → CELL FAB — MODULE FAB
   → INTEGRAL CELL FAB

2. GaAs — Purification
   SINGLE X-TAL
   → CVD GaAs + GaAs
   → Thin film CVD on Si-Ge SUBSTRATE
   → CELL FAB — MODULE FAB

3. CuTe (Commercial?)
4. InP
5. Other Binary Compounds (Will BENEFITS JUSTIFY DEVELOPMENT COSTS?)
6. Cu In Se/CdS (Hopeful as a Thin Film Device)
7. Other Ternary and Higher Order Compounds (Will BENEFITS JUSTIFY DEVELOPMENT COSTS?)
8. Multi Bandgap Systems — OPTICAL BEAM SPLITTING
   INTEGRAL CELL APPROACH (MULTIPLE LOAD CIRCUITS?)
PLENARY SESSION

The Options

1. Technology Evolution:
   Successful in Cz, slicing, cell fab, module fab, integrated processing. (Long-range progress often hard to predict because of successive nature.)

2. Technology Adaptation:
   (Often combined with 1.)
   Sapphire technology adapted to Si in EFG and HEM (partially successful)
   Ion implantation in lieu of diffusion, laser scribing in lieu of etching, Si-casting, RTR ribbon process.

3. Technology New-Start:
   (Often combined with 2.)
   Si purification by SiH₄ process (apparently successful)
   Web-dendrite ribbon process (slow, apparently successful)
   SOC, Plasma processes (deposition, etching), Pulse annealing, Material combinations (Si-Ge-GaAs, Ga₁₋ₓAlₓAs-GaAs), Multi-bandgap systems. Integrated module.

Basic Structure of Integrated Si Solar Array

Module Fabricated With Integrated Cells: Concept

CONTINUOUS PROCESS

SEMICONDUCTOR MATERIAL GROWN OR DEPOSITED IN MODULE WIDTHS

SOLAR CELLS FABRICATED ON SEMICONDUCTOR

ENCAPSULATED MODULE
PLENARY SESSION

Likely Technology Trends

1.) Economical systems through high performance (single x-tal?)
   low price (thin film, poly x-tal.) (bipolar vs. FET)
   amorphous?)

2.) Cell efficiencies ~ 20% single bandgap, ~ 30% multibandgap. Module prices
   in $0.40 to 2.00/kWp range, depending on performance.

3.) Si will remain a competitor,
4.) Any approach involving slicing (sawing) unlikely to succeed (sleeper?),
5.) Can semi-crystal and low-quality substrate approaches yield enough price/
   performance margin to survive?
6.) Evolution to integrated, continuous processing (batch or quasi-batch should
   disappear),
7.) Integrated modules, requiring wide sheet,
8.) Not all possibilities can be pursued. Thus, there will always be other
   options, (Criterion: Lowest risk/benefit ratio, but how to assess?)
EVOLVING MODULE AND ARRAY TECHNOLOGY

- FAILURE DATA ACQUISITION
- APPLICATION EXPERIMENTS

APPROACH

- SPECIFY REQUIREMENTS
- SYNTHESIZE DESIGNS
- SCREEN DESIGNS USING QUAL TESTS
- ACQUIRE AND FEED BACK PERFORMANCE DATA
- DEVELOP IMPROVED TECHNOLOGIES
- USE FEEDBACK AND TECHNOLOGY TO IMPROVE DESIGNS
PLENARY SESSION

Module and Array Technology

CELL OBJECTIVE • ELECTRICAL PERFORMANCE AT LOW COST ($/WATT)

MODULE/ARRAY OBJECTIVE • ENVIRONMENTAL ENDURANCE, RELIABILITY, AND SAFETY AT LOW COST ($/m²)

MODULE AND ARRAY ELEMENTS:
- ENCAPSULANT SYSTEM
- ELECTRICAL CIRCUIT
- SUPPORT STRUCTURE
  - GROUND-MOUNTED
  - RESIDENTIAL ROOF-MOUNTED

Encapsulant System Objectives

- PROTECT CELL FROM ENVIRONMENTAL STRESSES
  - WIND AND SNOW
  - HAIL
  - DIFFERENTIAL EXPANSION
  - HUMIDITY

- MAXIMIZE SUNLIGHT TO CELL
  - OPTICAL TRANSMISSION
  - LOW SOILING

- PROTECT USER FROM SAFETY HAZARDS
  - ELECTRICAL
  - FIRE

- MAINTAIN 20-YEAR LIFETIME

- MAINTAIN LOW AREAL COST

## Electrical Circuit Objectives

- Provide voltage current levels required by system
- Provide fault tolerance against cell and circuit failures
  - Cell cracking
  - Partial shadowing
  - Interconnect open circuits
- Provide safety protection against circuit/encapsulant failures
  - Circuit to frame ground faults
  - Exposed live circuit elements
  - In-circuit or ground fault arcing
- Maintain low cost

Conclusions

• SUBSTANTIAL PROGRESS HAS BEEN ACHIEVED
  • IMPROVED ENCAPSULANTS (GLASS, EVA, ACRYLICS)
    • LOW COST LAMINATION PROCESSING
    • GOOD OPTICAL STABILITY (LOW SOILING)
    • HAIL RESISTANCE
  • IMPROVED FAULT TOLERANCE
    • CELL AND INTERCONNECT FAILURE
    • HOT-SPOT ENDURANCE
  • LOW-COST GROUND-MOUNTED STRUCTURES

• A NUMBER OF TECHNOLOGY GAPS REMAIN
  • SOLAR CELL BREAKAGE
  • ENCAPSULANT ENDURANCE (LONG LIFE)
  • MODULE AND ARRAY ELECTRICAL SAFETY
  • ROOF-MOUNTED ARRAY TECHNOLOGIES
ASSUMPTION: SINGLE, POLYCRYSTALLINE OR RIBBON SILICON WILL BE THE DOMINANT MATERIAL IN THE NEXT 5-15 YEARS

EXACT YEAR-BY-YEAR MARKET PROJECTIONS

Overall Business Strategy

Technology developments and manufacturing investments will drive the cost of solar power systems down.

As this occurs, the economic markets will increase because the costs of traditional methods of remote power generation will be undercut.

When the costs of PV systems begin to compete with near-grid and on-grid power generation, the markets will grow exponentially.

Traditional power system cost increases in excess of inflation will serve to accelerate this growth.

The Dilemma

Significant manufacturing investments in limited lifetime technologies can be a very costly business strategy.

Major investments in technology without simultaneous market development could make late entry very difficult and expensive, even with a lower cost product.

The government program, with its published time-phased cost goals, has caused unjustified early price pressure which severely eroded margins.
The Strategies

**Early Market Share**

**Description:** Gain market share by aggressive pricing and investment in manufacturing capacity and automation.

**Risks:**
- Margins low or negative, due to aggressive pricing, needed to gain market share.
- Significant investments in plant and equipment, which could become obsolete long before end of useful life.
- Market may be smaller or develop slower than forecasted.

**Rewards:**
- Early market share gains are far less costly than at the time when competitors are further down the learning curve.

**Long-Term Technology Development**

**Description:** Current markets are secondary or ignored, major investment in technology development.

**Risks:**
- Technology developed may not meet needed cost goals.
- Rapid production build up of new technology will be costly, technology may take much longer to develop than expected.
- Marketing and distribution channels may be irrevocably lost.

**Rewards:**
- Can develop the "Model T" of the solar industry and sweep aside all competitors with low cost products.

Most companies are attempting to strike a balance between the two extremes, the role of government in both product procurement and technology development funding can have a significant effect on the amount and type of resources that the company must provide.

Which Will Come First?
PLENARY SESSION

IF THE COST OF SILICON DOES NOT DROP SIGNIFICANTLY, THERE WILL BE NO SOLAR MARKET; AND IF THERE IS NO SOLAR MARKET, THERE IS NO REASON FOR THE MATERIAL SUPPLIERS TO INVEST LARGE SUMS OF MONEY IN LOW COST SILICON MANUFACTURING.

GOVERNMENT FUNDING OF TECHNOLOGY DEVELOPMENT PROVIDES RISK REDUCTION ALTERNATIVE TO GOVERNMENT FUNDING MUST COME FROM WELL-HEELED SOLAR COMPANIES WHO WILL FUND THIS DEVELOPMENT INTERNALLY FOR THEIR EXCLUSIVE USE

Near-Term Perspective (One to Five Years)

0 GREAT DEAL OF SHIFTING AND CONFUSION REGARDING THE GOVERNMENT POSITION VIS-A-VIS THE SOLAR BUSINESS

0 MODERATE GROWTH OF THE COMMERCIAL INDUSTRIAL MARKET

0 GROWING AWARENESS OF THE DOMESTIC CONSUMER OF THE POTENTIAL OF PHOTOVOLTAICS

Cost Trends

0 COSTS WILL TEND TO FLATTEN OUT IN THE SHORT TERM DEPENDING ON THE PROCESS COST, DEGREE OF VERTICAL INTEGRATION AND EXTENT OF AUTOMATION

0 COST OF SILICON SHEET STILL DOMINANT FACTOR IN OVERALL MODULE COSTS

102
PLENARY SESSION

Business Trends

- Large solar companies will pursue internally funded programs for technology development or drop out of the business.
- Small solar companies will continue to look for potential large buyers in order to stay in the game.
- Materials suppliers have the most difficult decisions to make.

Prospects

- Photovoltaics will become a part of the world’s energy supply.
- The overall investments that will be made will be large.
- The ultimate margins will be comparable to those in other forms of energy supply.
- The existing energy companies will play a major role in the future of PV business.
- The PV business will develop more slowly than anticipated but will be a much larger market than we now forecast.
WAFTERING WORKSHOP SUMMARY

PHOENIX, ARIZONA, JUNE 8-10, 1981

JET PROPULSION LABORATORY

• INTRODUCTION
• HIGHLIGHTS OF TECHNICAL PRESENTATIONS
• CONCLUSIONS
• 27 PAPERS
• 86 ATTENDEES
• INDUSTRY, GOVERNMENT, UNIVERSITY AND INTERNATIONAL REPRESENTATION
• 30% FROM CORPORATE MANAGEMENT

Objectives

• ASSESS THE STATE-OF-THE-ART IN SILICON WAFTERING
• INVITE AND EXPLORE INNOVATIVE IDEAS IN WAFTERING
• STIMULATE PRODUCTIVE EXCHANGE OF INFORMATION WITHIN THE WAFTERING COMMUNITY
PLENARY SESSION

Sessions

1. OPENING
2. ID TECHNOLOGY
3. MULTIPLE BLADE TECHNOLOGY
4. MATERIALS
5. CHARACTERIZATION
6. NEW TECHNOLOGY
7. ECONOMICS

Critical Elements of Wafering Technology

- BLADE/WIRE DEVELOPMENT
- LOW KERF, THIN WAFERS
- HIGH THROUGHPUT SLICING
- EXPENDABLE MATERIALS USAGE

Technology Drivers

- MATERIAL CONSERVATION
- HIGH THROUGHPUT
PLENARY SESSION

PRESENTATIONS

"KINEMATICAL AND MECHANICAL ASPECTS OF WAFER SLICING"
- P. G. WERNER

• A NEW MODEL OF WORK-TOOL INTERACTIONS AND PERTINENT MICRO-MECHANICS OF MATERIAL REMOVAL FOR A SLURRY SAWING PROCESS IS呈現ED

• RESULTANT FUNCTIONAL EXPRESSIONS RELATING PROCESS CRITERIA (e.g. CUTTING RATE, TOOL WEAR) TO PROCESS PARAMETERS (e.g. STROKE LENGTH, FREQUENCY AND FORCE) ARE DERIVED

• MATERIAL REMOVAL RATE IS DIRECTLY PROPORTIONAL TO BLADE LOAD AND SLICING SPEED

• OPTIMUM SLICING CONDITIONS ARE ACHIEVED WHEN BLADE AND WORKPIECE CUTTING CONTOURS HAVE STABILIZED

"ALLOWABLE SILICON WAFER THICKNESS versus DIAMETER FOR ROTATION INGOT ID WAFERING" - C. P. CHEN et al

• FRACTURE MECHANICS ANALYSIS WAS UTILIZED TO ANALYZE THE LOADING CONDITIONS UPON A WAFER DURING WAVERING

• THE ALLOWABLE WAFER THICKNESS versus INGOT DIAMETER WAS FOUND TO BE DEPENDENT ON THE DEPTH OF SURFACE DAMAGE, SAW VIBRATION AND CUTTING RATE

• APPLICATION OF A TENSIONAL FORCE PERPENDICULAR TO THE WAFER SURFACE DURING WAVERING CAN ENHANCE CLEAVAGE OF \( \langle 111 \rangle \) SILICON INGOTS AND POINTS TO A POTENTIAL FOR REDUCTION OF MINIMAL OBTAINABLE WAFER THICKNESS

"EXIT CHIPPING IN ID SAWING OF SILICON CRYSTALS"
- L. D. DYER

• STUDY RELATES THE EXISTENCE AND AMOUNT OF EXIT-CHIP OR SAW FRACTURE FORMATION TO ID WAFERING PARAMETERS

• FRACTURE FORMATION IS ORIENTATION-DEPENDENT

• EXIT CHIP SIZE INDICATES 'HARSHNESS' OF SAWING CONDITION
PLENARY SESSION

"EFFECT OF LUBRICANT ENVIRONMENT ON SAW-INDUCED DAMAGE IN SILICON WAFERS" - T. S. KUAN et al

- CHEMOMECHANICAL EFFECT OF DIFFERENT LUBRICANT SOLUTIONS UPON SAW-INDUCED DAMAGE
- EFFECT OF APPLIED ELECTRIC POTENTIAL ON SILICON CRYSTAL DURING WAFERING
- LUBRICANTS ARE GOOD CATALYSTS FOR BREAKING SILICON BONDS AND CAN DAMPEN OUT-OF-PLANE BLADE VIBRATIONS
- EXPERIMENTAL DATA SHOWS A 30-50% REDUCTION IN SAW-INDUCED DAMAGE WITH A PROPER LUBRICANT ENVIRONMENT

"INFLUENCE OF FLUIDS ON THE ABRASION OF SILICON BY DIAMOND" - S. DANYLUK

- THE WEAR RATE OF SILICON IS IN THE RATIO OF 1:2:3 FOR WATER, ETHANOL AND ACETONE, RESPECTIVELY, FOR A CONICAL DIAMOND ABRADING SILICON AT ROOM TEMPERATURE
- ABRASION MODE CHANGES FROM BRITTLE TO DUCTILE WHEN FLUID IS CHANGED
- SUBSURFACE CRACKS (SAW-INDUCED DAMAGE) PRESENT ARE AFFECTED IN MAGNITUDE BY THE FLUID ENVIRONMENT
- SURFACE HARDNESS OF SILICON IS INFLUENCED BY THE DIELECTRIC CONSTANT OF FLUID

"CORROSION INHIBITORS FOR WATER-BASED SLURRY MULTIPLE BLADE SAWING" - C. P. CHEN et al

- FAILURES OF HIGH CARBON STEEL BLADES USING WATER-BASED SLURRIES ARE DUE TO STRESS CORROSION INDUCED BY AN OXYGEN CONCENTRATION CELL EFFECT AND RESIDUAL AND CYCLIC BLADE TENSION LOADS
- FOUR CORROSION INHIBITOR/WATER SOLUTIONS HAVE BEEN IDENTIFIED WITH SIGNIFICANT POTENTIAL FOR WATER-BASED SLURRY MULTIPLE BLADE WAFERING APPLICATIONS
PLENARY SESSION

"FUNDAMENTAL STUDIES OF THE SOLID-PARTICLE EROSION OF SILICON" - J. L. ROUTBORT et al

- Existing models of solid-particle erosion ofbrittle materials are modified for the case of silicon single crystals
- Systematic experiments are needed to provide data to incorporate the effects into a predictive model for existing wafering techniques
- Some projectile properties (particle shape and hardness) are factors yet to be investigated

"PRE AND POST ANNEALING OF MECHANICAL DAMAGE IN SILICON WAFERS" - G. H. SCHWUTKE

- Basic properties of mechanical damage in silicon were studied using TEM
- Abrasion damage consists primarily of shear loops that frequently result in sub-micron cracks due to dislocation pile-ups
- High temperature annealing of these cracks results in dislocations and stacking faults
- Their presence reduces the minority carrier lifetime of the silicon material
- Chemical etching requires removal of up to four times the original damage depth because of crack propagation during etching

"WAFFERING INSIGHT PROVIDED BY THE ODE METHOD" - S. I. SOCOLF et al

- Orientation-dependent slicing uses preferential etching of narrow slots on a silicon slab to form slices
- Advantages include high material yield ($m^2/kg$), plane parallel surfaces and very thin slices (50 $\mu$m) with no surface damage
PLENARY SESSION

"SYSTEM FOR SLICING SILICON WAFERS" - E. R. COLLINS

- NEWLY-PATENTED PROCESS FOR EFFICIENT SLICING OF A LARGE NUMBER OF INGOTS IN A HIGH SPEED MODE

- COMBINES ADVANTAGES OF A MULTIPLE BLADE WAFERING PROCESS, FIXED ABRASIVES AND HIGH BLADE VELOCITIES

HIGHLIGHTS SUMMARY

SILICON INGOT → WAFERING PROCESS → SILICON WAFER

Conclusions

1. WAFFERING IS A MAJOR FACTOR IN DETERMINING THE SUCCESS OF INGOT TECHNOLOGY FOR LOW-COST SOLAR ARRAYS

2. CONSIDERABLE OPPORTUNITIES EXIST TO ADVANCE WAFFERING TECHNOLOGY SIGNIFICANTLY THROUGH BASIC INVESTIGATIONS INTO THE FUNDAMENTAL MECHANISMS OF WAFFERING
Technology Sessions

TECHNOLOGY DEVELOPMENT AREA

Silicon Material Task
Ralph Lutwack, Chairman

Reports on progress in developing Si processes and in supporting activities were presented by five contractors and by JPL.

Union Carbide Corp. reviewed the status of its effort to build an EPSDU (experimental process system development unit). All civil and structural work is complete, the bulk of equipment has been delivered to the site at East Chicago, Indiana, and most major pieces have been placed in position. In the R&D area, the silicon (Si) powder melter and shotter was assembled and put into operation. Using chunk Si as feed material, the unit produced free-flowing shot for periods up to 45 minutes. The fluidized-bed process development unit (PDU) was assembled, and an initial series of tests with mixtures of 10% to 21% silane (SiH₄) in hydrogen was successfully completed.

Massachusetts Institute of Technology summarized the results of its two-year contract to develop a process for making trichlorosilane (SiHCl₃) by the hydrochlorination of metallurgical-grade Si and silicon tetrachloride (SiCl₄). The contract ended, and the follow-on effort at Solarelectronics, Inc., was started.

Hemlock Semiconductor Corp. completed construction of the PDU for investigating the rearrangement of SiHCl₃ to dichlorosilane (SiH₂Cl₂), integrated the unit with an intermediate-scale Siemens-type reactor, and conducted 17 tests by the end of June.

Westinghouse R&D Center completed all experimental phases of the impurity study, and presented a summary of the entire program, including the effects of specific impurities on the performance of both n-base and p-base solar cells and the effects of gettering.

Design calculations for cell efficiency, open-circuit voltage, short-circuit current, and fill factor as functions of cell thickness were presented by C. T. Sah Associates.

Progress in two in-house JPL programs (research on the operation of fluidized bed reactors for depositing Si from SiH₄, and the conversion of SiH₄ to molten Si in a one-step process) was reported.
# Polycrystalline Silicon

## Union Carbide Corp.

### Technology
- **Polycrystalline Silicon**

### Approach
- **High-purity Silane Production from Metallurgical-grade Silicon** and Silane Pyrolysis and Consolidation to form Semiconductor-grade Polycrystalline Silicon

### Contractor
- Union Carbide Corporation

### Goals
- Demonstrate process feasibility and engineering practicality.
- Establish Technology Readiness using "EPSDU" sized to 100 MT/yr.
- Silicon price of less than $14/kg for high volume process.
- Define process economics.

### Assumptions:

<table>

*Incremental product price increase going from liquid silicon to polycrystalline silicon shot has not been determined. One to two dollar/kg increase is anticipated.*
SILICON MATERIAL TASK

Problems and Concerns

EPSDU ENGINEERING, INSTALLATION AND OPERATION

- A portion of the waste treatment system design is relatively novel, and some field adjustment may be needed for proper operation.

SILANE PYROLYSIS R & D

- Erosion of the quartz nozzle in the Si powder melting/shotting system may be excessive to be economical. A multiple nozzle design may have to be developed.

Silane-to-Silicon EPSDU Chemistry

A. HYDROCHLORINATION

\[ \text{Si} + 3 \text{SiCl}_4 + 2 \text{H}_2 \xrightarrow{\text{Cu}} 4 \text{HSiCl}_3 \]

B. REDISTRIBUTION

\[ 2 \text{HSiCl}_3 \xrightarrow{A-21} \text{H}_2\text{SiCl}_2 + \text{SiCl}_4 \]

\[ 3 \text{H}_2\text{SiCl}_2 \xrightarrow{A-21} 2 \text{HSiCl}_3 + \text{SiH}_4 \]

C. SILANE DEPOLYMERIZATION

\[ \text{SiH}_4 \rightarrow 2 \text{H}_2 + \text{Si} \]
EPSDU Engineering Summary

A. M. G. SILICON-TO-SILANE

• PROCESS DESIGN COMPLETE
• FACILITY DESIGN COMPLETE
• MAJOR EQUIPMENT FABRICATED AND RECEIVED AT EPSDU SITE
• INSTALLATION DESIGN COMPLETE
• INSTALLATION BID PACKAGES SENT TO BIDDERS
• BIDS FOR MECHANICAL INSTALLATION RECEIVED AND READY TO
  AWARD AS SOON AS FUNDS BECOME AVAILABLE

B. SILANE-TO-POLYSILICON

• PROCESS DESIGN COMPLETE
• ENGINEERING DESIGN ONGOING

Process Support R&D Summary

A. Si POWDER MELTING & SHOTTING (KAYEX)

• MELTER/SHOTTER SYSTEM ASSEMBLED
• CHUNK SILICON MELTED AND SHOT PRODUCED AT VARIOUS
  NOZZLE SIZES
• AT SMALL NOZZLE SIZES (UNDER 1 MM DIA), CONTROL OF
  SHOT PRODUCTION DEMONSTRATED
• FREE-SPACE Si POWDER SUCCESSFULLY TRANSPORTED TO
  FEED HOPPER, AND THE POWDER MELTED IN THE MELTER/SHOTTER

B. SILANE PYROLYSIS IN FLUID-BED PDU

• FLUID-BED PDU ASSEMBLED
• SERIES OF BED FLUIDIZATION AND HEATING TESTS WITH
  NITROGEN AND HYDROGEN SUCCESSFULLY COMPLETED
• 10 TO 21 PERCENT SILANE IN HYDROGEN SUCCESSFULLY
  FED TO HOT SILICON SEED BED
• DENSE POLYSILICON COATING ON SEED PARTICLES OBTAINED
• FURTHER TESTING STOPPED DUE TO FUNDING RECISION
SEM photomicrograph showing a random selection of Sample No.1 particles. This view shows particles' vivid edges, with high definition of surface characteristics. 50 X.

SEM view of a random particle from Sample No.1. The surface appears to be relatively bare, with the exception of some surface debris. 5000 X.
SEM photomicrograph showing a random selection of Sample No.2 particles. The particles in this view exhibit coated surfaces and well-rounded edges. 50 X.

SEM view of a random particle from Sample No.2. Heavy silicon deposition is apparent on this random-particle surface. 5000 X.

SILICON MATERIAL TASK

Corrosion Test for Incoloy 800H

CONDITION: 500°C, 300 PSIG, H₂/Cl₂ = 2.0
DURATION: 238 HOURS

SAMPLE WEIGHT
BEFORE = 53.195 g.
AFTER = 53.520 g.
GAIN = 0.325 g.

TOTAL SURFACE AREA = 120 cm²

ASSUMING DEPOSITED MATERIAL IS SILICON

Si FILM OF ABOUT 11.6 MICRONS THICK

THUS, NO SIGNIFICANT AMOUNTS OF CORROSION OCCURS INSIDE THE REACTOR IN VIEW OF THE WEIGHT GAIN BY THE SAMPLE.

Effect of Atmospheric Corrosion

SCALE BROKE OFF AFTER EXPOSURE TO AIR AND MOISTURE

TOTAL SURFACE AREA OF TEST SAMPLE = 27 cm²

SAMPLE WEIGHT:
BEFORE = 12.4026 g.
AFTER = 12.1445 g.
LOSS = 0.2581 g.
Si FILM WEIGHT = 0.0732 g.
NET LOSS OF METAL = 0.1849 g.

DENSITY OF INCOLOY ≈ 8.0 g/C.C.
LOSS OF BASE METAL ≈ 8.6 MICRONS

• EVIDENCE OF Si PENETRATION INTO THE BASE METAL TO FORM A SILICIDE PROTECTIVE FILM OF ABOUT 20 MICRONS THICK
• PREVIOUS CORROSION RESULTS APPEAR DUE TO ATMOSPHERIC CORROSION AND NOT DUE TO THE REACTION ITSELF.
SILICON MATERIAL TASK

Summary of Progress

- Reaction rate at 500 psig, 500°C reinforces the Union Carbide engineering design.
- Copper catalyst increases reaction rate by 100%.
- Reaction rate independent of Si particle size.
- Impurities in m.g. silicon increase reaction rate.
- Long mass life means reaction can be run for long periods of time with no interruption.
- Corrosion of the metal reactor is not a problem.
- Incoloy 800 is a good choice as the material of construction of the hydrochlorination reactor.
### Silicon Material Task

**PolyCrystalLine Silicon**

**SolareElectronics, Inc.**

<table>

</tr>
</thead>
</table>

**Goals**

- To continue the hydrochlorination study in supporting the Union Carbide EPSDU, Silane-to-Silicon process
- Collect engineering data for scale-up
- Quality control - analyse for organic and inorganic impurities
- Select the most suitable material of construction for the reactor
- Increase process efficiency and reduce cost

**Planned Activities:**

- Two inch-diameter and four inch-diameter hydrochlorination reactors
- Reaction kinetics measurements
- Corrosion measurements on various conventional metal alloys
- Fluidization mechanics - static-bed versus fluidized-bed design
- Waste disposal - with by-product HCL recycle to the hydrochlorination reactor

**Refine Engineering Data for Scale-up**

- Optimize process parameter - 2 inch reactor, 500 psig, 500°C
- Fluidization mechanics - 4 inch reactor, merits of a fixed-bed or a fluidized-bed reactor design
- Maximize raw material utilization - recycle by-product waste stream, e.g., HCL to the hydrochlorination reactor
- Quality control - analyse organic and inorganic impurities in the chlorosilane products

**Corrosion Study**

- Mechanism of corrosion
- Screen material of construction for the reactor
- Select the most suitable material of construction for the hydrochlorination reactor on a cost-effective basis

NOTE:

A Starting Condition For Runs After PDU Start-Up

QUESTIONS:

- Are Entire Runs With DCS Possible
- Can Goals Be Met When Entire Runs Are Made

PDU Objectives

- DCS Production 70 lb/hr
- Redistribution Conversion >10%; Temperature and Residence Time to Achieve This
- Pressure Drop vs. Velocity in Catalyst Bed
- Catalyst Life >90% Original Capacity After 2 Months Operation At Capacity
- Determine If Catalyst Migration Occurs
PDU Start-Up Summary

- Operational June 1 with DCS feed to a Decomposition Reactor

- No significant problems; several minor leaks (valve stems, screwed connections, etc.)

- Control scheme works fine; instrument adjustments made to fine tune

- Routine, reliable operation at up to 47 lb/hr DCS production

- Redistribution reactor conversion of 10.7% DCS, based on STC in still bottoms

Decomposition Goals

- Make rate 2.0 g/h/cm

- Conversion efficiency 40%+

- Power consumption <60 kWh/kg

- Run time 100h+

**Phase IV**

**Goals**

- Evaluate impurity effects in:
  - High efficiency cells
  - Experimental silicon material
  - Cells subjected to processing e.g., gettering
  - Cells treated to simulate long term behavior

- Impurity sensitivity of high efficiency cells reduced in thinner devices
- Ar implant damage gettering raises efficiency of Ti-doped cells but not as much as HCl or POCl3 alone
- D for impurities calculated from crystal breakdown data lie in range 1 to $4 \times 10^{-4}$ cm$^2$/sec
- Cr electrical activity reduced tenfold in grain boundaries vs. bulk

## Approach
- Analysis of the effects of cell thickness and defective back-surface-field (BSF) junction in impurity-doped cells.

## Contractor
C. T. Sah Associates

## Goals
- Determine the optimum cell thickness and its impurity dependencies.
- Determine the open-circuit voltage degradation due to defective BSF junction.
- Experimental verification of thin cell performance.

## Status
- Design calculations for optimum cell thickness of high-efficiency (17% AM1) impurity-doped (Zn) BSF cells completed.
- Effects of perimeter shunts across the BSF junction on open-circuit voltage $V_{OC}$ as a function of cell size, thickness and base minority carrier diffusion length analyzed.
- Effects of random bulk shunts across the BSF junction on $V_{OC}$ analyzed.
- Comparison of analysis with experimental zinc-doped thin (100 µm) cells started.

![Graph showing efficiency as a function of thickness](image_url)
SILICON MATERIAL TASK

FLUIDIZED–BED REACTOR PROGRAM

JET PROPULSION LABORATORY

- OBJECTIVE
  - EXPERIMENTAL AND THEORETICAL STUDY OF EFFECTS OF OPERATION PARAMETERS ON CHARACTERISTICS OF FBR IN SILANE SYSTEM

- CHARACTERISTICS TO BE STUDIED
  - RATE AND TYPE OF PARTICLE GROWTH
  - YIELDS
  - FINES FORMATION
  - BED AGGLOMERATION

- EXPERIMENTAL VARIABLES
  - SILANE CONCENTRATION
  - TEMPERATURE
  - U/Umf
  - DISTRIBUTOR PLATE DESIGN
  - FBR SIZE
SILICON MATERIAL TASK

Results From 2-in.-Dia FBR

- RATE AND TYPE OF PARTICLE GROWTH
  - RATE \(- 0.39 \mu m/min\) AT 12\% SILANE AND 700°C
  - \(- 0.81 \mu m/min\) AT 60\% - 100\% SILANE AND 700°C
  - TYPE \(- DENSE, COHERENT\) FROM 10 TO 100\% SILANE AT TEMPERATURE \(> 600°C\)

- YIELDS
  - SILANE TO SILICON CONVERSION \(- 96\% TO 100\% AT TEMPERATURE ABOVE 650°C\)
  - OVERALL YIELD \(- 90\%\)

- FINES FORMATION
  - INCREASE WITH TEMPERATURE AND SILANE CONCENTRATION
  - LESS THAN 10\% FOR 650°C \(<\) TEMPERATURE \(<\) 800°C AND 10\% \(\leq\) SILANE \(\leq\) 100\%

- BED AGGLOMERATION
  - INSENSITIVE TO DISTRIBUTOR PLATES USED SO FAR
  - PRIMARILY DEPENDENT ON \(U/U_{mf}\)
    - \(U/U_{mf} > 3\) \(- CLOG-FREE\)
    - SUGGESTED OPERATION AT \(U/U_{mf} \sim 5\)

Present FBR Program

- COMPLETE DETERMINATION OF OPERATIONAL WINDOW BY EXTENDING PARAMETRIC STUDY OF 2-inch FBR

- APPLIED R&D PROGRAM \(- 6" FBR\)
  - DESIGN COMPLETED
  - FABRICATION UNDERWAY
  - STUDY OF REACTOR CHARACTERISTICS AS FUNCTION OF OPERATION VARIABLES
  - COLLABORATION WITH OREGON STATE UNIVERSITY
SILICON MATERIAL TASK

SILANE–TO–MOLTEN–SILICON (SMS) PROGRAM

JET PROPULSION LABORATORY

OBJECTIVE:
EXPERIMENTAL STUDY TO DETERMINE CONDITIONS NEEDED TO PRODUCE MOLTEN SILICON FROM SILANE IN A SINGLE-STAGE PROCESS

PROBLEMS TO BE SOLVED:
• PLUGGING OF SILANE INLET
• EFFLUX OF SILICON POWDER
• CONVERSION TO MOLTEN SILICON
• NON-CONTAMINATING, LONG-LIFE REACTOR MATERIAL

EXPERIMENTAL VARIABLES:
• CONCENTRATION
• FLOW RATE
• TEMPERATURE
• REACTOR DESIGN AND MATERIALS

SMS Converter System

SILANE SUPPLY → COOLING WATER → GAS EFFLUX → SILANE INDUCTOR → PRESSURE SAFETY RELIEF VALVE
SPARK-TYPE BURN-OFF → MOISTURE SENSOR → GAS SAMPLE BOTTLE → ARGON SUPPLY → IMPEDANCE-TYPE PARTICLE COLLECTOR
180-AMP 70-VOLT POWER SUPPLY → HEAVY CABLE → CARTRIDGE-TYPE FILTER

138
TECHNOLOGY DEVELOPMENT AREA
Large-Area Silicon Sheet Task
J. K. Liu, Chairman

SHAPED-SHEET TECHNOLOGY

Mobil Tyco Solar Energy Corp. (EFG)

A three-ribbon (each 10 cm wide) growth run was made in March with Machine No. 16. Total growth run time was approximately 6.5 h and the total of 10-cm-wide ribbon produced was ≈33.8 m. Cartridge No. 1 produced 10.2 m of ribbon at an average growth rate of ≈3.6 cm/min; Cartridge No. 2 produced ≈12.3 m at an average growth rate of ≈3.2 cm/min, and Cartridge No. 3 produced ≈10.6 m at an average growth rate of ≈3.2 cm/min. Two single-cartridge runs were made in April to check the automatic width-control system and the ribbon-pull-system guidance. A 10-cm-wide ribbon with a uniform thickness of 6 mils was grown at a speed of 4 cm/min by refining the die-top temperature profile and improving the die design. Two runs were made in June, continuing the evaluation of the effect on material quality by CO2 ambient manipulation. A gas-tight ribbon seal was made. It controls the gas ambient in the cartridge to achieve repeatable ambient growth conditions. Cartridges longer than 10 cm for Machine No. 16 have been designed.

Face heaters for Machine No. 17 have been installed and the hollow-die design has been completed. Several runs were made with the single ribbon machine to evaluate face heaters and a hollow die. Six runs were made in June 1981 to test growth rates. A growth of 4.1 cm/min was achieved by using the cold shoe with a modified die and thermal configuration. Four runs were made in July to evaluate new linear cooling plates used to flatten the thermal profile in the cartridge.

Several runs were made with Machine No. 18 without using the cold shoe. The main-zone temperature in this machine was found to be nonuniform. New die-face heaters were installed to improve the growth rate and ribbon thickness uniformity. Three runs were made in June to evaluate a two-piece die and a modified thermal shield between the afterheater and the die top; both worked well. Six runs were made with Machine No. 18 in July. No cold shoe was used. Two-piece dies and a special shield were used. Ribbons produced were thinner at the center. A critical design review of new multiple ribbon growth Machine No. 21 was completed in April and the block diagram and line sketches of the machine were provided to JPL. Its cartridges will be longer than those of Machine No. 16. The heating power supply for Machine No. 21 has been delivered; fabrication of the main zone of the furnace of Machine No. 21 has been completed.

Westinghouse Electric Corp. (Web)

A Reticon diode array was evaluated for dendrite thickness and/or web-width control. Westinghouse hopes that the dendrite thickness will change slowly enough that an operator can maintain control manually and that the ribbon width can be handled passively. It is believed, however, that the array
LARGE-AREA SILICON SHEET TASK

sensor system can now be considered a back-up if required. Programmed start-up of growth has been demonstrated successfully in a series of trials.

Mechanical design has been completed for the growth chamber and chamber top and bottom plates. The frame has been redesigned to accommodate the modified chamber. A ribbon take-up reel material, a molded high-density polyurethane, has been settled on.

Continuous width control, a significant milestone achievement, has been demonstrated. Westinghouse has grown 5 m of ribbon at 10.1 mm width deviation. Successful control is attributed to a combination of fine melt-temperature control and heat-shield design. Westinghouse will use ribbon-width drift as a long-term temperature drift indication and will control both with a closed-loop system. This is expected to obviate dendrite thickness monitoring.

The new melt-replenishment crucibles are 33% longer than the original design and are working well. The new automatic melt-level controller has been tested on the ribbon machine and is performing as designed.

The improved melt-level-control and melt-replenishment circuitry received its initial test, actually pulling web, and performed well. The programmed growth start-up has now been successfully interfaced with a second puller. Switch-over from automatic start-up to melt-level-control and constant width control still is manual, but routine. Longer crucibles, which were designed to allow the growth of wider ribbon, were operated on a trial basis growing 1-in.-wide ribbon. No problems were observed.

In the area of process analysis, stress modeling has essentially been completed. Temperature profile modeling has been initiated. Stress data from production runs correlates well with the modeling results.

The first iteration of a mathematical model explaining stress-induced buckling of web is now completed. It has been verified against known lid and shield configurations in use in the laboratory today. Heretofore, shield design has evolved empirically. New configurations will now be designed, based on previous growth experience and on the model.

Experimental growth runs to identify a thermal geometry suitable for the high-speed growth of low-stress ribbons continued. Design of a "wide" geometry to allow the growth of >1 in. ribbon is under way. The mechanical design of the ESGU is complete. Mechanical and electrical construction have begun.

INGOT TECHNOLOGY

Kayex Corp. (Advanced Cz)

The ESGU CG6000 puller was run for the first time on March 19. Except for a few minor problems, the machine ran well, producing 13.7-cm-dia 22-kg ingot from a 30-kg melt. The crystal diameter was limited by a misalignment of the pull cable.

Kayex has completed five growth attempts with the new ESGU Czochralski system. These were debugging runs using 14-in.-dia crucibles. For the
LARGE-AREA SILICON SHEET TASK

most part, the system worked well and some 15-cm-dia zero-dislocation ingot sections have been obtained. Power-line functions and acoustic noise, both from the power supply, originally a cause for concern, now appear to have been solved.

Three crystal-growth runs were made in the Advanced Cz ESGU puller in May. The first yielded an 18-in.-long 18-kg ingot, \( \approx 30\% \) dislocation. The growth rate was low (\( \approx 2\text{in.} / \text{h} \)) due to poor thermal gradients. The second run was made at an increased chamber argon pressure (30 vs 10 torr). Considerably less 'smoke' was observed. Although this is an effective way to achieve better crystals, it is more expensive. The crystal grown was 5.4 in. in diameter, 24 in. long, 20 kg in weight, and was totally zero-dislocation. For the third growth run, a graphite chimney was used to reduce the growth chamber size above the crucible. This was intended to increase the purging effect of lower argon flows (20 torr). The resulting crystal was cleaner than any before it, but was polycrystalline.

The gas chromatograph has been assembled and installed on the ESGU.

Three additional crystal-growth runs were made in the advanced Cz ESGU puller in June. The first run yielded 15 in. (\( \approx 15 \) kg) of zero-dislocation 6-in.-dia. ingot: 32 kg were solidified in total from the 35-kg melt at a growth rate of 1.29 kg/h. The purpose of the second run was to set up and test the melt sensor for a planned 150-kg run. Twenty-five kg of zero-dislocation single-crystal were grown from the 32-kg melt. An attempt to extend this run to 150 kg failed because the virgin poly used to recharge the crucible proved to be contaminated as received from the supplier. The third run was a successful attempt to grow 150 kg from a single crucible in the ESGU unit. Approximately 30% of the silicon pulled was zero-D. Kayex believes that the progressive loss of structure of the ingots as the run proceeded and the more frequent icing of silicon on the crucible walls can be attributed directly to crucible degradation. This may be a serious problem; it will be addressed by Kayex as the program proceeds.

After the successful 150-kg growth run in June, the machine was shut down for retrofitting of the Kayex-developed microprocessor hardware for process automation. The interfacing with the microprocessor (dubbed AGL, for Automatic Grower Logic, by Kayex) will be completed and testing will begin soon.

Crystal Systems, Inc. (HEM)

In March CSI grew a 35-kg HEM ingot in 18 h (growth rate of 1.9 kg/h). This is the fastest growth rate of their recent six-ingot growth series. Typical growth rates had been \( \approx 1 \text{kg/h} \). To achieve the faster growth rate the furnace temperature was made lower than usual; as a result the top of the ingot experienced some freezing problems.

In May CSI grew a \( \times 30\text{-cm} \), 35-kg ingot that meets the specifications set forth for this demonstration.

Using a new vacuum pump and trap on the HEM crystal growth system, CSI grew the fifth 35 kg ingot in a series of six for JPL in June. The ingot solidified in 21 h and had a total cycle time of approximately 52 h. The
LARGE-AREA SILICON SHEET TASK

material is very shiny. Some silicon carbide particles can be seen on the surface of the ingot. A new 2-in. heat exchanger will be used in growing the next ingot in order to increase the solidification rate by increasing the heat extraction rate.

The final 35-kg ingot required under the current contract has been grown. The solidification time for the ingot was 40 hours and the total cycle time was 70 hours.

In an ongoing JPL effort to characterize HEM ingots, CSI's material was found to contain a high density of dislocations and of silicon carbide precipitates. To reduce the number of SiC particles, CSI replaced the trap on the mechanical pump with one of a different design. The function of the trap is to prevent the backstreaming of oil into the furnace during the growth cycle. The ingot grown after the change has a bright metallic shiny surface and no large SiC particles were detected visually.

Semix Inc. (Semicrystalline Casting)

A program review was held at Semix on March 3 and 4. Considerable insight was gained into the technology underlying the Semix program. Differences in solar-cell performance measurements have been resolved. Present performance of 10 x 10-cm cells was found to range up to 11% AM1.

The first quarterly report was reviewed and approved in May for public release. The second quarterly report was released in July; the third quarterly report has been returned to Semix for revisions.

Solar cells and wafers have been received by JPL on schedule. Two 10 x 10 x 15 cm ingots were received by JPL in June.

The detailed ESGU implementation plan is expected to be completed by the end of July.

Some Semix wafers have been sent to Applied Solar Energy Corp. (ASEC) for cell fabrication.

A revised technology projection for $.70/watt and a continuation program plan for FY82 and beyond continue under review. Negotiations continue to produce a plan consistent with technology requirements and budget limitations.

Cells manufactured by Applied Solar Energy Corp. (ASEC) using an unsophisticated baseline process gave efficiencies comparable to other polycrystalline sheet materials. Advanced processing methods are being applied by ASEC and Semix to determine material limits.

Differences in predicted SAMIS price for Semix material continue to be reviewed and narrowed.

Silicon Technology Corp. (ID Wafering)

HEM material of 11 x 11-cm cross section was cut by STC with the RD-22 machine. The wafers were 7 mils (175 μm) thick and the kerf was 11 mils (275 μm).
LARGE-AREA SILICON SHEET TASK

This results in a material utilization of 0.94 m²/kg (22 wafers/cm). The cutting rate was increased from 1.3 cm/min to 3.8 cm/min with production yields of 98% to 99%. A combination of handling experience and encapsulation of the ingots in epoxy is responsible for this progress.

Crystal Systems, Inc. (FAST)

CSI was able to slice a 10-cm-dia ingot with 99% yield, using a soft Ni plating on a tungsten core wire. The average slicing rate was 3.1 mils/min. This 157-wire pack used wires produced by CSI in-house facilities; it cut 19 slices/cm in its first run. The same wire pack was being reused for a second run.

CSI had two significant accomplishments in April: the first wafering run to slice through a 15-cm-dia ingot successfully, at a cutting rate of 2.0 mils/min, slicing at 19 wafers/cm with a yield of only 20%, and two successive runs slicing 10-cm-dia ingots at 25 wafers/cm. The cutting rate for the first run was 3.6 mils/min; the yield was 34% and the wafer thickness was 8.3 mils with a kerf of 7.7 mils. The yield of the second run was 99.1%, with only two wafers broken out of their largest wire pack yet (224 wires). The average cutting rate for the run was 3.03 mils/min with a wafer thickness of 8.1 mils and kerf loss of 7.9 mils.

CSI continued to slice 15-cm-dia material at 19 wafers/cm and 10-cm-dia material at 25 wafers/cm. All of the 15-cm-dia ingot runs have had very poor yields (as low as 4%). The reason for this is not well understood by CSI. They speculate that if one wafer breaks, the broken pieces become lodged between the wires and the next wafer, tending to cause a domino effect and resulting in a low yield. To eliminate this problem they plan to feed the ingot into the wire pack from the top rather than the bottom and flush broken pieces downward. A 10 x 10-cm section ingot run was completed at 25 wafers/cm with a resultant yield of 46%.

Using a steel-core copper-flashed wire instead of the usual expensive tungsten wire, CSI fabricated a wirepack that successfully sliced through three 4-in.-dia poly Cz ingots. The wirepack was electroplated all around with 45-µm natural diamond. The wires were spaced 19/cm and were baked to eliminate hydrogen embrittlement. The first cut sliced at an average rate of 3.5 mil/min (the goal was 4.1 mil/min) and had a yield of 99.4%. The second run averaged 1.7 mil/min with a 63% yield. Most significant is that the wire-pack was dressed before the third run, which is not normally done. The results of the third run were an average cutting rate of 2.58 mil/min (a substantial increase over the second run) and a yield of 37%. The low yield is attributed to the fact that a bearing in the drive mechanism had to be replaced, leaving the ingot half-sawn for four days while repairs were completed.

Two attempts were made in July to slice 4-in.-square cross-section ingots but were aborted due to alignment problems. A third 4-in.-square cross-section ingot was sliced, resulting in a poor yield of only 19%. An unusual cutting profile was cited by CSI as the reason for the failure.

Two 6-in.-dia ingot wafering runs were aborted, the first due to excessive wire breakage and the second due to diamond pullout in the wire. Efforts to improve the yields are continuing.
P. R. Hoffman Division of Norlin Industries completed the first two MBS wafering runs on the new contract in April. These were intended to be baseline runs that would yield slurry for reclamation studies. The Norlin-owned Varian saw was debugged during the runs and run yields were excellent. Details of plans for future runs were reviewed during a visit to Hoffman.

In addition to two sets of three runs each to study the effects of blade-head speed and vertical feed force, two runs were made in May to evaluate various vehicle:grit ratios.

Preliminary design of the wafer lift-off mechanism has been started. The detailed design has not yet been specified.

A series of sawing runs were made to evaluate the effect of varying the vehicle (PC oil):abrasive (SiC) ratio. When all other parameters are standard and held constant, preliminary results indicate that optimum cutting speeds are achieved at a 1-gal-vehicle:2.5-lb-abrasive ratio. Cutting rate fell off gradually on either side of this mix. A limited series of runs with increasing blade pressure showed increasing cutting rates. High blade pressure, a shortened stroke, high blade speed and a 1:4 slurry ratio produced cutting rates greater than twice those seen at standard conditions and 1:25 slurry ratio.

Preliminary used-vehicle recycling experiments were run for the contractor at the Bureau of Mines (Department of the Interior) at Rolla, Missouri. A successful process, possibly scaleable, was identified. It includes centrifuging to reclaim the oil (less filler, identified as diatomaceous earth by Sanborn Associates for the contractor), and heavy-liquid centrifuging to separate the silicon (<1-3 μm particle size) from the SiC, and drying of the sludge product. Initial microscopic examination of the SiC shows no apparent wear of the abrasive particle surface. The oil may be reconstituted by adding diatomaceous earth (lost in the first centrifuging step) or silica flour.

The alternative cutting oils received in June have been evaluated relative to the standard PC oil. Gardoil and Lubrizol, both petroleum- rather than fat-based fluids, appear have advantages over the PC oil. Lubrizol, especially, has price, clean-up and surface-tension advantages. Filtration, rather than centrifugation, is being considered for the oil recycling process because of the high costs of the heavy liquids used in the centrifugation.

MATERIAL EVALUATION

Applied Solar Energy Corp. (Cell Fabrication)

Cells of web material characterized by MRI did not show significant variations in performance. This uniformity was expected, since the MRI study revealed a fairly uniform distribution of defect densities for these samples.

Cells made from EFG ribbon grown with and without ambient CO₂ during the same run (baseline cell process) showed no difference in efficiency, \( V_{oc} \) or \( I_{sc} \). Samples from a similar EFG ribbon run that did show significant difference in efficiency have been stripped of metallization and sent for chemical analysis.
HEM ingot No. 41-48 was wafered into horizontal and vertical cross-sections. Cells were fabricated from wafers taken from the top, middle and the bottom of the horizontally cut sections and from a vertical section taken through the center of the ingot. All cells showed signs of shunting on series resistance, partly due to poorly sintered front contacts. However, 30% of the area covered by the wafers was excluded from measurement due to severe shunting. Cell efficiencies and fill factors indicate that only 39% of the top portion of the ingot was usable, showing efficiencies 79% of that of the CZ controls. Microcracks were indicated as a probable cause for the poor initial condition of the ingots, which had chipped and crumbling corners and sides. The material yielding the highest efficiency was from the center, where cells had 91% of the efficiency of the controls, with 67% usable area. The horizontal slice from the bottom yielded cells with 83% usable area. Microprecipitates—apparently SiC; see Crystal System Inc. (HEM above—are still suspected as the cause of the low efficiencies and non-uniform results obtained from the HEM material.

Gettering experiments to improve efficiencies of HEM cells from ingot No. 41-48 are under way. Phosphorus-glass gettering and subsequent surface removal before junction formation is being used.

Solar cells were fabricated on Semix ubiquitous crystallization process (UCP) silicon material. Sixteen 2 x 2-cm cells were cut from each of six wafers to map the response of the material over the entire wafer. Adjacent wafers were kept at JPL for studies to correlate electrical characteristics with structure.

Fabrication of solar cells from UCP silicon with an extra diffusion glass-gettering step revealed that there is no significant difference in efficiencies of cells with and without a gettering step. Diffusion lengths of baseline cells predictably correlated with the short-circuit current.

Cell fabrication from ribbon was held up due to difficulties in obtaining a flat surface on the ribbon.

Material sent to Semix for correlation of their cell fabrication results with those of ASEC did not yield useful data, due to Semix processing problems.

Cornell University (Characterization)

A report has been prepared on work done on RTR material. Cornell researchers observed that one electrically active defect consists of a pair of coherent twins interacting with two stacking faults. Presumably the interaction makes the defect electrically active.

Cornell has done high-resolution lattice imaging of grain boundaries in EFG. They have discovered small precipitates in processed EFG material that did not exist before processing. They have also completed some electron-beam induced-current (EBIC) experiments on silicon-on-ceramics (SOC).

Cornell continues to make progress in the characterization of structural defects in silicon-sheet materials. They have completed EBIC experiments on HEM material. In order to investigate structural defects responsible for the reduction of the EBIC signal, several specimens are being prepared for TEM studies. They also have discovered high-order twin boundaries in some sheet materials using the lattice-image technique.
LARGE-AREA SILICON SHEET TASK

During July, Cornell continued studies of high-order twins and low-angle boundaries using high-resolution TEM.

A program was initiated to study hydrogen-plasma passivation of grain boundaries in EFG materials using conventional hydrogen-plasma generators and Cornell's high-power plasma diode. The latter is a plasma machine that provides a high-current beam of hydrogen ions on the order of several thousand amperes. Under the high current bombardment, the top level of the material is melted and regrown in a hydrogen-rich environment.

Materials Research, Inc. (MRI) (Si Sheet Microstructure)

Approximately 450 cm² of Si material was delivered to MRI for structural characterization using a Quantimet 720. Seventy 2 x 2-cm wafers of HEM Si, 60 cm² of as-grown EFG ribbon and 20 cm² of cell-processed EFG ribbon were included. Four levels of step etching were to be performed on the solar-cell processed EFG material. The material was grown under varying atmospheres, e.g., CO₂ on or off, argon low or high volume. The cells were made at ASEC. MRI has reported the results of their analysis to JPL.

University of Illinois (Silicon Surface Study)

A contract was signed between the University of Illinois and JPL to support a study of surface-softening effects on silicon. Silicon will be abraded by a diamond stylus in the presence of various n-alcohols at selected temperatures to determine the mechanism of wear of the silicon surface and to characterize the surface damage. An optimum combination of temperature and coolant (n-alcohol) will be identified. It is hoped that this study will shed some light on the interactions of coolants and silicon surfaces that occur during silicon wafering.

A detailed program plan has been received from UI. Experiments have begun to establish force normal to the surface and speed of rotation baselines for abrasion of p-type single crystal silicon at room temperature to deionized water, acetone and ethanol. Future experiments will involve varying the speed or rotation and abrading the silicon in the presence of mixtures of n-alcohols with water.

IN-HOUSE ACTIVITIES

Crystal Growth

Four directionally solidified silicon ingots produced from in-house growth facilities were sectioned for macrostructure determination. The crucible materials for these ingots were hot-pressed SiC coated with CNTD (a manufacturer's designation) SiC, hot-pressed with Si₃N₄ with CNTD Si₃N₄ coating, and bulk graphite (Run 6A) (nonpurified). Semiconductor-grade Si was melted in the graphite, SiC and one of the Si₃N₄ crucibles. The other Si₃N₄ crucible contained metallurgical-grade Si. Grain size was largest for the Si grown in the SiC crucible. Cracking of both crucible and Si ingot was evident in each of the runs.
LARGE-AREA SILICON SHEET TASK

Eight Cz ingot growth runs were successfully completed. The purpose of the runs was to grow shaped Cz ingots.

Four square-cross-section crystals were successfully pulled during June 1981. The critical growth parameters to achieve and maintain the square cross section are being defined.

During July 1981, seven (100) silicon single crystals and one 211/211 10° bicrystal were grown. All of the (100) ingots were square and approximately 2 to 4 in. long.

Wafering

The first demonstration run using the restored Varian 686 multiblade slurry (MBS) saw has been completed. A 100-blade pre-pinned 7.5 cm-blade pack with 8-mil (200-μm)-thick steel blades, 0.25-in. (0.65 cm) height and 14-mil (350-μm) spacers was used. The wafered ingot measured approximately 11.5 x 14 x 5 cm and was mounted on a Plexiglas submount. Final wafering yield was ≥80%. The slurry was composed on PC oil with 2 lb/gal of No. 600-grit SiC.

Present activities include jigging the MBS manufacturing saw for a second demonstration run using a recently procured 30-blade pack made up of 8-mil (200-μm) thick by 0.5 in. (1.3-cm)-high blades.

Seven HEM Si wafer samples, wafered by a high-speed Meyer-Burger MBS saw, were received for depth of damage, bow, taper and thickness analysis. Thirty-eight coupons were sectioned out of the wafers for saw-damage study. Saw damage was observed to be nonuniform. Statistically, depth measurements were made from zero to ≈75 μm. Average depth of damage appeared to be in the 8-to-12 μm range, while random surface areas exhibited depth of damage in the 25-to-50 μm range (maximum). Wafer thickness, bow and taper were also measured and reported.

A second demonstration run using the restored MBS Varian 686 manufacturing saw has been completed. Final wafering yield was 88%; only five wafers were broken during the first half of the cut. Cutting rate was ≈1 to ≈2 mils/min. Renovation of the research MBS varian saw is nearing completion. A cutting-feed pressure transducer loop and other types of control instrumentation have been installed. The central sections, 2 x 2 x 4 cm, of four ingots grown by directionally solidified casting have been obtained. These sections are now being sliced into 15-to-20-mil-thick wafers for electrical characterization.

Optimization testing of selected corrosion inhibitors continued for MBS application by using fatigue tests of 1095 high-carbon steel blades in a water solution of corrosion inhibitors. Several concentrations of these selected corrosion inhibitors in water were tested. A 20-h water-base SiC abrasive slurry recirculation simulation run was made to investigate the suspension characteristics of 2 lb SiC to 1 gal water.

First attempts to run the instrumented Varian MBS wafering machine resulted in a gear-box failure. A new gear was ordered. The instrumented Varian multi-blade wafering machine includes all electronic controls and digital force readout (in pounds).
LARGE-AREA SILICON SHEET TASK

Eight-mil-nominal-diameter Laser Technology, Inc, Super Wire, a candidate for the FAST saw, was studied. Evaluation consisted of tensile-strength testing and scanning electron microscopy (SEM) examination. The Super Wire consists of a high-tensile core material and an electrolyte copper sheath for holding 45 μm diamond. Three tensile pull tests were performed on as-received wire. There was very little scatter in the load value at failure, one indication of uniform quality material. The average failure load was 8.34 lbs. At the nominal 8-mil diameter this corresponds to a tensile strength of about 170 klb/in². However, the core diameter measures out at about 5 mil. The tensile strength of the core material is then about 427 klb/in².

Material Characterization

Work on the surface-recombination velocity-measurement technique has been completed. Different Si surfaces have been used for measurement. An in-house document is being prepared. Surface passivation experiments will be done soon.

Reasonably good EBIC pictures of Silso and HEM polycrystalline solar cells have been obtained using SEM with electron energy down to 2 KeV. Since the depth penetration range of 2 KeV electrons in Si is about 0.06 μm, the EBIC pictures reflect the lateral distribution of minority carrier diffusion length in the n⁺ region. Various differences in contrast among grains were observed, which could be due to the differences in minority carrier diffusion length and/or electron scattering rate among the grains. The lack of EBIC contrast in the intergranular regions could have either or both of two causes: the minority carrier recombination rate in the grains is at least as high as that at the grain boundaries, or the phosphorus diffusion process used to form the n⁺ layer has passivated the grain boundaries.

A technique employing temperature dependence measurements of grain-boundary resistance, capacitance and capacitance transients is being developed to study the effects of heat treatments not only on intergranular sites but also on the properties of the material in the vicinity of grain boundary.

EBIC measurements of grain boundaries in the diffused n⁺ regions of silicon solar cell continue. Grain boundary lines with line widths larger than 0.5 μm have been observed. Grain boundaries in the diffused region observed by EBIC have line widths that are usually on the order of 1 μm. Some grain boundaries in this region become unobservable. All of the grain boundaries in the base region seem to be electrically active and easily observed. The difference in observability of grain boundaries using EBIC between diffused and base regions can be attributed to the difference in diffusion length.

Several experiments were performed on light-induced transient and static capacitance changes of grain boundaries in bicrystalline samples. The results support the premise that a grain boundary having a suitable potential barrier acts as a minority carrier trap when it is illuminated with weak light. The data also show that the light-induced transient capacitance could be used to measure minority carrier trapping levels at the grain boundary. More experiments and detailed studies are needed to explore the potential of the technique.

Deep-level transient spectroscopy (DLTS) measurements on Si bicrystal samples were performed. Three additional bicrystalline ingots were grown and their properties have been tested. In addition to the bicrystals grown, one run was made to evaluate the chamber contamination level in the Cz puller.
Economic Analysis

Price-sensitivity analysis runs were made for the web process with updated data and modification of some of the subroutines of the SAIPEG program. Using computer programs developed within the Task, analysis was performed on the effect of silicon cost on sheet and module prices.

LARGE-AREA SILICON SHEET TASK

Electroplating

1. It has been possible to prevent breakage of wire by plating softer nickel.
2. Use of copper flash high-strength steel as a core wire has been demonstrated.

Summary

1. Slicing of 10 cm diameter ingots at 25 wafers/cm has been demonstrated with over 99% yield.
2. 15 cm diameter ingots have been sliced at 19 wafers/cm.
3. Electroformed wirepacks have been used for effective slicing.
4. Softer nickel plating has prevented embrittlement of wires.
5. Cu flash high-strength steel has been demonstrated as suitable core material.

Problems

1. Wire life
2. Yields
3. Large kerf length
# Large-Area Silicon SEET Task

## Multiblade SAWING

**P. R. Hoffman Co.**

### Technology

<table>
<thead>
<tr>
<th>Ingot Slicing</th>
</tr>
</thead>
</table>

### Approach

- **Multi-blade Slurry Technique (MBS)**
- **Contractor**
  - P. R. Hoffman Co. (Norlin Ind.)

### Goals

- Up to 15 cm Diameter Workpiece
- Cutting Rate 0.5 Wafers/minute
- 25 Wafers/cm
- 95% Yield
- < $14.00/m² (1980$)

### Status

- 10 cm Diameter Workpiece
- 1.5 mil/min Cut Rate (0.15 Wafers/min)
- 18 Wafers/cm
- 95% Yield

### Demonstration

- Reclaim of vehicle and abrasive in laboratory test (small volume)

## Strategic Plan

- Evaluate Process Constraints
- Develop Process Improvements
- Evaluate Alternative Consumables
- Cost Reduction via Recycle of Vehicle and Abrasive
- Define Optimum Process
- Evaluate Design Constraints
- Develop Design Improvements
- Define Optimum Saw Design Consistent with Definition of Optimized Process
LARGE-AREA SILICON SHEET TASK

Tactical Concerns: Process

- Blade Package Specifications
- Abrasive Particle Size
- Abrasive/Vehicle Ratio
- Slurry Application Methods (Methods System)
- Slurry Application Methods (Volume)
- Blade Head Speed
- Feed Force/Cutting Rate

Tactical Concerns: Cost Reduction

- Evaluate Vehicle Recycling
- Evaluate Abrasive Recycling
- Investigate Alternative Vehicles
- Investigate Alternative Abrasives
- Investigate Alternative Blade Materials

Tactical Concerns: Design

- Improve Feed Force Control
- Wafer Lift-off/Support Device
- Ingot Mounting/Demounting System
- Process Definition Impact on Equipment Design

Concerns - Ingot Mounting

- Eliminate Grinding of Flat Surface
- Eliminate Effective "hinge" at Bond Line
- Bond Strength During Wafering
- Ease of Release of Completed Wafers

Concerns - Wafer Lift-off Device

- Support Wafers
- Avoid Stresses on Wafers
- Minimal Operator Training, Attention
- Compatible with Cleaning Process
LARGE-AREA SILICON SHEET TASK

Reclamation of Vehicle and Abrasive: Proposed Process

SPENT SLURRY → CONTINUOUS CENTRIFUGE → RECLAIM OIL

SOLVENT WASH HEAVIES → CONTINUOUS CENTRIFUGE

SOLVENT WASH HEAVIES → MAGNETIC FILTER → MAGNETICS (WASTE)

CONTINUOUS CENTRIFUGE HEAVIES & SOLVENT → DISTILL

HEAVY LIQUID → CONTINUOUS CENTRIFUGE HEAVIES & HEAVY LIQUID → DISTILL

CONTINUOUS CENTRIFUGE HEAVIES & HEAVY LIQUID → LIQUID & SILICON → RECLAIM SILICON CARBIDE

Baseline Test Series Completed

- Preliminary Evaluation—effect Abrasive Particle Size (2 Tests)
- Effect Blade Head Speed on Cutting Rate (3 Tests)
- Brief Evaluation of Minimum Stroke/Max Speed (Segment)
- Effect of Vertical Feed Force on Cutting Rate (4 Tests)
- Evaluate Alternative Vehicle (1 Test to date)

Cost Projections (1980 $) IPEG

ASSUMPTIONS:

- EQUIPMENT COST - $42K/MACHINE
- FLOOR SPACE - 36 SQ. FT.
- 1 OPERATOR/15 UNITS
- EXPENDABLES/RUN - $140.89 (BLADE PACK, OIL, ABRASIVE)
- 455 WAFERS/RUN (20 WAFERS/CM)
- 45 HOUR RUN TIME
- 95% YIELD
- 95% DUTY CYCLE

PROJECTION:

$104.4/\mu^2$ VALUE ADDED

LARGE-AREA SILICON SHEET TASK

Work in Progress

• Development of advanced web growth techniques for high throughput
• Fabrication and assembly of prototype web growth machine

Development Plan

Advanced Web Growth Techniques For High Throughput

High Speed Growth  Increase dissipation of latent heat.

• Develop new lid design
• Develop new shield configurations
• Control melt height (continuous melt replenishment)
• Manage gas flow

Wide Web Growth  Manage melt profile and thermal stress

• Control thermal stress (elastic)
  • Develop criteria for buckling stress
  • Identify acceptable thermal profile in web
  • Design lid/shield system to generate this profile
• Maintain control of melt profile

Combine Speed and Width Designs

Status

Advanced Web Growth Techniques For High Throughput

High Speed Growth

• A lid and shield design concept for improved speed with stable growth conditions has been demonstrated
• Automatically controlled melt level is now established
• Methods for control of gas flow and oxide deposition have been developed

Wide Web Growth

• Melt profile control is now routinely attained
• A computer model for critical buckling stress has been developed and verified
• A computer model of thermal stress/temperature profile is developed and in use

Status of Design of Prototype Web Growth Machine

Mechanical Design

• Detail design drawings complete
• Assembly drawings nearing completion

Electronic Design

• Design complete
• Detail design drawings nearing completion

192
Prototype Furnace and Controller: Initial State of Assembly
LARGE-AREA SILICON SHEET TASK

Automatic Web Width Control

Now Functional:
- Holds width to within tenths of millimeter
- Low-cost principle uses passive shields without electronics or moving parts
- Simple operation requires little operator skill
- 3 cm web width routine, 5 cm width under development

Web Growth Run J-374, Width vs Length

Programmed Start of Growth

- Repeatable high quality wide starts demonstrated
- Standard commercial process programmer is used
- Minimal operator skill required
- Single programmer serves many furnaces

Web Width - Centimeters

Web Length - Meters
Test Setup for Programmed Start
(Programmer at Front Center)
Automatic Melt-Level Control System

Improved Circuitry:

- Utilizes existing melt replenishment system
- Provides continuously variable polysilicon feed rate
- Insensitive to changes in laser beam intensity
- Operation demonstrated

Control Panel for Improved Melt Level Control

(Commercial Controller at Left)
LARGE-AREA SILICON SHEET TASK

Polysilicon Pellets From Kayex Shot Tower:
Left 0.4 to 2 mm, Right 2.0 to 2.8 mm

Problems
- Long delivery time for components
- Availability of low-cost pellet-form polysilicon

Summary
All Tasks On Schedule Per Contract Requirement
- Prototype furnace design, fabrication, assembly
- Development of techniques for higher throughput

BLACK AND WHITE PHOTOGRAPH
LARGE-AREA SILICON SHEET TASK

MULTIPLE RIBBON GROWTH BY EFG

MOBIL TYCO SOLAR ENERGY CORP.

1981 Goals

• DESIGN, FABRICATION AND OPERATION OF NEW EXPERIMENTAL SHEET GROWTH UNIT (ESGU), FURNACE 21, FOR GROWTH OF FOUR 10 CM WIDE RIBBONS AT 4 CM/MINUTE WITH AUTOMATIC WIDTH CONTROLS AND MELT REPLENISHMENT.

• DEMONSTRATION OF LARGE AREA (50 cm²) CELL OF EFFICIENCY GREATER THAN 12.0%

1981 Program

MULTIPLE RIBBON FURNACES

• FURNACE 16 - TESTING OF NEW CARTRIDGE DESIGNS FOR STRESS REDUCTION, AMBIENT CONTROL, AUTOMATIC CONTROL SYSTEMS, AND UPGRADED MELT REPLENISHER.

• FURNACE 21 - NEW ESGU UNIT IS TO BE BUILT AT MOBIL TYCO EXPENSE AND INCORPORATED INTO THE PROGRAM ON NOVEMBER 1, 1981 FOR DEVELOPMENT WORK

SINGLE 10 CM CARTRIDGE FURNACES

• FURNACE 17 - OPTIMIZATION OF SPEED CAPABILITY AND QUALITY AT 4 CM/MINUTE.

• FURNACE 18 - DEVELOPMENT OF 10 CM WIDE RIBBON GROWTH WITHOUT CONVENTIONAL COLD SHOES.

CELL AND MATERIAL CHARACTERIZATION

• STUDY OF GROWTH PARAMETER, MATERIAL PROPERTY AND CELL PROCESSING INTERRELATIONSHIPS.
LARGE-AREA SILICON SHEET TASK

Ambient Effects in Multiple-Ribbon Furnace Environment

- PRELIMINARY TEST IN FURNACE 16 OF INTERFACE AMBIENT CONTROL SYSTEM DEVELOPED IN SINGLE-CARTRIDGE FURNACE 17 WAS SUCCESSFUL.

- FACTORS IDENTIFIED FOR ACHIEVING REPRODUCIBILITY:
  - CO LEVEL IN MAIN FURNACE IS HIGH AND VARIABLE WITH TIME; MAIN ZONE GASES EXIT THROUGH CARTRIDGES.
  - GAS OUTFLOW THROUGH EACH CARTRIDGE IS INDETERMINATE BECAUSE OF MULTIPLE OPENINGS.

FUTURE WORK: DESIGN OF A GAS TIGHT RIBBON SEAL TO EXCLUDE EXTERNAL ATMOSPHERE FROM MENISCUS AREA IS COMPLETE; SEAL COMPONENTS NOW BEING PREPARED FOR TESTING.

High-Speed Growth Performance: Furnace 17

- IMPACT OF DIE AND COLD SHOE DESIGN ON GROWTH STABILITY AT 4 CM/MINUTE IS UNDER EXAMINATION.
- THICKNESS UNIFORMITY AT 200 MICROMETERS (8 MILS) AND GUIDANCE/FLATNESS IMPROVEMENT STUDIES IN PROGRESS.

STATUS: GROWTH STABILITY WITH AMBIENT CONTROL IMPLEMENTATION GOOD AT 3.5 CM/MINUTE.

RIBBON FLATNESS AT 8 MILS (200 MICROMETERS) NOT SATISFACTORY ABOVE 3 CM/MINUTE DUE TO GUIDANCE AND STRESS-INDUCED BUCKLING PERTURBATIONS.
LARGE-AREA SILICON SHEET TASK

Quality Studies: Furnace 17

- Properties of ribbon grown with cold shoes respond to ambient gas changes in much the same way as for ribbon grown without cold shoes.

- Quartz in the melt in graphite crucibles and meniscus CO$_2$/O$_2$ have similar impact in improving cell properties.

Status: Cell performance (10 to 11%) for system with cold shoes is below that of system without cold shoes (12 to 13%).

Summary of averaged solar cell data for phosphorus processed cells from ribbon growth run no. 17-136, with CO$_2$ plus O$_2$ in ambient.

NA = NOT AVAILABLE
LARGE-AREA Si!.ICON SHEET TASK

Quality and Stress Basic Studies: Furnace 18

- COLD SHOE IMPACT ON QUALITY AND STRESS IS UNKNOWN.
- GROWTH SPEED INFLUENCE ON QUALITY IS UNKNOWN.

THESE QUESTIONS ARE BEING ADDRESSED THROUGH DEVELOPMENT OF SYSTEM FOR GROWTH OF 10 CM WIDE RIBBON AT 3 TO 4 CM/MINUTE WITHOUT USE OF CONVENTIONAL COLD SHOES.

- GROWTH WITHOUT COLD SHOES AT 2 CM/MINUTE HAS BEEN ESTABLISHED.
- HIGHER SPEEDS SOUGHT WITH USE OF END-ONLY AND ASYMMETRIC COLD SHOES.

Construction and Operation of Furnace 21

- NEW UNIT FOR SIMULTANEOUS GROWTH OF FOUR 10 CM WIDE RIBBONS.
  - DESIGN OF FURNACE COMPLETED.
  - FABRICATION OF MAIN ZONE COMPONENTS IS NEARLY COMPLETE.
  - ASSEMBLY OF SUBSYSTEMS IS NOW UNDERWAY.

- INPUT TO 10 CM CARTRIDGE DESIGN IS TO CONTINUE UNTIL SEPTEMBER.
Summary

QUALITY

- Improvement of high speed ribbon cell efficiencies above current 11% is required:
  - Growth parameters have been identified that change as-grown properties and behavior of ribbon in processing, but specific mechanisms are not known.

SPEED

- Productivity and throughput increases require higher growth speeds that must be achieved without compromising quality:
  - The influence of cold shoes on quality and stress level not known.
  - Guidance and buckling perturbations of ribbon flatness at 200 micrometers (8 mils) limit productivity above 3 cm/minute.
LARGE-AREA SILICON SHEET TASK

Future Work: Quality

- **COLD SHOE/SPEED INCREASE EFFECTS ON QUALITY:**
  - Dynamic (melt and growth interface) phenomena influence.
  - Temperature profile, in situ cooling cycle.
  - Ambient gas-meniscus surface reactions.
  - Defect generation by increased level of stresses.
  - Impurity contamination.

- **APPROACHES**
  - Development and characterization of system for growth without conventional cold shoes.
  - Study of melt transport phenomena by finite element computer simulation (collaboration with MIT).
  - Optimization of gas introduction system in multiple and single ribbon furnaces and study of influence of different gas species, concentrations and gas flow patterns.
  - Material property (resistivity, oxygen level) studies comparing low and high speed grown ribbon.
LARGE-AREA SILICON SHEET TASK

Future Work: Productivity

- COLD SHOE/SPEED INCREASE EFFECTS ON PRODUCTIVITY:
  - STRESS AND BUCKLING CHARACTERIZATION
  - GROWTH STABILITY AT 4 CM/MINUTE

- APPROACHES
  - COMPARISON OF RIBBON STRESS/BUCKLING LEVELS WITH AND WITHOUT CONVENTIONAL COLD SHOES.
  - TESTING OF MODIFIED TEMPERATURE PROFILES IN POST-GROWTH ENVIRONMENT.
  - DESIGN WORK WITH NEW DIES, COLD SHOES.
  - GROWTH IN MULTIPLE RIBBON FURNACE 21 WITH ONE OPERATOR TO EXAMINE 12 RIBBON PER OPERATOR ESGU GROWTH CONCEPT.

ADDED CONSTRAINT: SPEED AND PRODUCTIVITY INCREASES MUST BE CONSISTENT WITH MAINTAINING OF GOOD QUALITY LEVEL.

- IT IS THEREFORE NECESSARY TO HAVE CONCURRENT RIBBON PROPERTY STUDIES AND BASIC MATERIAL CHARACTERIZATION AND CELL PROCESSING EFFORT.
This report on Contract 955733 is titled "Advanced Czochralski Ingot Growth for Technology Readiness."

The contract work started October 1, 1980, and was first scheduled for completion 13 months later on November 1, 1981. Subsequently, at the request of JPL, the program plan was extended five months for a new completion date of March 31, 1982, to minimize current fiscal year expenditures.

All references to program plan and status will be made on the revised schedule, which became effective May 1, 1981.

Presentation Format

1. OBJECTIVES OF CONTRACT
2. APPROACH
3. PROGRAM PLAN
4. PRESENT STATUS
5. AREAS OF CONCERN
6. PLANS

This is the presentation format I will follow. After stating the contract objectives, I will describe our approach to achieving these objectives.

The program plan will describe how we have broken down the project into separate tasks. Although the program plan does illustrate current status, I will elaborate considerably on our status in this presentation.

There are certain areas of concern, or problems, which present obstacles to the achievement on our status in this presentation.

Finally, I will describe our plans for the balance of the contract and what we hope to achieve.
LARGE-AREA SILICON SHEET TASK

Goals

- GROWTH OF 150 KG OF INGOTS FROM ONE CRUCIBLE USING PERIODIC MELT REPLENISHMENT
- DIAMETER - 15 CM
- THROUGHPUT - 2.5 KG/HR
- RECHARGE MELTING RATE - 25 KG/HR
- AFTER GROWTH YIELD - 90%
- MICROPROCESSOR CONTROLS PLUS IMPROVED SENSORS FOR MELT TEMP, INGOT DIAMETER, AND MELT LEVEL
- PROTOTYPE EQUIPMENT SUITABLE FOR HIGH VOLUME SILICON PRODUCTION, TRANSFERABLE DIRECTLY TO INDUSTRY

Of course, the whole effect is designed to reduce the add-on cost of ingot growth.

We have, in the past, established that 100 kilograms can be grown from one crucible (using semiconductor-grade poly) and that the efficiency of the last material produced is the same as the first, provided single-crystal structure is achieved. (Loss of single crystallinity degrades solar efficiency somewhat.)

Also, we have achieved up to 88% of high-quality single-crystal ingot from 100-kilogram runs.

In this program, we have increased the goal to 150 kilograms and the diameter to 15 centimeters in an attempt to reduce the cost further.

Additional cost savings, however, will not come from even larger quantities. (Indeed, the add-on cost per kilogram is essentially flat as you approach 150 kilograms.) Cost improvements will now come from improvements in throughput and process parameter control, yields, automation and equipment performance.

-- A significant portion of this project is devoted to understanding the process parameters as they relate to yields and throughput.

-- Yield improvement means more material per run that meets the required solar efficiency.

-- Automation improvement means not only reduced labor, but consistent product.

-- Equipment can impact cost by performing more reliably with less down-time.

The equipment that has been designed and built on this project has a large number of improvements, specifically addressing the needs and requirements for the production of large quantities of ingot material.
LARGE-AREA SILICON SHEET TASK

Approach

- CONSTRUCT AN IMPROVED CRYSTAL GROWER HAVING THE PERFORMANCE REQUIRED TO ACHIEVE GOALS

- CONSTRUCT AN AUTOMATED SYSTEM WHICH WILL OFFER RELIABLE PERFORMANCE LEADING TO IMPROVED YIELDS AND REDUCED LABOR COST

- CONDUCT PROCESS DEVELOPMENT ON LARGE SIZE CRYSTAL GROWTH, MELT REPLENISHMENT AND IMPROVED THROUGHPUT AND YIELDS

- CONDUCT A PARALLEL ANALYTICAL PROGRAM TO HELP UNDERSTAND THE PROCESS

Kayex personnel continue to believe that there are a number of areas in conventional Cz that can be cost-improved. In our approach, we started first by constructing improved equipment.

Long runs, lasting 60 to 100 hours, multiple recharge cycles, large ingots up to 50 kilograms requiring up to 60 kilograms of melt, all require special consideration in equipment design.

The JPL facility design has incorporated these improvements. Improved areas include seals, sectional furnace chambers, increased capacity, longer-life graphite designs, additional sight ports for sensors and the like.

All these improvements have been reported in detail previously and are expected to help achieve the improved cost goals.

The growth facility also is controlled with a microprocessor-based programmable controller. This will result in significant cost benefits relating to labor, throughput, yields, etc. The controller is easily programmed on the factory floor by a supervising engineer for the particular material being produced or process required.

The equipment is the tool; however, process development is required to demonstrate what can be achieved with the tool. The process development task will identify important variables and attempt to optimize them. Specifically, we will attempt to demonstrate improved throughputs and yields.

The analytical program is being conducted in support of the process development task for the purpose of better understanding of the process.

Here, the main approach is to:

(1) Conduct crucible and silicon purity analyses

(2) Fabricate and evaluate solar cells prepared from grown ingots

(3) Analyze furnace gas atmosphere (CO, CO₂, H₂O, etc.) and correlate the results with crucible performance and ingot quality.

*Kayex Corporation April 21, 1981*
LARGE-AREA SILICON SHEET TASK

This plan, dated April 21, 1981, reflects the recent schedule change, but includes all of the original tasks.

It shows that the crystal grower was completed nearly to schedule plan.

A number of single-ingot runs have been made and one 150-kilogram run was recently completed. This run was performed to establish that the equipment was totally functional for the process development work to be performed subsequently.

The simultaneous program on sensor development was conducted up to the present on another grower (a standard Hamco CG2000).

Although the program plan reflects the substantial reduction of effort for the current fiscal year, we are doing some preparatory work in anticipation of completion of the contract.

This is specifically in the area of gas analysis. We now have a completed gas chromatography system capable of measuring CO in the exhaust gas. We believe determination of CO in the furnace atmosphere to be indicative of the condition of the furnace and the reactions taking place during growth. This system is functional now and preliminary calibrations and CO measurements have been performed on one growth run.

Purity analyses, solar cell fabrication and further sensor development work have been postponed until later in the program.
LARGE-AREA SILICON SHEET TASK

This program block diagram illustrates a little better where we are in the program and how the various tasks relate to the overall projects.

Dates in the blocks indicate the date of milestone completion.

I have already indicated that the JPL grower is now complete and functional and that the first 150-kilogram run has been performed on it.

We are now preparing to install the microprocessor control system on the grower. That will be complete this month.

With regard to sensors, we have demonstrated automatic melt temperature trim (before seeding) and automatic shouldering on 10-centimeter-diameter crystals using a standard CG2000 machine. The software for these sensors has been incorporated in the microprocessor program and is ready for tests on large-diameter crystals and large charge melts.

Automatic melt level control will be integrated in the system later in the program.

We are now just beginning the key portion of the program: the process development task. Here we hope to be able to demonstrate faster throughput and improved yields. This involves a number of experiments relating to crucible performance, gas-flow control, and a radiation shield to assist in heat transfer from the crystal.

Finally, the technology readiness demonstration will consist of a number of 150-kilogram runs.
Gas Analysis System
Gas Analysis Task: Objective, Approach and Status

OBJECTIVE - To quantitatively analyse gaseous components of the crystal growth environment during growth.
Operating pressure, 7.6 Torr (1/100 atm)

APPROACH - Gas chromatography for CO and H₂
Calcium stabilized zirconia for O₂
Aluminum oxide hygrometer for H₂O

STATUS - GCA operating
Preliminary measurements of CO obtained
O₂ and H₂ on hold until FY 82
Typical CO Analysis With Gas Chromatography System

CALIBRATION PEAK

Goals

1. Demonstration of $2.80/Wp commercial readiness department of energy goal.

2. Demonstration of $0.70/Wp technology readiness department of energy goal.

Status

1. SEMIX has demonstrated to the satisfaction of JPL and DOE that target technology projections can be met for the commercial readiness goal and will proceed toward the $2.80/Wp target with internal funds.

2. The cooperative agreement has been rescoped to focus on the basic critical technology elements necessary to demonstrate technical feasibility for $0.70/Wp.

Technical Feasibility
Demonstration

100 MWP/YEAR CAPACITY

TECHNOLOGY

UBIQUITOUS CRYSTALLIZATION
PROCESS TO YIELD SILICON SHEET

GOALS:

1. CRYSTALLIZATION:
   - Crystallization Rate: 2.5 KG/HR
   - Brick Size: 30 X 30 X 19 CM
   - Process Yield: 99%
   - 1 Man/Machine
   - Automated Controls

2. WAFFERING:
   A. INTERNAL DIAMETER
      - 100 X 150 X .227 MM
      - .454 MM CENTERS
      - Throughput Rate: .3 M2/HR
      - Process Yield: 95%
      - 12 Machines/Man

   B. HIGH SPEED MULTI-BLADE SLURRY
      - 100 X 150 X .254 MM
      - .508 MM CENTERS
      - Throughput Rate: 1.0 M2/HR
      - Process Yield: 95%
      - 4 Machines/Man

   C. CONTROLS & ANALOG PROGRAMMED
      - Process Yield: 95%

3. GENERAL:
   - Overall Silicon Utilization: >.81 M2/KG
   - AML Cell Efficiency: 15% 10 X 15 CM
   - 120 X 160 X .343 MM WAFERS HAVE BEEN DEMONSTRATED.

LARGE-AREA SILICON SHEET TASK

SEMIX MATERIAL JPL EVALUATION PLAN

JET PROPULSION LABORATORY

Purpose

• PROVIDE TECHNICAL DATA FOR PROGRAM MANAGEMENT

• INCREASE JPL UNDERSTANDING OF SOLAR CELL PERFORMANCE OF UNCONVENTIONAL SILICON

• AID CONTRACTOR IN MAXIMIZING PERFORMANCE

• PROVIDE PRELIMINARY INFORMATION TO PV INDUSTRY ON PERFORMANCE OF THE FUTURE SHEET

Material Received by JPL

THRU 7/1/81

• 100 SOLAR CELLS
  10cm x 10cm

• 200 AS SAWN WAFERS
  10cm x 10cm

• 2 INGOTS
  10cm x 10cm x 12cm

Performance Evaluation

CELLS (SEMIX)

• MUTUALLY ACCEPTABLE MEASUREMENT TECHNIQUE HAS BEEN ESTABLISHED

• PRESENT BARE CELL PERFORMANCE ON 10 x 10cm CELLS IS 11 - 12% AM1 (10 CELLS)

• LARGER NUMBER OF CELLS (90) ARE IN MEASUREMENT PROCESS

• PERFORMANCE EVALUATION WILL CONTINUE ON A PERIODIC BASIS
LARGE-AREA SILICON SHEET TASK

CELL PROCESSING SHEET:

- BASE LINE CELLS 2 x 2cm PRODUCED BY ASEQ

- ENHANCED PROCESS CELLS (2 x 2cm) PRODUCED BY SEMIX FROM JPL MATERIAL

- ENHANCED PROCESS CELLS (2 x 2cm) PRODUCED BY ASEQ

- ENHANCED PROCESSING TO CONTINUE AS DIRECTED BY JPL/SEMIX

- MATERIAL QUALITY EVALUATION WILL CONTINUE ON PERIODIC BASIS

LARGE-AREA SILICON SHEET TASK

Baseline Performance

ASEC RESULT:
- 10 x 10 cm wafers as supplied were cut into 16 2 x 2 cm pieces
- 12 - 15 cells per initial wafer
Mean for each initial wafer varied from 10.3 to 11.0%; S.D. from .4 to .7
Grand mean was 10.7%; S.D. was .3

3 Cz control - cells mean was 13.1%; S.D. = .1
All results @ 28°C

SEMIX/JPL RESULTS
- 10 x 10 cm cells as supplied were measured by SEMIX and JPL
SEMIX - 11.6%; S.D. = .3 @ 26°C
JPL - 11.3% S.D. = .13 @ 22°C

*One shunted cell was rejected and omitted from results

INGOT CASTING: HEAT EXCHANGER METHOD (HEM)

CRYSTAL SYSTEMS INC.
F. Schmid and C. P. Khattak

Characterization of Two HEM Ingots

CONCLUSIONS:

1. Resistivity is very uniform throughout the ingot.
2. Oxygen concentration varies 3-33 ppma.
   No correlation with efficiency.
3. Overall efficiency is 85% of control cells.
4. Large grain polycrystalline HEM material is comparable to single crystal HEM.
5. Large SiC precipitates (50-100 μm) may be limiting solar cell efficiency.
6. High dislocation density (10^6/cm^2).

TECHNOLOGY DEVELOPMENT AREA

Encapsulation Task

C. D. Coulbert, Chairman

MATERIAL DURABILITY AND LIFE ASSESSMENT

Developing quantitative relationships that relate environmental stress such as solar ultraviolet, wind, temperature extremes, and moisture to the rate of degradation of module performance and structural integrity are objectives of the Encapsulation Task in-house efforts. These activities are integrated with contractual activities to develop an overall module-life-prediction method.

Photothermal degradation rates and mechanisms and ultraviolet absorption characteristics of polymeric encapsulants are being measured as a function of polymer composition and test-exposure conditions. Data are being obtained for silicones, EVA, PnBA, polyurethane, EMA, PVB, and acrylic films. Failure mechanisms and critical temperature limits associated with module hot-cell experience are being identified for use in establishing module circuit design and diode protection criteria.

Encapsulation material degradation data for cost-competitive advanced encapsulant systems is being gathered using various test hardware such as minimodules (12 x 16 in.), two-cell modules and individual material samples. Exposure facilities include the JPL laboratory test chamber and selected California field test sites at Point Vicente, JPL, Goldstone, and Table Mountain.

Solar-cell corrosion protection provided by various encapsulants, coatings and primers is being studied by Rockwell Science Center using a galvanic-cell atmospheric corrosion monitor (ACM). Initial results confirm that metallic surfaces encapsulated with properly bonded polymers will not corrode even in the presence of strong acidic or alkaline liquids in contact with the surface of the protective polymer. Further studies will assess the effects of contaminated interfaces and polymer encapsulants that have been photothermally degraded.

ENCAPSULATION ENGINEERING

New material products tailored to the specific requirements defined and publicized by the LSA Project for PV module encapsulation are now available from Du Pont and 3M for the PV manufacturers. These products include non-blocking EVA film in production quantities, laminated EVA-Tedlar sheets, and PMMA UV-screening cover films.

A display of these and other candidate polymeric encapsulation materials was presented in the 18th PIM exhibit area. These materials, provided at the request of the Encapsulant Task, were assembled to demonstrate the status, source, availability and form of candidate module encapsulants for pottants, cover films, edge seals and gaskets, adhesives and primers.

A JPL report titled Photovoltaic Module Encapsulation Design and Materials Selection, JPL Document No. 5101-177, has been written and is in
ENCAPSULATION TASK

press; it describes the module encapsulant material requirements for the various functional elements of a complete photovoltaic module encapsulation package. This information is presented in terms of material properties, performance, life and cost requirements. It describes the status and availability of potential material and process candidates with criteria and guidelines for their selection, processing, and optimizing configurations for specific applications. A preliminary draft volume of this report was available in the exhibit area and its publication and distribution is expected in about three months.

Under a contract with the University of Massachusetts to develop polymerizable UV stabilizers, the synthesis of 2(2-hydroxy-5-isopropenylphenyl) 2H-benzotriazole (2H5P) and its copolymerization has been accomplished. The compound does not homopolymerize and grafting with 2H5P has not been successful. At the same time, and based on the same intermediates as those used for the synthesis of 2H5P, a new synthesis of 2(2-hydroxy-5-vinylphenyl) 2H-benzotriazole (2H5V) has been carried out that promises to have advantages over that accomplished earlier.

Grafting of 2H5V onto a number of common polymers has been accomplished, including atactic polypropylene, poly-[ethylene-co-vinyl (acetate)], poly-(methyl methacrylate), poly-(butyl acrylate) and polycarbonate. In preliminary experiments 2H5B does not graft under similar conditions.

Efforts will continue to evaluate the spectral characteristics of these compounds in attempts to establish clearly and beyond any doubt the most effective polymerizable derivative of 2(2-hydroxyphenyl) 2H-benzotriazole as the prime candidate for polymerizable UV stabilizers for the Low-Cost Solar Array Project.

Progress was reported on the Illinois Tool Works contract to develop and demonstrate the capability to produce operational solar cells having front and back metallizations and antireflective coatings deposited by gasless ion plating. In summary, it is noteworthy that the process has repeatedly produced cells that perform as well as or better than comparable commercial cells at a projected (SAMIS) production cost of 5.6¢/Wp for the metallization plus AR coating.

Spectrolab, Inc., reported progress in the experimental verification of their module-design analysis methods, evaluating the effects of various module encapsulant-design parameters on module thermal response, optical performance, electrical isolation, and solar-cell stresses. A summary of the tests on optical performance and electrical isolation is included in its presentation, below. One significant result of the electrical tests was that module electrical isolation approaching intrinsic material properties could be achieved with two or more dielectric layers (pottant plus film). All breakdowns, however, occurred finally at sharp corners and edges of solar cell or circuit components. Voids and bubbles in the encapsulant did not significantly contribute to electrical breakdown.

A joint effort with Spectrolab is under way to develop graphical design analysis curves, i.e., master curves with reduced variables. These curves, when defined and verified, will enable the module designer to optimize the encapsulant system design parameters such as pottant thickness, pottant modulus,
ENCAPSULATION TASK

and cover-film properties and to determine which module performance characteristics are most affected by encapsulant configuration and material choices.

Progress in the development and characterization of other advanced encapsulant materials by Springborn Laboratories, Inc., JPL, and the interested industrial groups was summarized by E. F. Cuddihy of JPL and F. Willis of Springborn. A summary of property and performance data is included below.

ION PLATING

ILLINOIS TOOL WORKS—ENDUREX

-- DEVELOP ION PLATING FOR DEPOSITION OF METALLIZATION ON SOLAR CELLS.

-- DEVELOP MASKING TECHNIQUES TO BEST MAKE USE OF ION PLATING DEPOSITED METALLIZATION.

-- DEVELOP LOW COST METALLIZATION SYSTEMS FOR USE ON SOLAR CELLS.

-- DEVELOP ION PLATING DEPOSITED AR COATINGS.
ENCAPSULATION TASK

Sample of 9 cells average $n = 12.49$

Controls (3) average $n = 11.2$

Ion Plating SAMIS Results

$0.056 (\$1980)/\text{peak-matt}$

Based on:

-- 50 MW/year production
-- 4" diameter round cells
-- Ni/Cu front metallization
-- Ti/Cu back metallization
-- $\text{SiO}_x$ AR
-- 6 vacuum systems + 1 recycle station

IPEG sensitivity analysis is in process
ENCAPSULATION TASK

Future Opportunities and Problems

A) Metallization of cells with other than round shapes,
   -- Square cells
   -- Ribbon silicon

B) Junction formation and metallization in same machine,
   -- Ion implant junction
   -- Laser recrystallization
   -- Ion plate metallization and AR
   Requires:
   -- Separate vacuum systems for implant and ion plating operations
   -- Matched throughputs

C) Deposition of junction and metallization by ion plating in one machine
   -- Deposit doped Si layer ~4000 Å thick
   -- Laser recrystallization
   -- Ion plate metallization and AR
   Requires:
   -- Developing recrystallization techniques
   -- Determining profile of resulting junction

ENCAPSULATION TASK

Electrical Results

- Breakdown at corners and edges
- Voids and bubbles not significant
- Relatively high dielectric strengths for all samples

Technology Voids in Electrical Test

- Effects of weathering ignored
- Model does not take field concentration effects into account
- Effects of continuous electrical field not investigated
- Edge problems in framing not investigated

TOPICS IDENTIFIED REQUIRING FURTHER RESEARCH

Thermal-Structural

- Effect of potting surrounding cell completely
- Temperature variations of structural properties
- Material properties of polycrystalline versus single crystal silicon
- Weathering effects on material properties
- Residual stress from encapsulation process
ENCAPSULATION TASK

Structural-Deflection

- Loading from both sides of module
- Complete encapsulation
- Residual stress
- Stress measurements at various points on cell
- Stress at interconnect points
- Varying material properties with temperature
- Cell shape and size/module size
- Cell thickness
- Weathering effects

Thermal

- Location of module in array field
- Wind patterns in array field
- Refinement of convective heat transfer algorithm

Optical

- Off normal radiation
- Zero depth concentrator effects
- Diffuse reflection effects
- Diffuse sunlight effects
ENCAPSULATION TASK

Electrical

- Field concentration
- Effects of bubbles and voids
- Effects of moisture
- Effects of encapsulant aging

*AIR OVEN AGING*
PROCESS DEVELOPMENT AREA

D. B. Bickler, Chairman

Process Development Area progress and status reports included an introduction and detailed presentations on the two MEPSDU processes and individual contractor reports on other process developments.

MEPSDU

Westinghouse presented its MEPSDU Prototype Module Design Review in a workshop session, and during its process development presentation a summary of the module design was presented, as was material on SAMICS coating and alternative process developments.

The Solarex Corp. presentation covered its MEPSDU process, module design and input material selection. Technical progress included work on spray-dopant belt-furnace diffusion, optimized back-junction formation, spray AR processing and encapsulation process development.

Contract Review

The following highlights are summarized from the LSA contract review session, which also covered JPL in-house efforts on robotics, ion implantation, lamination and technology transfer.

Tracor MBA discussed robotics and computer-assisted assembly concepts being developed: cell-stringing by a robot, module layup, automated vacuum lamination and edge sealing. A videotape of equipment operation and a poster were presented.

Motorola Inc. has been working on process sequence developments in process technology, cell design and metallization. Its process technology efforts include surface preparation, etching and texturizing; substrate drying, and the handling of rectangular shapes. Plated metallization advances and thermal stress studies of metallized silicon were reported.

Photowatt International, Inc., is developing a metallization system using thick-film and electroplating technologies.

The RCA process sequence efforts are centered on the processing of upgraded metallurgical-grade silicon substrates.

Spectrolab, Inc., discussed progress on the Midfilm metallization process. A bimodal cell-efficiency plot was obtained that showed a contact-resistance problem; use of an indium-tin oxide AR coating solved it, and gave average cell efficiencies of 12%.
PROCESS DEVELOPMENT AREA

Junction formation by ion implantation and electron-beam pulse annealing was described by Spire Corp.

Westinghouse Electric Corp.'s efforts to provide base-metal contacts of evaporated titanium and nickel with electroplated copper have shown good electrical characteristics but poor adherence.

The University of Pennsylvania independent assessment of the MEPSDU processes has reached the final compilation and reporting stage.

JPL In-House Activities

Labor reduction and quality improvement are two areas of interest to the JPL robotics assembly effort. An improved computer vision system and force sensors have been developed.

Non-mass-analyzed ion implantation has been demonstrated by JPL and industry transfer is following.

Contractor-developed solar-cell processes are made available for industry evaluation by JPL. Since more processes are being developed, a continuing industry review is needed.

A progress report on JPL laminating process development and materials research was presented to an encapsulation session. Recent results have shown some adherent, chemically bonded surfaces.

Goals and Approach

- DESIGN MODULE MEETING JPL 5101-138 SPECIFICATIONS
- SELECT AND VERIFY PROCESS SEQUENCE FOR FABRICATING MODULES
- DESIGN AND BUILD A TEST FACILITY TO FABRICATE MODULES USING SELECTED PROCESS SEQUENCE
- PERFORM 3 TECHNICAL FEASIBILITY EXPERIMENTS
- ACCEPTANCE AND QUALIFICATION TESTING OF MODULES PRODUCED
- DETERMINATION OF 1986 MODULE PRODUCTION COSTS
PROCESS DEVELOPMENT AREA

Baseline Process Sequence

PRE-DIFFUSION CLEAN → RACK JUNCTION FORMATION → FRONT JUNCTION FORMATION

AR/PR DEPOSITION/BAKE → FRONT GRID DELINEATION → METALLIZE - FRONT & BACK (Ti/Pd)

REJECTION/ Cu PLATING → CELL SEPARATION AND TEST → CELL INTERCONNECT

MODULE LAMINATION → MODULE TEST → CRATE

Cost Analysis - SAMICS

ASSUMPTIONS
1. 3 SHIFT, 345 DAYS/YEAR OPERATION
2. 12% MODULE EFFICIENCY AT 25°C AND 100 mW/cm² INSOLATION
3. 90% CELL YIELD; 95% MODULE YIELD
4. 25 MW/YR PRODUCTION
### PROCESS DEVELOPMENT AREA

### Alternative Process Sequence Steps

**Under Evaluation**

- ION IMPLANTATION JUNCTION FORMATION

- LIQUID DOPANT JUNCTION FORMATION

- LOWER COST METALLIZATION SYSTEMS
  - ELECTROLESS NI DEPOSITED ON SI
  - ELECTROLESS NI DEPOSITED ON TI
PROCESS DEVELOPMENT AREA

Cell Metallization Configuration

- TI/PD DIFFUSION BARRIER QUALIFIED FOR SPACE SOLAR CELL APPLICATIONS
- LONG-TERM EFFECTIVENESS OF BARRIER BASED ON 20 YEARS OF OPERATING DATA

Module Design Innovations

- USE OF DENDRITIC WEB SINGLE-CRYSTAL SILICON
- USE OF HIGH ASPECT RATIO (3.5:1) RECTANGULAR PHOTOVOLTAIC CELLS
- TEMPERED GLASS SUPERSTRATE
- FRAMELESS CONSTRUCTION
- ELIMINATION OF SOLDER JOINTS INSIDE THE ENCAPSULATION ENVELOPE
- HIGH CELL INTERCONNECT REDUNDANCY
- 12 PARALLEL CELL CIRCUITS

Module Layup

```
1/8" TEMPERED GLASS
.005" CRANEGLAS
.020" EVA
.006" SOLAR CELLS
.020" EVA
.005" CRANEGLAS
.003" MYLAR (KORAD)
```
## Module Layup Lifetime Considerations

- **1/8'' TEMPERED GLASS**: Survived 1979 ft. Collins Hailstorm
- **CRANEGLAS**: Assists in removal of entrapped air during lamination
- **EVA POTTANT**: Accumulated over 16,000 hours without degradation under accel. tests
- **KORAD BACKING**: Good adherence achieved, UV degradation secondary, alternates under investigation.
- **EDGE TAPES**: Various candidates under investigation

## Module Electrical Circuit

- **12 Parallel Strings of 15 Series Connected Cells**
  - No cell carries over 9% of module current
  - Cell damage potential during shaded/short circuit operation eliminated
  - No diodes required
- **Lateral contact of cells will not affect performance**
PROCESS DEVELOPMENT AREA

12 X 15 CELL MATRIX
PROCESS DEVELOPMENT AREA

Cell Electrical Interconnects

- **ULTRASONIC BONDING REPLACES REFLOW SOLDERING**
  - REDUCED ELECTRICAL CONTACT RESISTANCES MEASURED
  - FASTER PROCESS ALLOWS INCREASED BOND REDUNDANCY
  - NO FLUXES INTRODUCED INSIDE LAMINATED LAYUP

- **INTERCONNECT FAILURE CONSIDERATIONS**
  - EXTENSIVE ANALYSIS INDICATE THAT INTERCONNECT STRESSES CANNOT EXCEED ENDURANCE LIMIT
  - THERMAL CYCLE TESTING OF PROTOTYPE MODULES HAS CONFIRMED RESULTS
  - NEED FOR STRESS RELIEF ELIMINATED BY GEOMETRY

Maintainability Considerations

- AMP TERMINAL CONNECTIONS REQUIRE NO FIELD TOOLS
- REMOVAL OF MODULE FROM ARRAY IS ONE-MAN OPERATION
- NO EXPOSED METAL ON MODULE SURFACE

MEPSDU Module Operation

- **MODULE OPERATING PARAMETERS AT 80 mW/cm²; 20°C AMBIENT**
  
  OPEN CIRCUIT VOLTAGE = 8.16 V
  SHORT CIRCUIT CURRENT = 7.52 A
  POWER = 44.9 W
  EFFICIENCY = 11.9 %
  NOM OPERATING VOLTAGE = 6.63 V

- **MODULE OPERATING PARAMETERS AT 100 mW/cm²; AM1.5, AND 28°C CELL OPERATING TEMPERATURE**
  
  POWER = 59.6 W
  EFFICIENCY = 12.6 %
Conclusions

- MEPSDU PROJECT CURRENTLY ON SCHEDULE AND BUDGET
- ADDITIONAL PROCESS SEQUENCE STUDY WORK UNDERWAY IN REVISED PROGRAM PLAN
- MEPSDU MODULE DESIGN COMPLETED
  - MEETS JPL 5101-138 SPECIFICATIONS
  - LONG-LIFE PERFORMANCE, PRIMARY DESIGN CONSIDERATION
- PRELIMINARY ECONOMIC ANALYSIS (SAMICS) COMPLETED SHOWING COST EFFECTIVE PROCESS
PROCESS DEVELOPMENT AREA

CONTENTS

General Process Description
Module Design
Input Material Specification
Technical Progress
Expected Performance
Schedule

Design Philosophy

- Use processes that have already been verified, in most cases by more than one contractor.
- Use commercially available equipment or modifications of such equipment.
- Use production equipment, not laboratory-scale equipment.
- No manual handling of cells.
PROCESS DEVELOPMENT AREA

General Process Description

- **INCOMING MATERIAL**
  - SEMICRYSTALLINE
  - 10 CM X 10 CM WAFER

- **SURFACE PREPARATION**
  - NAOH ETCH

- **FRONT JUNCTION FORMATION**
  - SPRAY-ON DOPANT
  - AND BELT DIFFUSION

- **BACK JUNCTION FORMATION**
  - AL PASTE
  - BELT FIRE

- **AR COATING**
  - SPRAY-ON

- **METALLIZATION**
  - NEGATIVE SCREEN PRINT
  - ELECTROLESS NI PLATE
  - SOLDER DIP
PROCESS DEVELOPMENT AREA

Laser Scribe

USE OF LASER TRENCHING UNDER REEVALUATION. COMBINATION OF NEGATIVE SCREEN PRINTING METAL HALO AND LASER SCRIBING TRENCH RESULTS IN HIGH LIKELIHOOD OF SHORTING INTERCONNECT TO HALO.

FOUR ALTERNATIVES UNDER EVALUATION:

- Oxide mask edge to protect edge during diffusion and Ni plating,
- Plasma etch to remove n+ and Ni from edge on large stack of wafers,
- Laser scribe all the way through the silicon rather than trenching,
- Screen print all the way to the edge and still use laser trenching.
PROCESS DEVELOPMENT AREA

Module Design

72 10 cm x 10 cm Semicrystalline cells

2 Parallel - 36 Series

Approximate Envelope Dimensions

66 cm x 120 cm
26" x 49.6"

Design Voltage - 14.5 V

Glass Superstrate

Ethylene Vinyl Acetate Encapsulant

Polyethylene Vapor Barrier

Gasket for Mounting (No Frame)

AMP Output Connectors

Internal Diode Protection - 3 Diodes per module
Module Design Rationale

Requirements:
- Module capable of charging 12 volt battery.
- Size reasonably handleable both in production equipment and in field, but large enough for economic production.
- Paralleling to provide reliability.
- Use 10 cm x 10 cm semicrystalline cells.
- Provide diode protection.

Designs:
- Use 36 cells in series to provide 14 to 15 volts output at peak power and NOCT.
- Use 2 cells in parallel to provide reliability.
- Place 72 cells in 6 rows of 12 cells each to make a module close to 2 feet by 4 feet.
- Protect each parallel set of 12 cells with a diode to minimize diode cost but provide required protection.

Module Cross Section
PROCESS DEVELOPMENT AREA

Glass Selection

Originally selected 1/8 inch annealed soda-lime glass.

- Analysis showed that for module costs below two dollars per watt, the lower cost of soda-lime glass more than offset the reduced optical transmission.

- However, the reduced strength of annealed soda-lime glass may compromise the reliability of the module to mechanical loading.

Decision was to use 1/8 inch tempered low iron glass as baseline. However, we will continue to experiment with lower cost glass.

Interconnect Design

Initial Proposal

- Standard over-under design
- Two pads per cell on one edge

Problems With This Design

- No crack tolerance
- Reduced cell efficiency because of large travel distance of carriers across cell face
- Maybe insufficient stress relief in high density package
PROCESS DEVELOPMENT AREA

Solution

• Use wraparound contacts with four pads on each cell
• Four take-off points on front and back provide crack tolerance.
• Using two pads on two opposite edges breaks 10 x 10 into four 5 x 5s, resulting in higher cell efficiency.
• Wraparound and in plane stress relief improves stress relief properties.

Module Layout

Initial module design called for series strings of twelve cells along four foot dimensions with parallel cross-straps of pairs of strings every three series pairs and diodes protecting each double string of twelve cells.

This design had two main problems:

• Parallel cross-strapping three cells added significant complication to the tabbing and stringing machine.

• Diode configuration required a wire traveling the length of the module between cell strings.

To alleviate the problems, series string six cells along two foot dimensions. Retain two cells in parallel, but only cross-strap at buses. Mount diodes in bus bars with only short tabs between buses.
PROCESS DEVELOPMENT AREA

Wafer Size and Tolerances

**Nominal Size**
10.0 cm x 10.0 cm

**Acceptable Length of Any Edge**
9.97 cm to 10.03 cm

**Rectangularity**
90° ± 0.5°

**Corner Crop**
Between 3/32" and 1/8" on each corner

**Thickness**
0.012" to 0.016"

**Taper**
Thickness variation in one wafer
Less than 0.003"
Electrical Requirements

**Type**

"P" Type

**Resistivity**

0.5 ohm-cm to 10.0 ohm-cm

**Lifetime**

Minimum of 4 μ second lifetime

10 x 10-cm Grid Pattern

---

**Note:**

All dimensions in cm, unless marked otherwise.

---

BUS DETAIL
PROCESS DEVELOPMENT AREA

Technical Progress

- Preliminary process, module and equipment design
- Development of spray doping - belt diffusion process
- Optimization of back junction formation
- Back cleanup experimentation - HCl etch or glass bead spray
- Development of spray AR process
- Resist ink experiments
- Metallization tab pull tests
- Encapsulation process development and materials investigation
- Preliminary cell fabrication and testing

Diffusion Process

Spray Doping

Must use oxygen or air flow or diffusion oxide is impossible to remove.

Use very little dopant for ease of oxide removal. Cell performance insensitive to amount of dopant as long as entire wafer surface is wetted.

Cell performance indistinguishable between spray doping and gaseous diffusion for same tube diffusion process.

Small area semicrystalline cells made using spray dopant with efficiency greater than twelve percent AM1.
PROCESS DEVELOPMENT AREA

Diffusion Temperature Experiments:
10-min Diffusion Time

<table>
<thead>

<td>32</td>
<td>8.5</td>
</tr>
</tbody>
</table>

Experimenting with electroless Ni at sheet resistance up to 60 Ω/□ - initial results encouraging.

Belt vs Tube Diffusion

Tube ≈ 15 percent more power than belt.

Now optimizing belt diffusion parameters.
PROCESS DEVELOPMENT AREA

Back-Junction Formation

Al paste alloy at 850°C.

Use different screen sizes and alloy times.

<table>
<thead>
<tr>
<th>Screen Size</th>
<th>Alloy Time (sec)</th>

</tr>
</tbody>
</table>

Need large screen openings with longer alloy times. However, must compromise with warpage of wafers for thicker Al paste. Will probably use 100 mesh screen.

Back Cleanup

FSI etch-strip machine (2120)

Process: HCl (60°C) 300 sec.
        DI Rinse 180 sec.
        HF Etch 60 sec.
        DI Rinse 120 sec.
        Spin Dry 150 sec.

Problems:

IR Transmission tests show 300 sec. HCl cleanup is not sufficient cleanup to make adequate solar cells.

At 60°C HCl degrades rapidly, requiring excessive material and long heat-up times.
PROCESS DEVELOPMENT AREA

Glass Bead Cleanup

Standard sandblasting equipment using glass beads satisfactorily removes contamination but leaves most of Al.

Subsequent Ni plating gives good adherence. Pull strengths from 11.5 to 35 oz, 326 to 992 grams.

Cells had higher efficiencies than standard HCl cleanup and solder dip on both sides.

Spray AR

Average film thickness - 850 Å ± 100 Å

Index of refraction - 2.1 to 2.2

Consistent blue color on polished surface.

On NaOH etched semicrystalline Si get gray color with approximately 16 percent reflection.

Upon encapsulating gain 7 to 15 percent short circuit current.

Try to pretreat wafer to yield more uniform AR thickness. So far materials either evaporate too fast having no effect or dry too slowly, leaving uneven deposits of TiOx.
PROCESS DEVELOPMENT AREA

Resist Ink

MUST BE CAPABLE OF:

- Surviving AR coating etch
- Surviving Ni plating bath
- Being screen printed easily with good control
- Curing quickly
- Not bleeding into the pattern area during processing
- Being easily and completely removed.

LOOKED AT A LARGE NUMBER:

- Warnow
- Hilton-Davis
- Chroma-Chem
- Inmont

HOMEMADE FROM ACRYLOIDS AND BUTYL CELLUSOLVE

Select Colonial Resist ER-6055

CLEANUP IN EITHER:

- Trichloroethylene
- 1,1,2-Trichloroethane
- Methylene Chloride

Each works well with good ultrasonic agitation. (Cassettes tend to absorb a lot of ultrasonic energy.)
PROCESS DEVELOPMENT AREA

Tab Pull Tests

USE LOW TEMPERATURE SOLDERING IRON (600°C)

CONSISTENT HIGH PULL STRENGTHS FOR Ni-SOLDER.
Almost none below 7 oz.
Many above 20 oz.

No effect from heating at 150°C for one hour (lamination conditions).

Encapsulation

Cure Tests

Testing of EVA to determine time-temperature cure relationship

Use oscillating disc rheometer (ODR) test - Done by Monsanto. See results on graphs for 140°C and 150°C

AT 140°C, 70-75% CURE - 96 MINUTES
AT 150°C, 70-75% CURE - 30 MINUTES

Results agree with springborn data.

Creep tests at 70°C and 90°C indicate that 70-75% cure required so that cells do not move at a significant rate.
PROCESS DEVELOPMENT AREA

ODR Test at 140°C

TIME, MINUTES

ODR Test at 150°C

TIME, MINUTES
PROCESS DEVELOPMENT AREA

Cure Process

During lamination, gas by-product is evolved.

If lamination pressure is too low, then gas will not be expelled from EVA and bubbles result.

So options are higher pressure - higher temperature - shorter cure time
lower pressure - lower temperature - longer cure time

Now using 7-10 lb/sq ft - 150°C - 30 minutes

Polyethylene Vapor Barrier

Good puncture resistance
Low permeability to water vapor
Long lifetime
Sufficient dielectric strength
Compatibility with processes and materials (EVA)
Very low cost
Problems with shrinkage

Proper selection of material
Proper layup and lamination results in uniformly good back covering with excellent adhesion
PROCESSES DEVELOPMENT AREA

Insulation Tapes

Single sided adhesive tapes that adhere to cell and EVA as well as providing the required electrical isolation.

Polyken - Polyethylene tape with acrylic adhesive 832
Permacel - Polyester tape with acrylic adhesive P280
Adhesive Research - Polyester tape with acrylic adhesive S5913
3M - Polyester tape with acrylic adhesive 480
Shuford - Polypropylene with acrylic adhesive PS748

All are now undergoing environmental tests.

Cell Fabrication

Preliminary fabrication of 10 cm x 10 cm cells by MEPSDU laboratory process average lot efficiencies as high as 8.8% have been obtained.

Upon encapsulation, short circuit current and maximum power increase from 7 to 15%.

So lot averages as high as 9.5 to 10% have been obtained before optimization of the processes.
PROCESS DEVELOPMENT AREA

Efficiency of Semicrystalline Material

SMALL AREA SAMPLES (2.0 cm x 2 cm)

best - 17%
best lot average - 16.5%

LARGE AREA SAMPLES (9.5 cm x 9.5 cm)

best - 13.5%
best lot average - 12%

TYPICAL PRODUCTION

10 - 11% Lot Average

ALL EFFICIENCIES MEASURED AT 100mW/cm² - AMI - 25°C.

PRE-PROTOTYPE CELLS - 10-11%

PROTOTYPE DEV. CELLS - 11-12%

TDR CELLS - 12%

LONG TERM PRODUCTION GOAL - 15%

AREAS REQUIRED FOR IMPROVEMENT

• DIFFUSION TO IMPROVE OPEN CIRCUIT VOLTAGE AND BLUE CURRENT.

• ALLOY PROCEDURE TO IMPROVE OPEN CIRCUIT VOLTAGE AND RED CURRENT

• FRONT SURFACE PASIVATION TO IMPROVE OPEN CIRCUIT VOLTAGE

• CONTROL OF NARROWER METALLIZATION TO REDUCE SHADOWING AND IMPROVE FILL FACTOR

• IMPROVED LIFETIME OF SEMICRYSTALLINE SILICON
PROCESS DEVELOPMENT AREA

FIRST 4 WILL BE ADDRESSED IN THIS PROGRAM.

LAST IS BEING ADDRESSED IN DOE COOPERATIVE AGREEMENT.

TYPICAL CELL VALUES FOR TDR

Eff. = 12%
Power = 1.2 Watts
Voc = 0.59 Volts
Isc = 2.75 Amp
Vmax Power = 0.47 Volts
Imax Power = 2.55 Amp

FROM PREVIOUS EXPERIENCE INCLUDING BLOCK IV -

TEMPERATURE COEFFICIENTS FOR CELL ARE:

\[
\frac{\Delta V}{\Delta T} = -2.4 \text{ (mV/}^\circ\text{C)}
\]

\[
\frac{\Delta I}{\Delta T} = +2.25 \text{ (mA/}^\circ\text{C)}
\]

So AT 50°C

Eff. = 10.7%
Power = 1.07 Watts
Voc = 0.53 Volts
Isc = 2.81 Amp
Vmax Power = 0.41 Volts
Imax Power = 2.6 Amp
PROCESS DEVELOPMENT AREA

Module Performance

NOCT

Block IV Measurement - 56°C

However this was measured at 100 mW/cm² while MEPSDU SPEC (5101-138) calls for measurement at 80mW/cm².

Estimate that this may make 6°C difference.

So use 50°C as preliminary value

Estimated Module Efficiency - TDR

72 cells 10cm x 10cm
2 parallel - 36 series

Expect to have reduction in power due to mismatch of cells. Assume two percent loss from sum of cell outputs.

Typical module output at room temperature:

\[
\begin{align*}
\text{EFF} & = 10.1\% \text{ (module area)} \\
\text{EFF} & = 11.75\% \text{ (cell area)} \\
\text{POWER} & = 84.6 \text{ watts} \\
\text{Voc} & = 21.2 \text{ watts} \\
\text{Isc} & = 5.44 \text{ amp} \\
\text{Vmax power} & = 16.75 \text{ volts} \\
\text{Imax power} & = 5.05 \text{ amp}
\end{align*}
\]
PROCESS DEVELOPMENT AREA

Temperature Coefficients for Modules

\[
\frac{\Delta V}{\Delta T} = -86.4 \text{ (mV/}^\circ\text{C)}
\]

\[
\frac{\Delta I}{\Delta T} = 4.5 \text{ (mA/}^\circ\text{C)}
\]

Typical Module Output at NOCT

Eff = 9\% (Module area)
Eff = 10.5\% (Cell area)
Power = 75.3 Watts
Voc = 19.0 Volts
Isc = 5.55 Amp
Vmax Power = 14.6 Volts
Imax Power = 5.16 Amp

PROCESSING EXPERIMENTS ON NON–CZOCZRALSKI SILICON SHEET

MOTOROLA INC.

Major Areas of Investigation

1. PROCESS TECHNOLOGY
   - SUBSTRATE SURFACE PREPARATION
   - SURFACE ETCHING
   - SURFACE TEXTURING
   - SUBSTRATE DRYING
   - HANDLING RECTANGULAR SHAPES

2. CELL DESIGN
   - METALLIZATION PATTERN OPTIMIZATION FOR RECTANGULAR CELLS

3. METALLIZATION
   - PLATED METALLIZATION ADVANCEMENTS
   - THERMAL STRESS STUDIES

4. COST ANALYSIS
   - DOCUMENTATION OF MOTOROLA APPROACH AND COMPARISON WITH SIHIS

Process Technology: Baseline Process Sequence

1. BLANKET PHOSPHORUS DIFFUSION, PH₃ AT 900°C.
2. MESA JUNCTION ETCH, PHOTORESIST WITH A PLASMA ETCH FOR SILICON.
3. SILICON NITRIDE COAT, LPCVD Sᵢ₃Nᵣ AT 780°C.
4. OHMIC PATTERN, PLASMA ETCH NITRIDE.
5. METAL PLATE, NICKEL-COPPER OR PALLADIUM-NICKEL-COPPER.
PROCESS DEVELOPMENT AREA

Surface Preparation Experiment

1. DESIRED STRUCTURE: SIDE-BY-SIDE COMPARISON OF TEXTURED AND NON-TEXTURED (FRONT SURFACE) CELLS.

2. PROCEDURE: USE SILICON NITRIDE COATING TO MASK TEXTURED SURFACE PREPARATION ON ENTIRE BACK SIDE AND HALF OF FRONT SIDE (LENGTHWISE) FOR 10 RIBBON SAMPLES.

3. SOLAR CELL STRUCTURE: FORM PAIRS OF SIDE-BY-SIDE 1 cm by 2 cm SOLAR CELLS, ONE CELL OF THE PAIR ON TEXTURED SIDE AND THE OTHER ON SMOOTH SIDE OF THE RIBBON. (USE BASELINE PROCESS.)

Substrates Used for Texture Etch and Surface Etch Studies

![Diagram showing non-textured and textured substrates]
PROCESS DEVELOPMENT AREA

Results

1. 10 RIBBONS PROCESSED, UP TO 11 CELL PAIRS PER RIBBON.
2. 48 PAIRS USED FOR ANALYSIS.
3. 32 PAIRS INDICATED IMPROVEMENT IN SHORT CIRCUIT CURRENT, $I_{SC}$, WITH TEXTURING.
   AVERAGE $I_{SC}$ INCREASE 2.1 mA OR 4.3%.
4. 15 PAIRS INDICATED DECREASE IN $I_{SC}$ WITH TEXTURING.
   AVERAGE $I_{SC}$ DECREASE 1.6 mA OR 3.2%.
5. TOTAL AVERAGE INCREASE WITH TEXTURING (FOR ALL 48) WAS 0.9 mA OR 1.9%.

Goals of the Contract

- TO DEVELOP A RELIABLE METALLIZATION WHICH:
  - USES NICKEL PASTE PRINTED OVER (Si$_3$N$_4$) AR COATING
  - WHEN SINTERED PENETRATES THROUGH Si$_3$N$_4$ AND BONDS TO SILICON
  - USES BRUSH PLATING OF COPPER FOR ADDITIONAL CONDUCTIVITY
  - Produces 4" DIAMETER CELLS OF EFFICIENCY IN EXCESS OF 10% UNDER AM 1.5G 28°C
  - HAS PULL STRENGTH WITH 5 MM WIDE STRAP OF > 2 LBS WHEN PULLED 90° TO SURFACE
- TO PROVIDE COST DATA ON THE ABOVE SYSTEM

Present Status of Contracts

**Subcontracts Negotiated**

- Nickel Paste Development - Electro-Science Lab, Pennsauken, NJ
- Brush Copper Plating - Vanguard Pacific, Santa Monica, CA

**Samples of Cells**

- With various nitride thickness provided to ESL Labs
- For reverse etching optimization provided to Vanguard Pacific
- Etching characteristics on nickel paste being evaluated
- Copper solution (pH) compatibility with nickel paste under evaluation

**Advantages of the Process**

- Uses low cost nickel paste
- Eliminates need for masking and etching—hence labor costs
- Utilizes state-of-the-art equipment for high throughput
- Utilizes continuous brush plating of copper instead of batch plating
- Overall cost of process sequence is lower, by a factor of 3, than the existing electroless nickel solder process sequence

Progress

A COPPER-LEAD SILVER FLUORIDE PASTE GAVE ADHERENT CONTACTS TO SILICON.

EARLIER SILVER PASTE RESULTS WERE REPRODUCED.

A COPPER-LEAD-CARBON FLUORIDE PASTE GAVE ADHERENT CONTACTS BEFORE AND AFTER DI WATER BOIL TEST.

A SOLAR CELL FABRICATED WITH ABOVE NONOPTIMUM CONTACT GAVE AMI EFFICIENCY OF 7% UNCOATED.
Reproduction of silver electrode with original silver paste S032 with 5 wt.% Pb, 2 wt.% AgF. Print was fired in hydrogen at 550°C for 5 min. Note tightly sintered structure with few open spaces. Cambridge SEM, 1800X.

Same as above, ~900 X
SEM photomicrograph of F17 copper print with 1.2 wt.% AgF fired at 625°C by two-step process. Exposure was done at oblique angle (64°) to bring out needle formations of the Cu-Si eutectic. This electrode passed the Scotch Tape adherence test. 2100X.

Same as above, 10 500X
Thermal gravimetric analysis (TGA) curve of lead acetate run in hydrogen (Courtesy Brian Gallagher, JPL).

TGA curve of lead acetate run in nitrogen (Courtesy Brian Gallagher, JPL).
Thermal gravimetric analysis and differential thermal analysis of carbon fluoride run in air. Runs have been made on several production runs of this material, and in nitrogen and hydrogen atmospheres, with similar results.
SEM photomicrograph of copper paste F13 with 1.1 wt.% carbon fluoride and 2.3 wt.% lead acetate, fired at 550°C by the two-step process. This material passed scrape and Scotch Tape tests and DI water boil. Note the relatively open structure, indicative of immature sintering process. Magnification 1800X.

Same as above, 9000X
IV curve of 2 x 2 cm solar cell with screened copper back electrode made with paste F16, containing 1.1 wt.% carbon fluoride and 4.5 wt.% lead acetate. Print was fired by two-step process at 625°C. Electrode on cofired pieces did not pass Scotch Tape or scratch tests. Projected AM1 efficiency 10%. Edge etch resulted in curve (2) with improved Voc but increased series resistance. (Courtesy Brian Gallagher, JPL).
Conclusions and Problems

1. An economical copper paste employing carbon fluoride powder oxide scavenger yielded good devices and shows further promise.

2. Previous copper electrodes using AgF did not survive 1 year's storage.

3. Problems exist with reproducibility of firing results both during a single run and between runs.

4. Copper electrode pastes with silver fluoride as well as carbon fluoride additives have passed scratch and Scotch tape tests, and shown solderability.

5. A copper paste with carbon fluoride additive passed the Scotch tape adherence test before and after immersion into boiling DI water for over 10 minutes.

6. The process window for base metal pastes is narrower than that for silver electrodes.

Non-Mass-Analyzed Ion-Implanted Cells: Preliminary Samples

- **IMPLANT:** Phosphorus, $3 \times 10^{15}$ ions/cm$^2$, Implanted at JPL Cell Processing at Spire

- **PURPOSE:** Preliminary Comparison with Normal Cell Processing

- **RESULTS:** Cell Efficiency Lot Average Slightly Less than Normal Production. This Appears to be Caused by:
  1. Lifetime Lower than Expected
  2. Non-Optimum AR Coating Lowered $J_{SC}$ (Minor Effect)

- **CONCLUSIONS:** More Cells will be Produced to Isolate Cause of Item 1.
Non-Mass-Analyzed Implant

**Voltage (V)**

**Current (A)**

**Non-Mass-Analyzed Implant**

Solar-Cell High-Throughput Ion Implanter (Task 3)

- Implant Rate: 1800/hour, Walking Beam Transport
- Implant Ions/Dose: $P_1^+$, $P_2^+$, etc. @ $2.5 \times 10^{15}$ ions/cm$^2$
- Ion Current: 2 Units @ 10-15 ma over 2 cm$^2$
- Ion Energy - 5-10 keV
- Diagnostics - Beam Current
  Beam Centering
  Transverse Uniformity
- Wafer Heating - 100°C Rise for Two Sources

Ion Implanter Beam Profile
SILICON DENDRITIC WEB MATERIAL PROCESS DEVELOPMENT

WESTINGHOUSE RESEARCH & DEVELOPMENT CENTER

D. L. Meier

Contact Systems

1. Baseline: Evaporated Ti Pd Ag, Plated Cu
2. First Experimental System: Evaporated Ti Ni Cu, Plated Cu
3. Second Experimental System: Evaporated Ni, Plated Cu, Heat-Treated to Form Ni₂Si

- Also Investigate Plating a Ni Layer on the Plated Cu to Protect Cu from Oxidizing and to Provide a Better Galvanic Match to the Al Interconnects
Contract Objectives

- Develop a Low-Cost Contact System for Solar Cells
- Fabricate Several Modules Using Dendritic Web Silicon

Solar Cell Contact Mask

- 1.6 x 4.0cm Solar Cell
- Contact Resistance Test Pattern
- Minority Carrier Lifetime Pattern
PROCESS DEVELOPMENT AREA

Contact Resistance Test Pattern

- Current Repeatedly Passes From Diffused Silicon Substrate to Metal Bar and Back to Substrate
- Given the Pattern Geometry, $R_C$ is Determined by Measuring Two Voltages and One Current (No Plots Are Required)

Baseline Contact System: Typical Results

Material: FZ Silicon, 4Ω cm, <111>, 250μm Thick
Evaporated Metal: 500 Å Ti, 300 Å Pd, 300 Å Ag
Electroplated Metal: 5μm Cu
Heat Treatment: None

- No Degradation at 300ºC for 15 Minutes for Either Contact System
- Rs’s Resistance and Contact Resistance Decrease From Initial Low Values (Does Not Alter Cell Performance)

Ultrasonic Bonding of Aluminum Interconnect To Nickel-Coated Cell Pad

- Bonds are Excellent
- In All 24 Pull Tests the Aluminum Finger (1.5 Mil Thick) Yielded Before the Aluminum Could Separate From the Nickel
- The Layer of Nickel on the Electroplated Copper Does Not Appear to Degrade Cells
Second Experimental Contact System

Material: FZ Silicon 4Ω cm <111>
Evaporated Metal: 600 Å Ni, 300 Å Cu
Heat Treatment: 300°C for 24 Minutes in H₂
Elemental Depth Profile by Auger Spectroscopy With Sputtering

- Copper Appears to Have Penetrated ~ 400 Å Into the Ni
PROCESS DEVELOPMENT AREA

Status of Ni-Cu System

- Poor Adherence of Metal System to Silicon for Initial Attempt with Evaporated Ni
- Additional Work in Progress Where Ni is Deposited by Sputtering After 100 Å of Si has Been Removed by Sputter Etching
- Indications are That Cu Can Penetrate Approximately 400 Å in 15 Minutes at 300 °C. Thus, a Thin Layer of Ni May Not be an Adequate Diffusion Barrier for Cu.

ANALYSIS AND EVALUATION OF MEPSDU PROCESSES

UNIVERSITY OF PENNSYLVANIA

M. Wolf

OBJECTIVE: The technical advantages and disadvantages of the proposed, developed, or alternate MEPSDU processes will be evaluated. Attention will be focused on the impacts of the process interfaces and sequences. The available data will be examined with respect to the projected process costs, with particular attention to be paid to critical indirect materials and expendable tooling.

STATUS: Reports received, organized, and read (with notations in margins).
PROCESS DEVELOPMENT AREA

JPL IN-HOUSE ROBOTICS

JET PROPULSION LABORATORY

T.L. Brooks and R. Cunningham

Task Objective

APPLICATION OF ADVANCED ROBOTIC AND MACHINE
PERCEPTION TECHNIQUES TO SOLAR CELL MODULE
PRODUCTION.

Milestones to Date and Planned

- AUTOMATION EVALUATION STUDY TO IDENTIFY POTENTIAL APPLICATIONS
  OF MACHINE INTELLIGENCE
  1) Strawman Based on 1978 JPL Process Sequence (October 1980)
  2) Automation Evaluation Study Final Report (in progress)
- LAB DEMONSTRATION OF SELECTED DEVELOPMENT TASK(S)
  1) Solar cell layup using computer vision (February 1981)
  2) Attachment of power-out connector to solar cell module (July 1981)
  3) Soldering of power-out tab to solar cell module (September 1981)
  4) Integration of items 3 & 4 to demonstrate totally automated
     connector assembly system (October 1981)
Demonstration Task Scenario No. 2

Concurrent Processes
- Pick up connector housing from magazine
- Determine connector tab location with computer vision
- Move to tab location and lay down glue bead

Concurrent Processes
- Visually inspect glue bead for width, breaks and positioning
- Orient hand above tab ready for insertion of tab into housing
- Move hand down until housing contacts tab
- Contact sensed through continuous monitoring of force feedback
- Slide housing across tab until tab "pops" into slot
- "Pop" sensed by sudden absence of contact force
- Slide housing down on tab and seat in glue
- Release housing and start next cycle

Components of Robotic System for Automated Attachment of Power-Out Connector
PROCESS DEVELOPMENT AREA

PUMA Robot for Advanced Automated Solar-Cell Module Production

Vision System Features

- Adapts to changes in the absolute location and orientation of AMP connector tab
- Inspects glue bead for width, breaks, and positioning
- Easily programmed to handle different connector configurations
PROCESS DEVELOPMENT AREA

Robot System Features

- Adapts to variable tab location and orientations
- Adapts to tab height inconsistencies
- Uses force feedback information to prevent damage to connector housing and tab
- Controls glue bead layup to give consistent seals

System Goals

- Attach, seal and inspect connectors on one module per minute (assuming 25 MW plant)
- Maintain system costs less than $150K

Key Points

- Automation of labor intensive task
- System cost with off-the-shelf technology ~ $100K
- Present system capable of better than two connectors per minute
- Bottom line - one robot system can handle output of 25 MW plant
PROCESS DEVELOPMENT AREA

Other Lab Activities Since 17th PIM

PUMA

- Installed and running under VAL
- Interim interface to spc-16 for sensory feedback to PUMA completed
- Modification of JARS (JPL Autonomous Robot System) to control PUMA ongoing
- Hand and force/torque sensor installed on PUMA

COMPUTER VISION SYSTEM

- Work on IMFEX (real-time image processing device) ongoing

NON-MASS-ANALYZED ION IMPLANTS

JET PROPULSION LABORATORY

Dennis Fitzgerald

Current Objectives

- Find effect of (diffuse) BSF on cell with N-M-A junction
- Implant N-M-A junctions and BSF with gaseous sources
- N-M-A implant phosphorous for Westinghouse and SPIRE for their evaluation
- Fabricate complete cells using N-M-A implantation and recommended annealing steps

* DIFFUSED JUNCTION! (APPLIED SOLAR ENERGY CORPORATION!)

### NMA Implant With Gaseous Sources

- Hollow cathode Freeman source did not perform well on PF₅ and BF₃.
- Ion source converted to conventional refractory cathode configuration for evaluation of gases.
- PF₅ implants (FX-MATERIAL) for Westinghouse did not work.
- PF₅ implants at ASEC in processing.
- Filament ion source ran well on both gases.

LSA PROJECT TO INDUSTRY

JET PROPULSION LABORATORY

B.D. Gallagher

Objective

• PROMOTE ADVANCEMENT OF PV INDUSTRY

• OBTAIN INFORMATION ON ADEQUACY OF SPECS
**Conclusions**

- N-M-A JUNCTIONS WITH DIFFUSED BSF COMPARED WELL WITH DIFFUSED CONTROLS (ASEC)

- WESTINGHOUSE/SPIRE EVALUATION SHOWS REDUCED MINORITY CARRIER LIFETIME WITH N-M-A P

- FIRST N-M-A CELLS MADE AT JPL HAD LOW F.F. AND Voc BUT SHOWED IMPROVEMENT WITH BSF

- TESTS SHOW POSSIBLE BAD ACTORS IN N-M-A ION BEAM AND/OR THERMAL ANNEAL PROBLEMS
PROCESS DEVELOPMENT AREA

Presentations from the Operations and Engineering Areas were offered in two joint technology sessions. Summaries of the presentations and reproductions of the visual materials that were presented are given below.

S. E. Forman of MIT Lincoln Laboratory reported on the module-procurement experience and module field performance at the Southwest and Northeast Residential Experiment Stations and at the innovative PV installations in Arizona, Florida and Hawaii. Histograms showing peak-power distributions of modules as received, discussions and illustrations of the quality of modules as received, performance curves and photographs of the installations were features of the presentation.

L. D. Runkle, LSA Operations Area manager, spoke on the performance and reliability of modules and the relations between field testing experience and the development of qualification testing. He emphasized that qualification testing is a step in the design process, and that implications drawn from such testing do not include any guarantees or certifications of module performance.

P. Jaffe reviewed the JPL field-testing experience and described test restructuring aimed toward early detection of module-failure modes, especially those that are triggered by arraying the modules. Endurance testing will continue, but with less emphasis.

R. W. Weaver of JPL described some details of a portable data logging device for field use and discussed the configuration of a test field for optimal data recovery.

A. H. Wilson of JPL discussed inexpensive techniques for cleaning flat-plate photovoltaic arrays that have been exposed to atmospheric soiling. Artificially and naturally soiled materials have been cleaned using a variety of detergent solutions. A commercially available detergent has proven to be effective in cleaning soiled glass samples exposed to an oil-refinery atmosphere. Unlike most glass samples tested, the oily samples were not effectively cleaned with multiple water washes.

The Clemson University accelerated-stress testing reliability study on silicon solar cells was presented by J. Lathrop. Twelve different cell types have been tested for reliability-attribute data and a wide range of differences in cells metallized by different techniques (i.e., vacuum deposition, plating, screen printing or soldering) were noted. Significant findings were presented from the wide range of stress tests performed on cells made with plated (copper) metallization and from a comparison test of electrical degradation in unencapsulated cells vs encapsulated cells. After the presentation, three cell manufacturers indicated their desire to participate with new cell types in the next round of testing at Clemson.

A. R. Hoffman of JPL compared U.S. and foreign environmental-testing criteria, including descriptions, test levels and field data. Foreign
ENGINEERING AREA AND OPERATIONS AREA JOINT SESSION

requirements, initially based on JPL specifications, are further influenced by field experience and International Electrotechnical Commission requirements. Similarities exist for most mechanical and electrical stress tests but research must address differences in humidity, freeze, temperature-humidity soak and UV tests.

D. M. Moore's presentation at the 16th PIM, "Cell Interconnect Fatigue Life Prediction," showed a strong correlation between the predicted fatigue life of the cell interconnects on a Block II glass-fiber substrate module and identical field-application modules. Interconnect strain was predicted using a finite-element model that agreed with Manson's empirical fatigue curve for copper and correcting for the exposure (cycles) at the Schuchull, Arizona, application site. At the 18th PIM, Moore presented a nomograph of the finite element model. Its usefulness was demonstrated; it permits the module designer to predict strain and fatigue life of various interconnect designs easily.

S. D. Glazer of JPL discussed a series of hot-spot tests performed under back-bias conditions on several modules by C. C. Gonzalez and E. S. Jetter. He also included the results of an analytical thermal model that predicts peak cell temperatures with back bias. Comparison of model predictions with data taken during the hot-spot tests showed good agreement for most module designs.

N. Shepard of General Electric Co. provided details of the integrated residential PV module-array concept selected for optimization. The design emphasis is on lower total cost through reduced material content and an integral mounting scheme with features that accommodate direct or standoff mounting. The modules mount directly on interlocking, roll-formed support sections that are attached to 2 x 4-in. purlins fastened directly to the roof rafters. Waterproofing is accomplished by horizontal module overlap and vertical closure strips. Module production and installation cost data were presented.

G. Royal of the American Institute of Architecture Research Corp. (AIA/RC) summarized work being done on the integrated residential PV module array involving eight architectural design teams that provided 15 concepts for initial consideration. The Burst Hill Kosar Rittelmann Associates concept was selected for detailed optimization. Preliminary estimates of cost data for module production, hardware fabrication, shipping and handling, installation, and operation were presented.

A. Levins of Underwriters Laboratories, Inc., reported on the progress of module and array safety requirements work in the area of the Interim Standard for Safety: Flat-Plate PV Modules and Panels (JPL Internal Document No. 5101-164), emphasizing the need for compatibility with, and recognition of, the requirements being proposed by a separate National Electrical Code Ad Hoc Subcommittee on Photovoltaics. In addition, generic aspects of safety systems relating to electrical shock and ground faults with their associated potential for fire hazards were discussed. Details of an arc detector, still in the concept development stage, were presented.

The effects of dynamic wind loads on flat-plate photovoltaic arrays were discussed by R. Miller of Boeing. The analysis combined structural dynamics with wind characteristics. The resulting load magnification factors were then applied to known pressure loads to determine design loads. Magnification factors as high as 1.8 were found for the shielded arrays in mid-field. The upper
ENGINEERING AREA AND OPERATIONS AREA JOINT SESSION

bound on the design load for 90 mph winds and a single array in an open area were shown to be 22 to 25 lb/ft².

An open session on reliability of modules addressed questions raised in earlier sessions. R. Willis of Solenergy Corp. was especially concerned with findings presented in a recent U.S. Coast Guard report that indicated that in a severely moist environment PVB has some limitations. A. R. Hoffman reviewed this report for the participants, and the matter was taken under advisement. User interest in qualification and warranties was expressed.

MIT-LL Prototype NE RES Module Problems

- Since turn-on, 7 modules have been removed with excessive leakage current.
  - Prior to installation, the measured module leakage current at 1500 volts DC was less than 0.1 microamps.
  - After installation, branch circuit leakage currents of as much as 400 microamps at the system open circuit voltage (260-280 volts) were measured.
  - Problem is caused by moisture penetration into voids in EVA encapsulant and subsequent conductive paths between cells busbars and metal frame.

Carlisle — ISEE

- 132 modules (black frame)
- Each module was flashed and Hi-Pot tested at 1500 volts DC
  -- Vendor rated power - 62.6 watts (100 MW/CM², 28°C)
  -- LL measured power (avg) - 67.4 watts (100 MW/CM², 28°C)
    High module 75.8 watts
    Low module 56.6 watts
  -- Two modules had zero output and were replaced
  -- All modules passed the Hi-Pot test

Problems

- 5 modules with excessive leakage current have been located and removed.
- Leakage currents as high as 2000 microamps at the system voltage have been measured.
- Problem is the same as at MIT LL prototype at NERES.
Quality Control Experience — NE RES

- In general, module physical appearance is greatly improved compared to those from Blocks I, II and III.
- Modules with stippled glass are difficult to inspect, as a fluid (alcohol) must be spread on the glass surface in order to clearly view cells through a microscope.
- Of 252 modules, 32 were inspected at LL, with the following observations:
  1. Solder usage was sparse on most interconnects.
  2. There was an ample number of twisted and distorted interconnects. Many were very short.
  3. Some interconnects were cracked, one was missing.
  4. The stippled glass was reversed, matted finish down, on many modules.
  5. Some modules had touching cells.
  6. Very few cracked cells were found.

**PV/T Quality Experience**

- As in the case of PV-only modules, the quality of the PV/T modules inspected ranged from excellent to poor.
- Very few cracked cells were found, considering the number of cells involved.
- The most prevalent visual anomaly was discoloration of various kinds on cells, interconnects and grid lines.
- One vendor had problems with interconnect solder joints.

Preproduction Module Quality Control Experience, NE RES and SW RES

- The visual quality of the preproduction modules received ranged from excellent to poor.
- The most obvious visual anomaly was the cracked cell. Each vendor suffered one or more of these of the lots received. Crack tolerant circuitry within the modules neutralizes the presence of cracks in most cases.
- On two 60 cell modules, from one vendor, 24 and 10 cells were found to be cracked. No design is that crack tolerant!

Observations From the Field

REAL-USE FAILURES OFTEN SURPRISE US

NEW MODULE FAILURE RATE IS DECLINING

QUAL TESTS ARE USEFUL IN REDUCING INFANT MORTALITY

HAILSTONES ARE A RELIABILITY DESIGN PROBLEM

NO SLOW MONOTONIC WEAROUT MECHANISM HAS BEEN OBSERVED TO CAUSE A DECREASE IN ELECTRICAL OUTPUT. TRAUMA IS THE ULTIMATE CAUSE OF MODULE FAILURE

DATA FROM JPL ENDURANCE SITES SHOWS NO OBVIOUS CORRELATION BETWEEN CLIMATE AND FAILURE RATE
Significance of Qualification

- A number of modules of a given design have been subjected to a specified set of stress tests without suffering more than the permissible degradation or allowable visible damage.

- The modules tested during JPL Block Procurements have had source inspection to an approved plan.

- There is no assurance that any subsequent module of identical part number will pass the same test.

JPL Field Test Structuring

Jet Propulsion Laboratory

P. Jaffe

Synopsis of Current Status

- Primary function of the field test program is collecting real-time endurance data.

- The activity maintains a network of 16 test sites providing a full range of climatic conditions:
  - Principal site at JPL
  - 3 Medium-sized Southern California sites
  - 12 smaller "Continental" remote sites -- "from Alaska to the Canal Zone"

- 650 pre-1979 modules are currently under test at these sites -- oldest have been in field 5 years, youngest 3 years.

- Unique characteristic of the program is that each module under test is individually monitored.
ENGINEERING AREA AND OPERATIONS AREA JOINT SESSION

Reasons for Restructuring

- Impending deployment of a large quantity of new state-of-the-art modules requires a reallocation of the test space and/or enlargement of test sites
- Budgetary reductions necessitate a curtailment of activities
- Majority of modules currently under test represent old design technology -- continued testing on a broad scale is of questionable value
- Data collected to date shows weak correlation between electrical failure and climate -- little justification to test in all environments
- Past experience suggests that larger samples at fewer sites is preferable
- Unexpected failure modes experienced in real-use applications point to the desirability of testing in array configurations

Restructuring Plan Highlights

- A major change in field test priorities is planned -- emphasis will be shifted away from collecting endurance data and toward early detection and analysis of module problems
- Testing will be consolidated into a 5 site network consisting of the 4 southern California sites and a new Florida site
- The 12 continental remote sites will be decommissioned
- 16 kw of new state-of-the-art modules, 6 kw in arrays, will be deployed
- 2 kw of the old modules will be relocated to an enlarged Goldstone site for continued testing
- A portion of the field test activity will be devoted to supporting the lead center's T & A activities
- Analysis of problems will be centered at the JPL site where new module/subarray test capabilities are being developed
Details

- Life testing of the new modules will be conducted under both individual and array load conditions:
  - 6 each of 6 different intermediate load module designs will be deployed and individually tested at each site.
  - 7 arrays of different type modules will be tested at JPL.

- In normal operation, individual modules will be resistive loaded near short-circuit current -- array modules will be series wired and resistive loaded near peak-power.

- IV data will be obtained daily at JPL on each intermediate load type module, including those in arrays. Total array I-V data will be obtained with a new array data logger.

- Remote site I-V data will be obtained twice a year with our module portable I-V data logger.

- Data on the old modules will be obtained on a as-time-is-available basis.

Goldstone Test Site

Diagram showing Goldstone Test Site with sections for Old Relocated Modules and New Modules, including brands and quantities.
Summary

- Restructuring of the LSA field test activity is currently going on.
- Restructuring should be complete by the end of September.
- Main features are:
  - Testing consolidated into 5 site network.
  - The 12 continental remote sites will be decommissioned.
  - Emphasis will shift from collecting endurance data to quick response problem recognition and analysis.
  - 16 KW of new state-of-art modules will be deployed.
  - 6 KW of these in array strings.
  - Array strings, in conjunction with new array data logger, will function as test bed for investigation of real-use problems.
NEW TEST CAPABILITIES

JET PROPULSION LABORATORY

R.W. Weaver

- THE NEW SOLAR PHOTOVOLTAIC SYSTEMS THAT ARE BEING INSTALLED HAVE A WIDE RANGE OF OPERATING CHARACTERISTICS

- DATA MUST BE OBTAINED IN ORDER TO EVALUATE PERFORMANCE AND DESIGN

- PAST EXPERIENCE INDICATES THAT FAILURE RATES INCREASE WHEN MODULES ARE SUBJECTED TO THE OPERATIONAL STRESSES FOUND IN ARRAY CONFIGURATIONS

- DETAILED DATA ARE REQUIRED TO DETERMINE EFFECTS OF ARRAY FAILURES AND ANOMALIES

- PORTABLE SOLAR ARRAY DATA ACQUISITION AND ANALYSIS SYSTEM (SADAAS)

- SOLAR ARRAY TEST FACILITY
Solar Array Data Acquisition and Analysis System (SADAAS)

- REQUIREMENTS
  - VOLTAGE RANGE TO 400 VOLTS
  - CURRENT RANGE TO 40 AMPS
  - ACCEPT SIMULTANEOUS INPUTS
    - INSOLATION
    - TEMPERATURES
    - REFERENCE CELLS
  - DATA STORAGE
    - TEMPORARY
    - PERMANENT
  - DATA MANIPULATION
    - STANDARD PROCESS
    - PROGRAMABLE
  - DISPLAY
    - DIGITAL
    - PLOTS
  - DATA RATE
    - COMMENSURATE WITH CURRENT-VOLTAGE
    - TO MINIMIZE VOLTAGE STEP SIZE
    - ACQUISITION TIME OF A SECOND OR LESS

- CONSTRAINTS
  - SELF POWERED, RECHARGEABLE AND OPERABLE FROM AC LINE POWER
  - MAXIMUM CARRY WEIGHT 40 pounds PER CASE
  - MUST SURVIVE BEING CHECKED THROUGH AIRLINE BAGGAGE OR FIT UNDER SEAT
• DESIGN APPROACH

• LOAD PATTERNED AFTER MIT/LL CAPACITIVE CHARGE TECHNIQUE WITH A BANK OF SWITCHABLE CAPACITORS

• USE PLUG-IN EPROMS FOR DATA AND ADDITIONAL PROGRAM STORAGE

• A PERMANENT RESIDENT PROGRAM FOR DATA ACQUISITION

• A BASIC LANGUAGE INTERPRETER FOR OTHER PROGRAMS

• CONTROL, INPUT AND OUTPUT VIA KEYBOARD WITH LCD DISPLAY

• PLOTS ON OSCILLOSCOPE (BATTERY POWERED)

• DATE RATE CONTROLLED VIA VOLTAGE-CURRENT RANGE SELECTORS WHICH CONFIGURE THE CAPACITOR BANK

• AUXILIARY OUTPUT INTERFACE FOR HARDCOPY DATA OR PLOTS (RS-232)

Major Component Diagram

ENGINEERING AND OPERATIONS AREA JOINT SESSION

- IT CAN GO ON AN AIRPLANE
- NO COMPONENT WEIGHS OVER 40 pounds
- SELF POWERED
- SPECIAL PROGRAMMING AVAILABLE
- DATA FROM EPROMS CAN BE FEED INTO EXISTING PDP 11 COMPUTER
- WILL BE READY IN SEPTEMBER

Array Simulation at the JPL Site

- OBTAIN DATA FROM ARRAYS OF LATEST TECHNOLOGY MODULES
- SIMULATE ANOMALIES AND FAILURES AND MEASURE THE EFFECTS
- VARY OPERATIONAL PARAMETERS TO DETERMINE EFFECTS
- CORRELATE OPERATIONAL DATA WITH ARRAY DATA

DATA

- INDIVIDUAL MODULE IV
- TOTAL ARRAY
- PARTIAL ARRAY
- VARYING LOAD
ENGINEERING AND OPERATIONS AREA JOINT SESSION

Typical Configuration

ARRAY RANGES

\[ V_{DC} \text{ 75 to 390 Volts} \]
\[ I_{SC} \text{ 2 to 7 Amps} \]
\[ \text{Max P 0.4 to 1.3 kW} \]

Summary

- EXPANDED IN FIELD TESTING
- ARRAY SIMULATION
- ANALYZE PERFORMANCE
ENGINEERING AREA AND OPERATIONS AREA JOINT SESSION

CLEANING STUDY OF SOILED GLASS PV MODULES

JET PROPULSION LABORATORY

A. H. Wilson

• OBJECTIVE
  • EFFECTIVELY CLEAN MODULE GLASS WITHOUT RUBBING OR WIPING

• PROCEDURE
  • OBTAIN SOILED GLASS SAMPLES
    • FROM SITES
    • FROM PREPARATION IN LABORATORY
  • CLEAN SAMPLES
    • WATER WASH ONLY
    • COVER WITH DETERGENT FILM, THEN WATER WASH
  • MEASURE CLEANING EFFECTIVENESS
    • PERFORMANCE OF MODULES BEFORE AND AFTER FIELD EXPOSURE TO RAIN
    • TRANSMITTANCE CHANGE OF SAMPLES
    • VISUAL EXAMINATION

FIELD APPLICATION FACTORS
• LABOR
• DISPENSER
• CHEMICALS

PRESSURE COOKER
121 °C, 15 PSIG
300 HOURS
ENGINEERING AREA AND OPERATIONS AREA JOINT SESSION

Catastrophic Failure Mode Conclusions

Slice Fracturing
1) Brought on by thermal cycle/thermal shock
2) Little problem for vacuum cells
3) Moderate problem for other types

Open Lead (Metal-Silicon)
1) Only brought on by pressure cooker
2) Serious problem for plated cells

Open Lead (Metal-Metal)
1) Mainly result of thermal cycle/thermal shock
2) Not a problem for solder or plated cells
3) Moderate problem for vacuum and printed cells

Open Lead (Silicon-Silicon)
1) Only brought on by thermal cycle/thermal shock
2) Not a problem for vacuum cells
3) Moderate problem for plated and printed cells
4) Can be workmanship/design problem for solder cells.

Average Normalized $I_{SC}$ as a Function of 150°C B-T Stress Time for Minimodules

![Graph showing normalized $I_{SC}$ as a function of time (hours) for different materials and stress conditions. The graph includes curves for unencapsulated glass, plastic, and glass with and without encapsulation. The x-axis represents time in hours, ranging from 0 to 10,000, with specific markers for 1 week, 1 month, and 1 year. The y-axis shows normalized $I_{SC}$ values ranging from 0 to 1.0. The graph highlights the degradation of performance over time for different materials.]
Average Normalized $P_m$ as a Function of 135°C B-T Stress Time for Minimodules

Encapsulated Cell Test Summary

HIGH TEMPERATURE (>120°C) TENDS TO INTRODUCE NEW FAILURE MODES ASSOCIATED WITH ENCAPSULATION AND IS NOT NECESSARILY AN ACCELERATING FACTOR.

NO INDICATION THAT ENCAPSULATION EITHER ENHANCES OR RETARDS ELECTRICAL DEGRADATION ASSOCIATED WITH TEMPERATURE (DIFFUSION) PHENOMENON.

NO INDICATION THAT ENCAPSULATION EITHER ENHANCES OR RETARDS ELECTRICAL DEGRADATION ASSOCIATED WITH PRESSURE COOKER (CORROSION) PHENOMENON.

SOME INDICATION THAT GLASS ENCAPSULATION MAY RESULT IN GREATER DEGRADATION DURING 85/85 TESTING.

PLASTIC ENCAPSULATION MAY BE SOMEWHAT MORE SENSITIVE TO THERMAL CYCLE STRESS THAN GLASS ENCAPSULATION.

Conclusions

• FOREIGN REQUIREMENTS BASED ON JPL SPECS, INFLUENCED BY OWN EXPERIENCE AND IEC REQUIREMENTS

• SIMILAR FOR MOST MECHANICAL AND ELECTRICAL-STRESS TESTS

• RESEARCH ADDRESSING DIFFERENCES IN HUMIDITY-FREEZE, TEMPERATURE SOAK, HUMIDITY-SOAK, AND UV
CALCULATION OF STRAIN IN CELL INTERCONNECTS

JET PROPULSION LABORATORY

D.M. Moore

Objective

- DEVELOP A SIMPLE TECHNIQUE FOR CALCULATING STRAIN IN INTERCONNECT MATERIAL FOR PREDICTION OF INTERCONNECT FATIGUE LIFE

Approach

- DEVELOP FINITE-ELEMENT AND CLOSED FORM ANALYTICAL MODELS TO PREDICT THE MAXIMUM LOCAL STRAIN IN THE INTERCONNECT MATERIAL

- IDENTIFY THE DOMINANT GEOMETRIC PARAMETERS

- CONSTRUCT A NOMOGRAPH PERMITTING RAPID CALCULATION OF INTERCONNECT STRAIN AS A FUNCTION OF THESE DIMENSIONLESS PARAMETERS
Interconnect Strain

\[ \Delta \varepsilon = \text{PEAK TO PEAK STRAIN EXCURSION} \]

\[ = f \left( \frac{e}{h} \right) \left( \frac{k}{h} \right) \]

WHERE \( f \) = FUNCTION OF \( \frac{h}{G} \) AND \( \frac{k}{h} \)

Interconnect Strain Nomograph
Example: Interconnect Fatigue Failure Prediction

PARTICULARS

• BLOCK II MODULE

• RANDOM ORIENTED FIBERGLASS SUBSTRATE

• 192 MODULES INSTALLED NOVEMBER 1978

• 34 MODULES FAILED AS OF MAY 1980 DUE TO BROKEN INTERCONNECTS

Cell Interconnect Deflection

• TOTAL TEMPERATURE EXCURSION

  \[ \Delta T_{DN} = 14^\circ C \text{ (YEARLY AVERAGE)} \]
  \[ \Delta T_{OP} = 32^\circ C \text{ (AT 100 mW/cm}^2\text{)} \]

  \[ \Delta T = 46^\circ C \text{ (YEARLY AVERAGE)} \]

• THERMAL EXPANSION COEFFICIENTS

  \[ \alpha_S = 2.78 \times 10^{-5}^\circ C \text{ (FIBERGLASS SUBSTRATE)} \]
  \[ \alpha_C = .29 \times 10^{-5}^\circ C \text{ (SILICON SOLAR CELL)} \]

• CELL INTERCONNECT DEFLECTION

  \[ \delta = (\alpha_SC - \alpha_CD) \Delta T \]

  \[ = .0035 " \]
Cell Interconnect B2, Sectioned from Solarex Block II Module S/N 023134

Cell Interconnect G2, Sectioned from Solarex Block II Module S/N 0234134
Calculate Interconnect Strain

\[ \Delta \varepsilon = f \left( \frac{1}{n} \frac{1}{G} \right) \]

Objectives

- DEVELOP GUIDELINES FOR FUTURE DESIGNS
- DEVELOP ANALYTICAL MODEL TO PREDICT HOT-SPOT TEMPERATURES
- DEVELOP SIMPLE DESIGN TOOL
ENGINEERING AND OPERATIONS AREA JOINT SESSION

Cases Run

A. UNINSULATED MODULE, LIGHT + POWER
B. INSULATED BACK MODULE, LIGHT + POWER
C. UNINSULATED MODULE, LIGHT, NO POWER
D. UNINSULATED MODULE, POWER, NO LIGHT
E. OUTDOOR TEST IN NATURAL SUNLIGHT, WITH POWER

Selected Hot-Spot Test Results: Peak $\Delta T$ vs Total Power Density for Several Modules

![Graph showing the relationship between $T_{c,peak} - T_{NOCT}$ and total power density for different modules.](image)
Analytical Thermal Model

KEY FEATURES
- 1-D MODEL GEOMETRY
- CONVECTION + LINEARIZED RADIATION HEAT TRANSFER
- HANDLES INSULATED AND UNINSULATED MODULE BACK
- SIMPLE CLOSED-FORM SOLUTION

REQUIRES
- MODULE + CELL GEOMETRY
- k, \( \rho \) OF MATERIALS
- AMBIENT CONDITIONS
- SOLAR FLUX + BACK-BIAS POWER

YIELDS
- TEMPERATURE PROFILE + PEAK CELL TEMPERATURE
- SENSITIVITY ANALYSIS

STEADY-STATE ENERGY BALANCE: REGION I

\[ \frac{1}{r} \frac{d}{dr} \left( r \left( k_1 \frac{dT}{dr} \right) \right) + \left( \alpha_1 q_s'' + P_{BB} \right) - 2h_{eff}(T - T_a) = 0 \]

HEAT CONDUCTED THROUGH MODULE INSOLATION + BACK-BIAS ENERGY

REGION II

\[ \frac{1}{r} \frac{d}{dr} \left( r \left( k_2 \frac{dT}{dr} \right) \right) + \alpha_2 q_s'' - 2h_{eff}(T - T_a) = 0 \]

SOLUTION FORM

\[ T_{HOT SPOT} = T_a + \Delta T_{PEAK} = \frac{k_1 q_s''}{2h_{eff}} + \frac{P_{BB}}{2h_{eff}} \left[ 1 - \frac{K_1 (m_2 R_c)}{(k_1/k_2)^{1/2} \left( K_0 (m_2 R_c)^{1/2} \right) \left( k_1 (m_2 R_c)^{1/2} + k_1 (m_2 R_c)^{1/2} \right)} \right] \]

*FINNED ALUMINUM SUBSTRATE*
RESIDENTIAL ARRAY DEVELOPMENT

GENERAL ELECTRIC CO.

N.F. Shepard

Program Objectives

• DEFINE AN INTEGRATED RESIDENTIAL MODULE/ARRAY DESIGN WHICH MEETS THE 1982 TECHNOLOGY READINESS GOALS
  - SUPPLY DETAILED DRAWINGS AND MATERIAL SPECIFICATIONS COMPATIBLE WITH LOW-COST, MASS PRODUCTION PROCESSES CURRENTLY IN USE
  - PROVIDE INSTALLATION DETAILS AND INSTRUCTIONS

• ASSEMBLE A PROTOTYPICAL ARRAY SECTION TO DEMONSTRATE THE SELECTED CONCEPT

Current Status

• DETAILED DESIGN OF SELECTED MODULE -- COMPLETE

• INSTALLATION DETAILS -- COMPLETE

• PRODUCTION COSTING ANALYSIS -- COMPLETE FOR 50,000 m² PER YEAR
  -- OTHER RATES TO BE INCLUDED IN QUARTERLY REPORT NO. 3

• INSTALLATION COST ESTIMATES -- COMPLETE (PRELIMINARY)
  -- TO BE REFINED FOR INCLUSION IN QUARTERLY REPORT NO. 3

• PROTOTYPE ARRAY ROOF SECTION -- CONCEPTUAL DESIGN COMPLETE
ENGINEERING AND OPERATIONS AREA JOINT SESSION

Program Assumptions and Constraints

- DEVELOPMENT OF CELLS AND ENCAPSULATION SYSTEMS NOT WITHIN WORK SCOPE
- BLOCK V RESIDENTIAL DESIGN, CONSTRUCTION AND TESTING REQUIREMENTS
- ARRAY SIZE APPROXIMATELY 74 m² PER HOUSE
- ARRAY DESIGN SHOULD PERMIT EXPANSION FOR VARIOUS SIZE HOUSES BETWEEN 140 AND 280 m² OF FLOOR SPACE
- CELL COST DATA SUPPLIED BY JPL
- USE 6 PERCENT DISCOUNT RATE FOR LIFE-CYCLE COST ESTIMATES
- COSTS TO BE IDENTIFIED IN 1980 DOLLARS
- ENCAPSULATED CELL EFFICIENCY OF 13.5 PERCENT AT 100 mW/cm² AND 280°C
- A CELL OPEN-CIRCUIT FAILURE RATE OF ONE CELL PER TEN THOUSAND PER YEAR

Observations From Previous Experience

- **Metal substrates lead to reliability and safety problems.**
- **Polymeric outer covers have questionable long-term weatherability and fire-resistance.**
- **Exposed conductive elements require grounding with associated cost.**
- **High areal power density is required for minimum installed cost.**
- **Safety is a critical design concern.**

Desirable Features of an Optimized Module/Array

- **FURTHER REDUCTION IN MODULE PRODUCTION COST THROUGH DESIGN SIMPLIFICATION AND REDUCED MATERIAL CONTENT.**

- **RETAIN LOW INSTALLATION COST ASSOCIATED WITH THE INTEGRAL MOUNTING SCHEME.**

- **INCORPORATE DESIGN FEATURES TO PERMIT UNIVERSAL MOUNTING (DIRECT, INTEGRAL, OR STAND-OFF).**

**Selected Array/Module Design**

INTEGRAL MOUNT PICTORIAL OF INSTALLATION SEQUENCE AT RAKE
Assumptions

- **PLANT OPERATES THREE (3) EIGHT HOUR SHIFTS/DAY, 6 DAYS/WEEK (144 WORK HOURS/WEEK), WITH NINE HOLIDAYS AND ONE WEEK PLANT SHUTDOWN. THIS YIELDS 297 WORKING DAYS/YEAR OR 7128 WORKING HOURS/YEAR.**

- **PRODUCTION OUTPUT REQUIREMENTS**
  
  \[ 50,000 \text{ m}^2/\text{YEAR} = 5,000,000 \text{ CELLS/yr} = 69445 \text{ MODULES/yr} = 9.74 \text{ MODULES/HR} \]

- **MATERIALS HANDLING AND STORAGE REQUIREMENTS BASED ON WEEKLY DELIVERIES OF INCOMING GOODS PLUS A ONE WEEK SAFETY STOCK**

Production Cost Methodology

Production costs are calculated as the sum of:

1. Direct Labor
   \[
   \text{(No. of Employees)} \times (7128) \times (1.25) \times (7.00)
   \div \text{(Annual Production Rate)}
   \]

2. 170 percent labor overhead

3. Direct material

4. 3 percent material overhead

5. Process equipment charge
   \[
   \text{(Original Cost)} \div \text{(5 Yrs.)} \times \text{(Annual Production Rate)}
   \]

6. Floor space rental
   \[
   5.50 \times \left( \frac{\text{Floor Space Required} - \text{ft}^2}{\text{Annual Production Rate}} \right)
   \]

7. Utility services
   - Electricity = \[
   \frac{\text{(Power - kw)} \times (7128) \times (0.04)}{\text{(Annual Production Rate)}}
   \]
   - Compressed air facility = \[
   \frac{\text{(cfm)} \times (20)}{\text{(5 Yrs.)} \times \text{(Annual Production Rate)}}
   \]
   - Chilled water facility = \[
   \frac{\text{(gpm)} \times (17)}{\text{(5 Yrs.)} \times \text{(Annual Production Rate)}}
   \]

INTEGRATED RESIDENTIAL PV ARRAY DEVELOPMENT
AIA RESEARCH CORP.

Objectives

- Develop integrated roof-mounted residential array for earliest and largest market penetration.
- Optimize array for least life cycle energy cost assuming annual production rate of 10,000, 50,000, and 500,000 M2.
- Follow integrated systems approach considering detailed electrical, mechanical, and environmental requirements.
- Optimize for regional variables such as codes, construction practices, and local costs.
- Prepare documentation of final design sufficient for third-party fabrication.
- Fabricate prototype of design to identify additional roof/array interface concerns.
ENGINEERING AREA AND OPERATIONS AREA JOINT SESSION

Program Tasks

TASK 1
- Convene Advisory Committee to review issues, approve draft of RFP
- Develop and distribute RFP
- Develop LCC data requirements
- Select 6 firms; Advisory Committee supplies technical assistance
- Advisory Committee selects three best concepts

TASK 2
- Advisory Committee reviews 3 designs and selects optimal design
- Subcontracting firm develops optimal design in detail
- Arch. P.V. contractor, manufacturer and LCC consultant provide technical assistance
- Advisory Committee reviews and approves construction and specification documents

TASK 3
- Model Fabricator provides full-scale prototypical model based on a representative section based on construction documents

Advisory Committee
- AIA/RC, research agency of American Institute of Architects
- HEERY, value-engineering firm
- EEM, principal investigator
- NABP/RF, research agency of National Association of Homebuilders
- SOLAREX, PV module manufacturer

ENGINEERING AREA AND OPERATIONS AREA JOINT SESSION

PHASE 1
Summary

OBJECTIVES

DEFINE ARRAY DESIGN TRADE-OFFS
MARKET PENETRATION
FABRICATION
DESIGN AND SPECIFICATION
INSTALLATION
OPERATION
MAINTENANCE

DEVELOP DESIGN REQUIREMENTS FOR CANDIDATE OPTIMUM CONCE...S

APPROACH

DEVELOP GROUND RULES AND CRITERIA
GENERATE REPRESENTATIVE DESIGN AND TRADE-OFF DATA
SYNTHESIZE DESIGN TRADE-OFFS

ANALYSIS
NORMALIZATION OF SYSTEM AND MODULE SIZE
SCREEN DESIGN TRADE-OFFS

RECOMMEND PREFERRED DESIGN(S) FOR FURTHER OPTIMIZATION
Design Concept Evaluation Criteria

**Market Penetration**
- SATISFY THE LARGEST MIDDLE-INCOME MASS MARKET
- SERVE A VARIETY OF HOUSING SIZES, TYPES AND ROOF SHAPES
- SELECTION BY BOTH LARGE AND SMALL VOLUME BUILDERS
- FLEXIBILITY IN INSTALLATION TIMING
- WITHIN THE TYPICAL PRODUCT DELIVERY AND SERVICE CHAIN OF THE HOMEBUILDING INDUSTRY

**Fabrication**
- MIXTURE OF FACTORY AND FIELD LABOR FOR ARRAY ASSEMBLY
- REQUIREMENTS FOR COMPONENT INVENTORY
- MINIMIZE THE COST FOR SHIPPING AND HANDLING WITH ACCEPTABLE DURABILITY

**Design and Specification**
- DESIGN ENGINEERING CAPABILITY NORMALLY EMPLOYED BY THE BUILDER OR CONTRACTOR
- MINIMIZE FIELD INSPECTION AND APPROVAL REQUIREMENTS OF LOCAL BUILDING AND ZONING CODES, THE NATIONAL ELECTRICAL CODE (NEC), FIRE CODES AND INSURANCE WARRANTS
- USE OF EQUIVALENT MATERIALS AND PRODUCTS IN STANDARD CONSTRUCTION PRACTICE
- FLEXIBILITY IN LABOR AND SCHEDULE COORDINATION THAT MEETS STANDARD PRACTICE CONDITIONS
- DOCUMENTATION FOLLOW STANDARD PRACTICE

**Installation**
- LITTLE IMPACT ON THE NORMAL STRUCTURAL AND ENVIRONMENTAL EXPOSURE OF THE BUILDING
- COMPATIBLE WITH STANDARD CONSTRUCTION PRACTICES, TOOLS AND EQUIPMENT
- MINIMIZE FIELD APPROVAL OF ELECTRICAL CONNECTIONS, FIELD CABLING AND GROUNDING
- MINIMIZE SAFETY RISK DURING INSTALLATION
- OPTIMIZE HANDLING AND INSTALLATION DURABILITY
- OPTIMIZE MECHANICAL ATTACHMENT AND ELECTRICAL CONNECTION REQUIREMENTS

**Operation**
- AN ACCEPTABLE OUTPUT RANGE FOR SIZE AND TEMPERATURE CONDITIONS
- ARRAY OUTPUT MUST SATISFY BALANCE OF SYSTEM INTERFACE REQUIREMENTS
- MINIMIZE GROUNDING CONCERNS AND REQUIREMENTS
- ADDRESS APPROPRIATE POWER AND DIMENSIONAL MODULARITY CONCERNS
- LIFETIME RELIABILITY AND DURABILITY CONDITIONS AT AN ACCEPTABLE COST

**Maintenance**
- MINIMIZE THE REQUIREMENTS FOR IDENTIFICATION, REMOVAL AND REPLACEMENT OF FAILED PARTS
- NOT INTERFERE WITH NORMAL BUILDING MAINTENANCE AND REPAIR
- MINIMIZE ADDITIONAL LIFE SAFETY AND BUILDING RISKS
ENGINEERING AREA AND OPERATIONS AREA JOINT SESSION

Ground Rules

CELL AND ENCAPSULATION PROCESSING BEYOND SCOPE OF STUDY

ENCAPSULATED CELL EFFICIENCY OF 135 Wp/m² AT 100 mW/cm², AM 1.5, 20°C

GLASS ENCAPSULATED MODULE COST OF $0.70/Wp IN $1980

EXCESSIVE HOT-SPOT HEATING PREVENTED

V_{oc} LESS THAN 30 Vdc AT -20°C FOR MODULES/PANELS WITH EXPOSED TERMINALS

ARRAY IS PV-ONLY, AIR-COOLED, FLAT-PLATE, SOUTH-FACING WITH FIXED TILT

ARRAY DESIGN LIFE IS 20 YEARS

ONE MODULE REPLACEMENT EVERY FOUR YEARS

ARRAY OUTPUT BETWEEN 4-10 kWp

USE OF REGIONAL CODE LOADS

ARRAY DESIGN AND INSTALLATION WITHIN STANDARD BUILDING PRACTICES

INITIAL COSTS ONLY CONSIDERED IN PHASE 1

LIFE CYCLE COSTS WITH 6% DISCOUNT RATE CONSIDERED IN PHASE 2

DESIGN TEAM SPECIFIES MARKET AND DISTRIBUTION ASSUMPTIONS FOR EARLIEST AND LARGEST PENETRATION

TECHNOLOGY PROVEN NOT LATER THAN 1982

491

</table>
Critical Factors

- MINIMIZE NEED FOR GROUNDING
  - NON-CONDUCTIVE SURFACES
  - UNEXPOSED TERMINATIONS

- SQUARE OR RECTANGULAR CELLS FOR IMPROVED PACKING DENSITY

- WRAPAROUND TECHNOLOGY DEVELOPMENT AND SERIES/PARALLELING FOR RELIABILITY

- MODULE EDGE TOLERANCES FOR HANDLING AND ATTACHMENT

- UNFRAMED, GASKETED MODULES

- SYSTEM INTERFACE
  - EXISTING INVERTER VOLTAGE WINDOW
  - FUTURE FAMILIES OF INVERTERS
  - CIRCUIT DESIGN FOR MODULE MISMATCH

- SAFETY AND CODE INSPECTION
## Concept Evaluation

- CONCEPTS CLASSIFIED FOR COMPARISON IN THREE CATEGORIES
- CONCEPTS EVALUATED WITHIN EACH CATEGORY FOR SELECTION

### Proof-of-Concept Stage

**OFF-THE-SHELF CONCEPTS**
- Prototype development completed
- Prototype testing completed
- Field applications within one year

**PILOT CONCEPTS**
- Prototype development near completion
- Prototype testing required
- Field applications within two years

**PROTOTYPE CONCEPTS**
- Prototype development continuing
- Prototype testing required
- Field applications within four years
ENGINEERING AREA AND OPERATIONS AREA JOINT SESSION

Innovative Design Features

- Module Area Greater Than 100 square or rectangular cells
- Redundant protection for modules
- Open-circuit voltages over 30 Vac at -20°C
- Minimum grounding
- Low soiling cover material
- Series/Parallelizing and Diode-Protected Reliability

Wiring

- Wiring Harness Elimination
- Pre-wired mounting hardware
- Minimized wire size and insulation
- Series/Parallelizing Reliability for Module Mismatch and System Interface

Installation

- Hardware applicable to several mounting types
- Minimized individual module/panel alignment
- Mechanical fastening replacement
- Pre-cut materials
- Minimized construction-train limits
- Limit module/panel rows to minimize mounting frame complexity

ENGINEERING AND OPERATIONS AREA JOINT SESSION

PHASE 2
Summary

OBJECTIVES

DEFINE ARRAY DESIGN TRADE-OFFS

MODULE GEOMETRY AND CIRCUIT DESIGN

ARRAY ALIGNMENT AND ATTACHMENT

ARRAY CONNECTION AND CABLING

DEVELOP DESIGN REQUIREMENTS FOR PREFERRED OPTIMIZED CONCEPT

APPROACH

DEVELOP CRITERIA AND METHODOLOGY FOR DESIGN TRADE-OFF ANALYSIS

GENERATE REPRESENTATIVE DESIGNS AND TRADE-OFF DATA

SYNTHESIZE DESIGN TRADE-OFFS

ANALYSIS

PROTOTYPING

SCREEN DESIGN TRADE-OFFS

RECOMMEND PREFERRED DESIGN FOR FABRICATION
Detailed Optimization Focus

Module Production
- module geometry
- circuit design
- production rates

Hardware Fabrication
- mounting attachment
- connectors
- pre-wiring
- production rates

Shipping, Handling and Distribution
- modules
- hardware
- end-use economies-of-scale

Installation and Specification
- system size
- module size
- builder profiles

Operation and Maintenance
- startup/shutdown
- minor upkeep
- diagnostics
- replacement
### Design Tradeoffs

#### Array Alignment

**Major Issues Include:**
- Array location on roof with respect to:
  - Dam penetration
  - 6" min.
- RGB. (t) free distance
- Establishment of any necessary datum line-plate placement error
- Tolerances

**Methods:**
- Block/Anchor
- Strap/Channel
- Clamp

#### Array Attachment

**Major Concerns Include:**
- Location of workable surface (i.e., metal or wood surface): Support conditions

**Methods:**
- Mechanical fasteners
- Pressure fitting gaskets

#### Array Connection

**Major Concerns Include:**
- Connector profile and location (i.e., pipe or wall)
- Connector flange and latching
- Safety protection from exposed conductive parts

**Methods:**
- Junction boxes
- Quick connect/disconnect
- Quick permanent connect

#### Array Cabling

**Major Issues Include:**
- Approval and qualification
- Factory vs. field requirement
- Safety protection from exposed conductive parts

**Methods:**
- Splice
- Ribbon
- Mat
Reference Cell and Encapsulation System

**REFERENCE CELL I-V CHARACTERISTICS**

10 CM x 10 CM SEMICRYSTALLINE SILICONE

Life-Cycle Cost Calculation

\[ R_L = \frac{C_M + C_{MD} + C_{MLC}}{\eta_M \cdot \eta_B \cdot S \cdot H \cdot \epsilon_{LC}} + \frac{C_{BLC}}{H \cdot \epsilon_{LC}} \]

- \( R_L \): Total system life-cycle energy cost ($/kWh)
- \( C_M \): Initial module cost per unit area of module ($/m^2)
- \( C_{MD} \): Balance of module-dependent system initial cost per unit of module ($/m^2)
- \( C_{MLC} \): Module-dependent life cycle cost exclusive of initial cost, per unit of module ($/m^2)
- \( C_{BLC} \): Total module-independent balance-of-plant life-cycle cost per kilowatt of total plant output power at insolation S and NOCT ($/kWp)
- \( \eta_M \): Module efficiency (power output per unit of total module area at insolation S and NOCT, divided by S)
- \( \eta_B \): Balance of plant efficiency (average plant power output divided by array power input)
- \( S \): Reference insolation level (kW/m^2)
- \( H \): Peak insolation hours per year captured by the array (Langleys/day divided by S, mW/cm^2 * 423.4 hrs/yr)
- \( \epsilon_{LC} \): Life cycle summation of annual fraction of initial energy output

ARRAY SAFETY DESIGN

UNDERWRITERS LABORATORIES INC.

A. Levins

I Draft Standard for flat-plate photovoltaic modules and panels

II Safety systems for photovoltaic arrays

III Components for use in implementing safety systems

Standard for Safety:
Flat-Plate PV Modules and Panels

Effort to develop standard was initiated by and in large part sponsored by the Jet Propulsion Laboratory (JPL) as a part of the LSA Project.

Standard is being written in recognition of proposed National Electrical Code (NEC) article on photovoltaics and the several proposed safety systems, so that modules and panels will be capable of being installed in conformance with provisions of the NEC.

Standard relates to factory built items, codes (E.g., NEC) relate to installation.

First draft of the standard was presented and used as a basis of discussion at safety workshop held at JPL, February 1981.

Standard is intended to address safety issues only as may arise from the generation and use of electricity and does not attempt to achieve any "standardization" of products, except where such may be necessary for safety.

Standard is now at a stage where trial evaluations to it are desirable, to determine its workability.

Standard is divided into two major parts:

A) Construction
B) Performance
Safety Systems

Ground fault systems for protection against hazards from shock, may serve as part of a mechanism as an alternative to restrictions on maximum voltage, voltage limit (300 or 600 volts) being proposed by National Electrical Code AD-HOC Committee.

As ground fault system will not protect against hazards arising from line-to-line contact, parts of the array which are more than a specified voltage with respect to each other should be spaced more than two arms lengths apart.

Ground fault system to protect against shock hazard situations will also provide protection against arcing to ground (fire) hazard situations.

Grounding - NEC AD-HOC committee has accepted concept of alternate means to achieve virtues otherwise associated with "solid grounding". If the section that is incorporated in the NEC reflects this, ground fault systems are a step closer to reality.

In-Circuit Arc Detection

0 Problem -- In-circuit arcing can result in material ignition and is difficult to detect because current appears normal.
0 Magnitude
0 Flow path

0 Approach -- Investigate arc characteristics
0 Material
0 Frequency
0 Bandwidth
0 Energy level

0 Experimental results
0 8 April 1981
0 Freq. spect. 110 kHz to 12 MHz
0 Arcing mode: Open
  Circuited cell interconnects
  (1 of 15 in parallel)
0 V<sub>DC</sub> = 147 V
0 P<sub>LOAD</sub> = 4 kW
HIGH FREQUENCY RESPONSE DEVICE: OUTPUT OPEN CIRCUITS ARRAY, THUS TERMINATING ARC.

PRESENT STATUS-CONCEPT APPEARS FEASIBLE
- LOCATION DEPENDENT
- SUSCEPTIBLE TO POWER CONDITIONER INTERFERENCE

FUTURE PLANS
- DEVELOP INCREASED SENSITIVITY AND DISCRIMINATION
- IN SITU TESTING
Grounding and Ground-Fault Systems

Ground fault systems may operate in either of two ways:

A) Differential  
B) Detecting current in ground path

Pros

Differential  
A) Function where basic ground is not under users control  
B) Can detect spurious gndss  
C) Can function on a segment of circuit  
A) Only one current is measured, circuit is simple

Cons

A) Costs and difficulty of detecting small imbalance in large overall current  
B) Power loss in detectors

Frame grounding should keep frame at potential of earth around array. This may necessitate multiple grounds depending upon soil restivity. When array circuit is grounded at conditioner, and no metal conductor (wire) is run between ground rods of frame (at array) and circuit (at conditioner), earth between the two is an electrolyte for leakage current path. One of the electrodes may be consumed as a result of electrolytic action. Therefore, a wire between ground rods is suggested.

Arc Detector - To detect in-circuit arcs.
ARRAY DYNAMIC WIND LOADING

BOEING ENGINEERING & CONSTRUCTION

Wind Loads on Flat-Plate PV Array Fields

Objective:

• Develop more refined estimates of wind loading on flat-plate photovoltaic modules and array support structures and develop design guidelines

Approach:

• Theoretical (Phase II - Report No. DOE/JPL954833-79/2)
  - Literature search
  - Separated flow analysis

• Experiment (Wind Tunnel Test - Phase III - Report No. DOE/JPL954833-81/3)
  - Colorado State University environmental tunnel
  - 1/24 scale model

• Dynamic Analysis (Phase IV)
  - Combined theoretical - experimental analysis

Wind Tunnel Test

Steady State Test

• Measured Steady State Pressure Coefficients (Report No. DOE/JPL954833-81/3)

• Calculated RMS Pressure Coefficients of Fluctuating Pressures

Non-Steady State Test

• Recorded Array Upper and Lower Pressures Simultaneously

• Calculated Auto and Cross Spectrums

526
Dynamic Analysis

Approach:
- Theoretical Structural Dynamic Model
- Utilizes Auto and Cross Spectrums
- Utilizes Random Harmonic Analysis Techniques

Results
- RMS Dynamic Loads
  - Dependent upon structural characteristics and configuration
- Magnification Factor
  Theoretical RMS Dynamic Loads/
  Experimental RMS Pressure Loads

A discussion of planned improvements in the SAMICS methodology was presented in response to a number of comments and criticisms made by participants in the SAMICS Critique at the 17th PIM.

Environmental Control Costs

The SAMICS Cost Account Catalog and the indirect charge matrix in SAMIS are being updated to include more recent and detailed environmental and effluent-control equipment and processing costs. The various effluents will create indirect requirements based on the type of effluent and the volume as specified on Format A. These improvements will be incorporated in SAMIS Release 4.

Energy Payback of Flat-Plate PV Modules and Arrays

An analysis of energy payback times was offered in response to several recent articles in popular and technical literature claiming that PV was subject to a 15-to-20 year energy payback time. The articles were based on obsolete or incorrect data. The present analysis incorporates the most recent energy content information accumulated over the past year by the PA&I Area.

The presentation in the PA&I technical session compared 1976 space modules, which had an energy payback time in terrestrial use of 11 to 21 years, with terrestrial modules in 1976 (6 to 11 years payback), 1982-83 modules (3 to 5.4 years payback) and 1986-90 ribbon-based technology (0.6 to 1.1 years payback). The balance of the systems add 0.8 to 1.5 years to the system energy payback time, for a total of 1.4 to 2.6 years.

This analysis will soon be published in a journal article.

Spinoff Benefits of the DOE PV Program

The PV program has conducted advanced research and technology development since 1976. Several unexpected technology spinoffs have developed in that time, and in some cases substantial economic benefits can be quantified. Continued R&D may produce further spinoffs of considerable value.

Consideration is given to the progress resulting from the DOE Program and to progress that was likely to have occurred within private industry in the absence of a federal program. The major reasons for net program benefits are:

(1) PV R&D has occurred in high-risk areas. For example, more than 80% of the silicon purification concepts studies have failed. This has discouraged innovations in that area for more than 20 years.
(2) R&D payback from spinoffs is very slow in several cases. For example, new techniques for sawing crystal ingots will require five to 10 years of development to catch up with and surpass conventional processes. The firms that are leading the way in this area are small companies that could not have sustained large negative cash flows over such a period.

(2) Many spinoffs will benefit the semiconductor industry and its customers. Semiconductor firms concentrate R&D funds on their big cost drivers, such as quality of product, miniaturization of devices, and improving process yields. PV program R&D has emphasized reduction of material costs and key process step costs that complement rather than duplicate semiconductor R&D. Small reductions in semiconductor materials costs do not attract many semiconductor firms' R&D dollars, but are of significant value to the industry as a whole.

Two spinoffs that have quantifiable benefits are low-cost semiconductor-grade silicon and more efficient crystal ingot pullers. The program originally sought solar-grade silicon and ingots; semiconductor quality is a windfall. For purposes of this analysis, it is assumed that in the absence of the program, silicon costs would have fallen according to historical trends and that the price will drop suddenly in 1991 to the low cost available from the program's technology. Also, it is assumed that in the absence of the program, the value added to that silicon by ingot growth also will fall at about a 75% learning-curve rate, consistent with historical trends, and that prices would have dropped to the levels available from the new PV program technology in 1987.

Using a real discount rate of 10%, the net present value of these benefits is $984 million in 1980 dollars.
PROJECT ANALYSIS AND INTEGRATION AREA

RESPONSE TO SAMICS CRITIQUE AT 17th PIM

JET PROPULSION LABORATORY

P. K. Henry

COMMENT/CRITICISM

• "SAMIS REPORTS DO NOT CONTAIN INFORMATION USEFUL TO CORPORATE FINANCIAL ANALYSTS AND PLANNERS"

ANALYSIS

• RIGHT!

ACTION

• SAMIS RELEASE 4 (OCT 1981) WILL HAVE YEAR-BY-YEAR FINANCIAL REPORTS; INCOME STATEMENT, BALANCE SHEET, SOURCE, AND APPLICATION OF FUNDS

COMMENT/CRITICISM

• "SAMIS COSTS TOO MUCH TO RUN AND IS HARD TO USE"

ANALYSIS

• MANY RUNS REQUIRED BY SOME USERS DUE TO IMPROPER OR ERRONEOUS INPUT DATA
• USERS UNFAMILIAR WITH COST SAVING OPTIONS
• USERS GUIDE DIFFICULT FOR UNINITIATED TO USE

ACTION

• SAMICS SHORT COURSE WILL BE OFFERED, POSSIBLY WITH NEXT PIM
• ENGINEER'S USERS GUIDE TO SAMIS BEING WRITTEN FOR NEXT SAMIS RELEASE IN OCTOBER 1981
• USER'S QUICK REFERENCE CARD BEING WRITTEN
• REVISED FORMAT A AND C FORMS WITH MORE EXPPLICIT INSTRUCTIONS AND FORMAT A DATA DERIVATION SHEET
PROJECT ANALYSIS AND INTEGRATION AREA

COMMENT/CRITICISM

- "ARE SAMICS RESULTS BELIEVABLE?"

ANALYSIS

- VALIDATION ACTIVITIES AND EXPERIENCE WERE NOT VISIBLE TO MOST USERS
- FORMAT A INPUT DATA FREQUENTLY NOT TRACEABLE
- SOME PRICES IN COST ACCOUNT CATALOG OUTDATED
- ENVIRONMENTAL CONTROL ALGORITHMS NEED IMPROVEMENT

ACTION

- PUBLISH DOCUMENT WITH DETAILED VALIDATION AND EXPERIENCE
- NEW FORMAT A SHOULD LEAD TO BETTER INPUT DATA DERIVATION AND TRACEABILITY
- COST ACCOUNT CATALOG BEING UPDATED FOR RELEASE 4
- MAJOR EFFORT TO IMPROVE EFFLUENT CONTROL ALGORITHMS AND UPDATE CONTROL EQUIPMENT AND PROCESS COSTS
PROJECT ANALYSIS AND INTEGRATION AREA

SAMICS CATALOGUE CHANGES

JET PROPULSION LABORATORY

R.W. Aster

PURPOSES:

• IMPROVE ESTIMATES OF ENVIRONMENTAL EFFLUENT COSTS
• UPDATE INFLATION ESTIMATES
• EXPAND, UPDATE, AND BETTER SPECIFY THE COMMODITIES LIST
• INCORPORATE SOME SUGGESTIONS MADE AT THE LAST LSA PIM

STATUS AND SCHEDULE:

INITIAL WORK ON ENVIRONMENTAL EFFLUENTS IS NOW COMPLETED. A REVIEW ALSO HAS BEEN COMPLETED

NEW INFLATION RATES HAVE BEEN PROJECTED. A JPL REVIEW OF THESE AND OF OTHER SAMICS FINANCIAL PARAMETERS IS SCHEDULED FOR NEXT WEEK

AN UPDATED COMMODITIES LIST HAS BEEN ASSEMBLED OVER THE LAST SEVERAL MONTHS (THIS IS AN ONGOING TASK). CONTRACTOR INPUTS HAVE BEEN MOST HELPFUL

DATA ENTRY WILL BEGIN IN 2 WEEKS. COST IMPACTS WILL BE INVESTIGATED BEFORE THE NEW CATALOG AND RELEASE 4 OF SAMIS ARE MADE AVAILABLE FOR GENERAL USE, PROBABLY IN AUGUST
Energy Content of Flat-Plate PV Modules

ENERGY CONTENT OF PV MODULES INCLUDES THE ENERGY CONTENT OF ALL MATERIALS AND SUPPLIES PLUS DIRECT AND INDIRECT ENERGY REQUIREMENTS OF THE PV FACTORY

THE MAIN CONTRIBUTORS TO PV ENERGY CONTENT HAVE BEEN:

- SILICON MATERIAL
- ENERGY REQUIRED TO GROW AND SAW INGOTS
- ENCAPSULATION MATERIALS

PV TECHNOLOGY IS CHANGING RAPIDLY:

- NEW SILICON PURIFICATION PROCESSES (1/3 LESS ENERGY CONTENT)
- SILICON REQUIREMENTS ARE BEING REDUCED
- ENCAPSULANT MATERIALS ARE BEING OPTIMIZED

THIS SUBJECT IS IMPORTANT BECAUSE OF NUMEROUS MISLEADING REPORTS IN RECENT POPULAR AND TECHNICAL JOURNALS

THE SCOPE OF THIS PRESENTATION INCLUDES THE EXPECTED EVOLUTION OF PV MODULES FROM 1976 TECHNOLOGY TO POTENTIAL GRID-CONNECTED TECHNOLOGY. FURTHERMORE, THE ENERGY CONTENT OF AN ARRAY STRUCTURE, INSTALLATION, AND OTHER ELEMENTS OF BOS ARE CALCULATED FOR A LARGE GROUND-MOUNTED ARRAY
**PROJECT ANALYSIS AND INTEGRATION AREA**

**1976 PV Technology Module Energy Content (kWh/kWp)**

Energy payback times for the BOS (no module) range from 0.8 to 1.5 yrs for central stations.
PROJECT ANALYSIS AND INTEGRATION AREA

Energy Payback as a Function of Module Efficiency

![Graph showing energy payback as a function of module efficiency.]

Based on 2000 kWh/kWp/yr insolation. Minimum area-related energy content based on BOS plus glass only.

Conclusions

Energy payback times are changing due to fundamental changes in PV technology.

Single-crystal-silicon flat-plate PV systems can have an energy payback time of 1.4 to 2.6 yrs, which is much less than expected system lifetime.

Low efficiency PV concepts (e.g., some thin films) will require longer energy payback times due to area-related energy requirements.
SPINOFF BENEFITS FROM LSA PROJECT R&D

JET PROPULSION LABORATORY

R.W. Aster

THESIS

THE LSA PROJECT HAS CONDUCTED R&D TO RESOLVE PROBLEMS OF LOW-COST PV MANUFACTURING. THE TECHNOLOGY DEVELOPED SO FAR, AND TECHNOLOGY THAT MAY BE DEVELOPED, CAN ALSO (IN SOME CASES) PROVIDE SIGNIFICANT SPINOFF BENEFITS TO SEMICONDUCTOR AND OTHER TECHNOLOGIES.

ANALYSIS PROBLEM

ESTIMATE THE NET SPINOFF BENEFITS OF LSA PROJECT PV R&D. "NET SPINOFF BENEFITS" MEANS ECONOMIC BENEFIT OF TECHNOLOGY ADVANCES ABOVE AND BEYOND WHAT COULD REASONABLY HAVE BEEN ACCOMPLISHED IN THE WORLD WITHOUT AN LSA PROJECT.

Why Would Any Net Benefits Occur?

PV R&D HAS OCCURRED IN HIGH-RISK AREAS

- SILICON MATERIAL R&D
- NEW INGOT SAWING AND RIBBON TECHNOLOGIES
- NEW MANUFACTURING PROCESSES

PAYBACK FROM PV R&D SPINOFFS (IF SUCCESSFUL) OCCURS MANY YEARS AFTER THE R&D EXPENDITURE, DISCOURAGING INVESTMENT IN PRIVATE R&D, PARTICULARLY IN SMALL FIRMS.

PAYBACK FROM AN R&D PROJECT MAY BE SMALL FOR INDIVIDUAL FIRMS, BUT LARGE FOR AN INDUSTRY.

SOME PV R&D SPINOFFS BENEFIT THE SEMICONDUCTOR INDUSTRY. SEMICONDUCTOR R&D EMPHASIZES DEVICE QUALITY AND MINIATURIZATION. PV R&D EMPHASIZES MATERIAL COSTS, YIELDS, AND AUTOMATION. THESE OBJECTIVES TEND TO BE COMPLEMENTARY RATHER THAN DUPLICATIVE.
PROJECT ANALYSIS AND INTEGRATION AREA

Some Potential Spinoffs

VERY LIKELY
- SEMICONDUCTOR-GRADE POLYCRYSTALLINE SILICON
- LOWER-COST SEMICONDUCTOR INGOTS
- LOWER-COST WAFERING
- ION IMPLANT COST REDUCTION (AUTOMATION)
- SILANE, LOW-COST/HIGH-PURITY SEMICONDUCTOR-GRADE
- NaOH ETCH, RATHER THAN ACID ETCHING OF WAFERS

POSSIBLE
- MIDDLE METALLIZATION OF PRINTED CIRCUITS
- EVA SUBSTITUTED FOR OTHER MATERIALS
- SILICON AND SILANE USED IN NEW APPLICATIONS

LESS LIKELY OR HARDER TO QUANTIFY
- GLASS THICKNESS SIZING ALGORITHM
- ION PLATING FOR CORROSION PROTECTION
- LOW-COST STRUCTURES

Semiconductor Polycrystalline Silicon

HIGH-RISK R&D ( < 20% SUCCESS RATE).

UNANTICIPATED (SOLAR-GRADE SILICON WAS EXPECTED).

A HIGH ESTIMATE OF NET BENEFITS IS BASED ON INDUSTRY (IN THE ABSENCE OF PV R&D) CONTINUING TO RELY ON SEIMENS PROCESS TECHNOLOGY, WITH THAT TECHNOLOGY IMPROVING OVER TIME.

A LOW ESTIMATE OF NET BENEFITS ASSUMES THAT INDUSTRY ACHIEVES A BREAKTHROUGH (IN THE ABSENCE OF PV R&D) THAT WOULD HAVE ALLOWED IT TO MEET PROJECT GOALS ($14/kg) BY 1991, ANYWAY.
High and Low Estimates of Silicon Benefits

<table>
<thead>
<tr>

<td></td>
</tr>
</tbody>
</table>

NET PRESENT VALUES ARE BASED ON 7% REAL DISCOUNTING. NOT EVERY SPINOFF HAS BEEN ANALYSED YET.
Concluding Comments

These spinoffs were not originally anticipated, and further investigation is required to obtain more precise estimates.

Their magnitude is large compared to PV R&D expenditures to date, but less than 1% of the size of the semiconductor industry ($300 to $500 billion in revenue between 1980 and 1995).

Spinoffs from future PV R&D are possible, but estimates cannot be made due in part to uncertainty about future program funding and emphasis.

Summary of the 18th PIM

As a user of modules for assembly in photovoltaic systems, Ron Matlin of TriSolar Corp. had comments and suggestions:

High price of modules is still the major barrier to widespread use of photovoltaics.

Cost of installation of today's small modules into systems of 1 kW or larger is significant.

Shift as much work as possible from field to factory; e.g., from installation viewpoint, ideal module size is 4 ft x 6 ft for a 3 kW or larger system.

System power mismatch losses can be reduced by as much as 3 to 5% by amount of paralleling in a module.

The viewpoints and requirements of the Arizona Public Service Utility for future use of photovoltaics were presented by Merwyn Brown. Photovoltaics can be utilized effectively, but the extent and manner of incorporation varies with the specific utility and its loading and other generating characteristics.

Nearly all of the equipment for the Union Carbide Corp. 100 MT/yr silane-to-silicon experimental process system development unit (EPSDU) has been delivered to the construction site; mechanical and electrical installation are scheduled next, before checkout and operation. Preliminary fluidized-bed process development unit (PDU) tests were successfully run using silane concentrations of 10% to 21% in hydrogen (minimum economic design point is 10%). Freecooling silicon shot was obtained in some initial tests of the silicon-powder-melting consolidation equipment.

The Hamlock Semiconductor Corp. PDU for investigating redistribution of trichlorosilane (TCS) to dichlorisilane (DCS) was completed, integrated with an intermediate-scale reactor, and operated successfully. Operation of the intermediate-scale reactor on cylinder-fed DCS confirmed silicon deposition rates required to meet the process goal.

In the investigation of the effects of impurities and processing on silicon solar-cell performance, Westinghouse confirmed that, at least for vanadium, molybdenum, and chromium, the threshold impurity concentration for breakdown of a smooth crystal-liquid interface is two to 10 times smaller for polycrystalline than for single-crystal ingots. Extensions of the experimentally supported impurity performance model to high-efficiency devices indicate that impurity tolerance is less in high-efficiency devices than in conventional n+p devices and that impurity sensitivity can be reduced by using thinner high-efficiency cells.

A 2-in.-dia fluidized-bed reactor (FBR) was successfully operated at JPL using very high silane concentrations in hydrogen, indicating an attractive potential usefulness of the FBR.
The advanced-Cz ESGU initial operation resulted in the growth of five 15-cm-dia ingots (total weight 150 kg) from one crucible, but using manual control (throughput rates and single crystal yield require improvement).

Semix Inc. has demonstrated that technical readiness for the $2.80 Wp goal has been met for its ubiquitous crystallization process (UCP) in module manufacturing.

Progress continues on the critical elements of the edge-defined film-fed growth (EFG) and web ribbon technologies.

Material suppliers (Du Pont Corp., Dow Corning Corp., 3M Corp., and others) recently made material, new or tailored for photovoltaics, available in commercial quantities for the photovoltaic industry. These materials were made to Low-Cost Solar Array Project (LSA) specifications but were not funded by LSA or the Department of Energy (DOE). LSA will perform life testing of these materials, which were on display. LSA encourages direct photovoltaic industry and material suppliers interaction.

Specific techniques for detecting and assessing corrosion mechanisms on solar cells and in modules have been developed.

Analytical models of chemical kinetic degradation rates in EVA have been developed. Accelerated experimental verification methods are being developed.

Spire's pulsed-electron-beam annealing (PEBA) machine successfully annealed 4-in.-dia wafers.

Bernd Ross Associates has metallized cells using a copper-based thick-film ink that incorporates a fluorocarbon as a fluxing agent.

A Westinghouse ultrasonically bonded aluminum-to-copper sample encapsulated in EVA withstood 30 days of immersion in water.

The Clemson University accelerated solar-cell stress study of 12 types of silicon solar cell was summarized. The major differences noted in cell reliability characteristics are attributed to metallization technology differences; i.e., vacuum deposition, plating, screen printing, and soldering. Cells with copper-plated metal contacts were the least durable from a contact adhesion and mechanical stress viewpoint. There was no evidence of Cu diffusion into the silicon of the tested cells (Ni barrier worked well). Thus, it is important that metallization studies continue, especially on Cu, which can be the lowest-cost type of metallization. Three cell manufacturers offered to donate new cell types for the next round of testing at Clemson.

Module hot-spot and cell-interconnect fatigue nomographs have been devised.
PIM SUMMARY

TECHNOLOGY DEVELOPMENT AREA

Silicon Material Task

Union Carbide Corp.

- Demonstrate experimental operation of Mg Si/SiH₄/Si process (capable of <$14/kg production)

- EPSDU -
  Civil and structural work completed -- nearly all equipment delivered to site -- most major equipment pieces inspected and placed in position -- mechanical installation bid packages being evaluated -- mechanical installation delayed from end of June due to funding limitations

- Fluidized-bed PDU -
  Tests successfully completed with 10% to 21% silane in hydrogen (minimum economic design point is 10%) -- program stopped in mid-July due to FY '81 funding recision

- Si powder melting/consolidation -
  Initial tests with chunk Si completed -- free-flowing shot obtained in some tests

- To be done -
  Remainder EPSDU program - mechanical and electrical installation, check-out, establish silane purity, experimental integrated/steady state process operation with FSR/shotter pyrolysis unit, demonstrating Si purity, experimental integrated/steady-state process operation with FBR unit
PIM SUMMARY

MIT-Solarelectronics, Inc.

Two-year program at MIT completed -- Study of Hyd氯orination JF M6-Si and STC to TCS to be continued under contract to Solarelectronics with same principal investigator -- Process provides TCS for both UCC and Hemlock processes and potentially for conventional (Siemens) process for semiconductor-grade Si -- In MIT study the fundamental operating parameters of process were well characterized -- in new contract fundamental process parameters will be investigated using engineering-scale FBR

Hemlock Semiconductor Corp.

· Objective -- Demonstrate feasibility of DCS-based CVD process for production of low-cost, high purity Si
· Construction of PDU for investigating redistribution of TCS to DCS completed
· Heat shield for intermediate-scale Si deposition reactor modified to contain bell jar fragments in case of explosion of DCS-hydrogen-air mixture -- Reactor with heat shield successfully passed safety test
· Intermediate-scale reactor operated successfully on cylinder-fed DCS -- Data confirm high Si deposition rates that are needed to meet program objectives
· PDU integrated with intermediate-scale reactor and operated successfully
· Two problems encountered -- Amount of Si deposited on reactor walls (2% of total deposit) greater than desired -- Reactor power consumption higher than desired
· To be done -- Complete experimental program with integrated PDU/intermediate-scale reactor to investigate process parameters

556
Westinghouse R&D Center

OBJECTIVE -- DETERMINE EFFECTS OF IMPURITIES, PROCESSING, AND IMPURITY-PROCESS INTERACTIONS ON PROPERTIES OF Si AND SOLAR CELLS TO PERMIT DEFINITION OF IMPURITY EFFECTS ON SOLAR CELL PERFORMANCE AND TO ALLOW COST-PERFORMANCE TRADE-OFFS TO BE MADE

• PHASE IV EFFORT COMPLETED -
  - EVALUATION OF EXPERIMENTAL Si MATERIALS
  - INVESTIGATION OF IMPURITY EFFECTS IN POLYCRYSTALLINE DEVICES
  - IDENTIFICATION OF IMPURITY THRESHOLDS FOR HIGH-EFFICIENCY CELLS
  - ASSESSMENT OF PROCESS EFFECTS SUCH AS ION IMPLANTATION ON IMPURITY-DOPED DEVICES
  - IDENTIFICATION OF LONG-TERM IMPURITY EFFECTS

• THRESHOLD IMPURITY CONCENTRATION FOR BREAKDOWN OF SMOOTH CRYSTAL-LIQUID INTERFACE IS 2 TO 10 TIMES SMALLER FOR POLY-Si THAN FOR SINGLE-CRYSTAL Si

  • IMPURITY TOLERANCE APPEARS LOWER IN HIGH-EFFICIENCY DEVICES THAN IN CONVENTIONAL n+p DEVICES -- IMPURITY SENSITIVITY REDUCED IN THINNER HIGH-EFFICIENCY CELLS

  • NO CONTINUATION -- BUDGET RESTRICTION

C.T. Sah Associates

• PURPOSE -- DEVELOP COMPUTER MODEL BASED ON FUNDAMENTAL PARAMETERS OF SOLAR CELLS AND APPLY IT TO DETERMINATION OF EFFECTS OF IMPURITIES AND DEFECTS IN Si ON SOLAR CELL PERFORMANCE

• EFFECT OF CELL THICKNESS ON PERFORMANCE OF Si SOLAR CELLS CONTAINING IMPURITY RECOMBINATION CENTERS WAS ANALYZED USING ZINC IMPURITY AS THE MODEL RECOMBINATION CENTER -- EFFICIENCY PEAKS AROUND CELL THICKNESS OF ABOUT 50μM BUT PEAK IS VERY WIDE (LESS THAN 0.1% VARIATION FROM 20 TO 70μM) IN BSF CELLS OF 17% EFFICIENCY -- OTHER FACTORS LIMITING PERFORMANCE OF THIN CELLS IDENTIFIED

TO BE DONE --

• EXPERIMENTAL AND THEORETICAL ANALYSIS OF RECOMBINATION RATE DATA TO MAKE ACCURATE PREDICTIONS OF MAXIMUM ALLOWABLE IMPURITY CONCENTRATIONS FOR GIVEN CELL EFFICIENCIES

557
JPL In-House Program

- PURPOSE -- OBTAIN (1) CHEMICAL AND CHEMICAL ENGINEERING DATA FOR HIGH POTENTIAL SI REACTORS AND (2) BASIC INFORMATION OF EFFECTS OF IMPURITIES ON SI MATERIAL AND SOLAR CELL CHARACTERISTICS
- TO PROVIDE BASIS FOR EXPERIMENTAL PROGRAM USING 6-INCH-DIA. FBR, TESTS WERE RUN IN 2-INCH DIA. FBR TO INVESTIGATE SI FINES FORMATION AND BED AGGLOMERATION -- TESTS CONDUCTED SUCCESSFULLY AT HIGH SILANE CONCENTRATION IN HYDROGEN (INCLUDING 100% SILANE) WITHOUT EXCESSIVE FINES FORMATION OR BED AGGLOMERATION -- RESULTS INDICATE POSSIBILITY OF ACHIEVING LOWER COST BY MEANS OF INCREASED THROUGHPUT SINCE FBR OPERATION WITH AS LOW AS 10% SILANE SHOWN TO BE ECONOMICALLY ATTRACTIVE
- MEASUREMENTS OF ENERGY LEVELS AND DENSITIES CAUSED BY IMPURITIES BEING MADE USING TSCAP
- ZEEMAN ATOMIC ABSORPTION SPECTROMETER BEING ADAPTED TO MEASUREMENTS OF SOME IMPURITIES IN PPBA RANGE

TO BE DONE --
- R&D PROGRAM WITH 6" FBR
- CONTINUE FUNDAMENTAL IMPURITY MEASUREMENTS AND RELATE THEM TO PERFORMANCE CHARACTERISTICS

Large-Area Silicon Sheet Task

Status

INGOT TECHNOLOGY

GROWTH

- 150 kg OF INGOTS HAVE BEEN GROWN FROM ONE CRUCIBLE IN THE ADVANCED CZ ESGU.
- FIVE 15 CM DIA INGOTS WERE GROWN UNDER MANUAL CONTROL.
- 50% OF THE INGOTS WERE SINGLE CRYSTAL.
- AVERAGE THROUGHPUT RATE IS 1.6 kg/hr (GROWTH RATE AT 2.5 kg/hr).
- SEMIX HAS DEMONSTRATED THAT TECHNOLOGY PROJECTIONS CAN BE MET FOR $2,80/Wp GOAL.
- ADDITIONAL WORK IS BEING RESCOoped TO FOCUS ON CRITICAL TECHNOLOGY ELEMENTS REQUIRED TO DEMONSTRATE TECHNICAL FEASIBILITY OF $0.70/Wp.
- BEST SIMULTANEOUS ACHIEVEMENT FOR HEM IS SOLIDIFICATION OF 30 x 30 x 15 cm. (36 kg) INGOT IN 18.5 HOURS. TOTAL GROWTH CYCLE TIME IS 51.5 HOURS.
INGOT TECHNOLOGY

WAFFERING
- Silicon material utilization goals have been demonstrated for 15 cm dia. and 10 x 10 cm ingot wafering. (17 wafers/cm and 25 wafers/cm respectively.) Kerf losses remain high at >10 mils.
- Waffer throughputs demonstrated are typically 0.25 wafers/min. (Goals are 0.5 wafers/min and 1 wafers/min for 15 cm dia and 10 x 10 cm ingot respectively.)
- Potential for slurry vehicle reclamation has been demonstrated for the MBS process.

RIBBON TECHNOLOGY
- Work continues on developing models for achievement of high web dendrite ribbon throughput (high growth rate of wide ribbon) with commensurate material quality (15% AM1 cells).
- Fabrication and assembly of an experimental growth unit to verify above is underway.
- Ongoing experiments for the EFG process continue to test new die designs and growth atmosphere variations for throughput and quality improvement. Three ribbons of 10 cm width each have been grown at 3.3 cm/min, simultaneously for 47% of a 7.5 hour growth cycle.

Additional Work

INGOT TECHNOLOGY
- Advanced Cz
  - Improvement of ingot quality
  - Increased throughput
  - Crucible/melt interaction

UCP
- Improvement of material quality for 15% AM1 cells
- Demonstration of high speed wafering of 10 x 15 cm ingots

HEM
- Improvement of material quality for 15% AM1 cells (e.g., reduce dislocations and precipitates)
- Improve ingot growth yield

WAFFERING
- Increase wafering throughput
- Reduce kerf losses
PIM SUMMARY

RIBBON TECHNOLOGY

WEB DENDRITE:  
- INCREASE HEAT DISSIPATION FOR HIGHER GROWTH SPEED.
- MELT PROFILE AND THERMAL STRESS ANALYSIS FOR WIDE WEB GROWTH.

EFG:  
- GROWTH AMBIENT ATMOSPHERE STUDIES FOR IMPROVED MATERIAL QUALITY.
- GROWTH ZONE THERMAL MODELLING TO REDUCE RIBBON STRESS AND BUCKLING.

Encapsulation Task

Encapsulant Materials

- STATUS
  - MATERIAL AND SYSTEM REQUIREMENTS IDENTIFIED FOR EACH FUNCTIONAL ELEMENT (COVERS, POTTANTS, PRIMERS, ADHESIVES, EDGES, ETC.) FOR OPTICAL, THERMAL, ELECTRICAL, STRUCTURAL, PROCESSING, COST, ETC.
  - NEW OR TAILORED MATERIALS FORMULATED, TESTED AND TRANSFERRED TO PV INDUSTRY FOR FABRICATION AND PERFORMANCE EVALUATION.
  - MATERIAL SUPPLY INDUSTRY (DUPONT, DOW CORNING, 3M, ETC.) RESPONDING TO LSA REQUIREMENTS WITH NEW PRODUCTS AND TECHNICAL ASSISTANCE DIRECTLY TO PV INDUSTRY. (NOT DOE FUNDED, SEE EXHIBITS)
  - TECHNOLOGY TRANSFER INTERFACES ESTABLISHED:
    - WITHIN LSA PROJECT
    - BETWEEN LSA PROJECT AND PV INDUSTRY
    - BETWEEN LSA PROJECT AND MATERIAL SUPPLIERS
    - BETWEEN PV INDUSTRY AND MATERIAL SUPPLIERS (E.G., ARCO, DUPONT, ETC.)
PIM SUMMARY

- NEEDED WORK

• THESE ARE NEW MATERIALS AND NEW INTERFACE COMBINATIONS THAT NEED EVALUATION AND CHARACTERIZATION TO DEFINE PROPERTIES, APPLICATION LIMITS, PERFORMANCE MARGINS AND PROCESS OPTIMIZATION. COMBINATION INDUSTRIAL AND DOE SUPPORT IS APPROPRIATE.

• DEFINE, COMPILE, UPDATE AND PUBLISH ENCAPSULANT DESIGN GUIDE LINES, DESIGN ANALYSIS METHODS AND MATERIAL SELECTION CRITERIA AND STANDARDS, FOR INDUSTRIAL EVALUATION AND ADOPTION.

• ASSESS ADVANCED (HIGH RISK) MATERIAL AND FABRICATION CONCEPTS THAT HAVE LONG-TERM HIGH PAY-OFF POTENTIAL. EVALUATE FOR IMPROVED ENVIRONMENTAL STABILITY, LOWER MODULE LIFE CYCLE ENERGY COST, APPLICATION TO ADVANCED SOLAR CELLS.

Encapsulation Durability and Module Life

- STATUS

• SCREENING AND RANKING TESTS OF CURRENT CANDIDATE MATERIAL SYSTEMS INDICATE 20-YEAR OR GREATER LIFE POTENTIAL IN RECOMMENDED DESIGNS (GLASS, EVA, EMA, SILICONES, PMMA, TEDLAR, ETC.)

• DEGRADATION MECHANISMS AND EXPECTED PROPERTY CHANGES DUE TO ENVIRONMENTAL AGING HAVE BEEN DEFINED AND MEASURED.

• PROGRESS MADE IN EVALUATING AND IMPROVING LIFE TESTING METHODS AND IN INTERPRETING ACCELERATION EFFECTS.

• CHEMICAL AND ANALYTICAL COMPUTER MODEL OF EVA DEGRADATION RATE DEVELOPED AND BEING EXPERIMENTALLY VALIDATED.
PIM SUMMARY

- NEEDED WORK

• ANSWER THE QUESTIONS
  HOW LONG WILL THE MODULE LAST?
  WHAT WILL BE THE PROBABLE WEAR-OUT FAILURE MODE?
  WHAT IS THE WEAK (LIFE-LIMITING) LINK IN THE DESIGN?
  WHAT CAN BE DONE TO INCREASE LIFE (REDUCE LIFE-CYCLE ENERGY COST)?

• DEVELOP A SPECIFIC SET OF DESIGN ANALYSES AND COMPONENT TESTS FOR
  THE ASSESSMENT OF MODULE LIFE. (PARTIALLY ACCOMPLISHED)

• UNDERSTAND AND BE ABLE TO DETECT AND CONTROL CORROSION MECHANISMS
  IN MODULE INTERNAL CIRCUIT ELEMENTS.

• DETERMINE AND SPECIFY PHOTOTHERMAL STABILITY LIMITS OF ENCAPSULANTS
  UNDER ALL MODULE OPERATIONAL CONDITIONS.

• DEFINE CRITICAL ENCAPSULANT INTERFACE STABILITY CRITERIA AS AFFECTED
  BY DISSIMILAR MATERIALS, BONDING TECHNIQUES AND OPERATIONAL STRESSES.

PROCESS DEVELOPMENT AREA

MEPSDU Status

• CONTRACTS RESCHEDULED; REDUCED FUNDING RATE
• PRELIMINARY DESIGN REVIEWS COMPLETED WITH MODIFIED DESIGN
• SOLAREX ESTABLISHED SUBCONTRACT FOR AUTOMATED SOLDERING MACHINE
• PROCESS DEVELOPMENT AREA LABORATORY BEGINNING TO PROCESS MEPSDU SILICON SHEET MATERIALS
Metallization

- Cu thick film system requires simultaneous mechanical and electrical demonstration
  - Cu-Pb-Cx Fy paste adheres after H2O boil test
  - Nonoptimum Cu cells equivalent to 10%.
- N1 silicide formation appears to be crystal orientation sensitive
- Photowatt working on N1 paste fired through A/R coating
- Midfilm® process has capability of putting base metals on irregular surfaces
- Copper penetrates 400 Å N1 after 15 minutes at 300°C (Westinghouse)

Junction Formation

- Spire beginning design of non-mass analyzed ion implantation
- Pulsed electron beam annealing (PEBA) machine successfully annealed four inch diameter wafers
- POCl3 diffusion with EPI on upgraded metalurgical grade silicon
- Solarex spray-on dopant appears successful

Surface Preparation

- Motorola showed small benefit from texturing polycrystalline silicon
- RCA EPI cells influenced by sawing surface damage
- ITO A/R coating reduces series resistance

Assembly

- Tracor MBA programmable robot for encapsulation and edge sealing at demonstration stage
- JPL in-house working to introduce sophisticated sensing techniques
- Westinghouse ultrasonic bonded Al to Cu sample EVA laminated withstood 30 day H2O immersion
PIM SUMMARY

ENGINEERING AREA

MODULE RESEARCH
- Solar Cell Reliability (Clemson)
- Interconnect Fatigue
- Hot-Spot Heating Thermal Analysis
- International Environmental Tests

ARRAY RESEARCH
- Integrated Residential Arrays (GE & AIA/RC)
- Electrical Safety System Development (UL)
- Cleaning Study

Activities Not Presented

MODULE RESEARCH
- Electrical Insulation Breakdown
- Encapsulant Soiling
- Long-Term Humidity Testing (Wylie)
- Module Reliability Study (IITRI)
- Wind Cooling (NOCT) Analysis
- Module Accelerated Weathering (DSET)

ARRAY RESEARCH
- Building Code Review (BHKRA)
- Residential Fire Testing (UL)
- Ground-Mounted Structures
- Wind Loading Analysis (Boeing)
- Power Conditioner Interface Requirements
