SILICON PRODUCTION PROCESS EVALUATIONS

QUARTERLY TECHNICAL PROGRESS REPORT (IV)

Issue Date: May 1, 1982

Reporting Period: Feb. 1, 1982 - April 30, 1982

TREI
Texas Research and Engineering Institute, Inc.
P.O. Box 9
Port Neches, Texas 77651

JPL Contract No. 956045

Contractual Acknowledgement

The JPL Flat-Plate Solar Array (FSA) Project is sponsored by the U.S. Department of Energy and forms part of the Solar Photovoltaic Conversion Program to initiate a major effort toward the development of low-cost solar arrays. This work was performed for the Jet Propulsion Laboratory, California Institute of Technology by agreement between NASA and DOE.
"This report was prepared as an account of work sponsored by the United States Government. Neither the United States nor the United States Department of Energy, nor any of their employees, nor any of their contractors, subcontractors, or their employees, makes any warranty, express or implied, or assumes any legal liability or responsibility for the accuracy, completeness or usefulness of any information, apparatus, product or process disclosed, or represents that its use would not infringe privately owned rights."
ABSTRACT

For the HSC process (Hemlock Semiconductor Corporation), chemical engineering analysis of the process for producing silicon from dichlorosilane in a 1,000 MT/yr plant is nearing completion. Progress and status for the major process engineering activities involved in the analysis are reported: base case conditions (100%), reaction chemistry (100%), process flow diagram (100%), material balance (100%), energy balance (100%), property data (100%), equipment design (90%), major equipment list (90%) and labor (90%).

Engineering design of the third distillation column (D-03, DCS column) in the process was accomplished. The initial design is based on a 94.35% recovery of the light key (DCS, dichlorosilane) in the distillate and a 99.9% recovery of the heavy key (TCS, trichlorosilane) in the bottoms. The specified separation of DCS and TCS is achieved at a reflux ratio of 15 with 20 trays (equilibrium stages). Additional specifications and results are reported including equipment size, temperatures and pressure.

Specific raw material requirements necessary to produce the silicon in the process are presented. The primary raw materials include metallurgical grade silicon, silicon tetrachloride, hydrogen, copper (catalyst) and lime (waste treatment). Hydrogen chloride is produced as a by-product in the silicon deposition.

Cost analysis of the HSC process (Hemlock Semiconductor Corporation) was initiated during this reporting period. The initial cost engineering activities are about 30% complete. The costs for raw materials and utilities necessary to produce silicon in HSC process are reported. Raw material costs are $2.66 (1980 dollars) and $3.07 (1982 dollars) per kg of silicon. Utility costs are $4.75 (1980 dollars) and $5.69 (1982 dollars) per kg of silicon.

Initial engineering design of the third distillation column (D-03, DCS column) in the process was accomplished. The function of the distillation column is to separate DCS (dichlorosilane) and TCS (trichlorosilane). The distillation column has a single feed which is the distillate from D-02 column.

For the initial process engineering design of D-03 distillation column, the specifications for the separation include a 94.35% recovery of the light key (DCS, dichlorosilane) in the distillate and a 99.9% recovery of the heavy key (TCS, trichlorosilane) in the bottoms. A partial condenser is used for safety reasons in the distillation which is conducted at 90 psia. Additional specifications used in performing the design are given in Appendix A1.

The results for the process engineering design of D-03 indicate the specified separation of DCS and TCS is achieved at a reflux ratio of 15 with 20 trays (equilibrium stages). Additional detailed results including feed tray location and equipment size are given in Appendix A2.

The design curve for D-03 distillation column is shown in Figure I-1. The design curve discloses the results for number of trays (equilibrium stages) required for the separation versus reflux ratio for the distillation.

Status details for the chemical engineering analysis are given in Table I-1. The preliminary process engineering design is based on a 1,000 MT/yr plant for producing silicon from dichlorosilane.
Raw material requirements necessary to produce the product are presented in Table I-2. In the process, the primary raw materials required to produce the silicon include metallurgical grade silicon, silicon tetrachloride, hydrogen, copper (catalyst) and lime (waste treatment). Hydrogen chloride is produced as a by-product in the silicon deposition. The detailed raw material requirements are summarized in the tabulation including hourly flow rate and mass required per kg of silicon produced.

The utility requirements for the process are given in Table I-3. The major utilities include electricity, steam, cooling water, refrigeration, process water and fuel. Among these utilities, the primary utility involving the greatest energy usage is the electricity for the deposition reaction in which silicon is produced by deposition on an electrically heated polycrystalline rod. The surface of the polycrystalline silicon rod is usually in the temperature range of 1000-1100°C for the silicon deposition.

Preparation of the list of major process equipment and production labor required to operate the equipment is in progress and nearing completion. The major process equipment and labor requirements are about 90% complete.

II. COST ANALYSIS

The cost analysis activity involves an economic analysis of the process under consideration for the production of silicon. The cost analysis for the particular technology is based on process design results, such as requirements for raw materials and major process equipment necessary to produce the product, from the chemical engineering analysis activity. Primary results issuing from the cost analysis include plant capital investment and product cost which are useful in identification of those processes showing promise for meeting project cost goals.

During this reporting period, cost analysis of the HSC process (Hemlock Semiconductor Corporation) was initiated for a 1,000 MT/yr silicon plant. Progress and status for the major cost engineering activities involved in the analysis are summarized below:

<table>
<thead>
<tr>
<th>Activity</th>
<th>Prior</th>
<th>Current</th>
</tr>
</thead>
<tbody>
<tr>
<td>1. Process Design Inputs</td>

<td>Plan</td>
</tr>
<tr>
<td>8. Total Product Cost</td>
<td>0%</td>
<td>Plan</td>
</tr>
</tbody>
</table>

Status details for the cost analysis are shown in Table II-1.

The cost of raw materials necessary to produce the product are presented in Table II-2. The tabulation indicates that raw material costs are $2.66 (1980 dollars) and $3.07 (1982 dollars) per kg of silicon.

The cost of utilities required for the production of the product are given in Table II-3. The utility costs are $4.75 (1980 dollars) and $5.69 (1982 dollars) per kg of silicon.

Cost estimation for the major process equipment necessary to produce the silicon product is in progress. Determination of the major process equipment costs is about 30% complete.

III. SUMMARY - CONCLUSIONS

As a result of accomplishments during this reporting period, the following summary-conclusions are made:

1. For the HSC process (Hemlock Semiconductor Corporation), chemical engineering analysis of the process for producing silicon from dichlorosilane in a 1,000 MT/yr plant is nearing completion. Progress and status for the major process engineering activities involved in the analysis are reported: base case conditions (100%), reaction chemistry (100%), process flow diagram (100%), material balance (100%), energy balance (100%), property data (100%), equipment design (90%), major equipment list (90%) and labor (90%).

2. Initial engineering design of the third distillation column (D-03, DCS column) in the process was accomplished. The initial design is based on a 94.35% recovery of the light key (DCS, dichlorosilane) in the distillate and a 99.9% recovery of the heavy key (TCS, trichlorosilane) in the bottoms. The specified separation of DCS and TCS is achieved at a reflux ratio of 15 with 20 trays (equilibrium stages). Additional specifications and results are reported including equipment size, temperatures and pressure.

3. Cost analysis of the HSC process (Hemlock Semiconductor Corporation) was initiated during this reporting period. The initial cost engineering activities are about 30% complete. The costs for raw materials and utilities necessary to produce silicon in HSC process are reported. Raw material costs are $2.66 (1980 dollars) and $3.07 (1982 dollars) per kg of silicon. Utility costs are $4.75 (1980 dollars) and $5.69 (1982 dollars) per kg of silicon.
IV. PLANS

Plans for the next reporting period are summarized below:

1. Continue chemical engineering analysis of the HSC process (Hemlock Semiconductor Corporation) for silicon.

2. For the preliminary process design, major efforts will be devoted to equipment design, major equipment list and labor requirements.

3. Cost analysis will continue as results issue from the chemical engineering analysis.
APPENDIX A1

PROCESS ENGINEERING: DESIGN SPECIFICATIONS FOR DISTILLATION, D-03

1. Process Equipment Name Distillation, D-03 (DCS Column)

2. Process Equipment Function Separation of DCS (Dichlorosilane) and TCS (Trichlorosilane).
