A COMPUTER PROGRAM FOR OBTAINING AIRPLANE CONFIGURATION PLOTS FROM DIGITAL DATCOM INPUT DATA

Marie-Louise Roy and Steven M. Sliwa

MARCH 1983
A computer program is described which reads the input file for the USAF Stability and Control Digital Datcom program and generates plots from the aircraft configuration data. These plots can be used to verify the geometric input data to the Digital Datcom program. The program described interfaces with utilities available at Langley Research Center for plotting aircraft configurations by creating a file from the Digital Datcom input data.

INTRODUCTION

The USAF Digital Datcom (Refs. 1 and 2) is a Fortran program implementation of the USAF Stability and Control Datcom (Ref. 3). Digital Datcom is useful for analyzing configurations in a wide range of flight conditions and can be used to find static and dynamic stability derivatives, as well as trim conditions and control power coefficients. The output data closely resembles reduced data from wind tunnel tests. Hence, Digital Datcom is valuable either for confirming experimental results or for estimating initial quantities for preliminary design.

This report describes a computer program, herein referred to as DATPLOT, which plots Digital Datcom input data as an airplane configuration. This provides a means of checking for data coding or keypunch errors, allowing the engineer to have greater confidence in using Digital Datcom.

Although a program, D2290, exists at Langley Research Center for plotting aircraft configurations in both batch and interactive modes (Ref. 4), the required input for this program is substantially different than that used for Digital Datcom. DATPLOT is a preprocessor which reads the pertinent data cards from a Digital Datcom input deck, finds and calculates the values needed by D2290, and prepares a file in the proper format for use by D2290. The procedure file for terminal or batch operation of DATPLOT is called PDTPLT. Table 1 is a compilation of pertinent files and their respective functions and Table 2 demonstrates the needed commands to execute PDTPLT in batch or interactive modes.

**Flight Dynamics and Control Division, NASA Langley Research Center, Hampton, VA.
Datcom Background

USAF Stability and Control Digital Datcom is a Fortran program available to LaRC users for computing static and dynamic stability derivatives as well as high lift and control power coefficients. The input to Digital Datcom consists of case control cards and up to 22 namelists.

The title of the plots is taken from the CASEID control card. All other information is obtained from reading 9 of the available 22 Digital Datcom namelists. These nine namelists are as follows:

- OPTINS: Defines the flight conditions
- SYNTHS: Reference parameters
- BODY: Body geometric data
- WGPLNF: Wing planform variables
- HTPLNF: Horizontal tail planform variables
- VTPLNF: Vertical tail planform variables
- VFPLNF: Vertical fin planform variables
- JETPWR: Jet power parameters
- PROPWR: Propeller power parameters

Namelists and case control cards may appear in any order in the input to Digital Datcom. This input file should be named TAPE4 when using the procedure file PDTPLT to execute the program DATPLOT (see Table 1 for file definitions). Since the nine namelists mentioned above and the CASEID card are needed by DATPLOT, the procedure file PDTPLT adds empty namelists and a CASEID card to TAPE4 prior to execution of DATPLOT. This prevents DATPLOT from failing even if the user does not specify one of the required namelists while building his or her Digital Datcom model (TAPE4). Sample input files to Digital Datcom (TAPE4) for four airplane configurations are tabulated in Appendix I. Plots generated from these data files are shown in Figures 2 through 7.

Program Logic and Organization

Flow charts for procedure file PDTPLT and program DATPLOT are shown as figures 8 and 9, respectively. A listing of program DATPLOT is included as Appendix II. As indicated in figure 8, DATPLOT reads TAPE4, an input file intended for Digital Datcom, and writes TAPE7, an input file for D2290, the airplane graphics program available at Langley Research Center. Appendix III is a tabulation of the four TAPE7 files generated when DATPLOT processed the Digital Datcom input files from Appendix I. The plots of these four airplane configurations are shown as figures 1 through 4.

The first line of TAPE7 is the plot title, which DATPLOT reads from the CASEID of the Digital Datcom input file. The second line of TAPE7, which is generated by DATPLOT, consists of the 24 control integers that are required by D2290. The first seven control integers indicate which parts of the aircraft configuration are to be plotted: wings, fuselage, pods, fins and canards. The other control integers indicate the number of wing sections to be described, the number of fuselage sections, the number of pods, fins, etc.
DATPLOT reads namelist OPTINS, SYNTHS and BODY on the Digital Datcom input file to determine whether the data necessary for plotting each configuration are present, and sets the 24 control integers accordingly. These values of control integers constitute the defaults for the aircraft configuration plots. The user has the option of not using the defaults and may look at less of the aircraft configuration, if it is so desired. This is especially useful when trying to eliminate errors in the Digital Datcom input deck. In this case of plotting partial configurations, DATPLOT calls subroutine OPTIONS and resets the first seven control integers.

DATPLOT checks against the first seven control integers to determine what is to be plotted. DATPLOT then calls a series of subroutines to read each namelist containing geometry information for each configuration part to be plotted. Coordinates and dimensions are computed and scaled prior to output to TAPE7 in accordance with D2290 requirements.

DATPLOT sets the wing control integers for three uncambered airfoil sections along the wing semi-span: (1) the root chord section; (2) the tip chord section; and (3) the breakpoint section. Each wing airfoil section is assumed to be symmetrical about its chord and is described by 10 points along its upper periphery. In the absence of an outboard wing section, a zero length wing tip section is written to TAPE7 in order to remain consistent with the control integer settings.

The fuselage can be represented two ways: as a cambered fuselage or as a circular fuselage. If the Z-coordinate of the upper and lower points of the fuselage are given at each station, a cambered fuselage is assumed. In this case, 20 points along the positive Y portion of the Y-Z cross section are computed as input for TAPE7. Otherwise, the value of the area of each cross section is written to TAPE7.

Digital Datcom input provides for up to two engines. DATPLOT reads namelist JETPWR to determine the presence of jet engines. If no jets are described, DATPLOT reads namelist PROPWR. If the number of propeller engines described is also zero, data for a pod of zero length and zero diameter will be written on TAPE7 (See Figs. 4a and 4b).

In the case of engine data, DATPLOT calculates the location of the engines, estimates the dimensions and writes the information on TAPE7 as pod data for D2290. Only one engine is described since D2290 assumes all aircraft configurations to be symmetrical about the X-Z plane.

The vertical tail is read from namelist VTPLWF and is written as fin data for D2290 on TAPE7. If the vertical tail has a dorsal fin, the data is contained in namelist SYNTHS. XVF is assumed to be the X-coordinate of the leading edge of the triangular dorsal fin where it meets the fuselage. ZVF is assumed to be the vertical position along the leading edge of the vertical tail where the dorsal fin joins it. DATPLOT calculates the coordinates and dimensions as a fin that approximates the shape of a vertical tail with a dorsal fin protruding forwards.

If the horizontal tail or canard has outboard vertical fins (see Figs. 3a and 3b), DATPLOT assumes that they are given in Digital Datcom as the outboard sections of the horizontal tail surface with a dihedral angle approaching 90°. The dimensions and coordinates of outboard vertical panels and horizontal tail planes are computed from the data in namelist HTPLNF. The horizontal tail is plotted as a canard by D2290.
After all of the appropriate namelists are read and the aircraft configuration data has been written on TAPE7 in a format useable by D2290, plotting instructions are required. The view and rotations are selected by subroutine PLTCARD. PLTCARD writes the lines on TAPE7 needed for two default views or allows the user to specify alternatives. The two default views chosen by DATPLOT are an orthogonal projection of the configuration and a three-in-one view of the aircraft.

**PROGRAM USE AND OPERATION**

The procedure file PDTPLT is used to operate DATPLOT and consists of three records. The first two records are used for batch jobs and the third record is used for interactive jobs. A listing of PDTPLT is shown as Appendix IV and a block diagram showing the relationship of PDTPLT, DATPLOT, Digital Datcom and D2290 is shown in figure 8.

**Batch Operations**

The first record on the procedure file PDTPLT contains a submit file. The user needs to complete the file with the appropriate delivery information, account number, charge number, the name of the Digital Datcom input file (GET, TAPE4=filename.) and the kind of plotting device desired (PLOT.device). Table 2(b) shows the commands needed to operate PDTPLT in batch mode.

The second record is the user input to the submit file and indicates the plotting options. A YES or a NO must appear on the first line and answer the question: Do you want to accept plotting default values? If the answer is YES, no other lines of input are needed and none are read. If NO appears on the first line, another YES or NO must appear on the second line. It answers the question: Do you want to plot the entire configuration?

If the answer is NO, two more lines are needed prior to continuing. The first card is the plot title and the second card includes the 24 plot control integers in fields of three columns as required by D2290. See reference 4 for details.

If the first line of this input data record is NO, then viewing instructions need to be given. They will start on line three if the second line is YES and line five if the second line is NO. There are four viewing choices as specified by D2290:

- ORT Orthographic views
- W3 Three-in-one views
- PER Perspective views
- STE Stereographic views

Viewnames and view instructions are listed until no more plots are desired. This is indicated by a value of one (1) for KODE on the instruction line. Refer to reference 4 for complete plotting instructions.

To submit PDTPLT for batch operation, type: SUBMIT,PDTPLT,B. To send PDTPLT, type: SEND,PDTPLT,M = machine code.
Interactive Operations

DATPLOT is best suited for use on a Tektronix graphics terminal. The third record on file PDTPLT contains procedure PLOT. The user needs to name his Digital Datcom input file as TAPE4 (i.e., GET,TAPE4=filename) and type BEGIN,PLOT,PDTPLT. Configuration and plotting view options are answered by typing a "Y" or "N". A sample session using the first and fourth input file of Appendix I is shown as Appendix V and the plots that were obtained are shown as figures 5 through 7. Generally, the user need only answer a series of questions and then plots will be generated at the screen.

CONCLUDING REMARKS

A Fortran computer program (DATPLOT) and a procedure file (PDTPLT) have been described which interface the USAF Stability and Control Digital Datcom with D229U, a Langley Research Center utility for plotting aircraft configurations. DATPLOT allows the input data to Digital Datcom to be plotted providing an opportunity for Digital Datcom users to validate models undergoing analysis. Although the DATPLOT is intended primarily as an interactive tool, its use for batch operations is also presented.
