LANDSAT-4 BAND 6 DATA EVALUATION

Contract #NAS5-27323

Second Quarterly Report
March 15, 1983

Prepared For:

NASA/Goddard Space Flight Center
Greenbelt, Maryland 20771
Objectives:

The objectives of this investigation are to evaluate and monitor the radiometric integrity of the Landsat-5 Thematic Mapper (TM) thermal infrared channel (band 6) data to develop improved radiometric preprocessing calibration techniques for removal of atmospheric effects.

Problems:

A satellite underflight was made in January; however, a mechanical failure in the film transport caused a loss of data. This problem has been corrected and underflight data will be collected as soon as data transmission resumes.

Accomplishments:

Primary data analysis this reporting period has been spent in evaluating the line to line and detector to detector variation in the thermal infrared data. The data studied was in the core area of Lake Ontario where very stable temperatures were expected. The detectors and the scan direction were taken as separate parameters and an analysis of variance was conducted. The results displayed in Table 1 and Table 2 show the detector means and variances as well as the ANOVA results. These data indicate that significant variability exists both between detectors and between scan directions. Methods to further define the form of this variability and to reduce it will be considered during the next reporting period.

The radiosonde data corresponding to the September image over the target area was received and input into the LOWTRAN Model. Figure 1 and Figure 2 were generated from the model output. These figures represent the variation in the atmospheric transmission and path radiance as a function of altitude. This type of modeled data will be compared to the underflight data in evaluating the potential use of the LOWTRAN models to evaluate Thematic Mapper data.

Significant Results:

None this reporting period.

Publications:

A draft of the paper presented at the Landsat-4 Early Results Symposium is attached.

Recommendations:

None this reporting period.
Funds Expended:

$27,192, representing 23% of the total program effort.

Data Utility:

N/A

JRS: mp

Introduction and Background

The data from the thermal infrared channel (Band 6) aboard the thematic mapper represent the highest spatial resolution thermal information yet available from space. The radiometric response function of the thermal sensor must be carefully evaluated to permit proper interpretation of these unique data. Probably the most generally accepted method for processing radiometric data from space is to correct the observed radiance or apparent temperature to a surface radiance or temperature value using atmospheric propagation models. For example using radiosonde data from the study area at the time of an overpass the atmospheric transmission and path radiance terms (τ and Wa) can be computed using AFCRL's LOWTRAN code (Ref. 1) or NASA's RADI TRAN code (Ref. 2). These terms can be used to compute the surface radiance from

\[ W_s = \frac{(W - W_a)}{τ}. \]  

Where; \( W \) is the observed radiance and \( W_s \) is the surface radiance which can be associated with an equivalent black body temperature (\( T_s \)).

As part of NASA's Heat Capacity Mapping Mission (HCMM) experiment the atmospheric propagation models were used in reverse in an attempt to evaluate the post launch radiometric response of the Heat Capacity Mapping Radiometer (HCMR). Bohse et al 1979, describe how surface radiometric readings were used in conjunction with radiosonde data to predict the radiance at the top of the atmosphere using atmospheric propagation models. Surface data taken with a point radiometer viewing a lake were averaged to define \( W_a \) and the atmospheric propagation models were used to define \( τ \) and \( W_a \) at the time of the overpass. Therefore the radiance observed by the spacecraft sensor \( W' \) and the radiance calculated from the model \( (W = τ \cdot W_a + W) \) should be identical. In fact for the five dates studied the difference in observed and predicted values ranged from 4.15 to 6.14°C with an average difference of 5.24°C (radiance values have been converted to equivalent blackbody temperatures). As a result of these analysis, NASA offset the prelaunch calibration values for the sensor by -5.5°C and applied this offset to all standard HCMM products (Ref. 4).

This offset was based on the assumption that the sensor response and/or the calibration standard had somehow changed since the prelaunch calibration. Subsequent studies five months later conducted in an identical fashion indicated that the offset should be moved back toward the
original value by 3.3 to 7.7°C (Ref 5). This would essentially nullify the original offset. If we accept the initial premise of a shift in the HCMR response function we must now speculate on the possibility of long term drift in the sensor calibration. An alternative and perhaps more acceptable hypothesis is that the atmospheric propagation models are inadequate and part or all of the variance is associated with changes in the atmosphere insufficiently accounted for by the models.

Whether the sensor or the models were at fault - the fact remains that the radiometric calibration of the data was seriously in question. Both the actual radiance reaching the sensor and surface radiance values generated by processing the raw data were in doubt.

Lest these same doubts plague the thermal data from Landsat D, it is imperative that the radiometric response function of the sensor be carefully evaluated after launch using reliable experimental data. Since nearly all users have a requirement for surface radiance data it is also essential that the atmospheric propagation models be more carefully evaluated and refined as preprocessing algorithms. This paper describes a program to experimentally evaluate the radiometric calibration of the Landsat 4 band 6 data. This approach draws on a method employed by Schott and Schimminger, 1981 as part of the HCM experiment to radiometrically calibrate the HCMR data. Schott and Schimminger 1981 successfully utilized an approach to radiometric calibration of HCMR data that involved underflying the satellite with an infrared line scanner. This approach enabled calibration of the satellite sensor to within 1°C of surface temperature values. By extending this technology to higher altitudes experimental radiance data suitable for radiometric calibration of the TM band 6 sensor can be generated. Repetition of this experiment will permit evaluation of long term drift in the sensor and provide a data base for the second phase of the program.

The second phase of the experiment involves evaluation of the atmospheric propagation models for radiation transfer. Along with the underflight data from phase one, radiosonde data (suitable for input to the propagation models) will be available. The propagation models can be used to predict atmospheric transmission and path radiance values as a function of altitude and at slant paths to the satellite. These same values are derivable from the empirical data gathered during the underflight. By comparing these values it should be possible to begin to evaluate any systematic errors in the models. During this phase modifications to the models based on systematic errors and/or additional surface truth data will be evaluated. If sufficiently accurate models can be defined then underflight data would not be required for continued evaluation of sensor performance. In addition satellite data could be preprocessed to produce direct surface radiance or equivalent temperature images.

**TECHNICAL DISCUSSION**

Data collection for this effort involves an extension of techniques successfully used to radiometrically calibrate the HCM sensor. We will briefly describe the HCM experiment and use this as a base for describing the evaluation of the TM band 6 sensor. To account for atmospheric effects we utilized a model involving collection of ground truth simultaneously...
with satellite data collection. Great care must be taken to insure that ground truth data for a satellite sensor represents the true integrated surface radiance or temperature over the entire projected instantaneous field of view (IFOV) of the sensor. To accomplish this large areas of uniform temperature are employed — usually water bodies. However most water bodies have significant variation in them such that integration of the temperature or radiance pattern observed is often desirable. To accomplish this on the HCMM experiment the satellite sensor was underflown with an infrared line scanner to image large areas at different temperatures. Fractions of the imaged areas could then be registered with satellite pixels and integrated to provide corresponding radiance fields (cf., Figure 1). These radiance data however are degraded by the atmosphere between the aircraft and the ground. These atmospheric effects are accounted for by a method described by Schott 1979 which involved flying the aircraft at a series of altitudes over the same target areas. This method yields the atmospheric transmission term \( \tau \) and the path radiance term \( W_A \) at flight altitude and therefore permits computation of the surface radiance \( W_S \) or equivalent temperature \( T \) for any target imaged at the flight altitude. This method was extensively tested in blindfold experiments which showed a standard error of 0.4°C between the temperature predicted from the aircraft data and independently observed at the surface. By employing this method the true surface temperature or equivalent surface radiance of an area imaged by the aircraft and the satellite was defined by analysis of the apparent temperature observed by the aircraft. By regressing the observed radiance at the spacecraft against the true surface radiance the atmospheric transmission and path radiance terms affecting satellite data can be determined from

\[
W_0 = \tau W_S + W_A. \tag{2}
\]

Where \( W_0 \) is the observed radiance at the satellite. In practice a range of targets largely separated in temperature provide the best fit to equation 2. The spring thermal bar in the Laurentian Great Lakes provides this temperature range admirably with large areas of the lake surface (tens of km²) differing by as much as 10 to 12°C.

The approach described above was applied to the thermal infrared data from the HCMM. In addition radiosonde data were used to run the LOWTRAN and RADTRA models and predict surface temperatures. Figure 2 is a graphic display of the results of these analyses. This figure illustrates that the experimental underflight method checks against itself as expected but that neither of the atmospheric propagation models very effectively predicted surface temperature values. This experiment yields a suitable means of absolute calibration of a satellite thermal infrared sensor when appropriate underflight data are available. It does not however provide insight into whether the satellite response calibration or the propagation models or both are at fault in the LOWTRAN and RADTRA approaches. (N.B., Because the underflight method employs ground truth it does not require a calibrated sensor, only a linear response function; i.e., it only requires that observed radiance be linear with true radiance).

The method described above can be modified to permit empirical analysis of the radiance reaching the spacecraft. The airborne sensor has been filtered to match the spectral response of the TM band 6 sensors. Therefore the atmospheric transmission and path radiance terms computed for
FIGURE 1. CALIBRATION OF SATELLITE IMAGERY USING UNDERFLIGHTS
Figure 2. Plot of Water Surface Temperature vs. Temperatures Predicted by Various HCMR Calibration Methods. The Residual Error in the Predicted Temperatures Using the Underflight Calibration Technique is 1.0°C. The Residual Errors Associated with the LOWTRAN and RADTRAN Models are 9.0°C and 6.9°C Respectively.
each altitude are the same terms that affect the satellite data. By flying
the aerial sensor at several altitudes up to or approaching the top of the
atmosphere effective propagation terms can be directly measured or
simply extrapolated with the aid of radiosonde data (cf., Figure 3).
Previous studies over the target area indicated that nearly all the
atmospheric effects took place below 7 Km. This is within the range of
the turbo charged Aztec C which is being used for data collection. With
the atmospheric propagation terms defined in this manner the radiance
reaching the satellite can be defined for any targets imaged both by the
satellite and the aircraft. The satellite sensors post launch performance
can then be evaluated by comparing the observed satellite radiance to the
radiance values known to be incident on the sensor. Through repetitive
measurements the presence of drift or the existence of any systematic shift
in system performance will be verified. Since many points are available
for comparison between the satellite and the aerial images the functional
relationship between the radiance recorded by the satellite and the actual
radiance should be definable. Thus any corrections required to affect post
launch shifts in system response will be defined.

Radiosonde data collected in the study area will be accessed for each
underflight. These data are used to generate atmospheric propagation terms
using the models cited above. The propagation terms generated by the
models and the experimentally derived terms will be evaluated to determine
if the models are adequate for sensor evaluation and preprocessing of
radiometric data.

As necessary, further effort will be directed at defining and
developing corrections to the atmospheric propagation models to bring them
into agreement with experimental data. If these models can be sufficiently
improved then the method used in the attempt at validating the HCMN
calibration could be used for TM band 6 verification. In addition the
models could be used to preprocess TM band 6 data to provide actual surface
radiance or surface temperature images.

The models would be evaluated using the underflight data. The
underflight data can be used to observe the atmospheric transmission ($\tau$)
and path radiance ($W$) at each altitude sampled. In addition by
interpolation through the models described by Schott 1979 the transmission
and path radiance terms to any altitude and at various angles can be
computed. The atmospheric propagation models are also capable of
interpolating within the radiosonde data to provide transmission and path
radiance data as a function of altitude and view angle. Therefore, an
extensive data base will be developed for comparing the data derived from
the atmospheric propagation models to the empirical data. Through
statistical analysis of these data, corrections to the propagation models
can be inferred. Analyses of the various underflight data sets obtained
will provide information on the effects of varying atmospheric conditions
on the model performance. This added dimension will enable us to look for
a systematic pattern to the statistical corrections derived for an
individual data set. Using these data we will attempt to develop
corrections to the models either in the form of corrections to the model's
coefficients or refinements to the theoretical approach. The systematic
corrections developed in this manner will be applied to the satellite data
and compared to the known surface radiance values derived from the
Figure 3.
Plot of Atmospheric Transmission as a Function of Altitude

Approximate limits of data collected (underflight)

- - - - Atmospheric Propagation Model
- - - - Extrapolated Data
underflight data. Again, these results will be analyzed to determine if 
the revised models are suitable for evaluation of the radiometric 
calibration of TM band 6 and also therefore suitable for preprocessing of 
the band 6 data.

To date, efforts have concentrated on modification of the infrared 
line scanner to match the spectral response of the TM band 6 sensor and 
limited efforts to underfly the satellite on clear days. The major data 
collection thrust is scheduled for the spring of 1983 when the large 
temperature gradients in the Laurentian Great Lakes will insure the 
availability of properly dispersed data.
