May 1983
Mathematical formulas are presented which express the dimensionless minimum film thickness for the four lubrication regimes found in elliptical contacts: isoviscous-rigid regime; piezoviscous-rigid regime; isoviscous-elastic regime; and piezoviscous-elastic regime. The relative importance of pressure on elastic distortion and lubricant viscosity is the factor that distinguishes these regimes for a given conjunction geometry. In addition, these equations were used to develop maps of the lubrication regimes by plotting film thickness contours on a log-log grid of the dimensionless viscosity and elasticity parameters for three values of the ellipticity parameter. These results present a complete theoretical film thickness parameter solution for elliptical contacts in the four lubrication regimes. The results are particularly useful in initial investigations of many practical lubrication problems involving elliptical conjunctions.
Film Thickness for Different Regimes of Fluid-Film Lubrication

*Leeds, England*
It is evident from the discussion in previous chapters that there are a number of reasonably well-defined regimes within the full range of conditions of fluid-film lubrication of elliptical contacts. Each regime has characteristics determined by the operating conditions and the properties of the material.

The type of lubrication for a particular contact is influenced by two major physical effects: the elastic deformation of the solids under an applied load, and the increase in fluid viscosity with pressure. Therefore it is possible to have four main regimes of fluid-film lubrication, depending on the magnitude of these effects and on their importance. These four regimes are defined as:

1. Isoviscous-rigid: In this regime the magnitude of the elastic deformation of the surfaces is such an insignificant part of the thickness of the fluid film separating them that it can be neglected, and the maximum pressure in the contact is too low to increase fluid viscosity significantly. This form of lubrication is typically encountered in circular-arc thrust bearing pads; in industrial coating processes in which paint, emulsion, or protective coatings are applied to sheet or film.

*Published as Chapter 12 in Ball Bearing Lubrication by Bernard J. Hamrock and Duncan Dowson, John Wiley & Sons, Inc., Sept. 1981.
materials passing between rollers; and in very lightly loaded rolling bearings.

(2) **Piezo-viscous-rigid:** If the pressure within the contact is sufficiently high to increase the fluid viscosity within the conjunction significantly, it may be necessary to consider the pressure-viscosity characteristics of the lubricant while assuming that the solids remain rigid. For the latter part of this assumption to be valid it is necessary that the deformations of the surfaces remain an insignificant part of the fluid-film thickness. This form of lubrication may be encountered on roller end-guide flanges, in contacts in moderately loaded cylindrical tapered rollers, and between some piston rings and cylinder liners.

(3) **Isoviscous-elastic:** In this regime the elastic deformation of the solids is a significant part of the thickness of the fluid film separating them, but the pressure within the contact is quite low and insufficient to cause any substantial increase in viscosity. This situation arises with materials of low elastic modulus, and it is a form of lubrication that may be encountered in seals, human joints, tires, and elastomeric-material machine elements.

(4) **Piezo-viscous-elastic:** In fully developed elastohydrodynamic lubrication the elastic deformation of the solids is often a significant part of the thickness of the fluid film separating them, and the pressure within the contact is high enough to cause a significant increase in the viscosity of the lubri-
cant. This form of lubrication is typically encountered in ball and roller bearings, gears, and cams.

Several authors – Moes (1965-66), Theyse (1966), Archard (1968), Greenwood (1969), Johnson (1970), and Hooke (1977) – have contributed solutions for the film thickness in the four lubrication regimes, but their results have been confined largely to nominal line or rectangular contacts. The essential difference between these contributions is the way in which the dominant parameters were made dimensionless. In this chapter the film thickness is defined for the four fluid-film lubrication regimes just described for conjunctions ranging from circular to rectangular. The film thickness equations for the respective lubrication regimes come from theoretical studies reported in previous chapters on elastohydrodynamic and hydrodynamic lubrication of elliptical conjunctions. The results are valid for isothermal, fully flooded conjunctions. In addition to the film thickness equations for the various conditions a map is presented of the lubrication regimes, with film thickness contours being represented on a log-log grid of viscosity and elasticity parameters for five values of the ellipticity parameter. This chapter draws extensively on the work of Hamrock and Dowson (1979b).

12.1 Dimensionless Grouping

The representation of results of elastohydrodynamic theory
for elliptical contacts in this book in terms of the dimensionless groups (H, U, W, G, k) has been particularly helpful since the physical explanation of conjunction behavior can readily be associated with each set of numerical results. However, several authors have noted that this set of dimensionless groups can be reduced by one parameter, without any loss of generality, by using dimensionless analysis. The film thickness contours for the four fluid-film lubrication regimes can then be conveniently represented graphically by the smallest number of parameters, even though the physical meaning of each composite parameter requires careful consideration.

Johnson (1970) has pointed out that the behavior distinguishing the four lubrication regimes can be characterized by three quantities, each having the dimensions of pressure:

1. The reduced pressure parameter $q_f$, a measure of the fluid pressure generated by an isoviscous lubricant when elastic deformation is neglected
2. The inverse pressure-viscosity coefficient $1/\alpha$, a measure of the change of viscosity with pressure
3. The maximum Hertzian pressure $p_{\text{max}}$, the maximum pressure in a dry elastic contact

Although Johnson (1970) did not consider elliptical contacts, he did state what the nondimensional parameters for such configurations should be:
Dimensionless film parameter:

\[ \hat{H} = H \left( \frac{W}{U} \right)^2 \]  
(12.1)

Dimensionless viscosity parameter:

\[ g_V = a q_f = \frac{G W^3}{U^2} \]  
(12.2)

Dimensionless elasticity parameter:

\[ g_E = \frac{1}{\pi} \left( \frac{3}{2} \right)^{1/3} \left( \frac{q_f}{p_{\text{max}}} \right) = \frac{W^{8/3}}{U^2} \]  
(12.3)

The ellipticity parameter \( k \) remains as discussed in Chapter 3, equation (3.28). Therefore the reduced dimensionless group is \( (H, g_V, g_E, k) \).

12.2 Isoviscous-Rigid Regime

The influence of conjunction geometry on the isothermal hydrodynamic film separating two rigid solids was investigated in Chapter 6 for fully flooded, isoviscous conditions. The effect of geometry on the film thickness was determined by varying the radius ratio \( R_y/R_x \) from 1 (a circular configuration) to 36 (a configuration approaching a rectangular contact). The film thickness was varied over two orders of magnitude for conditions representative of steel solids separated by a paraffinic mineral oil. It was found that the computed minimum film thickness had the same speed, viscosity, and load dependence as the classical Kapitza (1955) solution. However, when the Reynolds
cavitation boundary condition \( \frac{\partial p}{\partial n} = 0 \) and \( p = 0 \) was introduced at the cavitation boundary, where \( n \) represents the normal coordinate to the interface between the full film and the cavitation region, an additional geometrical effect emerged. Therefore from Chapter 6 the dimensionless minimum, or central, film thickness parameter for the isoviscous-rigid lubrication regime can be written as

\[
\left( \hat{H}_{\text{min}} \right)_{IR} = \left( \hat{H}_c \right)_{IR} = 128 a_a \lambda_b^2 \left[ 0.131 \tan^{-1} \left( \frac{a_a}{2} \right) + 1.683 \right]^2 \quad (12.4)
\]

where

\[
a_a = \frac{R_y}{R_x} = \left( \frac{k}{1.03} \right)^{1/0.64} \quad (12.5)
\]

\[
\lambda_b = \left( 1 + \frac{2}{3a_a} \right)^{-1} \quad (12.6)
\]

In equation (12.4) the dimensionless film thickness parameter \( \hat{H} \) is shown to be strictly a function of the geometry of the contact \( R_y/R_x \).

12.3 Piezo-Viscous-Rigid Regime

Blok (1952) has shown that the minimum film thickness for the piezo-viscous-rigid lubrication regime in a rectangular contact can be expressed as
\[ h_{\text{min}} = h_{c} = 1.66 \left( \alpha \hat{\eta} u^{2} R_{x} \right)^{1/3} \quad (12.7) \]

By taking account of the ellipticity of the conjunction under consideration equation (12.7) can be rewritten as

\[ h_{\text{min}} = h_{c} = 1.66 \left( \alpha \hat{\eta} u^{2} R_{x} \right)^{1/3} (1 - e^{-0.68k}) \quad (12.8) \]

The absence of an applied-load term in (12.8) should be noted. When expressed in terms of the dimensionless parameters introduced in equations (12.1) and (12.2), this can be written as

\[ \left( \hat{h}_{\text{min}} \right)_{\text{PVR}} = \left( \hat{h}_{c} \right)_{\text{PVR}} = 1.66 \hat{g}_{V}^{2/3} \left( 1 - e^{-0.68k} \right) \quad (12.9) \]

Note the absence of the dimensionless elasticity parameter \( \hat{g}_{E} \) in equation (12.9).

12.4 Isoviscous-Elastic Regime

The influence of the ellipticity parameter \( k \) and the dimensionless speed \( U \), load \( W \), and materials \( G \) parameters on the minimum, or central, film thicknesses was investigated theoretically for the isoviscous-elastic regime, and the results have been presented in Chapter 11. The ellipticity parameter was varied from 1 (a circular configuration) to 12 (a configuration approaching a rectangular contact). The dimensionless speed and load parameters were each varied by one order of magnitude. Seventeen cases were considered in obtaining the dimensionless minimum-film-thickness equation
From equations (12.1) and (12.3) the general form of the dimensionless minimum-film-thickness parameter for the isoviscous-elastic lubrication regime can be expressed as

\[ H_{\text{min}} = A \varepsilon^2 (1 - 0.85 e^{-0.31k}) \]  

(12.11)

where \( A \) and \( \varepsilon \) are constants to be determined. From equation (12.1) and equation (12.3) we can write equation (12.11) as

\[ H_{\text{min}} = A U^2 c^{-2} (8/3c)^{-2} (1 - 0.85 e^{-0.31k}) \]  

(12.12)

Comparing equation (12.10) with equation (12.12) gives \( \varepsilon = 0.67 \). Substituting this into equation (12.11) while solving for \( A \) gives

\[ A = \frac{H_{\text{min}}}{\varepsilon^0.67(1 - 0.85 e^{-0.31k})} \]  

(12.13)

The arithmetic mean for \( A \) based on the 17 cases considered in Chapter 11 is 8.70, with a standard deviation of +0.05. Therefore the dimensionless minimum-film-thickness parameter for the isoviscous-elastic lubrication regime can be written as

\[ \left( H_{\text{min}} \right)_{\text{IE}} = 8.70 \varepsilon^0.67(1 - 0.85 e^{-0.31k}) \]  

(12.14)

With a similar approach the dimensionless central-film-thickness parameter for the isoviscous-elastic lubrication regime can be written as

\[ \left( H_c \right)_{\text{IE}} = 11.15 \varepsilon^0.67(1 - 0.72 e^{-0.28k}) \]  

(12.15)
12.5 Piezo-Viscous-Elastic Regime

In Chapter 8 the influence of the ellipticity parameter and the dimensionless speed, load, and materials parameters on the minimum and central film thicknesses was investigated theoretically for the piezo-viscous-elastic regime. The ellipticity parameter was varied from 1 to 8, the dimensionless speed parameter over nearly two orders of magnitude, and the dimensionless load parameter over one order of magnitude. Conditions corresponding to the use of solid materials of bronze, steel, and silicon nitride and lubricants of paraffinic and naphthenic oils were considered in obtaining the exponent on the dimensionless materials parameter. Thirty-four cases were used in obtaining the following dimensionless minimum-film-thickness formula:

\[ H_{\text{min}} = 3.63 \, u^{0.68} \, G^{0.49} \, w^{-0.073} (1 - e^{-0.68k}) \]  \hspace{1cm} (12.16)

The general form of the dimensionless minimum-film-thickness parameter for the piezo-viscous-elastic lubrication regime can be written as

\[ \hat{H}_{\text{min}} = B g^d v^f (1 - e^{-0.68k}) \]  \hspace{1cm} (12.17)

where \( B, d \) and \( f \) are constants to be determined. From equations (12.1), (12.2), and (12.3) we can write equation (12.17) as

\[ H_{\text{min}} = B g^d u^2 - 2d - 2f w^{-2+3d+(8f/3)} (1 - e^{-0.68k}) \]  \hspace{1cm} (12.18)
Comparing equation (12.16) with equation (12.18) gives $d = 0.49$ and $f = 0.17$. Substituting these values into equation (12.17) while solving for $B$ gives

$$B = \frac{\hat{H}_{\text{min}}}{g_v^0.49 \cdot g_E^0.17 \cdot (1 - e^{-0.68k})}$$

(12.19)

For the 34 cases considered in Chapter 8 for the derivation of equation (12.16) the arithmetic mean for $B$ was 3.42, with a standard deviation of $+0.03$. Therefore the dimensionless minimum-film-thickness parameter for the piezo-viscous-elastic lubrication regime can be written as

$$\left(\hat{H}_{\text{min}}\right)_{\text{PVE}} = 3.42 \cdot g_v^{0.49} \cdot g_E^{0.17} \cdot (1 - e^{-0.68k})$$

(12.20)

An interesting observation to make in comparing equations (12.9), (12.14), and (12.20) is that in each case the sum of the exponents on $g_v$ and $g_E$ is close to the value of 2/3 required for complete dimensional representation of these three lubrication regimes: piezo-viscous-rigid, isoviscous-elastic, and piezo-viscous-elastic.

By adopting a similar approach to that outlined here the dimensionless central-film-thickness parameter for the piezo-viscous-elastic lubrication regime can be written as

$$\left(\hat{H}_c\right)_{\text{PVE}} = 3.61 \cdot g_v^{0.53} \cdot g_E^{0.13} \cdot (1 - 0.61 \cdot e^{-0.73k})$$

(12.21)

12.6 Procedure for Mapping the Different Lubrication Regimes

Having expressed the dimensionless minimum-film-thickness parameters for the four fluid-film lubrication regimes in
equations (12.4), (12.9), (12.14), and (12.20) we used these relationships to develop a map of the lubrication regimes in the form of dimensionless minimum-film-thickness-parameter contours. These maps are shown in Figures 12.1 to 12.3 on a log-log grid of the dimensionless viscosity and elasticity parameters for ellipticity parameters of 1, 3, and 6, respectively. The procedure used to obtain these figures was as follows:

1. For a given value of the ellipticity parameter, \( \hat{H}_{\text{min}} \) as calculated from equation (12.4).

2. For a value of \( \hat{H}_{\text{min}} > \hat{H}_{\text{min}} \) and the value of \( k \) chosen in step 1, the dimensionless viscosity parameter was calculated from equation (12.9) as

\[
\hat{g}_V = \left[ \frac{\hat{H}_{\text{min}}}{1.66(1 - e^{-0.68k})} \right]^{3/2}
\]  

(12.22)

This established the dimensionless minimum-film-thickness-parameter contours \( \hat{H}_{\text{min}} \) as a function of \( g_V \) for a given value of \( k \) in the piezo-viscous-rigid regime.

3. For the values of \( k \) selected in step 1, \( \hat{H}_{\text{min}} \) selected in step 2, and \( g_V \) obtained from equation (12.22), the dimensionless elasticity parameter was calculated from the following
equation, which was derived from equation (12.20):

\[
\frac{1}{0.17} \left( \frac{H_{\text{min}}}{0.42 g_v (1 - e^{-0.68k})} \right) \quad (12.23)
\]

This established the boundary between the piezo-viscous-rigid and piezo-viscous-elastic regimes and enabled contours of \( H_{\text{min}} \) to be drawn in the piezo-viscous-elastic regime as functions of \( g_v \) and \( g_E \) for given values of \( k \).

(4) For the values of \( k \) and \( H_{\text{min}} \) chosen in steps 1 and 2 the dimensionless elasticity parameter was calculated from the following equation, obtained by rearranging equation (12.14):

\[
\frac{1}{0.67} \left( \frac{H_{\text{min}}}{8.70 (1 - 0.85 e^{-0.31k})} \right) \quad (12.24)
\]

This established the dimensionless minimum-film-thickness-parameter contour \( H_{\text{min}} \) as a function of \( g_E \) for a given value of \( k \) in the isoviscous-elastic lubrication regime.

(5) For the values of \( k \) and \( H_{\text{min}} \) selected in steps 1 and 2 and the value of \( g_E \) obtained from equation (12.24), the viscosity parameter was calculated from the following equation:

\[
\frac{1}{0.49} \left( \frac{H_{\text{min}}}{3.42 g_v^{0.17} (1 - e^{-0.68k})} \right) \quad (12.25)
\]

This established the isoviscous-elastic and piezo-viscous-
elastic boundaries for the particular values of $k$ and $\hat{H}_{\text{min}}$ chosen in steps 1 and 2.

(6) At this point, for particular values of $k$ and $\hat{H}_{\text{min}}$, the contours were drawn, through the piezo-viscous-rigid, piezo-viscous-elastic, and isoviscous-elastic regimes. A new value of $\hat{H}_{\text{min}}$ was then selected, and the new contour was constructed by returning to step 2. This procedure was continued until an adequate number of contours had been generated. A similar procedure was followed for the range of ellipticity ratios considered.

12.7 Contour Plots

The maps of the lubrication regimes shown in Figures 12.1 to 12.3 were generated by following the procedure outlined in the previous section. The contours of the dimensionless minimum-film-thickness parameter were plotted on a log-log grid of the dimensionless viscosity parameter and the dimensionless elasticity parameter for ellipticity parameters of 1, 3, and 6. The four lubrication regimes are clearly shown in these figures. The smallest contour of $\hat{H}_{\text{min}}$ considered in each case represents the values obtained from equation (12.4), and this forms a boundary to the isoviscous-rigid region. The value of $\hat{H}_{\text{min}}$ on the isoviscous-rigid boundary increases as the ellipticity ratio $k$ increases.
By using Figures 12.1 to 12.3 for given values of the parameters \(k, g_V,\) and \(g_E,\) the fluid-film lubrication regime in which any elliptical conjunction is operating can be ascertained and the approximate value of \(\hat{H}_{\text{min}}\) determined. When the lubrication regime is known, a more accurate value of \(\hat{H}_{\text{min}}\) can be obtained by using the appropriate dimensionless minimum-film-thickness-parameter equation.

A three-dimensional view of the surfaces developed by using constant values of \(\hat{H}_{\text{min}}\) of 500, 2000, and 6000 is shown in Figure 12.4. The coordinates in this figure are \(g_E, g_V,\) and \(k.\) The four fluid-film lubrication regimes are clearly shown. This figure not only defines the regimes of fluid-film lubrication clearly for elliptical contacts, but it also indicates in a single illustration how the parameters \(g_V, g_E,\) and \(k\) influence the dimensionless minimum-film-thickness parameter.

12.8 Closure

Relationships for the dimensionless minimum film thickness for the four lubrication regimes found in elliptical contacts have been developed and expressed as

(1) \textbf{I}so\textit{viscous-rigid regime:}

\[
\left( \hat{H}_{\text{min}} \right)_{\text{IR}} = \left( \hat{H}_c \right)_{\text{IR}} = 128 \alpha_a \lambda_b \left[ 0.131 \tan^{-1} \left( \frac{\alpha a}{2} \right) + 1.683 \right]^2
\]  

(12.4)
where

\[ \alpha_a = \frac{R_y}{R_x} = \left( \frac{k}{1.03} \right)^{1/0.64} \]  
(12.5)

\[ \lambda_b = \left( 1 + \frac{2}{3\alpha_a} \right)^{-1} \]  
(12.6)

(2) **Piezo-viscous-rigid regime:**

\[ \left( \hat{H}_{min} \right)_{PVR} = 1.66 \ g_v^{2/3} (1 - e^{-0.68k}) \]  
(12.9)

(3) **Isoviscous-elastic regime:**

\[ \left( \hat{H}_{min} \right)_{IE} = 8.70 \ g_E^{0.67} (1 - 0.85 e^{-0.31k}) \]  
(12.14)

(4) **Piezo-viscous-elastic regime:**

\[ \left( \hat{H}_{min} \right)_{PVE} = 3.42 \ g_v^{0.49} g_E^{0.17} (1 - e^{-0.68k}) \]  
(12.20)

The relative importance of the influence of pressure on elastic distortion and lubricant viscosity is the factor that distinguishes these regimes for a given conjunction geometry.

In addition, these equations have been used to develop maps of the lubrication regimes by plotting film thickness contours on a log-log grid of the dimensionless viscosity and elasticity parameters for three values of the ellipticity parameter. These results present a complete theoretical film-thickness-parameter solution for elliptical contacts in the four lubrication regimes. The results are particularly useful in initial investigations of many practical lubrication problems involving elliptical conjunctions.

Abstract

Relationships for the dimensionless minimum film thickness for the four lubrication regimes found in elliptical contacts have been developed and expressed as follows.

Isoviscous-rigid regime: \( \left( H_{\text{min}} \right)_{\text{IR}} = \left( H \right)_{\text{IR}} \)

\[ = 128 \alpha_i \lambda b^2 \left[ 0.131 \tan^{-1} \left( \alpha_d / 2 \right) + 1.683 \right]^2 \]

where \( \alpha_i = R_y / R_x = (k / 1.03)^{1/0.64} \) and \( \lambda b = (1 + 2/3 \alpha_k)^{-1} \)

Piezoviscous-rigid regime: \( \left( H_{\text{min}} \right)_{\text{PVR}} = 1.66 g_y^2 / (1 - e^{-0.68k}) \)

Isoviscous-elastic regime: \( \left( H_{\text{min}} \right)_{\text{IE}} = 8.70 \left( 1 - 0.85 e^{-0.31k} \right) g_e^2 \)

Piezoviscous-elastic regime: \( \left( H_{\text{min}} \right)_{\text{PVE}} = 3.42 g_y^0.49 \left( 1 - e^{-0.68k} \right) g_e^{0.17} \)

The relative importance of the influence of pressure on elastic distortion and lubricant viscosity is the factor that distinguishes these regimes for a given conjunction geometry. In addition, these equations have been used to develop maps of the lubrication regimes by plotting film thickness contours on a log-log grid of the dimensionless viscosity and elasticity parameters for three values of the ellipticity parameter. These results present a complete theoretical film-thickness-parameter solution for elliptical contacts in the four lubrication regimes. The results are particularly useful in initial investigations of many practical lubrication problems involving elliptical conjunctions.
