DBPSSP: A DATA BASE PROCESSOR
SEMANTICS SPECIFICATION PACKAGE

Paul A. Fishwick

Kentron Technical Center
Hampton, Virginia 23666

Contract NAS1-16000
June 1983
SUMMARY

A Semantics Specification Package (DBPSSP) for the Intel Data Base Processor (DBP) is defined. DBPSSP serves as a collection of cross-assembly tools that allow the analyst to assemble request blocks on the host computer for passage to the DBP. The assembly tools discussed in this report may be effectively used in conjunction with a DBP-compatible data communications protocol to form a query processor, precompiler, or file management system for the database processor. The source modules representing the components of DBPSSP are fully commented and included as an appendix to this report.

INTRODUCTION

DBPSSP (Data Base Processor Semantics Specification Package) is the second layer of the HILDA system. HILDA ("High Level Data Abstraction System") is a three layer data base management system supporting the data abstraction features of the Intel Data Base Processor (DBP). The purpose of HILDA is the establishment of a flexible method for efficiently communicating with the Intel Data Base Processor. Each layer within HILDA plays a specific role during this communication. These roles may be seen in figures 1 and 2. Figure 1 displays the method by which one may flexibly modify the syntax and semantics for the data base machine. Figure 2 shows the anatomy of a sample query made to the data base processor. The first layer within HILDA is SPP (Service Port Protocol) [1] and serves as the underlying data communications protocol allowing full access to the DBP data base management functionality. It is important to note that even though DBPSSP may be used with SPP, the assembly primitives and procedures within DBPSSP are independent of SPP. That is, another data communications protocol may be effectively used with DBPSSP if necessary. The purpose of this report is to document the design and implementation details associated with DBPSSP. A listing of the source modules is presented in appendix A.

AN OVERVIEW OF DBPSSP

DBPSSP is a collection of assembly tools used on the host computer to construct request modules that are to be sent to the Intel DBP. DBPSSP serves as a
cross assembler in that Intel DBP "machine code" is assembled on the host computer and then directed to the data base machine for execution. Each request module sent to the DBP is of the form shown in figure 3. Every module contains an arbitrary number of commands. A command is always composed of exactly three primary sections:

1. Opcode Byte - the operation to be performed on the DBP (fetch, store, define database, etc.)
2. Parameters/Data - parameters and data which relate to the operation being performed.
3. Terminator Bytes - two bytes which represent the end of the current operation to be performed by the DBP.

This report outlines the capabilities and suggested usage for the DBPSSP component modules. DBPSSP should be thought of as a collection of procedures (or subroutines) that permit the software developer to easily construct data base requests to the Intel DBP. In this manner the analyst is free to develop a flexible front-end interpreter or compiler to the data base machine. Some highlights of DBPSSP are as follows:

1. Relative and Absolute Offsets - When assembling machine code for the DBP, it is necessary to "place" the code at the proper offset within the request module. In many cases one may build the request module sequentially from start to finish. This sequential mode of assembling is termed "relative" offsetting since the current assembled code is simply "tacked on" to the previously assembled code. One may choose, however, to assemble code at a specific offset within the command block. This random mode of assembling is termed "absolute" offsetting. The mode used by the software developer depends on the front-end driver accessing the assembly tools. A particular parsing method (for a query language, for instance) used for constructing a driver may dictate the use of one offset method over another.

2. Primitive and High-Order Procedures - DBPSSP is composed of a set of general primitive procedures and a set of high-order procedures which are based on the primitives. The high-order procedures are similar in appearance to assembler mnemonics for a given microprocessor: they have short names and contain few operands.
3. Macro Capability - Since DBPSSP is a set of procedures, it is straight-forward and useful to develop new "macros" (or parameterized procedures) which access the fundamental DBPSSP procedures.

THE COMPONENTS OF DBPSSP

DBPSSP is composed of a minimal set of general primitives and a set of higher order procedures. Each set is divided into "Control" modules and "Assembly" modules. The control modules effect the data communications options while the assembly modules are pure assembly directives pertaining specifically to the construction of the command blocks. The control modules are discussed in reference 1. Modules that are dependent on the specific data communications protocol used are denoted "(D)" next to the respective module name. Each module set is depicted below:

PRIMITIVES

INIT_COMM(D) - initialize DBP communications
DBP_SEND(D) - send a request module to the DBP
DBP_RECV(D) - receive a response module from the DBP
TRACE_START(D) - start tracing
TRACE_STOP(D) - stop tracing
PERFORM_START - start performance monitoring
PERFORM_STOP - stop performance monitoring (gather statistics)
DBP_BEGIN - start to assemble a command block
DBP_BITS_BEGIN - start bit masking operations
DBP_BITS - perform logical 'or'ing of bits
DBP_BITS_END - end bit masking operations
DBP_BYTES - assemble an ASCII string
DBP_INTEGER - assemble a 1, 2, or 4 byte integer

HIGH-ORDER PROCEDURES

INIT(D) - initialize DBP communications
SEND(D) - send the built request module to the DBP
RECV(D) - receive a response module from the DBP
TRON(D) - start trace
TROFF(D) - stop trace
PRON - start performance monitoring
PROFF - stop performance monitoring (gather statistics)
START - start encoding a command block
TERMINATE - Add 2 terminator bytes to the command block
BITSB - begin bit masking (relative offset)
BITS - logical 'or' on command block (relative offset)
BITSE - end bit masking (relative offset)
BITSB_A - same as 'BITSB' (absolute offset)
ASC - assemble an ASCII string (relative offset)
ASC_A - same as 'ASC' (absolute offset)
INT1 - assemble a 1-byte integer (relative offset)
INT1_A - same as 'INT1' (absolute offset)
INT2 - assemble as 2-byte integer (relative offset)
INT2_A - same as 'INT2' (absolute offset)
INT4 - assemble a 4-byte integer (relative offset)
INT4_A - same as 'INT4' (absolute offset)

Details on using the above procedures may be found in the source which is included as appendix A.

THE ASSEMBLY PROCESS

Figure 4 displays the assembly process occurring for a "REMARK <HOST> <HELLO>" DBP command. It is assumed in figure 4 that the user has developed a parsing method which will activate the semantic assembly primitives within DBPSSP (START, INT1, ASC, and SEND) when the REMARK command is encountered. A more substantial program is presented in appendix B that performs the conceptual DBP operations listed below (note that the keywords are designated using small letters):

1. Submit keys ADMIN
   Submit the ADMIN key to the session keyring.
2. Define database TESTING
   Define a new database called TESTING.
3. Keep database TESTING
   Make the database TESTING a permanent database.

4. Define file FILE1 DBPSYS
   Define a new file called FILE1 on the system disk (DBPSYS).

5. Define schema INT1 int*4 INT2 int*4 INT3 int*4 FILE1
   Define a schema containing exactly three 4-byte integers (INT1, INT2, and
   INT3) for the previously defined file FILE1.

6. Keep file FILE1
   Make the file FILE1 a permanent file.

7. List database TESTING
   Show the schema description for files within database TESTING.

   For further information on the conceptual command syntax, see the DBP
   Reference Manual [2]. The program containing the above commands is presented in
   appendix B using two languages - FORTRAN 77 and Pascal. The FORTRAN program is
   coded using the primitives, while the Pascal program uses the high-order proce­
   dures. In general, the software designer will want to use the high-order
   procedures since the high-order procedures are more functionally precise with fewer
   parameters. Note the relative compactness of the Pascal program. The assembled
   modules and received DBP responses obtained after having sent the completed
   requests to the DBP are shown at the end of appendix B.

CONCLUDING REMARKS

The procedures within DBPSSP provide the developer with all of the necessary
tools to construct an interactive query processor, compiler, or file management
system for the Intel DBP. DBPSSP permits the definition of a complete semantics
specification associated with any given command or language syntax that the
developer may choose. For example, the third layer of HILDA in conjunction with a
parser generator package specifies the syntax and semantics for an interpretive
language "DBPQL" using DBPSSP.
APPENDIX A - DBPSSP Source

DBPSSP has been implemented using VAX VMS FORTRAN 77. The file "DBPSSP.FOR" contains the high-order procedures which will be used most often.

Figure 3 - Request Module Form
Figure 4 - A sample assembly for "REMARK"
A Semantics Specification Package (DBPSSP) for the Intel Data Base Processor (DBP) is defined. DBPSSP serves as a collection of cross-assembly tools that allow the analyst to assemble request blocks on the host computer for passage to the DBP. The assembly tools discussed in this report may be effectively used in conjunction with a DBP-compatible data communications protocol to form a query processor, precompiler, or file management system for the database processor. The source modules representing the components of DBPSSP are fully commented and included as an appendix to this report.
