ABSTRACT

New convenient stability criteria are provided in this paper for a large class of finite difference approximations to initial-boundary value problems associated with the hyperbolic system $u_t = Au_x + Bu + f$ in the quarter plane $x \geq 0, t \geq 0$. Using the new criteria, stability is easily established for numerous combinations of well known basic schemes and boundary conditions, thus generalizing many special cases studied in recent literature.

0. Introduction.

In this paper we extend the results of [3] to obtain convenient, more versatile, sufficient stability criteria for a wide class of difference approximations for initial-boundary value problems associated with the hyperbolic system $u_t = Au_x + Bu + f$ in the quarter plane $x \geq 0, t \geq 0$. Our difference approximation consists of a general difference scheme -- explicit or implicit, dissipative or not, two-level or multi-level -- and boundary conditions of the type discussed in [3].

We restrict attention to the case where the outflow part of our boundary conditions is translatory; i.e., determined at all boundary points by the same coefficients. Such boundary conditions are commonly used in practice; and in particular, when the boundary consists of a single point, the boundary conditions are translatory by definition.

Throughout the paper we assume that the basic scheme is stable for the pure Cauchy problem, and that the assumptions that guarantee the validity of the stability theory of Gustafsson, Kreiss and Sundström [5] hold in our case. With this in mind, we raise the question of stability for the entire approximation in the sense of Definition 3.3 in [5].

We begin our stability analysis in Section 1 by recalling Theorem 2.1 of [3], which implies that the entire approximation is stable if and only if the scalar outflow components of its principal part are stable. Thus, our global stability question is reduced to that of a scalar, homogeneous, outflow problem which is the main subject of this paper.

Our stability criteria for the reduced problem -- stated in Section 2 and proven in Section 3 -- depend both on the basic scheme and the boundary conditions, but very little on the intricate interaction between the two. Moreover, we show in Remark 3.1 that our old results in [3] easily follow from the present
ones. Thus, our new criteria provide in many cases a convenient alternative to the well known Gustafsson-Kreiss-Sundström criterion in [5].

In the second part of Section 2 we use the new stability criteria to reestablish all the main examples in our previous paper [3]. We show, for instance, that if the basic scheme is arbitrary (dissipative or not) and the boundary conditions are generated by either the explicit or implicit right-sided Euler schemes, then overall stability is assured. For dissipative basic schemes we prove stability if the boundary conditions are determined by either oblique extrapolation, by the Box-Scheme, or by the right-sided weighted Euler scheme. These and other examples incorporate most of the cases discussed in recent literature [1]-[3],[5],[6],[8]-[10],[12],[13],[15],[16].

Section 2 contains some new examples as well. Among these we find that if the basic scheme is arbitrary and two-level, then horizontal extrapolation at the boundary maintains overall stability. Other stable cases occur when the basic scheme is given by either the backward (implicit) Euler scheme or by the Crank-Nicolson scheme and the boundary conditions are determined by oblique extrapolation. Such examples, where neither the basic scheme nor the boundary conditions are necessarily dissipative, could not have been handled by our previous results in [3].

As in [3], we point out that there is no difficulty to extend our stability criteria to problems with two boundaries. This is so since if the corresponding left and right quarter-plane problems are stable, then by Theorem 5.4 of [5], the original problem is stable as well.
1. The Difference Approximation and the Reduced Problem.

Consider the first order hyperbolic system of partial differential equations

\[ \frac{\partial u(x, t)}{\partial t} = A \frac{\partial u(x, t)}{\partial x} + B u(x, t) + f(x, t), \quad x \geq 0, \ t \geq 0, \quad (1.1a) \]

where \( u(x, t) = (u^{(1)}(x, t), \ldots, u^{(n)}(x, t))' \) is the unknown vector (prime denoting the transpose), \( f(x, t) = (f^{(1)}(x, t), \ldots, f^{(n)}(x, t))' \) is a given vector, and \( A \) and \( B \) are fixed \( n \times n \) matrices such that \( A \) is Hermitian and nonsingular. Without restriction we may assume that \( A \) is diagonal of the form

\[ A = \begin{bmatrix} A^I & 0 \\ 0 & A^H \end{bmatrix}, \quad A^I < 0, \quad A^H > 0, \quad (1.2) \]

where \( A^I \) and \( A^H \) are of orders \( l \times l \) and \( (n - l) \times (n - l) \), respectively.

The solution of (1.1) is determined uniquely if we prescribe initial values

\[ u(x, 0) = u^0(x), \quad x \geq 0, \quad (1.1b) \]

and boundary conditions

\[ u^I(0, t) = S u^H(0, t) + g(t), \quad t \geq 0, \quad (1.1c) \]

where \( S \) is a fixed \( l \times (n - l) \) matrix, \( g(t) \) is a given \( l \)-vector, and

\[ u^I = (u^{(1)}, \ldots, u^{(l)})', \quad u^H = (u^{(l+1)}, \ldots, u^{(n)})', \quad (1.3) \]

is a partition of \( u \) into its inflow and outflow components, corresponding to the partition of \( A \) in (1.2).

In order to solve the initial-boundary value problem (1.1) by a finite difference approximation we introduce, as usual, a mesh size \( \Delta x > 0, \Delta t > 0 \), such that \( \lambda = \Delta t / \Delta x = \) constant; and using the notation \( v_\nu(t) = v(\nu \Delta x, t) \), we approximate (1.1a) by a general, consistent, two-sided, solvable, multi-level basic scheme of the form
Here, the \( nxn \) matrices \( A_{j\sigma} \) are polynomials in \( A \) and \( \Delta t B \), and the \( n \)-vectors \( b_\nu(t) \) depend smoothly on \( f(x, t) \) and its derivatives.

The equations in (1.4a) have a unique solution if we provide initial values

\[
T^{-1}v_\nu(t + \Delta t) = \sum_{\sigma=0}^{s} T_\sigma v_\nu(t - \sigma \Delta t) + \Delta t d_\nu(t),
\]

where in addition we must specify, at each time step \( t = \mu \Delta t, \mu = s, s + 1, \ldots, \)
boundary values \( v_\nu(t + \Delta t), \nu = 0, \ldots, r - 1. \) As in [3], these boundary values
will be determined by two sets of boundary conditions, the first of which is
obtained by taking the last \( n - l \) components of general boundary conditions of
the form

\[
T^{-1}v_\nu(t + \Delta t) = \sum_{\sigma=0}^{q} T_\sigma v_\nu(t - \sigma \Delta t) + \Delta t d_\nu(t),
\]

where the matrices \( C_{j\sigma} \) are polynomials in \( A \) and \( \Delta t B \), the \( C_{j(-1)} \) are nonsingular,
and the \( n \)-vectors \( d_\nu(t) \) are functions of \( f(x, t) \) and its derivatives.

If we put

\[
C_{j\sigma} = \begin{bmatrix} C_{j\sigma}^I & C_{j\sigma}^{II} \\ C_{j\sigma}^{II} & C_{j\sigma}^{III} \end{bmatrix}, \quad v_\nu = \begin{bmatrix} v_\nu^I \\ v_\nu^{II} \end{bmatrix}, \quad d_\nu = \begin{bmatrix} d_\nu^I \\ d_\nu^{II} \end{bmatrix}
\]
in accordance with the partition of \( A \) and \( u \) in (1.2), (1.3), then this set of condi-
tions takes the explicit form
We call such boundary conditions transatory since they are determined at all boundary points by the same coefficients.

For the second set of boundary conditions we use the analytic condition

\[ \mathbf{v}(t + \Delta t) = S \mathbf{v}(t + \Delta t) + \mathbf{g}(t + \Delta t), \tag{1.4d} \]

together with \( r - 1 \) additional conditions (not necessarily transatory) of the form

\[ \mathbf{v}(t + \Delta t) = \sum_{j=1}^{k} \left[ D^I_j \mathbf{v}(t + \Delta t) + D^II_j \mathbf{v}(t + \Delta t) \right] + \Delta t \mathbf{e}(t), \tag{1.4e} \]

where the matrices \( D^I_j \) and \( D^II_j \) -- of orders \( l \times l \) and \( l \times (n - l) \) respectively -- are polynomials in the blocks \( A^a \) and \( \Delta t B^{a\beta} \), \( a, \beta = I, II \), of the matching partitions

\[ A = \begin{pmatrix} A^I & 0 \\ 0 & A^II \end{pmatrix}, \quad \Delta t B = \begin{pmatrix} B^{I I} & B^{II} \\ B^{II I} & B^{III} \end{pmatrix}. \]

so that the \( D^I_j \) vanish whenever \( B \) does; and the \( l \)-vectors \( \mathbf{e}(t) \) are functions of \( \mathbf{f}(x, t), \mathbf{g}(t), \) and their derivatives.

It has been shown in \([3]\) that equations (1.4c, d, e) can be solved uniquely for the required boundary values \( \mathbf{v}(t + \Delta t), \mathbf{v} = 0, \ldots, r - 1 \), in terms of neighboring values of \( \mathbf{v} \), at least for sufficiently small \( \Delta t \); and that boundary conditions of the form (1.4e) can be constructed to any degree of accuracy. A concrete example of second order accurate boundary conditions of the form (1.4e),
for the special case $B = f = 0$, was given in [2].

The difference approximation is completely defined now by (1.4); so assuming that the basic scheme is stable for the pure Cauchy problem $(-\infty < \nu < \infty)$, we may ask whether the entire approximation is stable. More precisely, we make from now on the same assumptions about approximation (1.4) as in [5], so that the stability theory of Gustafsson, Kreiss and Sundström holds, and raise the above stability question in the sense of Definition 3.3 of [5].

As in [3], the first step will be to reduce our stability question to that of a scalar, outflow approximation with homogeneous translatory boundary conditions. This reduction is obtained by applying (1.4a, b, c) to the scalar outflow problem

$$u_t = au_x, \quad a = \text{constant} > 0, \quad x > 0, \quad t \geq 0 \quad (1.5)$$

(which requires no analytic boundary conditions). In other words, we set

$$A^I = B = f = 0, \quad A^H = a = \text{constant} > 0;$$

so that (1.1a) yields (1.5); and (1.4a, b, c) reduces to a self-contained, scalar, homogeneous approximation which consists of the basic scheme

$$Q_{-1}v_\nu(t + \Delta t) = \sum_{\sigma = 0}^s Q_\sigma v_\nu(t - \sigma \Delta t), \quad \nu = \tau, \tau + 1, \ldots, \quad (1.6a)$$

$$Q_\sigma = \sum_{t = -\tau}^{\tau} a_{j,t} E^i, \quad \sigma = -1, \ldots, s;$$

with initial values

$$v_\nu(0) = v_0^\nu(0), \quad \sigma = 0, \ldots, s, \quad \nu = 0, 1, 2, \ldots; \quad (1.6b)$$

and translatory outflow boundary conditions.
\[
T_{-1} v_\nu(t + \Delta t) = \sum_{\sigma=0}^{q} T_{\sigma} v_\nu(t - \sigma \Delta t), \quad \nu = 0, \ldots, r - 1.
\]

(1.6c)

where the scalars \( a_\sigma \) and \( c_{j\sigma} \) are polynomials in \( a \), and the basic scheme (1.6a) is consistent with (1.5).

We are now ready to use our main result in Section 2 of [3], which we reformulate as follows:

THEOREM 1.1 (Theorem 2.1, [3]). Approximation (1.4) is stable if and only if its reduced form in (1.6) is stable.

In other words, we have that approximation (1.4) is stable if and only if the scalar outflow components of its principal part are stable.

The above reduction theorem implies that from now on we may restrict our stability study to the scalar outflow approximation (1.6). Hence, we conclude this section by stating the following five assumptions which will hold throughout the paper, and guarantee the validity of the Gustafsson-Kreiss-Sundström theory [5] for approximation (1.6).

Assumption 1.1 (Assumption 3.1, [5]; Assumption 2.1, [3]). Approximation (1.6) is boundedly solvable; i.e., there exists a constant \( K > 0 \) such that for each \( y \in l_2(\Delta x) \) there is a unique solution \( w \in l_2(\Delta x) \) to the equations

\[
Q_{-1} w_\nu = y_\nu, \quad \nu = r, r + 1, \ldots,
\]

\[
T_{-1} w_\nu = y_\nu, \quad \nu = 0, \ldots, r - 1,
\]

with \( \|w\| \leq K \|y\| \); where \( Q_{-1} \) and \( T_{-1} \) are defined in (1.6a, c), and \( l_2(\Delta x) \) is the space of all grid functions \( w = \{w_\nu\}_{\nu=0}^{\infty} \) with \( \|w\|^2 = \Delta x \sum_{\nu=0}^{\infty} |w_\nu|^2 < \infty \).

Assumption 1.2 (Assumption 5.1, [5]; Assumption 2.2, [3]). The basic scheme is stable for the pure Cauchy problem \( -\infty < \nu < \infty \). That is, if we define
the basic characteristic function by

\[ P(z, \kappa) = \sum_{j=-r}^{p} a_j(z) \kappa^j \]  

(1.7)

where

\[ a_j(z) = a_j(-1) - \sum_{\sigma=0}^{q_j} z^{-\sigma-1} a_{j\sigma}, \quad j = -r, \ldots, p. \]  

(1.8)

then we have:

(i) The von Neumann condition; i.e., the solutions \( z(\kappa) \) of the basic characteristic equation

\[ P(z, \kappa) = 0 \]  

(1.9)

satisfy

\[ |z(\kappa)| \leq 1 \quad \text{for all } \kappa \text{ with } |\kappa| = 1. \]

(ii) If |\kappa| = 1, and if \( z(\kappa) \) is a root of (1.9) with |\( z(\kappa) \)| = 1, then \( z(\kappa) \) is a simple root of (1.9).

Assumption 1.3 (see Assumption 5.4 together with Definition 10.1, [5]; compare Osher [10]). The basic scheme (1.6a) belongs to the family of schemes for which the Gustafsson-Kreiss-Sundström theory in [5] holds. This family contains in particular the following two classes:

(i) Dissipative basic schemes; i.e., schemes for which the roots \( z(\kappa) \) of (1.9) satisfy

\[ |z(\kappa)| < 1 \quad \text{for all } \kappa \text{ with } |\kappa| = 1, \kappa \neq 1. \]  

(1.10)

(ii) Unitary basic schemes (also known as strictly nondissipative schemes) where the roots of (1.9) satisfy

\[ |z(\kappa)| = 1 \quad \text{for all } |\kappa| = 1. \]  

(1.11)

Obviously, if the basic scheme belongs to any of these two classes, then it satisfies the von Neumann condition in Assumption 1.2 (i).
Assumption 1.4 (Assumption 5.5, [5]; Assumption 2.4, [3]).

\[ a_r(z), \ a_p(z) \neq 0 \quad \text{for all } |z| \geq 1. \]

Assumption 1.5. We assume that

\[ \sum_{j=0}^{m} |c_j(z)| \neq 0 \quad \text{for all } |z| \geq 1 \]

where, in analogy with (1.8),

\[ c_j(z) = c_j(-1) - \sum_{c=0}^{g} z^{-c-1} c_j z, \quad j = 0, \ldots, m. \] (1.12)

Assumption 1.5 is necessary for stability, as shown in Remark 3.4 below. This last assumption -- which should have been included in [3] as well -- is easily verified for all practical boundary conditions.

2. Statement of Results and Examples.

In order to state our main stability criteria we define, in complete analogy with (1.7), the boundary characteristic function

\[ R(z, \kappa) = \sum_{j=0}^{m} c_j(z) \kappa^j \]

where the \( c_j(z) \) are given in (1.12). Defining the function

\[ \Omega(z, \kappa) = |P(z, \kappa)| + |R(z, \kappa)| \]

we shall prove in Section 3:

THEOREM 2.1 (1st Main Theorem). Approximation (1.8) is stable if

\[ \Omega(z, \kappa) \neq 0 \quad \text{for all } |z| \geq 1, \ 0 < |\kappa| \leq 1, \ (z, \kappa) \neq (1, 1). \] (2.1)

Next, let us divide the \( (z, \kappa) \) domain in (2.1) into three disjoint parts and restate Theorem 2.1 as follows:
THEOREM 2.1'. (1st Main Theorem revisited) \textit{Approximation} (1.6) is \textit{stable} if
\begin{align}
&\Omega(z, \kappa) \neq 0 \text{ for all } |z| \geq 1, |\kappa| = 1, \kappa \neq 1; \\
&\Omega(z, \kappa = 1) \neq 0 \text{ for all } |z| \geq 1, z \neq 1; \\
&\Omega(z, \kappa) \neq 0 \text{ for all } |z| \geq 1, 0 < |\kappa| < 1. 
\end{align}

The advantage of this setting is explained by Theorem 2.2 in which we provide useful sufficient conditions for each of the three inequalities in (2.2) to hold. Before stating this theorem, however, we need the following definitions:

\textit{Definition 2.1.} The boundary conditions (1.6c) are said to be \textit{dissipative} if the roots $z(\kappa)$ of the \textit{boundary characteristic equation}
\begin{equation}
R(z, \kappa) = 0
\end{equation}
satisfy
\begin{align}
|z(\kappa)| < 1 \text{ for all } |\kappa| \leq 1, \kappa \neq 1.
\end{align}

\textit{Definition 2.2.} We say that the boundary conditions (1.6c) satisfy the von Neumann condition if the roots $z(\kappa)$ of (2.3) satisfy
\begin{align}
|z(\kappa)| \leq 1 \text{ for all } |\kappa| = 1.
\end{align}

\textit{Definition 2.3.} The boundary conditions (1.6c) are called \textit{boundedly solvable} if there exists a constant $K > 0$ so that for each $y \in l_2(\Delta x)$ there is a unique solution $w \in l_2(\Delta x)$ to
\begin{equation}
T_{-1} w_\nu = y_\nu, \quad \nu = 0, 1, 2, \ldots,
\end{equation}
with $\|w\| \leq K \|y\|$.

Evidently, these definitions are analogous to those made for the basic scheme in Assumptions 1.3(i), 1.2(i) and 1.1, respectively; and again, dissipativity implies the von Neumann condition.
Having these definitions we shall prove:

**THEOREM 2.2 (2nd Main Theorem).**

(i) If either the basic scheme or the boundary conditions are dissipative, then (2.2a) holds.

(ii) Inequality (2.2b) is satisfied if any one of the following holds:

(a) The basic scheme is two-level.

(b) The basic scheme is three-level and

\[ \Omega(z = -1, \kappa = 1) \neq 0. \tag{2.5} \]

(c) The boundary conditions are two-level and at least of zero order of accuracy.

(d) The boundary conditions are three-level, at least zero order accurate, and (2.5) is satisfied.

(iii) If the boundary conditions satisfy the von Neumann condition and are boundedly solvable, then (2.2c) holds.

The proofs of Theorems 2.1 and 2.2 will be given in Section 3.

We turn now to examples. Before doing so, however, let us recall one more result which provides a useful sufficient condition for the boundary conditions to be boundedly solvable.

**LEMMA 2.1 (Lemma 3.2, [3]).**

(i) The boundary conditions (1.6c) are boundedly solvable if and only if

\[ T_{-1}(\kappa) = \sum_{j=0}^{\infty} c_{j(-1)} \kappa^j \neq 0 \quad \text{for all} \quad 0 < |\kappa| \leq 1. \tag{2.6} \]

(ii) In particular, explicit boundary conditions are always boundedly solvable.

This result is associated with important observations on solvability by Osher [11].
We remark that part (i) of Lemma 3.2 in [3] merely states that if (2.6) holds, then the boundary conditions are boundedly solvable. Following the proof of Lemma 3.2 in [3], however, one realizes without difficulty that in fact, (2.6) is both sufficient and necessary for the bounded solvability of the boundary conditions (1.6c), as stated above.

**Example 2.1** ([3, Example 3.5]; compare the special cases in [5, Theorems 6.1, 6.2 and 6.3], [13, (3.2)], and [2, Example 2]). Let the basic scheme (1.6a) be arbitrary (dissipative or not), and let the boundary conditions (1.6c) be generated by the right-sided, first order accurate, explicit Euler scheme:

\[ v_{\nu}(t + \Delta t) = v_{\nu}(t) + \lambda a[v_{\nu+1}(t) - v_{\nu}(t)], \quad 0 < \lambda a < 1, \quad \nu = 0,\ldots,r - 1. \]

These two-level boundary conditions are known to be dissipative (see Example 3.5, [3]), hence Theorem 2.2(i)(iiic) implies (2.2a, b). Since the boundary conditions are explicit, then by Lemma 2.1 they are solvable; and since they are dissipative, the von Neumann condition is satisfied. Consequently, Theorem 2.2(iii) yields (2.2c), and stability is established by Theorem 2.1''.

It is a trivial matter to verify that for this, as well as for all the following examples, Assumption 1.5 is fulfilled.

**Example 2.2** ([3, Example 3.6]; compare the special cases [13, (3.3)], and [2, Example 3]). Take an arbitrary basic scheme, and determine the boundary condition by the right-sided, first order accurate, implicit Euler scheme:

\[ v_{\nu}(t + \Delta t) - \lambda a[v_{\nu+1}(t + \Delta t) - v_{\nu}(t + \Delta t)] = v_{\nu}(t), \quad \lambda a > 0, \quad \nu = 0,\ldots,r - 1. \]

As in the previous example, the boundary conditions are two-level and dissipative (e.g. Example 3.6, [3]), so Theorem 2.2(i)(iiic) gives (2.2a, b). The dissipativity of the boundary conditions also implies the von Neumann condition. And it is trivially verified (Example 3.6 [3] again) that \( T_{-1}(\kappa) \neq 0 \) for \( |\kappa| \leq 1 \) (where \( T_{-1}(\kappa) \) is defined in (2.6)), so that Lemma 2.1(i) implies solvability. Thus, (2.2c)
follows from Theorem 2.2(iii); and Theorem 2.1' assures stability.

**Example 2.3** (Compare the special cases in [8, Theorem 6], [10, Section XXIII], [5, Theorems 6.1 and 6.3], [1], [6, Theorem 2.1], and [3, Example 3.1]).

Take an arbitrary two-level basic scheme, and define the boundary conditions by horizontal extrapolation of order $\omega - 1$:

$$v_\nu(t + \Delta t) = \sum_{j=1}^{\nu} \binom{\nu}{j}(-1)^{j+1}v_{\nu+j}(t + \Delta t), \quad \nu = 0, \ldots, \tau - 1. \quad (2.7)$$

We have

$$R(z, \kappa) = R(\kappa) = 1 - \sum_{j=1}^{\nu} \binom{\nu}{j}(-1)^{j+1}\kappa^j = (1 - \kappa)^\omega,$$

so $R(\kappa) \neq 0$ for $\kappa \neq 1$, which directly gives (2.2a, c). Moreover, since the basic scheme is two-level, Theorem 2.2(iiia) implies (2.2b); and Theorem 2.1' again proves stability.

It is interesting to note that the above result may fail, both for dissipative and nondissipative basic schemes, if the basic scheme is of more than two time-levels. A nondissipative counterexample was given by Gustafsson et al. in Theorem 6.2 of [5] (see also [6]) who showed that the unitary, 3-level Leap-Frog scheme

$$v_\nu(t + \Delta t) = v_\nu(t - \Delta t) + \lambda\alpha[v_{\nu+1}(t) - v_{\nu-1}(t)] \quad \nu = 1, 2, 3, \ldots, \quad (2.8)$$

provides an unstable approximation in combination with the linear boundary extrapolation ((2.7) with $\omega = 2$):

$$v_0(t + \Delta t) = 2v_1(t + \Delta t) - v_2(t + \Delta t).$$

We proved instability ([3], (3.6)) for the case where the basic scheme is the 3-level, 5-point, dissipative version of (2.8):
\[ v_\nu(t + \Delta t) = \left[ I - \frac{\epsilon}{16}(E - I)^2(I - E^{-1})^2 \right] v_\nu(t - \Delta t) + \lambda \alpha (E - E^{-1}) v_\nu(t), \]

\[ 0 < \epsilon < 1, \quad 0 < \lambda \alpha \leq 1 - \epsilon, \quad \nu = 2, 3, \ldots, \]

and the boundary conditions are given by (2.7) with \( \nu = 0, 1. \)

**Example 2.4** ([3, Example 3.2]; compare the special cases in [2, Example 1] and [6, Theorem 2.2]). Let the basic scheme be dissipative, and determine the boundary conditions by oblique extrapolation of order \( \omega - 1 \):

\[ v_\nu(t + \Delta t) = \sum_{j=1}^{\infty} \binom{\omega}{j} (-1)^{j+1} v_{\nu+j}[t - (j - 1)\Delta t], \quad \nu = 0, \ldots, \tau - 1. \quad (2.9) \]

Since the basic scheme is dissipative, then Theorem 2.2(i) implies (2.2a). Furthermore, the boundary characteristic function for (2.9) is

\[ R(z, \kappa) = 1 - \sum_{j=1}^{\infty} \binom{\omega}{j} (-1)^{j+1} z^{-j} \kappa^j = (1 - z^{-1} \kappa)\nu, \]

hence

\[ \Omega(z, \kappa) \geq |R(z, \kappa)| \neq 0, \quad z \neq \kappa. \quad (2.10) \]

This yields (2.2b, c); and Theorem 2.1' implies stability.

**Example 2.5** ([3, Example 3.3]; compare the special cases [5, Theorem 6.1], [12, (3.4)], and [2, Example 4]). Take any dissipative basic scheme, and let the boundary conditions be generated by the second order accurate Box-Scheme:

\[ v_\nu(t + \Delta t) + v_{\nu+1}(t + \Delta t) - \lambda \alpha [v_{\nu+1}(t + \Delta t) - v_\nu(t + \Delta t)] \]

\[ = v_\nu(t) + v_{\nu+1}(t) + \lambda \alpha [v_{\nu+1}(t) - v_\nu(t)], \quad \nu = 0, \ldots, \tau - 1. \]

As in the previous example, dissipativity implies (2.2a); and Theorem 2.2(iic) implies (2.2b). Next, we recall Example 3.3 of [3] where it was shown without difficulty that the roots \( z(\kappa) \) of the boundary characteristic function satisfy \( |z(\kappa)| = 1 \) for \( |\kappa| = 1 \), and that \( T_{-1}(\kappa) \neq 0 \) for \( |\kappa| \leq 1 \). Thus, the boundary con-
ditions satisfy the von Neumann condition; and Lemma 2.1(i) implies solvability. With this, Theorem 2.2(iii) gives (2.2c), and by Theorem 2.1' stability follows.

**Example 2.6** ([3, Example 3.4]; compare the special case in [13, (6.2b)]).

Take any dissipative basic scheme, and define the boundary conditions by the right-sided, 3-level, weighted Euler scheme:

\[
u(t + \Delta t) = \nu(t - \Delta t) + \lambda \alpha [2\nu_{v+1}(t) - \nu_v(t + \Delta t) - \nu_v(t - \Delta t)],
\]

\[
0 < \lambda \alpha \leq 1, \quad \nu = 0, \ldots, r - 1.
\]

As in the two previous examples, Theorem 2.2(i) implies (2.2a). Further, we have

\[
R(z, \kappa) = 1 - z^{-2} - \lambda \alpha (2Rz^{-1} - 1 - z^{-2});
\]

so

\[
|\Omega(z = -1, \kappa = 1) \geq |R(z = -1, \kappa = 1)| = 4\lambda \alpha > 0,
\]

and Theorem 2.2(iid) yields (2.2b). Next, as in Example 3.4 of [3], we find that the roots of \( R(z, \kappa) \) satisfy

\[
\xi(\kappa = e^{i\xi}) = e^{i\xi} \frac{\lambda \alpha \pm b(\xi)}{\lambda \alpha + 1}, \quad b(\xi) = \sqrt{\left(\lambda \alpha\right)^2 + e^{-2i\xi}\left[1 - (\lambda \alpha)^2\right]};
\]

and since \( 0 < \lambda \alpha \leq 1 \), then \( |b(\xi)| \leq 1 \) for \( |\xi| \leq \pi \); therefore

\[
|\xi(\kappa = e^{i\xi})| \leq \frac{\lambda \alpha + |b(\xi)|}{\lambda \alpha + 1} \leq 1, \quad |\xi| \leq \pi,
\]

so the von Neumann condition holds. By Lemma 2.1(ii) we also have solvability. Hence Theorem 2.2(iii) yields (2.2c); and Theorem 2.1' assures stability.

**Example 2.7.** Let us keep the boundary conditions in (2.11), and extend the result of Example 2.6 to nondissipative basic schemes whose characteristic functions satisfy

\[
P(z = -1, \kappa = -1) \neq 0.
\]

Evidently, we obtain (2.2b, c) precisely as for the previous example. In order to
prove (2.2a) we set $\rho = (\lambda \alpha)^2$ and observe that $b(\xi)$ in (2.12) satisfies for $0 < |\xi| < \pi$,

$$|b(\xi)|^2 = \rho^2 + (1 - \rho)^2 + 2\rho(1 - \rho) \cos 2\xi < \rho^2 + (1 - \rho)^2 + 2\rho(1 - \rho) = 1.$$  

Thus, by (2.12),

$$|z(\kappa = e^{it})| = \left| \frac{\lambda \alpha + |b(\xi)|}{\lambda \alpha + 1} \right| < 1, \quad 0 < |\xi| < \pi;$$

or in other words

$$R(z, \kappa) \neq 0, \quad |z| \geq 1, \quad |\kappa| = 1, \quad \kappa \neq \pm 1.$$  

(2.14)

By (2.12) again,

$$z(\kappa = -1) = -\frac{\lambda \alpha \pm 1}{\lambda \alpha + 1};$$

hence one root is $z(\kappa = -1) = -1$ and the other satisfies $|z(\kappa = -1)| < 1$; so

$$R(z, \kappa = -1) \neq 0, \quad |z| \geq 1, \quad z \neq -1.$$  

(2.15)

Collecting (2.13) - (2.15) we find therefore that

$$\Omega(z, \kappa) = |P(z, \kappa)| + |R(z, \kappa)| \neq 0, \quad |z| \geq 1, \quad |\kappa| = 1, \quad \kappa \neq 1.$$  

Thus, (2.2a) is established, and Theorem 2.1' implies stability.

We remark that certain well known nondissipative basic schemes satisfy (2.13). This includes, for example, the unitary Crank-Nicolson scheme

$$v_\nu(t + \Delta t) - \frac{\lambda \alpha}{4}[v_{\nu+1}(t + \Delta t) - v_{\nu-1}(t + \Delta t)]$$  

$$= v_\nu(t) + \frac{\lambda \alpha}{4}[v_{\nu+1}(t) - v_{\nu-1}(t)], \quad \nu = 1, 2, 3, \ldots;$$  

(2.16)

and the almost-dissipative* backward Euler scheme

\*We call a basic scheme almost dissipative if (1.10) holds, except for a finite number of $\kappa$, $|\kappa| = 1$. 

\[ v_\nu(t + \Delta t) - \frac{\lambda \alpha}{2} [v_{\nu+1}(t + \Delta t) - v_{\nu-1}(t + \Delta t)] = v_\nu(t). \quad (2.17) \]

\[ \nu = \tau, \tau + 1, \ldots, \]

which is included in the family of schemes for which the Gustafsson-Kreiss-Sundström theory holds.

If we consider, however, the almost-dissipative Lax-Friedrichs scheme

\[ v_\nu(t + \Delta t) = \frac{1}{2} [v_{\nu+1}(t) + v_{\nu-1}(t)] + \frac{\lambda \alpha}{2} [v_{\nu+1}(t) - v_{\nu-1}(t)]. \]

\[ 0 < \lambda \alpha < 1, \quad \nu = 1, 2, 3, \ldots \]

(which is also admitted by the Gustafsson-Kreiss-Sundström theory; e.g. Osher [10]), we find that \( P(z = -1, \kappa = -1) = 0 \), i.e., (2.13) fails. Indeed, it can be shown that this scheme together with the boundary conditions in (2.11) provides an unstable approximation.

**Example 2.8** ([15, Section 3]; compare [16, Example 6.2]). Take any two-level basic scheme, and determine the boundary conditions by the right-sided, two-step Euler scheme:

\[ v_\nu(t + \Delta t) = v_\nu(t - \Delta t) + 2\lambda \alpha [v_{\nu+1}(t - \Delta t) - v_\nu(t - \Delta t)]. \]

\[ 0 < \lambda \alpha < 1/2, \quad \nu = 0, \ldots, \tau - 1. \]

Then,

\[ R(z, \kappa) = 1 - z^{-\alpha}[1 + 2\lambda \alpha (\kappa - 1)]. \]

so the roots \( z(\kappa) \) of \( R(z, \kappa) \) satisfy

\[ |z(\kappa = e^{i\xi})|^4 = 1 + 2\lambda \alpha (2\lambda \alpha - 1)(1 - \cos \xi) < 1, \quad 0 < |\xi| \leq \pi. \]

That is, our explicit boundary conditions are dissipative and satisfy the von Neumann condition. Hence, by Lemma 2.1(ii) and Theorem 2.2 we obtain (2.2), and
Theorem 2.1' assures stability.

**Example 2.9** (in [5, Theorem 6.3] and [6, Theorem 2.2]). Consider the unitary, unconditionally stable Crank-Nicolson scheme in (2.16), with oblique extrapolation at the boundary:

\[
v_0(t + \Delta t) = \sum_{j=1}^{\infty} (\frac{\alpha}{j})(-1)^{j+1}v_j[t - (j - 1)\Delta t]
\]  

(2.18)
as in (2.9). Since we have (2.10), then in order to comply with the assumptions of Theorem 2.1 it remains to show that

\[
\Omega(z, \kappa) = |P(z, \kappa)| + |R(z, \kappa)| \neq 0, \quad z = \kappa, \quad |\kappa| = 1, \quad \kappa \neq 1;
\]

so it suffices to prove that

\[
P(z, \kappa) \equiv 1 - \frac{\lambda \alpha}{2} (\kappa - \kappa^{-1}) - z^{-1}[1 + \frac{\lambda \alpha}{2} (\kappa - \kappa^{-1})] \neq 0.
\]

(2.19)

Indeed,

\[
P(z = e^{it}, \kappa = e^{it}) = 1 - \cos \xi + \frac{\lambda \alpha}{2} (\cos^2 \xi - \cos \xi - 1) + i \sin \xi (1 - \frac{\lambda \alpha}{2} \cos \xi),
\]

so observing that the real and imaginary parts do not vanish simultaneously, we immediately obtain (2.19), and stability follows.

**Example 2.10** (in [6, Theorem 2.2]). Take the almost-dissipative, unconditionally stable backward Euler scheme in (2.17) with the oblique boundary extrapolation in (2.18). As in the previous example, in order to prove stability via Theorem 2.1 it is sufficient to show that

\[
P(z, \kappa) \equiv 1 - \frac{\lambda \alpha}{2} (\kappa - \kappa^{-1}) - z^{-1} \neq 0, \quad z = \kappa = e^{it}, \quad 0 < |\xi| \leq \pi.
\]

(2.20)

Since

\[
P(z = e^{it}, \kappa = e^{it}) = 1 - \lambda \alpha \cos \xi - \cos \xi + i \sin \xi,
\]
then, comparing the real and imaginary parts again, we get (2.20), and stability is established.

At the end of Section 3 we make several remarks concerning these examples.

In order to prove Theorems 2.1 and 2.2 we begin by considering the basic characteristic function $P(z, \kappa)$ in (1.7). By Assumption 1.4, for each $z$ with $|z| \geq 1$, $P(z, \kappa)$ has $r + p$ roots $\kappa(z)$. These roots, which play a major role in the stability analysis of approximation (1.6), have the following separation property:

**Lemma 3.1 ([3], Lemma 4.3; compare Lemmas 5.1 and 5.2, [5]).** For $|z| > 1$, the basic characteristic function $P(z, \kappa)$ has precisely $r$ roots $\kappa(z)$ with $0 < |\kappa(z)| < 1$, $p$ roots with $|\kappa(z)| > 1$, and no roots with $|\kappa(z)| = 1$.

According to this lemma, the roots $\kappa(z)$ of $P(z, \kappa)$ split for $|z| > 1$ into two groups: $r$ inner roots satisfying $|\kappa(z)| < 1$, and $p$ outer roots with $|\kappa(z)| > 1$.

Using Assumption 1.4 and a continuity argument, we see that these groups of inner and outer roots remain well defined for $|z| \geq 1$ as well, where milder inequalities, $|\kappa(z)| \leq 1$ and $|\kappa(z)| \geq 1$ hold, respectively. Since by Assumption 1.4, $\kappa = 0$ is not a root of $P(z, \kappa)$ for $|z| \geq 1$, we obtain

**Lemma 3.2 ([3], Lemma 4.3).** For $|z| \geq 1$, the $r + p$ roots $\kappa(z)$ of the basic characteristic function $P(z, \kappa)$ split into $r$ inner roots with $0 < |\kappa(z)| \leq 1$, and $p$ outer roots with $|\kappa(z)| \geq 1$.

We can now quote our main preliminary stability criterion in [3]:

**Theorem 3.1 ([3], Theorem 4.2).** Approximation (1.6) is stable if and only if for every $z$ with $|z| \geq 1$ and all corresponding inner roots $\kappa(z)$, the boundary
characteristic function $R(z, \kappa)$ satisfies

$$R(z, \kappa(z)) \neq 0. \quad (3.1)$$

If $\kappa(z)$ is an inner root for $z$, $|z| \geq 1$, then by definition,

$$P(z, \kappa(z)) = 0.$$

Thus, combining this fact with (3.1), we immediately obtain,

**COROLLARY 3.1.** Approximation (1.6) is stable if and only if for every $z$ with $|z| \geq 1$ and all corresponding inner roots $\kappa(z)$,

$$\Delta(z, \kappa(z)) = |P(z, \kappa(z))| + |R(z, \kappa(z))| \neq 0. \quad (3.2)$$

We shall need yet another result which describes the behavior of the inner roots for $z = 1$:

**LEMMA 3.3 ([3], Lemma 5.1).** If $z = 1$, then $\kappa = 1$ is not an inner root of $P(z, \kappa)$.

This brings us to

**Proof of Theorem 2.1.** Take any $z$, $|z| \geq 1$, and let $\kappa(z)$ be a corresponding inner root. If $z \neq 1$, then by Lemma 3.2, we have $0 < |\kappa(z)| \leq 1$; so the hypothesis in (2.1) implies (3.2). If on the other hand, $z = 1$, then by Lemma 3.3, $\kappa(z) = 1$ is excluded as an inner root; so by Lemma 3.2 we have $0 < |\kappa(z)| \leq 1$, $\kappa(z) \neq 1$, and again (2.1) yields (3.2). By Corollary 3.1 therefore, approximation 1.6 is stable, and the proof is complete.

**Proof of Theorem 2.2.** (i) If either the basic scheme or the boundary conditions are dissipative, then by Assumption 1.3(i) and Definition 2.1, either

$$P(z, \kappa) \neq 0, \quad |z| \geq 1, \quad |\kappa| = 1, \quad \kappa \neq 1,$$

or

$$R(z, \kappa) \neq 0, \quad |z| \geq 1, \quad |\kappa| = 1, \quad \kappa \neq 1;$$
and (2.2a) follows.

(iia) Since the boundary scheme is consistent with (1.5), it is at least first order accurate; so, in particular, it satisfies the ordinary zero order accuracy condition

\[ \sum_{j=-r}^{r} a_{j(-1)} \sigma_{0} = \sum_{j=-r}^{r} a_{j(0)} \]

which we equivalently write as

\[ P(z = 1, \kappa = 1) = 0. \] (3.3)

By assumption, the basic scheme is two-level, so the function \( P(z, \kappa = 1) \) is a first degree polynomial in \( z^{-1} \) which, by (3.3), has a unique root \( z^{-1} = 1 \). Thus,

\[ P(z, \kappa = 1) \neq 0, \quad |z| \geq 1, \quad z \neq 1, \]

and we obtain (2.2b).

(iib) In the 3-level case we still have (3.3), but now \( P(z, \kappa = 1) \) is a second degree polynomial in \( z^{-1} \) with real coefficients. By (3.3), \( z^{-1} = 1 \) is one of the roots, so the other root must be real as well; thus

\[ P(z, \kappa = 1) \neq 0, \quad |z| = 1, \quad z \neq \pm 1. \] (3.4)

In addition, since the basic scheme satisfies the von Neumann condition (Assumption 1.2(i)), then

\[ P(z, \kappa = 1) \neq 0, \quad |z| > 1. \] (3.5)

By (3.4) and (3.5) therefore,

\[ \Omega(z, \kappa = 1) \neq 0, \quad |z| \geq 1, \quad z \neq \pm 1, \] (3.6)

which together with the assumption in (2.5) gives us (2.2b).

The proof of (iic) is identical to that of (iia), except that \( P(z, \kappa) \) is replaced by \( R(z, \kappa) \), where by the zero order accuracy of the boundary conditions, we have \( R(z = 1, \kappa = 1) = 0 \) instead of (3.3).
For the proof of (iid) we still have (3.5); and since the boundary conditions are three-level we may replace (3.4) by

\[ R(z, \kappa = 1) \neq 0, \quad |z| = 1, \quad z \neq \pm 1. \]  \hspace{1cm} (3.7)

By (3.5) and (3.7) we obtain (3.6) again, which together with (2.5) yields (iid).

(iii) Since the function \( z^{q+1} R(z, \kappa) \) is a polynomial in \( z \) and \( \kappa \), it can be written as

\[ z^{q+1} R(z, \kappa) = (z - z_1)(z - z_d) R_0(z, \kappa) \]  \hspace{1cm} (3.8)

where \( R_0(z, \kappa) \) is a polynomial in \( \kappa \) whose leading coefficient is 1 and whose other coefficients are rational functions of \( z \). By Assumption 1.5, the boundary characteristic function

\[ R(z, \kappa) = \sum_{j=0}^{m} c_j(z) \kappa^j \]

is not the zero polynomial in \( \kappa \) for any (fixed) \( z \) with \( |z| \geq 1 \). Thus, the \( z_j \) in (3.8) must satisfy

\[ |z_j| < 1, \quad j = 1, \ldots, d. \]

It follows that the leading coefficient of \( z^{q+1} R(z, \kappa) \) in (3.8) is uniformly bounded away from zero for all \( |z| \geq 1 \). Hence, the roots \( \kappa = \kappa(z) \) of \( R_0(z, \kappa) \), and therefore those of \( R(z, \kappa) \), are continuous functions of \( z \) for \( |z| \geq 1 \).

Since the boundary conditions are assumed to be boundedly solvable, then by Lemma 2.1(i) we have

\[ T_{-1}(\kappa) = \sum_{j=0}^{d} c_{j(-1)} \kappa^j \neq 0, \quad 0 < |\kappa| \leq 1. \]  \hspace{1cm} (3.9a)

Moreover, by (1.6c)

\[ T_{-1}(0) = c_{0(-1)} \neq 0. \]  \hspace{1cm} (3.9b)

So, combining (3.9a, b) we obtain
Since by hypothesis, the boundary conditions also satisfy the von Neumann condition, then for $|z| > 1$, the function $R(z, \kappa)$ does not vanish on the unit circle $|\kappa| = 1$. Hence, by the continuity established above, the number of roots $\kappa = \kappa(z)$ of $R(z, \kappa)$ satisfying $|\kappa(z)| \leq 1$, is independent of $z$, $|z| > 1$, and it thus equals the number of roots $\kappa$, $|\kappa| \leq 1$, of the function

$$R(z \rightarrow \infty, \kappa) = T_{-1}(\kappa).$$

By (3.10) therefore, $R(z, \kappa)$ has no roots $|\kappa| \leq 1$ for $|z| > 1$, so we have

$$R(z, \kappa) \neq 0, \quad |\kappa| \leq 1, \quad |z| > 1. \quad (3.11)$$

By (3.11), the roots $\kappa(z)$ of $R(z, \kappa)$ satisfy $|\kappa(z)| > 1$ if $|z| > 1$. So for $|z| \geq 1$, these continuous roots satisfy $|\kappa(z)| \geq 1$, i.e.,

$$R(z, \kappa) \neq 0, \quad |\kappa| < 1, \quad |z| \geq 1,$$

and (2.2c) follows.

In concluding the paper we make the following remarks:

**Remark 3.1.** Our main results in [3] follow immediately from the present ones. Indeed, consider Theorem 3.3 of [3] where we assume that the basic scheme is dissipative, that the boundary conditions are boundedly solvable and satisfy the von Neumann condition, and that

$$R(z, \kappa = 1) \neq 0, \quad |z| = 1, \quad z \neq 1. \quad (3.12)$$

With these assumptions, Theorem 2.2(i)(iii) gives (2.2a, c). Moreover, by Assumption 1.2(i) we have (3.5), which together with (3.12) yields (2.2b). Thus, Theorem 2.1' implies stability, and Theorem 3.3 of [3] follows.

In Theorem 3.4 of [3] it is assumed that the basic scheme is arbitrary, that the boundary conditions are boundedly solvable and dissipative, and that (3.12) holds. Again, Theorem 2.2(i)(iii) yields (2.2a, c), and (3.12) together with (3.5)
Theorems 3.1 and 3.2 in [3] follow from Theorem 2.1' and 2.2 with similar ease.

Remark 3.2. Examples 2.1-2.6 contain all the main examples in [3]. Example 2.3 (with a nondissipative basic scheme), and Examples 2.7-2.10, are new, however, in the sense that they could not have been handled by our old results in [3]. For examples 2.3, 2.7, 2.9 and 2.10 this is true since Theorems 3.1-3.4 in [3] all require that either the basic scheme or the boundary conditions be dissipative. For Example 2.8, where the basic scheme is not necessarily dissipative but the boundary conditions are, one may hope that Theorem 3.4 of [3] would help. But $R(z = -1, \kappa = 1) = 0$; so (3.7) in [3] is violated, and Theorem 3.4 of [3] fails.

Remark 3.3. Not all interesting cases are covered by our results. For instance, Gustafsson et al. showed in Theorem 6.1 of [5] that the Leap-Frog scheme in (2.8) together with the linear oblique boundary extrapolation

$$v_0(t + \Delta t) = 2v_1(t) - v_2(t - \Delta t),$$

provides a stable approximation. We easily find, however, that

$$\Omega(z = -1, \kappa = -1) = |P(z = -1, \kappa = -1)| + |R(z = -1, \kappa = -1)| = 0,$$

so (2.1) may not hold. Consequently, Theorem 2.1 fails for this example, showing that our criteria are sufficient but not necessary for stability.

Remark 3.4. Let us show that Assumption 1.5 is necessary for the stability of approximation (1.6). Indeed, if Assumption 1.5 fails, then at some $z = z_0$ with $|z_0| \geq 1$, all the $c_j(z)$ in (1.12) vanish simultaneously. Hence,

$$R(z = z_0, \kappa) = \sum_{j=0}^{N} c_j(z_0) \kappa^j = 0; \quad (3.13)$$

that is, $R(z = z_0, \kappa)$ is the zero polynomial in $\kappa$. By Lemma 3.2, for $z = z_0$, the
basic characteristic function $P(z, \kappa)$ has $r$ inner roots $\kappa(z_0)$ with $0 < |\kappa(z_0)| \leq 1$. For each of these roots (3.13) implies

$$R(z = z_0, \kappa = \kappa(z_0)) = 0,$$

and Theorem 3.1 assures instability.

For example, consider any dissipative basic scheme with boundary conditions determined by the two-level, zero order vertical extrapolation:

$$v_\nu(t + \Delta t) = v_\nu(t), \; \nu = 0, \ldots, r - 1.$$  \hfill (3.14)

Clearly, these explicit boundary conditions are boundedly solvable (Lemma 2.1), and they satisfy the von Neumann condition. Thus the hypotheses of Theorem 2.2 hold, and Theorem 2.1' should have implied stability. As mentioned in Section 4 of \cite{14}, however, the approximation is unstable. The reason for this instability is that the boundary conditions in (3.14) fail to satisfy Assumption 1.5, since

$$\sum_{j=0}^{m} |c_j(z)|_{z=1} = |1 - z^{-1}|_{z=1} = 0.$$  

This example, though found unstable in the sense of Definition 3.3 of \cite{5}, is stable in the $l_2$ sense described in \cite{14}.

**Remark** 3.5. It is known that the accuracy of the boundary conditions plays a decisive role in determining the overall rate of convergence of the difference approximation. In particular, Gustafsson \cite{4} has shown that if approximation (1.6) is stable and the basic scheme is accurate of order $\delta$, then an overall $\delta$ rate of convergence is assured, if the boundary conditions are of $\delta - 1$ order of accuracy at least.

If we use horizontal or oblique boundary extrapolation as in (2.7) or (2.9), then obviously there is no restriction on accuracy at the boundary. In general, however, the question of maximal possible accuracy for the boundary conditions
can be quite difficult if the boundary conditions are to satisfy certain properties. For instance, it is not hard to see that the various boundary conditions in the examples of Section 2 (with the exception of horizontal extrapolation), are all stable in the sense of the definition in Assumption 1.2, with \( P(z, \kappa) \) replaced by the characteristic boundary function \( R(z, \kappa) \). Thus, it seems natural to raise the question of maximal accuracy for stable boundary conditions of type (1.6c). This question was answered by Iserles and Strang [7, Theorems 1 and 2] who treated the two-level case and showed that stable explicit boundary conditions of type (1.6c) may not be more than second order accurate, while implicit conditions of this type can be constructed to arbitrary order of accuracy.

References

**Abstract**

New convenient stability criteria are provided in this paper for a large class of finite difference approximations to initial-boundary value problems associated with the hyperbolic system \( u_t = A u_x + B u + f \) in the quarter plane \( x \geq 0, t \geq 0 \). Using the new criteria, stability is easily established for numerous combinations of well known basic schemes and boundary conditions, thus generalizing many special cases studied in recent literature.
