Information Branch
1983
This investigation was sponsored by the Structures Directorate, U. S. Army Research and Technology Laboratories, Langley Research Center, Virginia, and administered by the National Aeronautics and Space Administration at Langley Research Center under Contract NAS1-14568. The Army technical representative for this contract was Wayne R. Mantay. Henry E. Jones was the technical representative during the initial period of the contract. The Principal Investigator was T. Alan Egolf, Research Engineer, United Technologies Research Center (UTRC). The Program Manager and Co-investigator was Anton J. Landgrebe, Manager, Aeromechanics Research, UTRC. Donna Edwards, Engineering Assistant, UTRC, contributed significantly to the development of the computer graphics used to provide the wake charts presented herein.

This report consists of two volumes:

Volume I - Generalized Wake Geometry and Wake Effect on Rotor Airloads and Performance

Volume II - Wake Geometry Charts
SUMMARY

Wake geometry charts and figures are presented which provide the necessary information to estimate the location of tip vortices trailed from helicopter rotor blades for a range of parameters representative of steady level forward flight. The charts are based on theoretical wake geometries from the classical undistorted wake equations and the generalized distorted wake equations described in Volume I. The charts can be used for a variety of applications which require the geometric relationship between the tip vortices and spatial locations relative to the helicopter. In addition to tip vortex geometry, the geometry related to blade/tip vortex interactions and wake boundaries beneath the rotor can be rapidly defined using these charts. An example application is included as an instructional tool for the use of the charts.

INTRODUCTION

The intent of this volume is to provide wake geometry data in the form of easily usable charts and figures which allow for the rapid estimation of the geometric position of the tip vortex of a specific rotor blade at any instant in time (blade azimuth). This information can then be used to determine the potential for rotor blade/tip vortex interactions and other spatial point/tip vortex interactions through comparison of the relative geometric position of the point of interest and the tip vortex position. These charts and figures provide this information based on both undistorted wake methodology and the generalized distorted tip vortex model developed and discussed in Volume I of this report. The charts and figures are presented progressing from the elementary to the more complex model. The charts consist of isometric and projection views of wake geometry, inflow ratio nomographs, undistorted axial displacement nomographs, undistorted, generalized longitudinal and lateral coordinate charts, generalized axial distortion nomographs, blade/vortex passage charts, blade/vortex intersection angle nomographs and fore and aft wake boundary charts. These charts and figures have been prepared as functions of the parameters found to be of primary interest in the first level wake generalization as described in Volume I of this report. The range of these parameters for most of the charts and figures is listed below.

\[ 0.0025 \leq C_T \leq 0.01 \]
\[ -16^\circ \leq \alpha_{TPP} \leq 4^\circ \]
\[ 0 \leq \mu \leq 0.5 \]
\[ 2 \leq b \leq 6 \]

The charts are presented in a format which allows for the rapid estimation of the geometric positions of the tip vortex. They were developed such that they require only a minimum amount of hand calculations to obtain the desired information. All coordinate values on the charts are normalized by the rotor radius and are in a right handed tip path plane coordinate system. This coordinate system is illustrated in Fig. 1. Figures 2 to 10 are presented as an introduction to the wake charts and their application. These figures illustrate the variety and use of the wake charts that have been developed by way of an example application.
Isometric and Projection View Plots

To provide for the fundamental understanding of the wake and its parametric variations and to provide a realistic pictorial wake representation which complements the wake information to follow, isometric and projection view plots of both the undistorted and distorted wake geometries for selected conditions are presented. These plots will give the wake chart user a physical feeling of the output from the two dimensional wake charts that follow in relation to the actual three dimensional wake geometry. All of the figures presented in this section will contain the standard projection views (top, side, and rear) and an isometric view. They are presented as functions of blade number, thrust level, tip path plane attitude, advance ratio, and blade azimuth position.

Figure 11 presents the effect of advance ratio on the wake geometry of a four bladed configuration for the undistorted wake model. The variation in advance ratio changes the inflow ratio for the condition selected ($C_T = 0.005$, $\alpha_{TPP} = -2.0 \text{ deg}$). This effect results in both an axial and longitudinal variation in the wake geometry with increasing advance ratio, as seen in Fig. 11.

Figure 12 presents the effect of thrust level on the wake geometry of a two bladed configuration for the undistorted wake model. The influence of thrust level is limited to changes in the axial coordinate as seen in this figure. Higher thrust creates a larger inflow, and thus, a larger axial displacement from the rotor tip path plane. Figure 13 presents the effect of tip path plane attitude on the wake geometry of a two bladed configuration for an undistorted wake model. Changes in rotor tip path plane attitude with the other parameters held constant result in changes in both axial and longitudinal coordinates since the definition used for the rotor advance ratio does not include the $\cos \alpha_{TPP}$ term. The strongest influence of increasing (negatively) the tip path plane attitude is to displace the wake in an axially increasing (negative) direction. The effect of wake distortions as modeled by the generalized distorted tip vortex model is presented in Fig. 14 for the same conditions as presented in Fig. 12. As seen from the comparison of the undistorted and distorted wake geometries presented in these two figures, the effect of the distortions is a tendency for the tip vortex to rollup on the lateral edges of the wake. The increase in thrust level (Fig. 14c) is seen also to result in larger wake distortions from the comparatively undistorted position at the lower thrust level (Fig. 14a). The effect of wake distortion with changes in tip path plane attitude can be seen in a comparison of Fig. 15, the distorted wake model, with Fig. 13, the undistorted model.
Figure 16 presents the effect of advance ratio on the distorted wake geometries for the same conditions presented in Fig. 11. A comparison of these two figures shows the influence of the distorted wake model on the tip vortex geometry for changes in advance ratio. The effect of increasing advance ratio is seen to change the character of the wake distortions. This effect is better demonstrated in a following section on the generalized wake shape function. Figure 17 presents the specific condition presented in Fig. 11c for incremental values of the blade azimuth position using the distorted tip vortex model. From this figure, the variation of the wake geometry with blade azimuth position can be seen. A careful study of the plots of wake geometries presented in Figs. 11 to 17 should yield significant insight into the three dimensional representation of the tip vortex as modeled by either the undistorted or distorted wake models. This insight will be helpful in understanding the use of the following wake charts.

Inflow Ratio Nomographs

The first set of nomographic charts (Fig. 18) are used to determine the rotor tip path plane inflow ratio ($\lambda_{TPP}$) to define the axial displacement of the rotor wake. The inflow ratio is defined by momentum considerations in the tip path plane as a function of the rotor thrust coefficient (defined in the conventional sense, ($C_T$)), the rotor advance ratio ($\mu$) defined as the ratio of the rotor flight speed to rotor tip speed, and the rotor tip path plane angle (negative nose down, $\alpha_{TPP}$). Given these parameters, the rotor inflow ratio can be determined quickly by graphical means from these charts, or by finding the first positive root ($\lambda_{TPP}$) of the following relationship

$$\lambda_{TPP} = \mu \sin \alpha_{TPP} - \frac{C_T}{2} \left[ (\mu \cos \alpha_{TPP})^2 + \lambda_{TPP}^2 \right]^{-1/2}$$  \hspace{1cm} (1)

These charts are presented in terms of the tip path plane inflow ratio as a function of the tip path plane rotor advance ratio ($\mu \cos \alpha_{TPP}$) from 0 to .5 and the thrust coefficient ($C_T$) from 0.0 to .010 for two degree incremental values of the tip path plane angle from -16 to 4 degrees. This range of values should be adequate for most conventional rotorcraft.
Undistorted Axial Displacement Nomographs

Once the tip path plane inflow ratio is known, the classical undistorted axial (normal) displacement of any tip vortex can be found. Figure 19 provides nomographic charts which are used to determine this normalized axial displacement of the tip vortex as functions of wake age and inflow ratio. The wake age is defined as the azimuthal variation in time from the instant in time that the filament is trailed off the blade to its current position in time. Zero wake age is thus physically referenced to the blade tip (quarter chordline).

\[ \frac{Z}{R} = \lambda_{TPP} \psi_{age} \]  

The axial displacement referenced to the tip path plane is normalized by the blade radius and is plotted for four revolutions of wake age (1400 degrees) in Parts I and II of Fig. 19. The third part of this figure is a table of the normalized axial displacement versus inflow ratio for integer multiples of 360 degrees of wake age. With this table, and the graphs of Parts I and II, the axial displacement can be found for any wake age by the appropriate addition of the axial displacement for integer multiples of 360 degrees of wake age and the displacement for the positive fractional remainder of the wake age for the condition of interest. Note that the variation of this displacement is linear in terms of either the inflow ratio or the wake age.

Undistorted Longitudinal and Lateral Coordinate

The axial displacement by itself does not allow for the determination of the relative distance between a point of interest and the tip vortex in three dimensional space. The longitudinal and lateral positions of the tip vortex are also necessary to determine the relative geometry. As noted in Volume I of this report, the longitudinal and lateral positions are not highly distorted from the undistorted helicoidal shape. Thus, the first order approximation to these coordinate positions can be simply determined by the use of the undistorted equations in the tip path plane.

\[ X/R = \cos (\psi_B - \psi_{age}) + \mu \cos \alpha_{TPP} \psi_{age} \]  
\[ Y/R = \sin (\psi_B - \psi_{age}) \]
To avoid the necessity of calculating these functions to obtain the coordinate values, the charts in Figs. 20 and 21 are provided. These charts present the data as functions of the wake age, the blade azimuth position of the blade from which the wake is trailing ($\psi_B$), and the rotor advance ratio in the tip path plane ($\mu_{TPP} = \mu \cos \alpha_{TPP}$). Figure 20 provides sufficient information to determine the longitudinal position of the tip vortex. This figure has two parts, corresponding to the cyclic and steady terms in the above equation for the longitudinal term ($X/R$). The steady part is determined in a manner similar to the method for axial displacement and is linear with wake age. The table in Fig. 20a provides for the determination of the steady longitudinal displacement for integer multiples of 360 degrees of wake age for various tip path plane advance ratios. The steady longitudinal displacement for the positive fractional remainder of the wake age for a given condition is obtained graphically from the nomograph of displacement versus wake age, presented in the graphic part of Fig. 20a as a function of the appropriate tip path plane advance ratio. The addition of these two displacements results in the total steady longitudinal coordinate for a given tip path plane advance ratio and wake age. The cyclic portion is obtained by the use of the second portion of this figure (Fig. 20b). This figure presents the cyclic portion of the longitudinal coordinate as a function of the positive residual of the relative wake azimuth position ($\Psi$). The relative wake azimuth position is defined as the difference between the instantaneous blade azimuth position from which the filament is trailing ($\psi_B$) and the local wake age ($\psi_{age}$) of interest of the actual filament. The positive residual ($\Psi$) is defined as the remaining positive value after subtracting the largest integer multiple of 360 degrees which does not yield a negative fraction.

$$\Psi = PR [\psi_B - \psi_{age}] \quad (5)$$

It can be seen that this figure is simply a plot of the cosine function versus a reference angular position ($\Psi$). For a given blade azimuth position ($\psi_B$) from which a tip filament trails, and a particular wake age ($\psi_{age}$) of interest, the cyclic longitudinal position can then be obtained from this plot. The addition of the steady and cyclic portions results in the total longitudinal displacement of the tip vortex filament as a function of blade azimuth position, wake age and tip path plane advance ratio.

The lateral coordinate of the tip vortex is found by the use of the information presented in Fig. 21. Again, the positive residual of the relative blade wake azimuth position is used and the cyclic lateral position of the tip vortex is obtained from the plot for the particular combination of parameters of interest. These charts provide sufficient information to quickly determine the location of an undistorted tip vortex with respect to the rotor tip path plane based on rotor momentum transport concepts.
Generalized Axial Distortion Nomographs

As noted in Volume I of this report, the actual tip vortex does not follow the trajectory of the undistorted momentum wake. Thus, the use of the axial distortions based on momentum definitions will not accurately define the potential for strong close blade/vortex interactions. As an improvement to the estimate of this potential based on the undistorted wake, the generalized distorted wake model can be used. However, the complex nature of the relationships used in this model requires the use of somewhat more complex wake charts. It should also be noted that the wake charts provided for this model provide only an approximation to the actual wake geometry and that the use of the charts must be made with this understanding. Because it is only an approximation, the results obtained should be used only as an indicator of potential blade/vortex interactions, and not as an accurate measure of the relative distance between the blade (or field point) of interest. The generalized wake coordinates for a tip vortex are comprised of two parts, one of which is the undistorted wake position (Fig. 19) already described. Thus, it is only necessary to present the additional axial distortions from this momentum wake position

\[ Z/R = \lambda_{TPP} \psi_{age} + \Delta Z/R. \]  

(6)

The distortions from the momentum wake position (\(\Delta Z/R\)) are modeled by the combination of an envelope function (\(E_f\)) and a geometric shape function (\(G_f\)).

\[ \Delta Z/R = E_f \cdot G_f \]  

(7)

The exact expressions are presented in Volume I of this report and are functions of advance ratio, thrust level, blade number, blade azimuth position and wake age. Figures 22 through 25 present these functions as nomographic plots for the range in parameters for which they were developed. Figures 22 and 23 present the envelope function for 2 and 4 blades respectively at advance ratios of .05, .1, .15, .2, and .3, and for thrust coefficients of .0025 to .0075. Figures 24 and 25 present the generalized shape functions for 2 and 4 blades respectively for the same variation in parameters. Again, graphical means are used to obtain the appropriate values for these functions from the charts for the particular set of parameters of interest. The multiplication of these two values (Eq. 7) results in the axial displacement from the momentum wake position for the tip vortex. This value is then combined with the momentum wake position to define the axial position of the tip vortex (Eq. 6). With this information, an improved estimate can be made for the determination of the potential for close blade/vortex interaction.
Blade/Vortex Passage Charts

As noted earlier, the charts presented herein can be used to determine the relative position between a point in space and the tip vortex for any given time increment. The determination of the potential for a blade/tip vortex interaction to exist using these charts by themselves would be a tedious, time consuming task. To alleviate this tedious effort, the next set of charts was developed to simplify this task. These charts present the occurrence of an intersection of a rotor blade with the tip vortex of any of the blades of the rotor for a given tip path plane advance ratio. They are based only on the inplane projection of the longitudinal and lateral coordinates of the tip vortices and the intersection of the rotor blade of interest. The charts are presented in polar coordinate form where the axes represent the radial and azimuthal position of the blade of interest. These plots do not represent wake geometries, only the potential occurrence of an intersection. The occurrence of an intersection is represented by the solid lines and symbols. Superimposed at selected locations on these curves which correspond to the intersection occurrences are the wake ages for up to four revolutions of wake age (1440 degrees). Since these intersections are based on the projections of the tip vortices into the tip path plane, they do not recognize the axial displacement between the blade and vortex intersection of interest. However, the axial displacement for a potential intersection can be quickly obtained from the charts presented earlier if the thrust level, wake age, and rotor attitude are known (Figs. 18 and 19 and 22 through 25). Thus, the rapid determination for the potential for close blade/vortex interactions can be determined from these charts based on axially distorted wake considerations. These intersection plots are presented in polar coordinate format in Figs. 26 through 30 for two (2) through six (6) blades respectively as functions of the tip path plane advance ratios of .05, .1, .15, .2, .3 and .4. In addition, these results are also presented in rectilinear format, without the wake age indicated, on the plots in Figs. 31 and 32 for two (2) and four (4) blades respectively.

Blade/Vortex Intersection Angle Nomographs

The next set of charts, presented in Fig. 33, provides additional information about the intersections presented in Figs. 26 through 32. These charts provide the angle of intersection (θ) of a potential blade/tip vortex intersection for the tip path plane advance ratios of .05, .1, .15, .2, .3 and .4. If the reference blade azimuth position (ψ₀), wake age at the point of intersection (ψₐₑₐₑ), azimuthal position of the blade trailing the tip vortex (ψₑ), and the tip path plane advance ratio (μcos øₚₚₚ) are known, the angle of intersection can be obtained graphically from this figure. If the blade angle (ψ₀) is greater than 180 degrees, the value for use with the chart must be reduced by 180 degrees. This is because of the periodicity of the solution
for multiples of 180 degrees of blade azimuth angle position. This angle of intersection information can be useful in determining the nature of the intersection; for example, a normal or parallel encounter.

Fore and Aft Wake Boundary Charts

The information provided in the axial distortion charts (Figs. 19 and 22 through 25) can also be used to define fore and aft wake boundary information. However, to expedite this task, a set of wake boundary charts has been provided in Figs. 34 through 50. The use of these charts can be helpful in the determination of rotor/empennage/stores/body interactions beneath the rotor disk. In Fig. 34, the fore and aft wake boundary charts are presented based on the undistorted axial wake model. These boundaries are functions of the rotor attitude, inflow rotor and advance ratio. The lines representing the fore and aft boundaries for the zero lateral position (Y/R=0) along the centerline of the outer disk are presented in these charts. The use of the lateral position indicators provided in these charts also allows for the determination of the fore and aft boundaries for non-zero lateral positions by the appropriate parallel translation of the fore and aft reference lines to the appropriate lateral reference position. This procedure will be discussed in the example application section which follows.

In Figs. 35 through 50 the fore and aft boundaries based on the generalized distorted wake model are provided for various selected lateral positions, thrust levels, advance ratios, tip path plane attitudes, and two and four blades. A selection is necessary because the axial displacement based on the generalized distorted wake model must be determined numerically for each lateral position and would result in a very large number of plots. Careful examination of these selected charts indicates that the wake boundaries compress as the vertical and longitudinal sectional plane is moved in the lateral direction (advancing or retreating) toward the rotor tips. This is due to the wake rollup. It should also be noted that at the rotor centerline the distortions displace the wake toward the rotor.

The range of parameters is limited in scope due to the previously noted reason. Hopefully the selected range is sufficient for general applications and will give the user a "feel" for the distortion influence.
SAMPLE APPLICATION OF THE WAKE CHARTS

Example Condition

An example of the use of the provided charts is demonstrated for a fictitious aircraft operating at a prescribed flight condition. In this example, the objective is to determine whether or not a tip vortex passes close to a blade at 160 degrees azimuth. The parameters and the values for this example which are necessary for the use of these charts are:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Blade radius</td>
<td>20 ft</td>
</tr>
<tr>
<td>Blade number (b)</td>
<td>4</td>
</tr>
<tr>

</tr>
<tr>
<td>Advance ratio, (\mu)</td>
<td>.23</td>
</tr>
<tr>
<td>Blade azimuth position, (\Psi_B)</td>
<td>160°</td>
</tr>
</tbody>
</table>

The tip path plane advance ratio is calculated as

\[ \mu_{TPP} = \mu \cos \alpha_{TPP} = 0.23 \]

Inflow Ratio

The tip path plane inflow ratio \((\lambda_{TPP})\) for this particular condition is found by graphical means from Figs. 18g and 18h. This technique is demonstrated in Fig. 2, and the value obtained is approximately \(-.0283\). An exact calculation for the inflow rotor to five places would yield \(-.02822\) for this condition. This corresponds to a momentum induced velocity for the condition of 11.3 fps, using the relationship noted below.

\[ V_{imom} = \frac{1}{2} C_T (\lambda_{TPP})^{-1/2} \]
Undistorted Axial Location

With the above value for the tip path plane inflow ratio, the undistorted axial displacement of a tip vortex can be found using Fig. 19. To illustrate this procedure, consider a rotor blade's relationship to the tip vortex trailed from the preceding blade (one of four). For this condition, the blade azimuthal spacing is 90 degrees (360°/b). Thus, the wake age is approximately 90 degrees. From Fig. 19, Part I, the axial displacement for 90 degrees wake age is found by graphical means. This procedure is demonstrated in Fig. 3 for two methods, one of which allows for an increased graphical accuracy. For this condition, the displacement is found to be about -.0425 R using the more accurate method. The exact value is -.044328 R. This represents a relatively close blade/vortex interaction. For example, if the magnitude of the induced velocity of such an encounter can be modeled for first order accuracy by a straight infinite vortex with circulation strength of 250 ft²/sec, not an unreasonable value for this aircraft, the induced velocity using the Biot-Savart law for an infinite vortex filament would be about 45 fps.

\[
V_i \equiv \frac{T}{2\pi Rh} \left( \frac{250}{2\pi \cdot 0.44} \right) = 45.2
\]

This corresponds to four (4) times the momentum value for this condition. At the azimuthal position of 160 degrees at the .75 R radial location, this could represent a significant change in the induced angle of attack compared with that predicted based on the momentum value. As a result of this study, it is seen that a blade vortex interaction of potential significance could occur.

Longitudinal and Lateral Coordinates

Consider now that the preceding blade is at an azimuthal position (ψₚ) of 250 degrees for the above example, the longitudinal and lateral positions of the tip vortex shed from this blade near the reference blade of interest (ψₒ = 160°) can approximately be found by the use of Figs. 20 and 21. Since the approximate wake age (ψₚ) in this example is known to be about 90 degrees for the close interaction noted above, the relative wake azimuth position (ψ) is simply 160°.
From Fig. 20, Part I, the steady longitudinal component based on the wake age (90°) is found to be .37 R. From Fig. 20, Part II, the cyclic portion based on the relative wake age position (Ψ = 160°) is found to be -.93 R. The total of these two values results in a longitudinal coordinate of -.56 R. This technique is demonstrated in Fig. 4. The lateral coordinate is found from Fig. 21 in a manner similar to the cyclic portion of the longitudinal coordinate as shown in Fig. 5. The value obtained for the lateral coordinate is .34 R. The resulting undistorted coordinates for the tip vortex near the following blade at 160° for this condition are then:

<table>
<thead>
<tr>

<td>-.043</td>
<td>-.04432</td>
</tr>
</tbody>
</table>

**Axial Coordinate Distortions**

Since it is known that the actual tip vortices trailed by the rotor blades can undergo significant axial distortions, the occurrence of such distortions should be considered when studying close blade/vortex interaction. In order to provide additional insight into this problem, the use of the UTRC Generalized Wake Model can be used to further refine the axial displacement. Figures 22 and 24, and 23 and 25, for two and four blades respectively, present the generalized wake modeling functions for a range of advance ratios and thrust loads. For the example condition, the envelope function, Eₙ, is found by graphical means from Figs. 23d and 23e to be .035. This procedure is illustrated in Fig. 6. The generalized shape function, Gₙ, for this condition is also found by graphical means from Fig. 25 to be .90. This procedure is illustrated in Fig. 7. The multiplication of these values results in the distortion, ∆Z/R, from the undistorted wake model.

\[ \Delta Z/R = E_f \cdot G_f = 0.0350 \times 0.90 = 0.0315 \]
The addition of the undistorted and distorted displacement values results in the generalized wake distortion model value for the condition of interest,

\[
\psi_0 = 160^\circ, \\
\psi_b = 250^\circ, \\
\psi_{age} = 90^\circ, \\
\mu_{TPP} = .23, \\
\lambda_{TPP} = -.0283.
\]

\[
Z/R = \lambda_{TPP} \psi_{age} + \Delta Z/R = -.043 + .0315 = -.0115
\]

This value for the axial displacement places the tip vortex very near the rotor tip path plane for this condition. The implication of this result is that there is a very strong potential for a close blade/tip vortex interaction to occur. It should be noted that the exact wake age was not used, only an approximate value (\(\psi_{age} = 90^\circ\)). The exact value will be obtained in the next section.

Blade/Tip Vortex Intersections

For the example condition, it has been shown that there is the potential for a blade vortex interaction to be occurring based on the tip vortex trailed from the preceding blade. The potential for blade/tip vortex intersections can quickly be determined for any azimuthal position due to any tip vortex by the use of Figs. 26 to 32. For the example condition, Figs. 28d and 28e are used to determine the desired information using graphical interpolation techniques. This procedure is illustrated in Fig. 8. The radial position of the blade at 160 degrees, which intersects the tip filament trailed by the preceding blade, is found to be about .68 R and the actual wake age noted at discrete intervals on the intersection curves is determined graphically to be about 84 degrees. For this wake age the exact value for the radial coordinate is .6781 R. This information could have been obtained from Figs. 32d and 32e which present the same information in a rectilinear format. With this more exact value for the wake age, a slightly more exact value for the axial displacement of the tip vortex can be found by repeating the above procedures.
These blade/vortex intersection plots (Figs. 26 to 32) are of significant value if the user is basically interested in only tip vortex intersections. By first using these figures to determine if any intersection is possible from a plan view projection basis, the axial position can be rapidly determined by the use of Fig. 18 for the inflow ratio, Fig. 19 for the undistorted axial displacement, and if desired, Figs. 22 to 25 for the generalized wake distortions. The longitudinal and lateral coordinates for the intersection point are determined graphically from Figs. 20 and 21, or by the use of the trigonometric relationships between polar and cartesian coordinates, since the radial and azimuthal coordinates (polar) are now known from Figs. 26 to 32.

Angle of Intersection

Figure 33 can be used to obtain the relative angle of intersection between the blade and tip vortex for a plan view intersection obtained from the blade/tip vortex intersection plots. For the example condition, Fig. 9 illustrates this procedure, and the angle of intersection is found to be about 90 degrees. Note that 180 or 0 degrees represents a parallel blade/vortex encounter. As a further note, if the blade angle ($\psi$) is greater than 180 degrees, the value should be reduced by 180 degrees for use on the chart as noted in the earlier section describing this type of chart.

Fore and Aft Wake Boundaries

Now assume that the wake boundary defined by the passage of the tip vortices beneath the rotor is of interest. For instance, the geometric relationship between the launch point location of rocket stores and the rotor wake boundary of an attack helicopter might be of importance because the strong downwash of the wake could influence the rocket trajectory. For this example, the wake boundary location is significant for low speed rocket firings, since the downwash can strongly affect the accuracy of the rocket. Assume for illustrative purposes that a rocket launcher is located in the tip path plane coordinate system .4 R beneath the rotor, .05 R ahead of the hub center, and displaced laterally on the advancing side by .5 R. For this example flight condition, the undistorted fore and aft wake boundaries can be determined using Fig. 34c. Figure 10 illustrates this procedure for the determination of the position of the wake boundary relative to the rocket launch location. In this particular example, the results obtained in Fig. 10 indicate that there is no intersection of the rocket launch point, or trajectory with the wake boundary.

The wake boundaries are, in reality, changed due to the actual wake distortions. The approximate boundaries can be found for selected conditions by the use of Figs. 35 to 50. For the above example of a rocket launch point, the distorted wake boundaries can be found using a similar procedure (Fig. 50c).
FIGURE 1. COORDINATE DEFINITION AND BLADE NUMBERING SYSTEM
Instructions

A. For $\mu_{TPP} = .23$ and $C_T = .0075$, the inflow ratio for $\alpha = -6^\circ$ tip path plane is found by graphical means to be $-0.0325$.

B. For $\mu_{TPP} = .23$ and $C_T = .0075$, the inflow ratio for $\alpha = -2^\circ$ tip path plane is found by graphical means to be $-0.0240$.

C. Since the desired value is for a tip path plane of $-3^\circ$, the average of the two values can be used.

$$\lambda_{TPP} = \frac{-0.0325 + -0.0240}{2} = -0.0283$$

FIGURE 2. EXAMPLE USE OF THE INFLOW RATIO NOMOGRAPHS
AXIAL DISPLACEMENT OF TIP VORTEX FILAMENT FROM BLADE TIP PATH
PLAN A AS A FUNCTION OF WAKE AGE AND INFLOW RATIO - PART I

Information Desired
Undistorted axial displacement

Information Required
Infow ratio (λ = -.0283),
wake age (ψ_age = 90°).

Instructions

A. Determine Z/R by graphical interpolation for λ = -.0283
   at ψ_age of 90°.
   Z/R = -0.04

B. Determine Z/R by graphical interpolation for λ = -.0283
   at a larger ψ_age (720°) and divide answer by appropriate
   value to obtain more accurate estimate.
   Z/R (720°) = -0.34
   Divide by 8
   Z/R (90°) = -0.0425

FIGURE 3. EXAMPLE USE OF THE AXIAL DISPLACEMENT CHART
Information Desired

Longitudinal coordinate, X/R

Information Required

Tip path plane advance ratio (μTPP), wake age (ψage), and blade azimuth position from which the tip vortex trails (ψR)

Instructions

1. By graphical means the steady longitudinal component is found for a given μTPP (.23) and ψage (90°).
   \[ X/R_S = 0.36 \]

2. By graphical means the cyclic longitudinal component is found for the relative wake azimuth position \( \tilde{\psi} \).
   \[ \tilde{\psi} = FR |\psi_R - \psi_{age}| \]
   \[ \tilde{\psi} = FR |250 - 90| = 160 \]
   \[ X/R_c = -0.93 \]

3. \[ X/R = X/R_S + X/R_c = -0.56 \]

FIGURE 4. EXAMPLE USE OF THE GENERALIZED LONGITUDINAL COORDINATE CHART
By graphical means, the lateral coordinate for the relative wake azimuth position (ψ = 160) is found.*

Y/R = 0.34

*See Figure 4.
Information Desired
Envelope function for a particular thrust and wake age.

Information Required
Thrust coefficient ($C_T$), wake age ($\Phi_{age}$), number of blades ($b$), and advance ratio ($\mu = \frac{V}{DR}$).

Instructions
A) Interpolate by graphical means on the thrust level ($C_T = 0.0075$), wake age ($\Phi_{age} = 90^\circ$), blade number ($b = 4$), and advance ratio ($\mu = 0.2$).

$E_T = 0.038$

B) Interpolate by graphical means on the thrust level ($C_T = 0.0075$), wake age ($\Phi_{age} = 90^\circ$), blade number ($b = 4$), and advance ratio ($\mu = 0.3$).

$E_T = 0.028$

C) Using linear interpolation in the advance ratio ($\mu = 0.23$) and envelope functions found in A and B, the actual envelope function is found.

$E_T = 0.035$

**FIGURE 6. EXAMPLE USE OF THE GENERALIZED WAKE ENVELOPE FUNCTION CHART**
Information Desired
Wake shape function \( (G_F) \)

Information Required
Rotor advance ratio \( (\mu = \frac{V}{DR}) \), wake age \( (\psi_{\text{age}}) \), and number of blades.

Instructions

\( G_F = .90 \)

**FIGURE 7. EXAMPLE USE OF THE GENERALIZED WAKE SHAPE FUNCTION CHART**
FIGURE 8. EXAMPLE USE OF THE BLADE/TIP VORTEX INTERSECTION PLOTS

Instructions:

1. At a selected blade azimuth (φo = 160°) for a selected advance ratio (p = 0.2), determine by graphical means the radius for the tip (blade 0) at which the VFWIHC slnt = 0.6.

2. At a selected blade azimuth (φo = 160°), for a selected advance ratio (p = 0.2), determine from graphical means the radius for the tip (blade 0) of interest (φb = 250°, blade 4).

3. By linear interpolation on the solutions for the desired values of the radius bounding the slnt = 0.68 in the estimate for the blade azimuth and radius of intersection.

4. φb = 40°, T = 1.6.
Information Desired
Angle of intersection

Information Required
Tip path plane advance ratio, \( \mu \), reference blade azimuth position \( \phi_o \), and blade azimuth position from which tip filament trails \( \phi_b \).

Instructions

A. The positive residual of the relative wake azimuth position \( \phi_b - \phi_{age} = 250 - 84 - 166 \) on the bounding advance ratio \( \mu = 0.2 \) is determined, and the angle of intersection \( \beta \) is found by graphical means for the selected reference blade azimuth position \( \phi_o = 160 \).

\[ \beta = 98^\circ \]

B. This procedure is repeated for the other bounding advance ratio \( \mu = 0.3 \) to determine the corresponding angle of intersection.

\[ \beta = 102^\circ \]

C. The angle of intersection for the actual advance ratio \( \mu = 0.23 \) is then determined by interpolation.

\[ \beta = 99.2^\circ \]

**Figure 9. Example use of the angle of intersection chart**
Information Desired
Location of fore and aft wake boundary and wake skew angle relative to a reference point.

Information Required
Tip path plane advance ratio, inflow ratio, and desired reference locations if needed.

Instructions

A With a known lateral reference value \( Y/R = 0.5 \) the lateral reference guide can be used to determine, by construction, the appropriate lateral reference location ② on the \( Z/R \) axis.

B For the desired inflow ratio \( \lambda = -0.0283 \) the indices can be determined which define the fore and aft wake boundary reference lines. (Symbol from col. 1.)

C The wake boundary lines can be determined by graphical interpolation for the zero lateral location.

D The parallel translation of the graphically obtained wake boundary lines for the fore and aft coordinates is made to the appropriate lateral position ③.

E The determination of the rocket launch point in the tip path plane is made on the selected graph \( X/R = -0.05, Z/R = 0.4 \), resulting in ④.

F From this determination it is found that the wake has been displaced rearward from the launch point. Since the \( \mu = 0.23 \) condition will have the wake displaced further rearward there is no need to use any additional figures for interpolation on advance ratio.

An analytical investigation to generalize the wake geometry of a helicopter rotor in steady level forward flight and to demonstrate the influence of wake deformation in the prediction of rotor airloads and performance is described.

In Volume I, a first level generalized wake model is presented which is based on theoretically predicted tip vortex geometries for a selected representative blade design. The tip vortex distortions are generalized in equation form as displacements from the classical undistorted tip vortex geometry in terms of vortex age, blade azimuth, rotor advance ratio, thrust coefficient, and number of blades. These equations were programmed in a computer module to provide distorted wake coordinates at very low cost for use in rotor airflow and airloads prediction analyses. The sensitivity of predicted rotor airloads, performance, and blade bending moments to the modeling of the tip vortex distortion are demonstrated for low to moderately high advance ratios for a representative rotor and the H-34 rotor. Comparisons with H-34 rotor test data demonstrate the effects of the classical, predicted distorted, and the newly developed generalized wake models on airloads and blade bending moments. The use of distorted wake models results in the occurrence of numerous blade-vortex interactions on the forward and lateral sides of the rotor disk. The significance of these interactions is related to the number and degree of proximity to the blades of the tip vortices. The correlation obtained with the distorted wake models (generalized and predicted) is encouraging. However, the resulting high sensitivity of the predicted airloads to small deviations in tip vortex position demonstrate the requirement for improved blade-vortex interaction modeling.

A set of wake geometry charts are presented in Volume II to provide a convenient, readily accessible source for approximating rotor forward flight wake geometry and identifying wake boundaries and locations of blade-vortex passage.
