Summary

A general approach to the construction of convergence acceleration methods for vector sequences is proposed. Using this approach, one can generate some known methods, such as the minimal polynomial extrapolation, the reduced rank extrapolation, and the topological epsilon algorithm, and also some new ones. Some of the new methods are easier to implement than the known methods and are observed to have similar numerical properties. The convergence analysis of these new methods is carried out, and it is shown that they are especially suitable for accelerating the convergence of vector sequences that are obtained when one solves linear systems of equations iteratively. A stability analysis is also given, and numerical examples are provided. The convergence and stability properties of the topological epsilon algorithm are likewise given.

1. Introduction

In a recent work (ref. 1) a survey of convergence acceleration methods for sequences of vectors is given, and five of these methods are tested and compared numerically using a process that has been termed cycling: the minimal polynomial extrapolation (MPE), the reduced rank extrapolation (RRE), the scalar epsilon algorithm (SEA), the vector epsilon algorithm (VEA), and the topological epsilon algorithm (TEA). One of the conclusions of this survey is that the MPE and the RRE have about the same properties, and in general, have better convergence than others, in the sense that the MPE and the RRE achieve a given level of accuracy with fewer vectors than the SEA, VEA, and TEA. VEA and SEA are also similar in performance, except that the latter is more prone to numerical instability problems. However, TEA, while interesting from a theoretical point of view, appears to be not as effective as either VEA or SEA; see reference 1 for further details.

All of the methods above have the following important properties:

(1) It is observed numerically that in many instances they accelerate the convergence of a slowly converging vector sequence and they make a diverging sequence converge to an "anti-limit" that has an immediate interpretation.

(2) They depend solely on the given vector sequence whose convergence is being accelerated; they do not depend on how the vector sequence is generated.

(3) Their implementation is straightforward.

For more details and an extensive bibliography see reference 1.

It turns out that the implementation of the MPE and RRE requires the least-squares solution of an overdetermined and in general inconsistent set of linear equations, the number of the equations in this set being equal to the dimension of the vectors in the given sequence. For many practical problems, the dimension of these vectors may be finite but very large; consequently, one may have to store a large rectangular matrix in memory, making the MPE and RRE somewhat expensive in both storage and time. Therefore, it would be desirable to have methods as efficient as MPE and RRE but less demanding in storage and time.

In the next section a general framework for deriving convergence acceleration methods for vector sequences — vector accelerators for short — is proposed. Within this framework one can derive several methods, some old (MPE, RRE, and TEA) and some new. It turns out that one of the new methods is very similar to the MPE and RRE, but does not require the use of the least-squares method, requires very little storage, and, at least numerically, is as efficient as MPE. The convergence analysis of this method, which we shall call the modified MPE, (MMPE), is carried out in Section 3 for a class of vector sequences that includes those arising from the iterative solution of systems of linear equations. We prove that this method is a bona fide convergence acceleration method, and its rate of acceleration is also provided. The stability properties of this method are taken up in Section 4. In Section 5 the convergence and stability properties of the TEA are analyzed using the techniques of Sections 3 and 4. Finally in Section 6 we test the MMPE on some examples numerically, and compare it with the MPE. On the basis of this comparison one could conclude that the MPE and MMPE have similar performances, although there is as yet no complete theory to support this empirical conclusion.
2. Development of Vector Accelerators

In this section we shall develop a general framework within which one can derive vector accelerators of different kinds. We shall motivate this development in the way Shanks (ref. 2) motivates his development of the ek-transformation for scalar sequences.

2.1. The Shanks Transformation

Shanks starts with a scalar sequence $X_m, m=0, 1, \ldots$, that has the property

$$X_m \sim S + \sum_{i=1}^{\infty} a_i \lambda_i^m \text{ as } m \to \infty, \quad (2.1)$$

where $S$, $a_i$, and $\lambda_i$ are constants independent of $m$, $\lambda_i \neq 1$, $i=1, 2, \ldots$, $\lambda_i \neq \lambda_j$, for all $i \neq j$, and $|\lambda_1| \geq |\lambda_2| \geq \ldots$. In (2.1) $S$ is $\lim_{m \to \infty} X_m$ if all $|\lambda_i| < 1$; otherwise, $S$ is called the anti-limit of the sequence $X_m, m=0, 1, \ldots$. As one way of approximating $S$, Shanks proposes to solve the set of $2k+1$ nonlinear equations

$$X_m = S_{n,k} + \sum_{i=1}^{k} a_i \lambda_i^m, \quad n \leq m \leq n + 2k, \quad (2.2)$$

for $S_{n,k}$ which is taken to be an approximation to $S$, with $a_i, \lambda_i, i=1, \ldots, k$, being the rest of the unknowns. The solution $S_{n,k}$ turns out to have the following determinant representation:

$$S_{n,k} = \frac{\begin{vmatrix} X_n & X_{n+1} & \ldots & X_{n+k} \\ \Delta X_n & \Delta X_{n+1} & \ldots & \Delta X_{n+k} \\ \vdots & \vdots & \ddots & \vdots \\ \Delta X_{n+k-1} & \Delta X_{n+k} & \ldots & \Delta X_{n+2k-1} \end{vmatrix}}{\begin{vmatrix} 1 & 1 & \ldots & 1 \\ \Delta X_n & \Delta X_{n+1} & \ldots & \Delta X_{n+k} \\ \vdots & \vdots & \ddots & \vdots \\ \Delta X_{n+k-1} & \Delta X_{n+k} & \ldots & \Delta X_{n+2k-1} \end{vmatrix}}, \quad (2.3)$$

where $\Delta$ is the forward difference operator defined by $\Delta b_i = b_{i+1} - b_i$, $\Delta^p b_i = \Delta (\Delta^{p-1} b_i)$, $p \geq 2$, provided the determinant in the denominator of (2.3) is nonzero.

Two equivalent formulations follow from (2.3), independent of any reference to the nonlinear equations in (2.2).

(a) With $S_{n,k}$ as given in (2.3), there are $k$ parameters $\beta_i, i=0, 1, \ldots, k-1$, which solve the system of $k+1$ linear equations

$$\begin{align*}
\Delta X_n - \beta_0 \Delta X_{n+1} - \vdots - \beta_{k-1} \Delta X_{n+k} &= 0, \\
\Delta^2 X_n - \beta_0 \Delta^2 X_{n+1} - \vdots - \beta_{k-1} \Delta^2 X_{n+k} &= 0, \\
& \vdots \\
\Delta^k X_n - \beta_0 \Delta^k X_{n+1} - \vdots - \beta_{k-1} \Delta^k X_{n+k} &= 0.
\end{align*}$$

(b) Another equivalent formulation is

$$X_m = \sum_{i=1}^{k} \beta_i m^i, \quad n \leq m \leq n + 2k, \quad (2.4)$$

for $S_{n,k}$, with $\beta_i, i=0, 1, \ldots, k-1$, being the rest of the unknowns. The solution $S_{n,k}$ turns out to have the following determinant representation:
\[ X_m = S_{n,k} + \sum_{i=0}^{k-1} \beta_i \Delta X_{m+i}, \quad n \leq m \leq n+k, \quad (2.4) \]

as can be verified by solving (2.4) for \( S_{n,k} \) by Cramer's rule. By taking the differences of the equations in (2.4), we see that the \( \beta_i \) satisfy

\[ \Delta X_m = \sum_{i=0}^{k-1} \beta_i \Delta^2 X_{m+i}, \quad n \leq m \leq n+k-1, \quad (2.5) \]

and that, once the \( \beta_i \) have been determined from (2.5), \( S_{n,k} \) can be computed from one of the equations in (2.4), say that for which \( m=n \).

(b) From (2.4) it follows that \( S_{n,k} \), along with the parameters \( \gamma_i, i=0, 1, \ldots, k \), satisfies the system of linear equations

\[ S_{n,k} = \sum_{i=0}^{k} \gamma_i X_{m+i}, \quad n \leq m \leq n+k, \quad (2.6) \]

subject to

\[ \sum_{i=0}^{k} \gamma_i = 1. \quad (2.7) \]

By taking the differences of the equations in (2.6), we see that the \( \gamma_i \) satisfy

\[ 0 = \sum_{i=0}^{k} \gamma_i \Delta X_{m+i}, \quad n \leq m \leq n+k-1, \quad (2.8) \]

subject to (2.7). Once the \( \gamma_i \) have been determined from (2.7) and (2.8), \( S_{n,k} \) can be computed from one of the equations in (2.6). Furthermore, if \( \gamma_k \neq 0 \), then (2.7) and (2.8) are equivalent to

\[ \sum_{i=0}^{k-1} c_i \Delta X_{m+i} = - \Delta X_{m+k}, \quad n \leq m \leq n+k-1, \quad (2.9) \]

where

\[ \gamma_i = \frac{c_i}{\sum_{j=0}^{k} c_j}, \quad 0 \leq i \leq k, \quad c_k = 1, \quad (2.10) \]

provided \( \sum_{j=0}^{k} c_j \neq 0 \).

It has been proved by Wynn (ref. 3) that \( S_{n,k} \), when computed from a sequence \( X_m, m=0, 1, \ldots \), that is of the form given in (2.1), converges to \( S \) as \( n \to \infty \) (\( k \) fixed), under certain conditions on the \( \lambda_i \) faster than \( X_n \) itself. Wynn actually gives rates of convergence for \( S_{n,k} \) for \( n \to \infty \).
2.2. Derivation of Vector Accelerators

Let us now consider a sequence of vectors, \( x_m \), \( m = 0, 1, \ldots \), in a general normed vector space \( B \), satisfying

\[
x_m = s + \sum_{i=1}^{\infty} v_i \lambda_i^m \quad \text{as} \quad m \to \infty
\]

(2.11)

where \( s \) and \( v_i \) are vectors in \( B \), and \( \lambda_i \) are scalars, independent of \( m \), \( \lambda_i \neq 1 \), \( i = 1, 2, \ldots \), \( \lambda_i \neq \lambda_j \) for all \( i \neq j \), and \( |\lambda_i| \geq |\lambda_j| \geq \ldots \). We also assume that there can be only a finite number of \( \lambda_i \) having the same modulus. The meaning of (2.11) is that, for any integer \( N > 0 \), there exist a positive constant \( K \) and a positive integer \( m_0 \) that depend only on \( N \), such that for every \( m \geq m_0 \)

\[
\| x_m - s - \sum_{i=1}^{N-1} v_i \lambda_i^m \| \leq K |\lambda_N|^{-m}
\]

(2.11a)

with \( \| \cdot \| \) being the norm associated with the vector space \( B \).

A simple example of such a sequence is that produced by a matrix iterative technique for solving the linear system of equations

\[
x = Ax + b
\]

(2.12)

where \( A \) is a nondefective \( M \times M \) matrix, and \( b \) and \( x \) are \( M \)-dimensional column vectors. If \( s \) is the solution to (2.12), and for given \( x_0 \), the vectors \( x_m \) are generated by

\[
x_{m+1} = Ax_m + b, \quad m = 0, 1, \ldots,
\]

(2.13)

then

\[
x_m = s + \sum_{i=1}^{M'} \alpha_i \lambda_i^m, \quad m = 0, 1, \ldots
\]

(2.14)

where \( \alpha_i \) are scalars, \( \lambda_i \) and \( v_i \) are the eigenvalues and corresponding eigenvectors of the matrix \( A \), and \( M' \leq M \) is the number of the distinct eigenvalues.

The condition stated in (2.11) is analogous to that stated in (2.1) for scalar sequences. Since the Shanks transformation accelerates the convergence of scalar sequences satisfying (2.1), we expect that its extensions to vector sequences, through the formulations (a) and (b) following (2.3), may also produce acceleration of convergence for vector sequences satisfying (2.11). The extensions of the two formulations can be achieved as follows:

**Approach (a)**

In equations (2.5) replace \( X_j \) by \( x_j \), and "solve" in some sense the resulting overdetermined (and in general inconsistent) system

\[
\Delta x_m = \sum_{i=0}^{k-1} \beta_i \Delta^2 x_{m+i}, \quad n \leq m \leq n+k-1,
\]

(2.15)

for the \( \beta_i \). Once the \( \beta_i \) have been determined, compute the approximation \( s_{n,k} \) to \( s \) by

\[
s_{n,k} = x_n - \sum_{i=0}^{k-1} \beta_i \Delta X_{n+i},
\]

(2.16)
which is obtained by replacing $S_{n,k}$ and $X_j$ in (2.4) by $s_{n,k}$ and $x_j$, respectively, and considering $m = n$.

**Approach (b)**

In equations (2.9) replace $X_j$ by $x_j$, and "solve" in some sense the resulting overdetermined (and in general inconsistent) system

$$
\sum_{i=0}^{k-1} c_i \Delta x_{m+i} = -\Delta x_{m+k}, \quad n \leq m \leq n + k - 1,
$$

(2.17)

for the $c_i$. Once the $c_i, i = 0, 1, \ldots, k - 1$, have been determined, set

$$
c_k = 1, \quad \gamma_i = \frac{c_i}{\sum_{j=0}^{k} c_j}, \quad 0 \leq j \leq k,
$$

(2.18)

assuming $\sum_{j=0}^{k} c_j \neq 0$. Finally compute the approximation $s_{n,k}$ to $s$ by

$$
s_{n,k} = \sum_{i=0}^{k} \gamma_i x_{n+i},
$$

(2.19)

which is obtained by replacing $S_{n,k}$ and $X_j$ in (2.6) by $s_{n,k}$ and $x_j$, respectively, and considering $m = n$.

We see that for both approaches, we need to "solve" an overdetermined and, in general, inconsistent system of equations of the form

$$
\sum_{i=0}^{k-1} d_i w_{m+i} = \tilde{w}_m, \quad n \leq m \leq n + k - 1,
$$

(2.20)

where $w_j$ and $\tilde{w}_j$ are vectors in $B$, and $d_i$ are unknown scalars. If $r$, the dimension of $B$, is greater than $k$, then even one of the equations in (2.20) gives rise to an overdetermined system of $r$ equations. We can, however, propose various ways for obtaining a set of $d_i$ that solves (2.20) in some sense. In what follows, we give three such methods, with the understanding that other methods can also be proposed.

**Method (1)**

Assuming $r > k$, consider only one of the equations in (2.20), namely that with $m = n$, and solve for the $d_i$ that minimize some norm of the vector $\Delta = \sum_{i=0}^{k-1} d_i w_{n+i} - \tilde{w}_n$. Depending on the norm being used, different acceleration methods will be obtained. For example, if $r$ is finite and the (weighted) $\ell_p$ norms are used with $p = 1, 2, \infty$, then the determination of the $d_i$ becomes relatively easy. For $p = 2$ the solution can be achieved by using any one of the least-squares packages available, and for $p = 1$ and $p = \infty$ the minimization problems can be solved by using linear programming techniques; see the review paper by Rabinowitz (ref. 4). The $\ell_2$ norm with equal weights gives rise to RRE for Approach (a) and MPE for Approach (b). The rest of the acceleration methods have not appeared in the literature before.

**Method (2)**

Assuming $r > k$, consider only one of the equations in (2.20), namely that with $m = n$, and obtain the $d_i$ by solving the system of $k$ equations
\[ \sum_{i=0}^{k-1} d_i Q_j(w_{n+i}) = Q_j(\tilde{\omega}_n), \quad j = 1, \ldots, k, \]  

(2.21)

where \( Q_j \) are linearly independent bounded linear functionals on the space \( B \). When \( B \) is an inner product space, we can take \( Q_j(y) = \langle q_j, y \rangle \) where \( q_j \) are vectors in \( B \) and \( \langle \cdot, \cdot \rangle \) is the inner product associated with \( B \). If \( r \) is finite, and the vector \( q_j \) is chosen to be the \( j \)th unit vector, that is, \( (q_j, z) = j \)th component of \( z \), then the method above is equivalent to demanding that only \( k \) out of the \( r \) equations be satisfied, namely those corresponding to the \( j \)th components, \( j = 1, \ldots, k \). Obviously such an acceleration method demands less storage and time for its implementation than methods like the MPE and RRE. It is not difficult to see that Approaches (a) and (b) both give the same acceleration method, which has not been given in the literature before. Due to its similarity to the MPE, we shall call this method the modified MPE (MMPE). In Sections 3 and 4 we shall analyze the convergence and stability properties of this method in detail.

**Method (3)**

Consider all the equations in (2.20) and obtain the \( d_i \) by solving the system of \( k \) equations

\[ \sum_{i=0}^{k-1} d_i Q(w_{m+i}) = Q(\tilde{\omega}_m), \quad n \leq m \leq n + k - 1, \]  

(2.22)

where \( Q \) is a bounded linear functional on the space \( B \). In this case Approaches (a) and (b) give the same method, and this method is nothing but the TEA. In Section 5 we shall analyze the convergence and stability properties of this method in detail. By comparing (2.21) and (2.22), we see that for \( k = 1 \) the MMPE and the TEA are identical when we choose \( Q_1 = Q \).

Finally we note that all of the methods obtained as above are nonlinear in the \( x_i \).

### 3. Convergence Analysis Of MMPE

As in Section 2.2, we start with a sequence of vectors \( x_i, i = 0, 1, \ldots \), in a normed vector space \( B \) with norm \( \| \cdot \| \), that has a limit or anti-limit \( s \). We write \( u_i = \Delta x_i = x_{i+1} - x_i, i = 0, 1, \ldots \). Then the MMPE, as obtained from Approach (a) or (b) in conjunction with Method (2) (see Section 2.2), can be summarized (and reformulated) as follows: By Approach (b), the approximation \( s_{n,k} \) to \( s \) is given as

\[ s_{n,k} = \sum_{i=0}^{k} \gamma_i x_{n+i}, \]  

(3.1)

where \( \gamma_i \) are obtained from

\[ \sum_{i=0}^{k} \gamma_i = 1 \]  

(3.2)

\[ \sum_{i=0}^{k} \gamma_i Q_j(u_{n+i}) = 0, \quad 1 \leq j \leq k. \]

When \( \gamma_k \neq 0 \), equations (3.2) are equivalent to (2.18) and (2.21), in which \( d_i = c_i, \quad w_{n+i} = u_{n+i}, \quad 0 \leq i \leq k-1, \) and \( \tilde{\omega}_n = -u_{n+k} \), as can be verified by inspection.
We denote the scalars $Q_j(u_m)$ by $u_{m,j}$ for $1 \leq j \leq k$ and $m \geq 0$, and we define $D(\sigma_0, \sigma_1, \ldots, \sigma_k)$ to be the determinant

$$ D(\sigma_0, \sigma_1, \ldots, \sigma_k) = \begin{vmatrix} \sigma_0 & \sigma_1 & \cdots & \sigma_k \\ u_{n,1} & u_{n+1,1} & \cdots & u_{n+k,1} \\ u_{n,2} & u_{n+1,2} & \cdots & u_{n+k,2} \\ \vdots & \vdots & \ddots & \vdots \\ u_{n,k} & u_{n+1,k} & \cdots & u_{n+k,k} \end{vmatrix} \tag{3.3} $$

when $\sigma_i$ are scalars. Let $N_i$ be the cofactor of $\sigma_i$ in the first row expansion of this determinant. Then

$$ D(\sigma_0, \sigma_1, \ldots, \sigma_k) = \sum_{i=0}^{k} \sigma_i N_i. \tag{3.4} $$

When $\sigma_i$ are vectors, we again let $D(\sigma_0, \sigma_1, \ldots, \sigma_k)$ be defined by the determinant in (3.3), and take (3.4) as the interpretation of this determinant. Thus $D(\sigma_0, \sigma_1, \ldots, \sigma_k)$ is a scalar (or vector) if the $\sigma_i$ are scalars (or vectors).

Solving the system in (3.2) by Cramer's rule, we obtain

$$ \gamma_i = \frac{N_i}{D(1, 1, \ldots, 1)} = \frac{N_i}{\sum_{j=0}^{k} N_j}, \quad 0 \leq i \leq k, \tag{3.5} $$

provided $D(1, 1, \ldots, 1) \neq 0$; in what follows, we assume that this is so.

By (3.5), (3.1), and (3.4), we can finally express $s_{n,k}$ as

$$ s_{n,k} = \frac{D(x_n, x_{n+1}, \ldots, x_{n+k})}{D(1, 1, \ldots, 1)}. \tag{3.6} $$

**Lemma 3.1:** The error in $s_{n,k}$ can be expressed as

$$ s_{n,k} - s = \frac{D(x_n-s, x_{n+1}-s, \ldots, x_{n+k}-s)}{D(1, 1, \ldots, 1)}. \tag{3.7} $$

**Proof:** (3.7) follows easily from (3.4) to (3.6). \hfill \Box

In the sequel we shall assume that the vectors $x_m$ satisfy (2.11). Without loss of generality we shall also assume that $\lambda_i \neq 0$ and $v_i \neq 0$ for all $i \geq 1$. Then

$$ u_m \sim \sum_{i=1}^{\infty} z_i \lambda_i^m \text{ as } m \to \infty, \tag{3.8} $$
where \( z_i = (\lambda_i - 1)u_i \), \( i = 1, 2, \ldots \). Since \( \lambda_i \neq 1 \) and \( u_i \neq 0 \) for all \( i \geq 1 \), we have \( z_i \neq 0 \) for all \( i \geq 1 \). In addition, by (2.11), for any operator \( T \) in the dual space of \( B \),

\[
T(u_m) \sim \sum_{i=1}^{\infty} T(z_i) \lambda_i^m \quad \text{as} \quad m \to \infty. \tag{3.9}
\]

Consequently

\[
u_m,j \sim \sum_{i=1}^{\infty} z_{i,j} \lambda_i^m \quad \text{as} \quad m \to \infty, \tag{3.10}
\]

where \( z_{i,j} = Q_j(z_i) \), \( i \geq 1 \), \( 1 \leq j \leq k \).

Note that when the sequence \( x_m, \ m = 0, 1, \ldots \), is generated by the matrix iterative method described in Section 2.2, the summations over \( i \) in (3.8), (3.9), and (3.10) extend as far as \( M' \), which is a finite number; therefore, (3.9) and hence (3.10) hold automatically for this case, and \( \sim \) is replaced by \( = \).

The following theorem is the main result of this section.

**Theorem 3.2**: Define \( Q_j(v_i) = u_{i,j} \), \( i \geq 1 \), \( 1 \leq j \leq k \), and let

\[
F = \begin{bmatrix}
v_{1,1} & v_{2,1} & \cdots & v_{k,1} \\
v_{1,2} & v_{2,2} & \cdots & v_{k,2} \\
\vdots & \vdots & \ddots & \vdots \\
v_{1,k} & v_{2,k} & \cdots & v_{k,k}
\end{bmatrix} \neq 0. \tag{3.11}
\]

Assume that the \( v_i \) are linearly independent, and that the \( \lambda_i \) satisfy

\[
|\lambda_i| \geq \ldots \geq |\lambda_k| \geq |\lambda_{k+1}| \geq |\lambda_{k+2}| \geq \ldots \tag{3.12}
\]

Then, for all sufficiently large \( n \), \( D(1, 1, \ldots, 1) \neq 0 \); hence, \( s_{n,k} \), as given in (3.6), exists. Furthermore,

\[
s_{n,k} - s = \Gamma(n) \lambda_{k+1}^n \left[ 1 + o(1) \right] \quad \text{as} \quad n \to \infty, \tag{3.13}
\]

where the vector \( \Gamma(n) \) is nonzero and bounded for all sufficiently large \( n \). If, in addition, \( |\lambda_{k+1}| > |\lambda_{k+2}| \), then

\[
\Gamma(n) = \frac{1}{F} \begin{bmatrix}
v_1 & v_2 & \cdots & v_{k+1} \\
z_{1,1} & z_{2,1} & \cdots & z_{k+1,1} \\
z_{1,2} & z_{2,2} & \cdots & z_{k+1,2} \\
\vdots & \vdots & \ddots & \vdots \\
z_{1,k} & z_{2,k} & \cdots & z_{k+1,k}
\end{bmatrix} \prod_{i=1}^{k} \frac{(\lambda_{k+1} - \lambda_i)}{(|\lambda_i| - 1)^2}. \tag{3.14}
\]
Proof: For simplicity of notation we shall sometimes denote \( G_n = D(x_n - s, \ldots, x_{n+k} - s) \) and \( H_n = D(1, \ldots, 1) \), and we shall shorten "\( \alpha_n - \beta_n \) as \( n \to \infty \)" to "\( \alpha_n - \beta_n \)."

By (3.3) and (3.10) we have

\[
\begin{vmatrix}
1 & 1 & \ldots & 1 \\
\sum_{i_1=1}^{\infty} z_{i_1,1} \lambda_{i_1}^n & \sum_{i_1=1}^{\infty} z_{i_1,1} \lambda_{i_1}^{n+1} & \ldots & \sum_{i_1=1}^{\infty} z_{i_1,1} \lambda_{i_1}^{n+k} \\
\sum_{i_2=1}^{\infty} z_{i_2,2} \lambda_{i_2}^n & \sum_{i_2=1}^{\infty} z_{i_2,2} \lambda_{i_2}^{n+1} & \ldots & \sum_{i_2=1}^{\infty} z_{i_2,2} \lambda_{i_2}^{n+k} \\
\sum_{i_k=1}^{\infty} z_{i_k,k} \lambda_{i_k}^n & \sum_{i_k=1}^{\infty} z_{i_k,k} \lambda_{i_k}^{n+1} & \ldots & \sum_{i_k=1}^{\infty} z_{i_k,k} \lambda_{i_k}^{n+k}
\end{vmatrix}.
\]

(3.15)

We are allowed to write (3.15) since \( D(1, 1, \ldots, 1) \), being a determinant, is the sum of a finite number \((k!)\) of products of \( u_{i,j} \) and its asymptotic expansion as \( n \to \infty \) is the sum of the products of the asymptotic expansions of the respective \( u_{i,j} \). By the multilinearity property of determinants, (3.15) is equivalent to

\[
H_n \sim \sum_{i_1=1}^{\infty} \ldots \sum_{i_k=1}^{\infty} \left( \prod_{p=1}^{k} z_{i_p,p} \right) \left( \prod_{p=1}^{k} \lambda_{i_p}^n \right) V(1, \lambda_{i_1}, \ldots, \lambda_{i_k}),
\]

(3.16)

where \( V(\xi_0, \xi_1, \ldots, \xi_k) \) is the Vandermonde determinant defined by

\[
V(\xi_0, \xi_1, \ldots, \xi_k) =
\begin{vmatrix}
1 & 1 & \ldots & 1 \\
\xi_0 & \xi_1 & \ldots & \xi_k \\
\xi_0^2 & \xi_1^2 & \ldots & \xi_k^2 \\
\vdots & \vdots & \ddots & \vdots \\
\xi_0^k & \xi_1^k & \ldots & \xi_k^k
\end{vmatrix}.
\]

(3.17)

Since \( V(\xi_0, \ldots, \xi_k) \) is odd under an interchange of the indices \( 0, 1, \ldots, k \), by Lemma A.1 given in the appendix to this work, (3.16) can be expressed as

\[
H_n \sim \sum_{1 \leq i_1 < i_2 < \ldots < i_k} \left| \begin{array}{cccc}
z_{i_1,1} & z_{i_2,1} & \ldots & z_{i_k,1} \\
z_{i_1,2} & z_{i_2,2} & \ldots & z_{i_k,2} \\
\vdots & \vdots & \ddots & \vdots \\
z_{i_1,k} & z_{i_2,k} & \ldots & z_{i_k,k}
\end{array} \right| V(1, \lambda_{i_1}, \ldots, \lambda_{i_k}) \left( \prod_{p=1}^{k} \lambda_{i_p}^n \right).
\]

(3.18)
By (3.12), the most dominant term in the summation on the right side of (3.18) as \( n \to \infty \) is that for which \( i_1 = 1, i_2 = 2, \ldots, i_k = k \), provided that the determinant

\[
\tilde{F} = \begin{vmatrix}
  z_{11} & z_{21} & \cdots & z_{k1} \\
  z_{12} & z_{22} & \cdots & z_{k2} \\
  \vdots & \vdots & \ddots & \vdots \\
  z_{1k} & z_{2k} & \cdots & z_{kk}
\end{vmatrix}
\]

is nonzero. But since \( z_i = (\lambda_i - 1)\psi_i, i \geq 1 \), we have

\[
\tilde{F} = \left[ \prod_{i=1}^{k} (\lambda_i - 1) \right] F.
\]

(3.20)

where \( F \) is as defined in (3.11). Since \( F \neq 0 \) by assumption, \( \tilde{F} \neq 0 \) too; hence the first part of the theorem follows, with

\[
D(1, \ldots, 1) = \left[ \prod_{i=1}^{k} (\lambda_i - 1) \right] F \left( \prod_{p=1}^{k} \lambda_p^n \right) V(1, \lambda_1, \ldots, \lambda_k) [1 + o(1)] \text{ as } n \to \infty.
\]

(3.21)

For the proof of the second part we proceed similarly. By (2.11), (3.3), and (3.10), we have

\[
G_n \sim \sum_{i_0=1}^{\infty} \sum_{i_1=1}^{\infty} \cdots \sum_{i_k=1}^{\infty} \psi_{i_0} \lambda_{i_0}^n \psi_{i_1} \lambda_{i_1}^n + \cdots \psi_{i_k} \lambda_{i_k}^n + k
\]

\[
G_n = \sum_{i_0=1}^{\infty} \sum_{i_2=1}^{\infty} \cdots \sum_{i_k=1}^{\infty} \lambda_{i_0}^n \lambda_{i_2}^n + \cdots \lambda_{i_k}^n + k
\]

(3.22)

Again from the multilinearity property of determinants

\[
G_n \sim \sum_{i_0=1}^{\infty} \cdots \sum_{i_k=1}^{\infty} \psi_{i_0} \left( \prod_{p=1}^{k} z_{i_p} \right) \left( \prod_{p=0}^{k} \lambda_p^n \right) V(\lambda_{i_0}, \lambda_{i_1}, \ldots, \lambda_{i_k}).
\]

(3.23)

By Lemma A.1 given in the appendix to this work, (3.23) can be expressed as
By the assumptions made following (2.11), there is a finite number of $\lambda_i$ with moduli equal to $|\lambda_k+1|$. Let $|\lambda_k+1| = \ldots = |\lambda_k+r+1|$. From this and (3.12), it follows that the dominant term on the right side of (3.24) is the sum of those terms with indices $i_0 = 1, i_1 = 2, \ldots, i_k = k$, $i_{k-1} = k, i_k = k+l, \ell = 1, 2, \ldots, r$, that is,

$$D(x_{n-s}, \ldots, x_{n+k-s}) = \left( \prod_{p=1}^{k} \lambda_p^n \right) \sum_{\ell=1}^{r} \lambda_{k+\ell}^n V(\lambda_1, \ldots, \lambda_k, \lambda_{k+\ell})$$

Now the cofactor of $u_{k+\ell}$ in the determinant in (3.25) is $\tilde{F}$, which is nonzero since $F \neq 0$. Therefore, for $n$ sufficiently large, the coefficients of $u_{k+1}, \ldots, u_{k+r}$ are nonzero. Since we also assumed that the $v_i$ are linearly independent, the summation in (3.25) is never zero. Combining (3.21) and (3.25) in (3.7) results in (3.13). If $|\lambda_k+1| > |\lambda_k+2|$, then $r = 1$. In this case (3.14) follows from (3.21), (3.25), and the fact that

$$V(\xi_0, \xi_1, \ldots, \xi_k) = \prod_{0 \leq i < j \leq k} (\xi_j - \xi_i).$$

**Note:** The condition on the determinant given in (3.11) has some interesting implications when the normed vector space $B$ is a complete inner product space. In this case, for each $Q_j$ in the dual space of $B$, there exists a unique vector $q_j$ in $B$, such that $Q_j(z) = (q_j, z)$ for every $z$ in $B$, where $(\cdot, \cdot)$ is the inner product associated with $B$. Then (3.11) becomes

$$F = \begin{vmatrix} (q_1, v_1) & (q_1, v_2) & \ldots & (q_1, v_k) \\ (q_2, v_1) & (q_2, v_2) & \ldots & (q_2, v_k) \\ \vdots & \vdots & \ddots & \vdots \\ (q_k, v_1) & (q_k, v_2) & \ldots & (q_k, v_k) \end{vmatrix} \neq 0.$$
One of the consequences of (3.27) is that both sets of vectors $Q_k = \{q_1, \ldots, q_k\}$ and $V_k = \{v_1, \ldots, v_k\}$ have to be linearly independent. Another consequence is that the intersection of the subspace span $Q_k$ with that orthogonal to span $V_k$ must be $\{0\}$.

The asymptotic error analysis of the MMPE as given in Theorem 3.2 leads one to the following important conclusions:

1. Under the conditions stated in the theorem, the MMPE is a bona fide vector accelerator in the sense that

   $\frac{\|s_n - s\|}{\|x_{n+k+1} - s\|} = O\left(\left(\frac{\lambda_k + 1}{\lambda_1}\right)^n\right)$ as $n \to \infty$.  \hfill (3.28)

   This means that if $x_n \to s$, as $n \to \infty$, that is, $|\lambda_1| < 1$, then $s_{n,k} \to s$ as $n \to \infty$, and more quickly. Also if $\lim x_m$ does not exist, that is, $|\lambda_1| \geq 1$, then $s_{n,k} \to s$ as $n \to \infty$, provided that $|\lambda_{k+1}| < 1$. The reason that

   we write $x_{n+k+1}$ in (3.28) is that $s_{n,k}$ in the MMPE makes use of the $k+2$ vectors $x_n, x_{n+1}, \ldots, x_{n+k+1}$.

2. The result in (3.13) shows that when the MMPE is applied to a vector sequence generated by using the matrix iterative method described in Section 2.2, with the notation therein, it will be especially effective when the iteration matrix $A$ has a small number of large eigenvalues ($k$-many when $s_{n,k}$ is being used) that are well separated from the small eigenvalues.

3. By inspection of $\Gamma(n)$ in (3.13) and (3.14), it follows that a loss of accuracy will take place in $s_{n,k}$ when $\lambda_1, \ldots, \lambda_k$ are close to 1, since $\|\Gamma(n)\|$ becomes large in this case. When the vector sequence is obtained by solving the linear system of equations given in (2.12) by the iterative technique in (2.13), this means that if $A$ has large eigenvalues near 1, there will be a loss of accuracy in $s_{n,k}$. In fact eigenvalues near 1 would cause the system in (2.12) to be nearly singular.

4. Stability of MMPE

Let us denote the $\gamma_j$ of the previous section by $\gamma_j^{(n,k)}$. Then the propagation of errors introduced in the $x_m$ will be controlled, to some extent, by $\sum_{j=0}^{k} |\gamma_j^{(n,k)}|$; the larger this quantity, the worse the error propagation is expected to be. With this in mind, we say that $s_{n,k}$ is asymptotically stable if

$$\sup_n \sum_{j=0}^{k} |\gamma_j^{(n,k)}| < \infty. \hfill (4.1)$$

Since $\sum_{j=0}^{k} \gamma_j^{(n,k)} = 1$ by (3.2), then $\sum_{j=0}^{k} |\gamma_j^{(n,k)}| \geq 1$, so that the most ideal situation is that in which $\gamma_j^{(n,k)} \geq 0$, for $n$ sufficiently large. The following theorem shows that for the type of sequences considered in Theorem 3.2, $s_{n,k}$ as obtained from MMPE is asymptotically stable, and that $\gamma_j^{(n,k)} \geq 0$, for sufficiently large $n$, whenever $\lambda_i, 1 \leq i \leq k$, are real and negative.

**Theorem 4.1:** Under the conditions stated in Theorem 3.2, $s_{n,k}$ is asymptotically stable.

**Proof:** By (3.5), it is sufficient to show that $\gamma_j^{(n,k)}, 0 \leq j \leq k$, stay bounded for $n \to \infty$, which in turn guarantees (4.1). Now
Substituting the asymptotic expansions of $u_{m,j}$ as given in (3.10) and using the multilinearity property of determinants, we obtain

$$N_j = \sum_{i_1 = 1}^{\infty} \ldots \sum_{i_k = 1}^{\infty} \left( \prod_{p=1}^{k} z_{i_p,p} \right) \left( \prod_{p=1}^{k} \lambda_{i_p}^{n_p} \right) C_j(\lambda_{i_1}, \ldots, \lambda_{i_k}) \text{ as } n \to \infty,$$

where

$$C_j(\xi_1, \ldots, \xi_k) = (-1)^j \begin{vmatrix} 1 & \xi_1 & \cdots & \xi_1^{-1} & \xi_1^{j+1} & \cdots & \xi_1^k \\ 1 & \xi_2 & \cdots & \xi_2^{-1} & \xi_2^{j+1} & \cdots & \xi_2^k \\ \vdots & \vdots & \ddots & \vdots & \vdots & \ddots & \vdots \\ 1 & \xi_k & \cdots & \xi_k^{-1} & \xi_k^{j+1} & \cdots & \xi_k^k \end{vmatrix} \quad (4.4)$$

Since $C_j(\xi_1, \ldots, \xi_k)$ is odd under an interchange of the indices 1, \ldots, k, Lemma A.1 in the appendix again applies, and we have

$$N_j = \sum_{1 \leq i_1 < i_2 < \ldots < i_k} \begin{vmatrix} z_{i_1,1} & z_{i_2,1} & \cdots & z_{i_k,1} \\ z_{i_1,2} & z_{i_2,2} & \cdots & z_{i_k,2} \\ \vdots & \vdots & \ddots & \vdots \\ z_{i_1,k} & z_{i_2,k} & \cdots & z_{i_k,k} \end{vmatrix} C_j(\lambda_{i_1}, \ldots, \lambda_{i_k}) \left( \prod_{p=1}^{k} \lambda_{i_p}^{n_p} \right). \quad (4.5)$$

By (3.11), (3.19), (3.20), and (3.12)

$$N_j = F_j C_j(\lambda_1, \ldots, \lambda_k) \left( \prod_{p=1}^{k} \lambda_{i_p}^{n_p} \right) \left( 1 + o(1) \right) \text{ as } n \to \infty. \quad (4.6)$$
Combining (4.6) and (3.21) in (3.5), and using (3.20), we obtain

$$\gamma_j^{(n,k)} = \frac{C_j(\lambda_1, \ldots, \lambda_k)}{V(1, \lambda_1, \ldots, \lambda_k)} [1 + o(1)] \text{ as } n \to \infty. \quad (4.7)$$

Obviously, (4.7) also implies that $|\gamma_j^{(n,k)}| < \infty$ for sufficiently large $n$. This then proves (4.1).

Inspection of (4.4) reveals that $C_j(\lambda_1, \ldots, \lambda_k)$ is the cofactor of $\lambda^j$ in the first row of

$$V(\lambda, \lambda_1, \ldots, \lambda_k) = \begin{vmatrix}
1 & \lambda & \ldots & \lambda^k \\
1 & \lambda_1 & \ldots & \lambda_1^k \\
\vdots & \ddots & \ddots & \vdots \\
1 & \lambda_k & \ldots & \lambda_k^k
\end{vmatrix}, \quad (4.8)$$

that is,

$$V(\lambda, \lambda_1, \ldots, \lambda_k) = \sum_{j=0}^{k} C_j(\lambda_1, \ldots, \lambda_k) \lambda^j. \quad (4.9)$$

Combining (4.7) and (4.9), we obtain the following interesting result:

$$\lim_{n \to \infty} \sum_{j=0}^{k} \gamma_j^{(n,k)} \lambda^j = \frac{V(\lambda, \lambda_1, \ldots, \lambda_k)}{V(1, \lambda_1, \ldots, \lambda_k)}. \quad (4.10)$$

Invoking (3.26), (4.10) finally becomes

$$\lim_{n \to \infty} \sum_{j=0}^{k} \gamma_j^{(n,k)} \lambda^j = \prod_{i=1}^{k} \left(\frac{\lambda_i - \lambda}{\lambda_i - 1}\right). \quad (4.11)$$

Since $V(\lambda, \lambda_1, \ldots, \lambda_k)$ is a polynomial of degree $k$ and $\lambda$ and vanishes when $\lambda = \lambda_i, 1 \leq i \leq k$, we have

$$V(\lambda, \lambda_1, \ldots, \lambda_k) = C_k(\lambda_1, \ldots, \lambda_k) \prod_{p=1}^{k} (\lambda - \lambda_p). \quad (4.12)$$

Upon expanding the product on the right side of (4.12), and comparing with (4.9), we get

$$C_{k-j}(\lambda_1, \ldots, \lambda_k) = (-1)^j C_k(\lambda_1, \ldots, \lambda_k) \sum_{1 \leq i_1 < \ldots < i_j \leq k} \lambda_{i_1} \ldots \lambda_{i_j}, \quad 1 \leq j \leq k. \quad (4.13)$$
It is obvious from (4.13) that if $\lambda_i$, $1 \leq i \leq k$, are real and negative, then $\text{sgn} C_{k-j}(\lambda_1, \ldots, \lambda_k) = \text{sgn} C_k(\lambda_1, \ldots, \lambda_k)$ for $0 \leq j \leq k$, and this implies that $\gamma_{(n,k)}^{(n,k)} = 0$, $0 \leq j \leq k$, for $n$ sufficiently large. If $\lambda_i$, $1 \leq i \leq k$, are real and positive, then (4.13) implies that $\gamma_{(n,k)}^{(n,k)} < 0$, $0 \leq j \leq k - 1$.

5. Convergence and Stability of TEA

In this section we shall consider the convergence and stability properties of the TEA, which is obtained from Approach (a) or (b) in conjunction with Method (3) of Section 2.2. The TEA can be summarized as follows: The approximation $s_{n,k}$ to $s$ is given by

$$s_{n,k} = \sum_{i=0}^{k} \gamma_i x_{n+i},$$  \hspace{1cm} (5.1)

where $\gamma_i$ are obtained from the equations

$$\begin{align*}
\sum_{i=0}^{k} \gamma_i &= 1, \\
\sum_{i=0}^{k} \gamma_i Q(u_{m+i}) &= 0, \quad n \leq m \leq n + k - 1,
\end{align*}$$  \hspace{1cm} (5.2)

with $u_m = \Delta x_m = x_{m+1} - x_m$, $m \geq 0$, as before. When $\gamma_k \neq 0$, equations (5.2) are equivalent to (2.18) and (2.22), in which $d_i = c_i$, $w_{m+i} = u_{m+i}$, $0 \leq i \leq k - 1$, and $\bar{w}_m = -u_{m+k}$, as can be verified by inspection.

We now write the equations in (5.2) in the form

$$\begin{align*}
\sum_{i=0}^{k} \gamma_i &= 1, \\
\sum_{i=0}^{k} \gamma_i u_{n+i} &= 0, \quad 1 \leq j \leq k,
\end{align*}$$  \hspace{1cm} (5.3)

where this time $u_{m,j} = Q(u_{m+j-1})$, $m \geq 0$, $1 \leq j \leq k$. Defining $D(q_0, q_1, \ldots, q_k)$ as in (3.3) but with the $u_{m,j}$ of Section 3 replaced by the new $u_{m,j}$, we see that $s_{n,k}$ for TEA is given exactly by (3.6), as can be verified by Cramer's rule. Let us also define $z_{i,j} = Q(z_i) \lambda_i^{-1} = Q(v_i)(\lambda_i - 1)\lambda_i^{-1}$, $i \geq 1$, $1 \leq j \leq k$, where the $z_i$ are as defined in Section 3. Then under the assumptions preceding (3.10), (3.10) holds with the $z_{i,j}$ of Section 3 replaced by those of the present section. Starting with these observations, we now prove the following theorem:

**Theorem 5.1:** Assume that

$$Q(v_i) \neq 0, \quad 1 \leq i \leq k,$$  \hspace{1cm} (5.4)

and that all the conditions of Theorem 3.2 (with the exception of (3.11)) are satisfied. Then, for all
sufficiently large $n$, $\sum_{j=0}^{k} N_j \neq 0$, hence $s_{n,k}$ as given in (3.6) exists. Furthermore,

$$s_{n,k} - s = \Lambda(n) \lambda_{k+1}^{n} [1 + o(1)] \text{ as } n \to \infty,$$

(5.5)

where the vector $\Lambda(n)$ is nonzero and bounded for all sufficiently large $n$. If, in addition, $|\lambda_{k+1}| > |\lambda_{k+2}|$, then

$$\Lambda(n) = \begin{bmatrix} v_1 & v_2 & \cdots & v_{k+1} \\ z_{1,1} & z_{2,1} & \cdots & z_{k+1,1} \\ z_{1,2} & z_{2,2} & \cdots & z_{k+1,2} \\ \vdots & \vdots & \cdots & \vdots \\ z_{1,k} & z_{2,k} & \cdots & z_{k+1,k} \end{bmatrix} = \frac{\prod_{i=1}^{k} (\lambda_{k+1} - \lambda_i)}{V(\lambda_1, \ldots, \lambda_k) \left[ \prod_{i=1}^{k} (\lambda_i - 1)^2 \right] \left[ \prod_{i=1}^{k} Q(v_i) \right]} \prod_{i=1}^{k} (\lambda_{k+1} - \lambda_i)$$

(5.6)

Proof: The proof of this theorem proceeds along the same line as that of Theorem 3.2, using the additional relation

$$\begin{bmatrix} z_{1,1} & z_{2,1} & \cdots & z_{k,1} \\ z_{1,2} & z_{2,2} & \cdots & z_{k,2} \\ \vdots & \vdots & \cdots & \vdots \\ z_{1,k} & z_{2,k} & \cdots & z_{k,k} \end{bmatrix} = V(\lambda_1, \ldots, \lambda_k) \left[ \prod_{i=1}^{k} Q(v_i) \right]$$

(5.7)

Note: When the normed vector space $B$ is a Hilbert space, the condition (5.4) has the following implication: Let $q$ be the unique vector in $B$ for which $Q(z) = (q, z)$ for every $z$ in $B$. Then (5.4) implies that $q$ cannot be orthogonal to any of the vectors $v_i$, $1 \leq i \leq k$.

As a result of the asymptotic error analysis of the TEA given in Theorem 5.1, we can draw conclusions that are identical to those about the MMPE given at the end of Section 3. We find that (3.27) is replaced by

$$\frac{\|s_{n,k} - s\|}{\|x_{n+2k} - s\|} = O \left( \left( \frac{\lambda_{k+1}}{\lambda_1} \right)^n \right) \text{ as } n \to \infty,$$

(5.8)

since $s_{n,k}$ for TEA is formed by taking into account the $2k + 1$ vectors $x_n, x_{n+1}, \ldots, x_{n+2k}$, instead of the $k + 2$ vectors $x_n, x_{n+1}, \ldots, x_{n+k+1}$ used to form $s_{n,k}$ for the MMPE. This in turn implies that the MMPE is a more economical vector accelerator than the TEA, since it attains the same rate of acceleration as the TEA while using approximately half the number of vectors.

Finally the stability properties of the TEA are very similar to those of the MMPE as is stated in the following theorem.
Theorem 5.2: Under the conditions stated in Theorem 5.1 $s_{n,k}$ is asymptotically stable. Furthermore, (4.7) and (4.11) hold too.

Proof: Similar to that of Theorem 4.1.

The conclusions that were drawn from the stability analysis of the MMPE in Section 4, are true for the TEA too, as some analysis reveals.

6. Numerical Examples

In Section 3 we analyzed the convergence properties of $s_{n,k}$ for the MMPE as $n \to \infty$, and derived an asymptotic error estimate for it, obtaining at the same time its rate of convergence. In this section we apply the MMPE and the MPE to three vector sequences obtained as iterative approximations to linear systems of equations. The numerical results verify the conclusions of the asymptotic error analysis of Section 3. They also indicate that the MMPE and the MPE have very similar performances.

In all the examples below the MPE is implemented by solving the generally overdetermined system

$$\sum_{i=0}^{k-1} c_i u_{n+i} = -u_{n+k}$$

for the $c_i$ using the method of least squares and then setting $\gamma_i = c_i \left/ \sum_{j=0}^{k} c_j, \; 0 \leq i \leq k, \; \text{with} \; c_k = 1, \; \text{in (2.17)}. \right.$$

As before $u_j = x_{j+1} - x_j, \; j = 0, 1, \ldots$, The MMPE, on the other hand, is implemented by solving the linear system of $k$ equations

$$\sum_{i=0}^{k-1} c_i u_{n+i,j} = -u_{n+k,j}, \; 1 \leq j \leq k,$$

where $u_{m,j}$ denotes the $j$th component of the vector $u_m$. That is to say, we pick the linear functional $Q_j$ in (2.17) to be the projection operator onto the subspace spanned by the $j$th unit vector, $j = 1, \ldots, k$.

We then set $\gamma_i = c_i \left/ \sum_{j=0}^{k} c_j, \; 0 \leq i \leq k, \; \text{with} \; c_k = 1, \; \text{in (2.17)}. \right.$

Example 1. The vectors $x_i$ are obtained by setting $x_0 = 0$ and $x_{i+1} = Ax_i + b$, where $A$ is the iteration matrix associated with the Gauss-Seidel method for the system of linear equations $Cx = d$, where

$$C = \begin{bmatrix} 2 & 1 & 3 & 4 \\ 1 & -3 & 1 & 5 \\ 3 & 1 & 6 & -2 \\ 4 & 5 & -2 & -1 \end{bmatrix}$$

and $d$ and/or $b$ are determined by requiring that the solution $s$ to $Cx = d$ be the vector with all its entries equal to 1. The eigenvalues of $A$ are approximately $\lambda_1 = \lambda_2 = -2.3500 \pm i2.0506$, $\lambda_3 = -0.0228$, and $\lambda_4 = 0$. Therefore, $\lim_{i \to \infty} x_i$ does not exist. In Table I we give the errors $\|s_{n,k} - s\|_\infty$ computed in the $\ell_\infty$ norm for $k = 2$ and $0 \leq n \leq 5$, both for the MMPE and the MPE.
Example 2. The vectors $x_i$ are obtained by setting $x_0 = 0$ and $x_{i+1} = Ax_i + b$, $i = 0, 1, \ldots$, where

$$
\begin{bmatrix}
  5 & 2 & 1 & 1 \\
  2 & 6 & 3 & 1 & 1 \\
  1 & 3 & 6 & 3 & 1 & 1 \\
  1 & 1 & 3 & 6 & 3 & 1 & 1 \\
  1 & 1 & 3 & 6 & 3 & 1 & 1 \\
  1 & 1 & 3 & 6 & 3 & 1 & 1 \\
  1 & 1 & 3 & 6 & 3 & 1 & 1 \\
  1 & 1 & 3 & 6 & 3 & 1 & 1 \\
  1 & 1 & 3 & 6 & 2 \\
  1 & 1 & 2 & 5
\end{bmatrix}
$$

$$A = 0.06 \times
\begin{bmatrix}
  1 & 1 & 3 & 6 & 3 & 1 & 1 \\
  1 & 1 & 3 & 6 & 3 & 1 & 1 \\
  1 & 1 & 3 & 6 & 3 & 1 & 1 \\
  1 & 1 & 3 & 6 & 3 & 1 & 1 \\
  1 & 1 & 3 & 6 & 2 \\
  1 & 1 & 2 & 5
\end{bmatrix}
$$

and $b$ is determined by requiring that the solution $s$ of the system $x = Ax + b$ be the vector with all its entries equal to 1. The eigenvalues of $A$ are all real and in $(0,1)$, and are approximately $\lambda_1 = 0.8965$, $\lambda_2 = 0.7318$, $\lambda_3 = 0.5297$, $\lambda_4 = 0.3600$, $\ldots$, $\lambda_{11} = 0.0313$, in decreasing order. Since $\lambda_1 < 1$, the sequence $x_i$, $i = 0, 1, 2, \ldots$, converges.

In Figures 1 and 2 we give the results of the computations for $\|s_{n,k} - s\|_\infty$ using both the MMPE and the MPE with $k = 1$ and $k = 2$, respectively. The figures also include $\|x_{n+k+1} - s\|_\infty$. 

---

**TABLE I.** $\ell_\infty$ NORMS OF THE ERRORS $s_{n,k} - s$ FOR EXAMPLE 1, COMPUTED USING MMPE AND MPE, FOR $k = 2$ AND $0 \leq n \leq 5$

[The numbers have been rounded to one significant decimal digit. The base iterations $x_j$ diverge.]
Figure 1. - Results for Example 2 taking \( k = 1 \).
Example 3. The vectors \( x_i \) are obtained by setting \( x_0 = 0 \) and \( x_{i+1} = Ax_i + b \), \( i = 0, 1, \ldots \), where

\[
A = \begin{bmatrix} 12 & 11 \\ 11 & 11 & 10 \\ 10 & 10 & 10 & 9 \\ \vdots & \vdots & \vdots & \vdots & \vdots \\ 2 & 2 & 2 & \ldots & 2 & 1 \\ 1 & 1 & 1 & \ldots & 1 & 1 \\ \end{bmatrix}
\]

and \( b \) is determined by requiring that the solution \( s \) of the system \( x = Ax + b \) be the vector with all its entries equal to 1. The eigenvalues of \( A \) are all real and are approximately \( \lambda_1 = 1.2892 \), \( \lambda_2 = 0.8080 \), \( \lambda_3 = 0.4924 \), \( \lambda_4 = 0.2785 \), \ldots , \( \lambda_{12} = 0.0012 \), in decreasing order. Since \( \lambda_1 > 1 \), the sequence \( x_i \), \( i = 0, 1, 2, \ldots \), diverges. In figures 3 and 4 we give the results of the computations for \( \| S_{n,k} - s \|_\infty \) using both the MMPE and the MPE, with \( k = 2 \) and \( k = 3 \), respectively.
Figure 3. - Results for Example 3 taking $k = 2$. The base iterations $x_j$ diverge.
Figure 4. – Results for Example 3 taking $k = 3$. The base iterations $x_j$ diverge.
Lemma A.1: Let $i_0, i_1, \ldots, i_k$ be integers greater than or equal to 1, and assume that the scalars $u_{i_0}, \ldots, u_{i_k}$ are odd under an interchange of any two indices $i_0, \ldots, i_k$. Let $a_l$, $l \geq 1$, be scalars (or vectors), and let $t_{i_j,l}$, $i_j \geq 1$, $1 \leq j \leq k$, be scalars. Define

$$ I_{k,N} = \sum_{i_0=1}^{N} \cdots \sum_{i_k=1}^{N} \sigma_{i_0} \left( \prod_{p=1}^{k} t_{i_p,p} \right) u_{i_0}, \ldots, i_k $$ (A.1)

and

$$ J_{k,N} = \sum_{1 \leq i_0 < i_1 < \ldots < i_k \leq N} \sigma_{i_0} \sigma_{i_1} \cdots \sigma_{i_k} 
\begin{vmatrix} 
\sigma_{i_0} & \sigma_{i_1} & \cdots & \sigma_{i_k} \\
t_{i_0,1} & t_{i_1,1} & \cdots & t_{i_k,1} \\
t_{i_0,2} & t_{i_1,2} & \cdots & t_{i_k,2} \\
\vdots & \vdots & \ddots & \vdots \\
t_{i_0,k} & t_{i_1,k} & \cdots & t_{i_k,k} 
\end{vmatrix} u_{i_0}, \ldots, i_k $$ (A.2)

where the determinant in (A.2) is to be interpreted in the same way as $D(a_0, \ldots, a_k)$ in (3.3). Then

$$ I_{k,N} = J_{k,N} $$ (A.3)

Proof: Let $\Sigma_k$ be the set of all permutations of $\{0, 1, \ldots, k\}$. Then by the definition of determinants

$$ J_{k,N} = \sum_{1 \leq i_0 < i_1 < \ldots < i_k \leq N} \sum_{\pi \in \Sigma_k} \left( \text{sgn } \pi \sigma_{i_{\pi(0)}} \left( \prod_{p=1}^{k} t_{i_{\pi(p)},p} \right) u_{i_0}, \ldots, i_k \right) $$ (A.4)

Now $\pi^{-1}\pi(p) = p$, $0 \leq p \leq k$, and $\text{sgn } \pi^{-1} = \text{sgn } \pi$ for any permutation $\pi \in \Sigma_k$. Hence

$$ J_{k,N} = \sum_{1 \leq i_0 < i_1 < \ldots < i_k \leq N} \sum_{\pi \in \Sigma_k} \left( \text{sgn } \pi^{-1} \sigma_{i_{\pi(0)}} \left( \prod_{p=1}^{k} t_{i_{\pi(p)},p} \right) u_{i_{\pi^{-1}(0)}}, \ldots, i_{\pi^{-1}(k)} \right) $$ (A.5)

By the oddness of $u_{i_0}, \ldots, i_k$, we have

$$ (\text{sgn } \pi^{-1}) u_{i_{\pi^{-1}(0)}}, \ldots, i_{\pi^{-1}(k)} = u_{i_{\pi(0)}}, \ldots, i_{\pi(k)} $$ (A.6)
Substituting (A.6) in (A.5), we obtain

\[ J_{k,N} = \sum_{1 \leq l_0 < l_1 < \ldots < l_k \leq N} \sum_{\pi \in \Sigma_k} \sigma_{\pi(l_0)} \left( \prod_{p=1}^{k} l_{\pi(p)}, p \right) u_{i_{\pi(0)}}, \ldots, i_{\pi(p)}, \right. \]  \hspace{1cm} \text{(A.7)}

Since \( u_{i_0}, \ldots, i_k \) is odd under interchange of the indices \( i_0, \ldots, i_k \), it vanishes when any two of these indices are equal. Using this fact in (A.1), we see that \( I_{k,N} \) is just the sum over all permutations of the distinct indices \( i_0, \ldots, i_k \). The result now follows by comparison with (A.7).

Note that when the \( a_j \) are scalars, (A.3) remains true also for the case in which the \( u_{i_0}, \ldots, i_k \) are vectors. When the \( a_j \) and \( u_{i_0}, \ldots, i_k \) are vectors, (A.3) still holds provided \( a_{i_0} u_{i_0}, \ldots, i_k \) is interpreted as a direct (tensor) product.

References

A general approach to the construction of convergence acceleration methods for vector sequences is proposed. Using this approach, one can generate some known methods, such as the minimal polynomial extrapolation, the reduced rank extrapolation, and the topological epsilon algorithm, and also some new ones. Some of the new methods are easier to implement than the known methods and are observed to have similar numerical properties. The convergence analysis of these new methods is carried out, and it is shown that they are especially suitable for accelerating the convergence of vector sequences that are obtained when one solves linear systems of equations iteratively. A stability analysis is also given, and numerical examples are provided. The convergence and stability properties of the topological epsilon algorithm are likewise given.
