GT&PDL Report No. 171 March 1983

This research, carried out in the Gas Turbine and
Plasma Dynamics Laboratory, MIT, was supported by the NASA
Lewis Research Center under Grant No. NAG3-9.
Abstract

An asymptotic technique is developed for analysing the propagation and dissipation of wave-like solutions to finite difference equations. It is shown that for each fixed complex frequency there are usually several wave solutions with different wavenumbers and the slowly varying amplitude of each satisfies an asymptotic amplitude equation which includes the effects of smoothly varying coefficients in the finite difference equation's. The local group velocity appears in this equation as the velocity of convection of the amplitude. Asymptotic boundary conditions coupling the amplitudes of the different wave solutions are also derived.

A wavepacket theory is developed which predicts the motion, and interaction at boundaries, of wavepackets, wave-like disturbances of finite length. Comparison with numerical experiments demonstrates the success and limitations of the theory.

Finally an asymptotic global stability analysis is developed which gives results which agree with other stability analyses and which can be applied to a wider range of problems.

1. Introduction

Consider the following very simple problem and numerical solution. The partial differential equation is

\[ \frac{\partial u}{\partial t} + c \frac{\partial u}{\partial x} = 0 \] (1.1)

where \( c \) is a positive constant. The domain considered is \( 0 < x < 1 \). The initial condition is

\[ u(x, 0) = \exp[-200(x-0.5)^2] \cos(kx) \] (1.2)

with \( k = 80 \). This form of distribution is usually called a wavepacket. The \( \cos(kx) \) term defines the oscillation of a group of waves and the \( \exp[-200(x-0.5)^2] \) term is an amplitude 'envelope'.

The upstream condition is

\[ u(0, t) = 0 \] (1.3)

The solution of this problem is

\[ u(x, t) = \begin{cases} 
  u(x-ct, 0) & ct < x < 1 \\
  0 & 0 < x < ct 
\end{cases} \] (1.4)

The numerical solution uses a uniform grid with computational domain \( 0 < j < 200 \) and a trapezoidal scheme.

\[ u_{j}^{n+1} - u_{j}^{n} + \frac{r}{4} \left( u_{j+1}^{n+1} + u_{j+1}^{n} - (u_{j-1}^{n+1} + u_{j-1}^{n}) \right) = 0 \] (1.5)

where \( r = \frac{ct}{\Delta x} \) (1.6)

In this example \( r = 1 \). The initial condition is

\[ u_{j}^{0} = u(x_{j}, 0) \] (1.7)

and the upstream boundary condition is
\[ u^n_0 = 0 \] (1.8)

In addition a numerical boundary condition is required at the downstream boundary. For this condition space extrapolation is used.

\[ u^n_{200} = u^n_{199} \] (1.9)

Figure 1 shows the numerical solution at intervals of 60 time steps with each plot drawn to the same scale. The first two plots show the initial wavepacket travelling downstream in the direction of the physical characteristic. Corresponding wavecrests are labelled a-e and it can be seen that the propagation velocity for the wave crests is greater than for the amplitude envelope. Note for example that the amplitude maximum lies approximately midway between crests b and d at \( n=60 \) but at \( n=120 \) the maximum is clearly nearer crest b. At \( n=180 \) the numerical disturbance is interacting with the downstream boundary. The solution appears to be the sum of two waves, one with the original wavelength, and one with a very much shorter wavelength. At \( n=240 \) there is a reflected wavepacket of wavelength slightly greater than 2, and the plots at \( n=300, 360 \) show that this wavepacket travels back up the domain at approximately the same speed as the original wavepacket. This solution is clearly numerical and not physical since the analytic, physical solution moves from left to right across the domain and then out the downstream boundary. The analytic equation does not have any solutions with waves travelling from right to left. At \( n=420 \) the wavepacket is interacting with the upstream boundary, and at \( n=480 \) there is a reflected wavepacket with the original wavelength. This completes one cycle. If the solution was continued the wavepacket would travel down to the downstream boundary and then reflect again into a
n = 60 Wavepacket Disturbance With Constant Frequency and Finite Amplitude Envelope.

n = 120 The Amplitude Envelope Has Moved at a Slightly Smaller Velocity Than the Wavecrests.

n = 180 The Wavepacket is Interacting With the Downstream Boundary.

n = 240 The Reflected Wavepacket Has Smaller Amplitude and a Wavelength Slightly Greater Than 2.

n = 300 The Wavepacket Travels Upstream.

n = 360 The Wavepacket Continues To Travel Upstream.

n = 420 The Wavepacket is Interacting With the Upstream Boundary.

n = 480 The Reflected Wavepacket Has the Same Wavelength as the Original Wavepacket.

FIGURE 1. NUMERICAL SOLUTION OF CONVECTION EQUATION
wavepacket with short wavelength, and a decreased amplitude, travelling upstream.

The qualitative and quantitative prediction of the behaviour of numerical solutions in problems such as the above is one of the two objectives of this paper. The second objective is a global stability analysis incorporating boundary conditions and smoothly varying coefficients and predicting both stability and accurate asymptotic estimates of convergence rates.

To achieve these aims a technique is developed to analyse the approximate time evolution of an amplitude modulated wave, i.e. a wave with fixed frequency and a slowly varying amplitude. Chapter 2 derives the theory for partial differential equations, while chapter 3 derives the theory for finite difference equations incorporating smoothly varying coefficients and boundary conditions. In the case of dispersive, non-dissipative wave propagation, it is found that the amplitude is convected at the local group velocity, a principle which is well understood in partial differential equations.

Chapter 4 applies the theory to the motion of wavepackets which are wave-like disturbances of finite length and constant frequency such as in the earlier example. Chapters 5 and 6 derive global stability analyses with different levels of asymptotic approximation. Chapters 7-9 develop further topics and examples including comparisons between numerical experiments and theoretical predictions.

Throughout this paper a finite operator notation is used which greatly simplifies analysis and is a necessity
for general proofs. Since there is no universally accepted standard notation Appendix 1 details the notation used.

Very little previous work appears to have been done along the lines of this paper. The concept of group velocity in partial differential equations is well understood and is explained in many texts \(^1,2\). The asymptotic approach of chapter 2 is not common due to the advantages of other methods but is discussed by Whitham \(^1\). Kentzer \(^3\) has discussed the use of group velocity in analysing finite difference equations but does not derive a general equation for the amplitude or calculate the quantitative effects of boundary conditions. Vichnevetsky and Bowles \(^4\) derive the group velocity in finite difference equations using an approach which is valid only for constant coefficients. They also derive amplitude reflection coefficients at boundaries and discuss some of the examples given in this paper.
2. Amplitude Analysis of Partial Differential Equations

2.1 Fourier Analysis

Consider a homogeneous partial differential equation

\[ L \, u(x,t) = 0 \quad -\infty < x < \infty, \ t > 0 \]  

(2.1)

where \( L \) is a constant linear differential operator defined by,

\[ L = \sum_{m,n} C_{mn} \left( \frac{\partial}{\partial x} \right)^m \left( \frac{\partial}{\partial t} \right)^n \]  

(2.2)

and the coefficients \( C_{mn} \) are constants.

An eigenfunction of the operator \( L \) is a function \( u(x,t) \) satisfying

\[ L \, u = \lambda u \]  

(2.3)

where \( \lambda \) is a constant called the eigenvalue.

An eigenmode is a solution of the homogeneous equation (2.1) i.e. it is an eigenfunction with eigenvalue zero.

\[ \frac{\partial}{\partial x} \exp[i(kx-\omega t)] = i(kx-\omega t) \exp[i(kx-\omega t)] \]  

(2.4a)

\[ \frac{\partial}{\partial t} \exp[i(kx-\omega t)] = -i\omega \exp[i(kx-\omega t)] \]  

(2.4b)

\[ \left( \frac{\partial}{\partial x} \right)^m \left( \frac{\partial}{\partial t} \right)^n \exp[i(kx-\omega t)] = (ik)^m(-i\omega)^n \exp[i(kx-\omega t)] \]  

(2.4c)
\[ \sum_{m,n} C_{mn} \left( \frac{\partial^m}{\partial x^m} \frac{\partial^n}{\partial t^n} \right) \exp[i(kx-\omega t)] = \sum_{m,n} C_{mn} (ik)^m (-i\omega)^n \exp[i(kx-\omega t)] \quad (2.4d) \]

Thus \( \exp[i(kx-\omega t)] \) is an eigenfunction of \( \frac{\partial^m}{\partial x^m} \frac{\partial^n}{\partial t^n} \) and \( L \) with eigenvalues \( ik, -i\omega \), \( (ik)^m (-i\omega)^n \), and \( \sum_{m,n} C_{mn} (ik)^m (-i\omega)^n \) respectively.

Hence,

\[ u(x,t) = \exp[i(kx-\omega t)] \quad (2.5) \]

is an exact solution of (2.1) provided

\[ \sum_{m,n} C_{mn} (ik)^m (-i\omega)^n = 0 \quad (2.6) \]

This relation between \( k \) and \( \omega \) is called the dispersion relation.

Examples of dispersion relations are:

- Surface waves on deep water
  \[ \omega^2 = |gk| \quad (2.7a) \]
- Acoustic waves
  \[ \omega^2 = c^2 k^2 \quad (2.7b) \]
- Waves propagating along a waveguide
  \[ \omega^2 = c^2 (k^2 + k_0^2) \quad (2.7c) \]

where \( g, c \) and \( k_0 \) are constants.

A general solution of (2.1) is a superposition of eigenmodes which in the case of a partial differential equation is expressed as an integral over all the wavenumbers \( k \) of the sum of all the eigenmodes with wavenumber \( k \).

\[ u(x,t) = \int_{-\infty}^{\infty} \sum_{n=1}^{N} A_n(k) \exp[i(kx-\omega_n t)] \, dk \quad (2.8) \]
If the dispersion relation is of order \( N \) in \( \omega \), i.e. it contains powers of \( \omega \) up to \( \omega^N \), then

\[ \omega_1(k), \omega_2(k), \ldots, \omega_N(k) \]

are the \( N \) values of \( \omega \) which satisfy the dispersion relation for a given value of \( k \) and the \( \lambda_n(k) \) are the corresponding constant amplitudes of those eigenmodes.

If \( \lambda_n(k) \) is non-zero for all \( k,n \) then a necessary and sufficient condition for \( u(x,t) \) to remain bounded and not increase exponentially is that each eigenmode must remain bounded. Splitting \( \omega \) into its real and imaginary components gives,

\[ \omega = \omega_R + i\omega_I \]  

(2.9)

\[ \exp[-i\omega t] = \exp[-i\omega_R t + \omega_I t] \]  

(2.10)

Thus the condition that every eigenmode remain bounded, and hence a general solution remain bounded, is

\[ \omega_I < 0 \]  

for all \( k,n \).

This analysis is lacking in three respects. The first is that in some situations the initial disturbance is zero except for a finite region and one wants to know the time evolution of this disturbance, in particular the propagation velocity for the energy. The second failing is that when the initial-value problem is replaced by an initial-value / boundary-value problem with boundary conditions at \( x = 0,1 \) there is no easy way to include the effect of the boundary conditions in this stability analysis. The third failing is that \( \exp[i(kx-\omega t)] \) is an eigenfunction of \( L \) only when the coefficients \( C_{mn} \) are constant. The analysis breaks down when the coefficients are non-constant.
The resolution of these problems requires the analysis of a wave of constant frequency with an amplitude which varies over a characteristic length scale much greater than the wavelength.
2.2 Asymptotic Amplitude Equation

The problem now being considered is
\[ L(x) u(x,t) = 0 \quad -\infty < x < \infty, \ t > 0 \quad (2.11) \]
where \( L(x) \) is a non-constant linear differential operator defined by,
\[ L(x) = \sum_{m,n} C_{mn}(x) \left( \frac{\partial}{\partial x} \right)^m \left( \frac{\partial}{\partial t} \right)^n \quad (2.12) \]
and the coefficients \( C_{mn}(x) \) are slowly varying functions of \( x \).

The theory calculates the approximate evolution of a wavetrain with waves of a constant frequency \( \omega \) and a slowly varying amplitude, so \( u(x,t) \) is written as,
\[ u(x,t) = A(x,t) \exp(i\varphi(x,t)) \quad (2.13) \]
where \( A(x,t) \) is the slowly varying amplitude and \( \varphi(x,t) \) is the phase of the wave which is related to the frequency \( \omega \) and wavenumber \( k \) by
\[ \frac{\partial \varphi}{\partial t} = -\omega \quad (2.14) \]
\[ \frac{\partial \varphi}{\partial x} = k \quad (2.15) \]

The frequency \( \omega \) is constant but the wavenumber \( k \) will vary slowly with \( x \) because of the slowly varying coefficients \( C_{mn}(x) \) so the above relations can be integrated to give,
\[ \varphi(x,t) = \int_{0}^{x} k(\xi) \, d\xi - \omega t \quad (2.16) \]
To explain the asymptotic approximations which are made two characteristic length scales $L_k$ and $L_A$ and one characteristic time scale $T_A$ are defined. $L_k$ is the length scale for variations in $k$, $L_A$ is the length scale for variations in the amplitude $A$, and $T_A$ is the time scale for variations in $A$. Numerical values for $L_k$, $L_A$ and $T_A$ are given by,

\begin{align}
L_k &= \min \left( k, \frac{\partial k}{\partial x} \right) \\
L_A &= \min \left( A, \frac{\partial A}{\partial x} \right) \\
T_A &= \min \left( A, \frac{\partial A}{\partial t} \right)
\end{align}

The asymptotic approximations used in this theory are

$L_k \gg k^{-1} \quad L_A \gg k^{-1} \quad T_A \gg \omega^{-1}$

which imply

\begin{align}
\frac{\partial k}{\partial x} \ll k^2 & \quad \frac{\partial A}{\partial x} \ll Ak \\
\frac{\partial A}{\partial t} \ll A\omega
\end{align}

A Taylor series expansion of $A$ and $\mathcal{F}$ about a point $(x_0, t_0)$ gives

\begin{align}
A(x, t) &= A_0 + \frac{\partial A}{\partial x_0} (x-x_0) + \frac{\partial A}{\partial t_0} (t-t_0) + H.O.T \\
\mathcal{F}(x, t) &= \mathcal{F}_0 - \omega(t-t_0) + \int_{x_0}^{x} k(\xi) \, d\xi
\end{align}

\begin{align}
= \mathcal{F}_0 - \omega(t-t_0) + \int_{x_0}^{x} [k_0 + \frac{\partial k}{\partial x_0} (\xi-x_0) + H.O.T] \, d\xi
\end{align}
\[ u(x,t) = \exp \left[ i \varphi_0 + i k_0 (x-x_0) - i \omega (t-t_0) + \frac{1}{2} \frac{3k}{\partial x_0} (x-x_0)^2 + \text{H.O.T.} \right] \] (2.19)

Subscript \( \scriptscriptstyle o \) denotes terms evaluated at \((x_0,t_0)\).

The H.O.T., higher order terms, includes terms like
\[ \frac{3^2 A}{\partial x^2}, \frac{3^2 A}{\partial t^2}, \frac{3^1 k}{\partial x^1} A \] which are \( \mathcal{O}(A(L_A)^{-1}, A(T_A)^{-2}, A(L_k)^{-1}) \)
and are neglected in this asymptotic approximation.

\[ \exp[i\varphi(x,t)] = \exp \left[ i \varphi_0 + i k_0 (x-x_0) - i \omega (t-t_0) + \frac{1}{2} \frac{3k}{\partial x_0} (x-x_0)^2 + \text{H.O.T.} \right] \]

Subscript \( \scriptscriptstyle o \) denotes terms evaluated at \((x_0,t_0)\).

\[ \text{Hence,} \]
\[ u(x,t) = \exp \left[ i \varphi_0 + i k_0 (x-x_0) - i \omega (t-t_0) \right] \left( 1 + \frac{1}{2} \frac{3k}{\partial x_0} (x-x_0)^2 \right) \]
\[ \left( A_0 + \frac{3A}{\partial x_0} (x-x_0) + \frac{3A}{\partial t_0} (t-t_0) \right) + \text{H.O.T.} \] (2.20)

To evaluate derivatives of \( u(x,t) \) at \((x_0,t_0)\) a two-variable version of Leibnitz's rule is used.

\[ \left( \frac{\partial}{\partial x} \right)^m \left( \frac{\partial}{\partial t} \right)^n \left[ f(x,t) g(x,t) \right] = \]
\[ \sum_{p=0}^{m} \sum_{q=0}^{n} \frac{m!}{p!(m-p)!} \frac{n!}{q!(n-q)!} \left( \frac{\partial}{\partial x} \right)^p \left( \frac{\partial}{\partial t} \right)^q f \left( \frac{\partial}{\partial x} \right)^{m-p} \left( \frac{\partial}{\partial t} \right)^{n-q} g \]
Let
\[ f(x,t) = \exp\left[i\varphi_0 + ik_0(x-x_0) - i\omega(t-t_0)\right] \]  
(2.22)

\[ g(x,t) = A_0 + 3A_0 \frac{\partial^2}{\partial x_0^2} (x-x_0) + \frac{3A_0}{2} \frac{\partial^2}{\partial t_0^2} (t-t_0) + \frac{i}{2} A_0 \frac{\partial^2}{\partial x_0^2} (x-x_0)^2 \]  
(2.23)

Then,
\[ \left( \frac{\partial}{\partial x} \right)^n \left( \frac{\partial}{\partial t} \right)^m \left( \frac{\partial}{\partial x_0} \right)^i \left( \frac{\partial}{\partial t_0} \right)^j f \right)_{x_0,t_0} = (ik_0)^P (-i\omega)^Q \exp[i\varphi_0] \]  
(2.24)

\[ g_0 = A_0 \]  
(2.25)

\[ \frac{3g}{3x_0} = \frac{3A}{3x_0} \]  
(2.26)

\[ \frac{3g}{3t_0} = \frac{3A}{3t_0} \]  
(2.27)

\[ \frac{3^i g}{3x_0^i} = iA_0 \frac{\partial^i}{\partial x_0^i} \]  
(2.28)

and all other derivatives of \( g(x,t) \) evaluated at \( (x_0, t_0) \) are zero. Hence,
\[ \left( \frac{\partial}{\partial x} \right)^m \left( \frac{\partial}{\partial t} \right)^n u(x,t) = \exp[i\varphi_0] \cdot \]  
(2.29)

\[ A_0 (ik_0)^m (-i\omega)^n + m \frac{3A_0}{3x_0} (ik_0)^{m-1} (-i\omega)^n + n \frac{3A_0}{3t_0} (ik_0)^m (-i\omega)^{n-1} \]
\[ + i \frac{m(m-1)}{2} A_0 \frac{3k}{3x_0} (ik_0)^{m-2} (-i\omega)^n \]  
(2.30)

and so,
L(x) u(x,t) = \exp\{\text{i} \tilde{\gamma}\} \sum_{m,n} C_{mn} \left[ A(ik)^m (-i\omega)^n + \right.

\left. \frac{3A}{\delta x} (ik)^{m-1} (-i\omega)^n + n \frac{3A}{\delta t} (ik)^m (-i\omega)^{n-1} + \right.

\left. i \frac{m(m-1)}{2} \frac{3 k}{\delta x} (ik)^{m-2} (-i\omega)^n \right] + \text{H.O.T.} \quad (2.31)

To satisfy the homogeneous equation (2.12) the amplitude \(A(x,t)\) must satisfy,

\[ a_0(k,\omega,x) A + a_1(k,\omega,x) \frac{3A}{\delta t} + a_2(k,\omega,x) \frac{3A}{\delta x} + a_2(k,\omega,x) A \frac{3 k}{\delta x} \]

\[ = 0 + \text{H.O.T.} \quad (2.32) \]

where,

\[ a_0(k,\omega,x) = \sum_{m,n} C_{mn}(x) (ik)^m (-i\omega)^n \quad (2.33a) \]

\[ a_1(k,\omega,x) = \sum_{m,n} C_{mn}(x) n (ik)^m (-i\omega)^{n-1} \]

\[ = i \frac{3 a_0}{\delta \omega} \quad (2.33b) \]

\[ a_2(k,\omega,x) = \sum_{m,n} C_{mn}(x) m (ik)^{m-1} (-i\omega)^n \]

\[ = -i \frac{3 a_0}{\delta k} \quad (2.33c) \]

and \[ a_2(k,\omega,x) = \sum_{m,n} C_{mn}(x) i \frac{m(m-1)}{2} (ik)^{m-2} (-i\omega)^n \]

\[ = \frac{i}{2} \frac{3^2 a_0}{\delta k^2} \quad (2.33d) \]

Because of the asymptotic assumptions,

\[ A \gg \omega^{-1} \frac{3A}{\delta t}, \quad k^{-1} \frac{3A}{\delta x}, \quad k^{-2} A \frac{3 k}{\delta x} \]

so (2.32) can only be satisfied if
21

\[ a_s(k, \omega, x) = 0 \quad (2.34) \]

This is the dispersion relation between \( k \) and \( \omega \). 
\( k \) is now a slowly varying function of \( x \) due to the slow 
variation in the coefficients. Thus the characteristic 
length scale \( L_k \) is related to some characteristic length 
scale \( L_c \) for variations in the coefficients.

Neglecting the H.O.T. and dividing by \( a_1 \) gives the 
asymptotic amplitude equation.

\[ \frac{\partial A}{\partial t} + c_g \frac{\partial A}{\partial x} = \varepsilon A \quad (2.35) \]

where \( c_g = a_1 / a_1 \) \( (2.36) \)

and \( \varepsilon = -a_1 \frac{\partial k}{\partial x} / a_1 \) \( (2.37) \)

If \( c_g \) is real the left hand side of \((2.35)\) is a 
Lagrangian-type total time derivative with respect to an 
observer moving with velocity \( c_g \). If the coefficients \( C_{mn} \) 
are all constant, \( k \) is constant, \( \varepsilon = 0 \) and so the amplitude 
\( A \) is constant along rays moving with velocity \( c_g \). In a 
wavepacket individual wavecrests move with phase velocity 
\( \omega/k \), usually denoted \( c_p \), but the wavepacket, or amplitude 
'envelope', moves with velocity \( c_g \). For this reason \( c_g \) is 
called the group velocity.

Because the group velocity is the propagation 
velocity for the amplitude and energy of the wavepacket the 
group velocity is often more important than the phase 
velocity. One example is the Sommerfeld radiation condition 
which states that the waves generated by a fixed source have 
a group velocity directed away from the source. In some
unusual cases the phase velocity of the waves is actually
directed towards the source. A second example is that the
group velocity never exceeds the speed of light which is the
limiting speed of propagation of information while the phase
velocity can exceed the speed of light, as happens in wave
propagation along an electromagnetic waveguide.

To link this derivation of group velocity to other
derivations the dispersion relation (2.34) is differentiated
with x held constant.

\[ \frac{da}{da} = \frac{3a}{\partial k} \partial k + \frac{3a}{\partial \omega} \partial \omega \]

\[ = 0 \]

Hence \( \frac{3\omega}{\partial k} \) \( x \text{ const} \) = \( \frac{3a}{\partial k} \) / \( \frac{3a}{\partial \omega} \)

\[ = a / a \]

\[ = c \]

The most common method of showing that \( \frac{3\omega}{\partial k} \) \( x \text{ const} \)
is the group velocity uses the method of stationary phase
which is well explained in the available literature [1,2].
The usual approach is to combine the dispersion relation,
the definition of the group velocity and some physical
principle such as energy conservation to calculate the
propagation of energy. The approach given above is not
usually used partly because sometimes the exact partial
differential equation is not known and the dispersion
relation has been determined by asymptotic methods (e.g.
water waves) or from empirical data (e.g. seismic waves).
This approach is however suited to analysing finite
difference schemes in which the exact finite difference
equations are known and there is no general equivalent to
the principle of energy conservation.
3. Amplitude Analysis of Finite Difference Equations

3.1 Fourier Analysis

Consider a homogeneous finite difference equation

\[ L U^n_j = 0 \] (3.1)

As explained in the appendix A.1, \( L \) can always be expressed as a sum of step operators,

\[ L = \sum_{m,p} C_{mp} E_{mx} E_{pt} \] (3.2)

where the coefficients \( C_{mp} \) are constants, but it is often more simply expressed as a polynomial of finite difference operators written symbolically as,

\[ L = P(E_x, \delta_x, \mu_x, E_t, \delta_t, \mu_t) \] (3.3)

The eigenfunctions and eigenmodes of \( L \) are defined exactly as in §2.1. The finite operators all have the same eigenfunctions, \( \exp[i(j\phi-n\Omega)] \). \( \phi \) and \( \Omega \) are related to the wavenumber \( k \) and frequency \( \omega \) of the physical wave being modelled by,

\[ \phi = k \Delta x \] (3.4)
\[ \Omega = \omega \Delta t \] (3.5)

As shown in the appendix A.1

\[ E_x \exp[i(j\phi-n\Omega)] = \exp(i\phi) \exp[i(j\phi-n\Omega)] \] (3.6a)
\[ \delta_x \exp[i(j\phi-n\Omega)] = 2i \sin(\phi/2) \exp[i(j\phi-n\Omega)] \] (3.6b)
\[ \mu_x \exp[i(j\phi-n\Omega)] = \cos(\phi/2) \exp[i(j\phi-n\Omega)] \] (3.6c)
\[ E_t \exp[i(j\phi-n\Omega)] = \exp(-\Omega) \exp[i(j\phi-n\Omega)] \] (3.6d)
\[ \delta_t \exp[i(j \phi - n \omega)] = -2i \sin(\omega/2) \exp[i(j \phi - n \omega)] \quad (3.6e) \]

\[ \mu_t \exp[i(j \phi - n \omega)] = \cos(\omega/2) \exp[i(j \phi - n \omega)] \quad (3.6f) \]

\[ E^\text{mx} E^\text{tp} \exp[i(j \phi - n \omega)] = \exp[i(m \phi - p \omega)] \exp[i(j \phi - n \omega)] \quad (3.6g) \]

Thus \( \exp[i(j \phi - n \omega)] \) is an eigenfunction of \( E_x, \delta_x, \mu_x, E_t, \delta_t, \mu_t \) and \( E^\text{mx} E^\text{tp} \) with eigenvalues \( \exp(i \phi), 2i \sin(\phi/2), \cos(\phi/2), \exp(-i \omega), -2i \sin(\omega/2), \cos(\omega/2), \exp[i(m \phi - p \omega)] \) respectively, and \( L \) has eigenvalue

\[ \sum_{m, p} C_{mp} \exp[i(m \phi - p \omega)] \text{ or } \]

\[ P[\exp(i \phi), 2i \sin(\phi/2), \cos(\phi/2), \exp(-i \omega), -2i \sin(\omega/2), \cos(\omega/2)] \]

depending which expression for \( L \) is used.

\[ U^n_j = \exp[i(j \phi - n \omega)] \quad (3.7) \]

is an exact solution of (3.1) provided

\[ \sum_{m, p} C_{mp} \exp[i(m \phi - p \omega)] = 0 \quad (3.8) \]

This is the dispersion relation between \( \phi \) and \( \omega \).

Since \( \exp[2n \pi i] = 1 \) for all integers \( n \), \( \phi + 2n \pi \) is equivalent to \( \phi \) so only solutions in the ranges

\[ -\pi < \text{Re}(\phi) < \pi \]
\[ -\pi < \text{Re}(\omega) < \pi \]

need be considered.

If \( L \) involves \( P+1 \) time levels and \( M+1 \) spatial nodes the dispersion relation is a polynomial of degree \( P \) in \( \exp(-i \omega) \) and of degree \( M \) in \( \exp(i \phi) \). Thus for a given \( \phi \) there are \( P \) corresponding values of \( \omega \), and for a given \( \omega \)
there are \( M \) corresponding values of \( \phi \).

A general solution of (3.1) for periodic boundary conditions is a superposition of eigenmodes.

\[
U_j^n = \sum_\phi \sum_{p=1}^P A_p(\phi) \exp[i(j\phi-n\omega_p)]
\]  \( (3.9) \)

The \( \phi \) summation is a summation over all the values of \( \phi \) which satisfy the periodic boundary conditions, and the \( p \) summation is over the \( P \) values of \( \Omega \) corresponding to each value of \( \phi \).

If \( A_p(\phi) \) is non-zero for all \( \phi, p \) then a necessary and sufficient condition for \( U_j^n \) to remain bounded and not increase exponentially is that each eigenmode must remain bounded. Splitting \( \Omega \) into its real and imaginary components gives,

\[
\Omega = \Omega_R + i\Omega_I
\]  \( (3.10) \)

\[
\exp[-in\Omega_I] = \exp[-in\Omega_R + n\Omega_I]
\]  \( (3.11) \)

Thus the condition that every eigenmode remain bounded, and hence a general solution remain bounded, is \( \Omega_I < 0 \) for all \( \phi, p \).

This analysis is lacking in the same three respects as the analysis of partial differential equations by eigenmode expansion in the last chapter. The analysis gives no information about the movement of an initially localised disturbance, cannot incorporate boundary conditions or analyse schemes with non-constant coefficients.
3.2 Asymptotic Amplitude Equation

In this section the coefficients $C_m^p$ in the definition of $L$ (3.2) are assumed to be slowly varying functions of $j$. The analysis is performed in computational space with coordinates $(j,n)$ in which the grid spacing is $\Delta j=1, \Delta n=1$. Variations in mesh spacing in physical coordinates are incorporated directly into the variable coefficients of the finite difference equations.

The theory calculates the approximate evolution of a wavetrain with waves of a constant frequency $\bar{\Omega}$ and a slowly varying amplitude, so $U_{jn}^n$ is written as,

$$U_{jn}^n = A(j,n) \exp[i\Phi(j,n)] \tag{3.12}$$

where $A(j,n)$ is the slowly varying amplitude and $\Phi(j,n)$ is the phase of the wave and is related to the frequency $\bar{\Omega}$ and wavenumber $\phi$ by

$$\frac{\partial \Phi}{\partial n} = -\bar{\Omega} \tag{3.13}$$

$$\frac{\partial \Phi}{\partial j} = \phi \tag{3.14}$$

which can be integrated to give,

$$\Phi(j,n) = \int_0^j \psi(\xi) \, d\xi - n\bar{\Omega} \tag{3.15}$$

As in §2.2 two characteristic length scales, $L_\phi$ for variations in $\phi$, and $L_A$ for variations in the amplitude $A$ and one characteristic time scale $T_A$ for variations in the amplitude $A$, can be defined with numerical values being given by,
\[ L_\phi = \min \left( \frac{1}{\frac{3 \phi}{3 j}} \right) \]  
\[ L_A = \min \left( A / \frac{3 A}{3 j} \right) \]  
\[ T_A = \min \left( A / \frac{3 A}{3 n} \right) \]  

The asymptotic approximations are
\[ L_\phi >> 1 \quad L_A >> 1 \quad T_A >> 1 \]
which imply
\[ \frac{3 \phi}{3 j} << 1 \quad \frac{3 A}{3 j} << A \quad \frac{3 A}{3 n} << A \]

A Taylor series expansion of \( A \) and \( \psi \) about a point \((j_0, n_0)\) gives,
\[ A(j_0 + m, n_0 + n) = A_0 + m \frac{3 A}{3 j_0} + n \frac{3 A}{3 n_0} + \text{H.O.T} \]  
\[ \psi(j_0 + m, n_0 + n) = \psi_0 - p \Omega + \int_{j_0}^{j_0 + m} \phi(\xi) \, d\xi \]
\[ = \psi_0 - p \Omega + \int_{j_0}^{j_0 + m} \left[ \phi_0 + \frac{3 \phi}{3 j_0} (\xi - j_0) + \text{H.O.T.} \right] \, d\xi \]
\[ = \psi_0 - p \Omega + m \phi_0 + \frac{m^2}{2} \frac{3 \phi}{3 j_0^2} + \text{H.O.T.} \]  

Subscript 0 denotes terms evaluated at \((j_0, n_0)\).

The H.O.T., higher order terms, includes terms like
\[ \frac{3^2 A}{3 j^2}, \frac{3^4 A}{3 n^2}, \frac{3^4 \phi}{3 j^2} A \] which are \( O(AL_{\phi}^{-2}, AT_A^{-2}, AL_\phi^{-2}) \) and are neglected in this asymptotic approximation.
\[
\exp[i\psi(j_0+m,n_0+p)]
\]
\[
= \exp\left[i\psi_0 - ip\phi + im\phi_0 + \frac{im^2}{2} \frac{3\phi}{3j_0}\right] + \text{H.O.T.}
\]
\[
= \exp\left[i\psi_0 - ip\phi + im\phi_0\right] \left(1 + \frac{im^2}{2} \frac{3\phi}{3j_0}\right) + \text{H.O.T. (3.19)}
\]

Hence,
\[
U^{n_0+p}_{j_0+m} = \exp[i\psi_0] \exp[i(m\phi_0 - pn_0)] \left(A_0 + m \frac{3A}{3j_0} + p \frac{3A}{3n_0}\right) + \text{H.O.T.}
\]
\[
= \exp[i\psi_0] \exp[i(m\phi_0 - pn_0)] \left(A_0 + m \frac{3A}{3j_0} + p \frac{3A}{3n_0} + \frac{im^2}{2} A \frac{3\phi}{3j_0}\right) + \text{H.O.T. (3.20)}
\]

Hence,
\[
L \cdot U^n_j = \exp[i\psi] \sum_{m,n} C^j_{mp}(j) \exp[i(m\phi - pn)] \cdot
\]
\[
\left(A + m \frac{3A}{3j} + p \frac{3A}{3n} + \frac{im^2}{2} A \frac{3\phi}{3j}\right) + \text{H.O.T. (3.21)}
\]

To satisfy the homogeneous equation (3.1) the amplitude \(A(j,n)\) must satisfy,
\[
a_0(\phi,\Omega,j) A + a_1(\phi,\Omega,j) \frac{3A}{3n} + a_2(\phi,\Omega,j) \frac{3A}{3j} + s_j(\phi,\Omega,j) A \frac{3\phi}{3j} = 0 + \text{H.O.T. (3.22)}
\]

where,
\[
a_0(\phi,\Omega,j) = \sum_{m,n} C^j_{mp}(j) \exp[i(m\phi - pn)] (3.23a)
\]
\[
a_1(\phi,\Omega,j) = \sum_{m,n} C^j_{mp}(j) p \exp[i(m\phi - pn)] (3.23b)
\]
\[
a_2(\phi,\Omega,j) = \sum_{m,n} C^j_{mp}(j) \frac{3A}{3n} \exp[i(m\phi - pn)]
\]
\[
s_j(\phi,\Omega,j) = \frac{im^2}{2} A \frac{3\phi}{3j} \Phi, j \text{ const}
\]
\[ a_2(\phi, \Omega, j) = \sum_{m,p} C_{mp}(j) \cdot m \exp[i(m\phi - p\Omega)] \]
\[ = -i \left( \frac{3a_2}{\partial \phi} \right) \Omega, j \text{ const} \]  
(3.23c)

and
\[ a_3(\phi, \Omega, j) = \sum_{m,p} C_{mp}(j) \cdot \frac{im^2}{2} \exp[i(m\phi - p\Omega)] \]
\[ = -\frac{i}{2} \left( \frac{3a_3}{\partial \phi} \right) \Omega, j \text{ const} \]  
(3.23d)

In the above derivation of \( a_2, a_3, a_4, a_5 \), the general shift operator expression for \( L_j \) (3.2) is used. In applications it is more convenient to use the finite operator polynomial expression (3.3). \( a_5 \) is obtained by replacing each operator with its corresponding eigenvalue and then \( a_1, a_3, a_5, a_7 \) are calculated by differentiating \( a_5 \).

Because of the asymptotic assumptions,
\[ \Lambda \gg \frac{3\Lambda}{\partial \eta}, \frac{3\Lambda}{\partial j}, A \frac{3\Lambda}{\partial j} \]
so (3.22) can only be satisfied if
\[ a_1(\phi, \Omega, j) = 0 + O \{ L_{\phi}^{-1}, L_A^{-1}, T_A^{-1} \} \]  
(3.24)

This is the asymptotic form of the dispersion relation between \( \phi \) and \( \Omega \) and will usually be satisfied by setting \( a_5 \) identically equal to zero. \( \phi \) is now a slowly varying function of \( j \) due to the slow variation in the coefficients. The characteristic length scale \( L_\phi \) is related to some characteristic length scale \( L_\Omega \) for variations in the coefficients.

Neglecting the H.O.T. and dividing by \( a_4 \) gives the asymptotic amplitude equation.
\[ \frac{\partial A}{\partial n} + r_g \frac{\partial A}{\partial j} = \epsilon A \]  
(3.25)

where  
\[ r_g = \frac{a_2}{a_1} \]  
(3.26)

and  
\[ \epsilon = - (a_2 \frac{\partial \phi}{\partial j} + a_1) / a_1 \]  
(3.27)

Differentiating (3.24) with \( \Omega \) held constant gives,
\[ da_1 = \left( \frac{\partial a_2}{\partial \phi} \right)_\Omega, j \ \text{const} \ \partial \phi + \left( \frac{\partial a_2}{\partial j} \right)_\phi, \Omega \ \text{const} \ \partial j = 0 + \text{H.O.T.} \]  
(3.28)

Hence, neglecting the higher order terms,
\[ \frac{\partial \phi}{\partial j} = - \left( \frac{\partial a_2}{\partial j} \right)_\phi, \Omega \ \text{const} / \left( \frac{\partial a_2}{\partial \phi} \right)_\Omega, j \ \text{const} = \frac{i \left( \frac{\partial a_2}{\partial j} \right)_\phi, \Omega \ \text{const}}{a_1} \]  
(3.29)

so  
\[ \epsilon = -i a_1 \left( \frac{\partial a_2}{\partial j} \right)_\phi, \Omega \ \text{const} / a_1 a_2 \]  
(3.30)

If \( r_g \) is real the left hand side of (3.25) is a Lagrangian-type total time derivative with respect to an observer moving with velocity \( r_g \). Thus the amplitude \( A \) is being convected with velocity \( r_g \) in computational space.

Differentiating (3.24) with \( j \) held constant gives,
\[ da_1 = \left( \frac{\partial a_2}{\partial \phi} \right)_\phi, j \ \text{const} \ \partial \phi + \left( \frac{\partial a_2}{\partial j} \right)_\Omega, j \ \text{const} \ \partial j = 0 + \text{H.O.T.} \]  
(3.31)

Hence, neglecting the higher order terms,
\[ \left( \frac{\partial \Omega}{\partial \phi} \right)_j \ \text{const} = - \left( \frac{\partial a_2}{\partial \phi} \right)_\Omega, j \ \text{const} / \left( \frac{\partial a_2}{\partial \Omega} \right)_\phi, j \ \text{const} = a_2 / a_1 = r_g \]  
(3.32)
Substituting for $a$ and $\omega$ using (3.5a,b),

$$r_g = \frac{3(\omega \Delta t)}{3(k \Delta x)}$$

$$= \frac{\Delta t}{\Delta x} \frac{\omega}{\Delta k}$$

$$= \frac{c \Delta t}{\Delta x}$$

Thus $r_g$ is the CFL number corresponding to the group velocity in physical space of the propagating numerical wave. It is the number of spatial mesh intervals which a localised disturbance travels in one time step. For the rest of the paper $r_g$ is called the group CFL number.
3.3 Examples

The model problem which is considered is,

\[ \frac{\partial u}{\partial t} + c(x) \frac{\partial u}{\partial x} = 0 \quad -\infty < x < \infty \]  

(3.34)

Three different methods are analysed.

3.3.1 Trapezoidal Scheme

The trapezoidal scheme is

\[ \frac{1}{\Delta t} (u_{j+1}^{n+1} - u_j^n) + \frac{c_j}{4\Delta x_j} \left( (u_{j+1}^{n+1} + u_{j+1}^n) - (u_{j-1}^{n+1} + u_{j-1}^n) \right) = 0 \]  

(3.35)

which can be written using operator notation as

\[ \frac{1}{\Delta t} \left( \delta_t + \frac{\delta}{2} + \frac{\delta}{2} = 0 \right) u_j^{n+1} = 0 \]  

(3.36)

where the CFL number \( r \) is defined as

\[ r_j = \frac{c \Delta t}{\Delta x_j} \]  

(3.37)

and \( \Delta x_j = \frac{1}{2} (x_{j+1} - x_{j-1}) \)  

(3.38)

\( a_1 \) is obtained by replacing the operators by their eigenvalues.

\[ a_1 = -2i \sin(q/2) + \frac{r}{2} 2i \sin(\phi) \cos(q/2) \]  

(3.39)

The dispersion relation is

\[ a_0 = 0 \]  

(3.40)

so \[ \tan(q/2) = \frac{r}{2} \sin(\phi) \]  

(3.41)

\( a_1, a_2, a_3 \) are obtained by differentiating \( a_1 \).
\[ a_1 = i \frac{\partial a_0}{\partial \phi} \]
\[ = \cos(\Omega/2) + \frac{r}{2} \sin(\phi) \sin(\Omega/2) \tag{3.42} \]
\[ a_2 = -i \frac{\partial a_0}{\partial \phi} \]
\[ = r \cos(\phi) \cos(\Omega/2) \tag{3.43} \]
\[ a_3 = -\frac{1}{2} i \frac{\partial^2 a_0}{\partial \phi^2} \]
\[ = \frac{1}{2} \frac{\partial a_2}{\partial \phi} \]
\[ = -\frac{r}{2} \sin(\phi) \cos(\Omega/2) \tag{3.44} \]

Using the dispersion relation \( a_1 \) and \( a_3 \) can be simplified.

\[ a_1 = \cos(\Omega/2) + \frac{r}{2} \sin(\phi) \sin(\Omega/2) \]
\[ = \cos(\Omega/2) + \tan(\Omega/2) \sin(\Omega/2) \]
\[ = \left[ \cos^2(\Omega/2) + \sin^2(\Omega/2) \right] / \cos(\Omega/2) \]
\[ = 1 / \cos(\Omega/2) \tag{3.45} \]
\[ a_3 = -\frac{r}{2} \sin(\phi) \cos(\Omega/2) \]
\[ = -\tan(\Omega/2) \cos(\Omega/2) \]
\[ = -\sin(\Omega/2) \tag{3.46} \]

so \( r_g = a_2 / a_1 \)
\[ = r \cos(\phi) \cos^2(\Omega/2) \tag{3.47} \]

and \( \epsilon = -i a_3 \left( \frac{\partial a_2}{\partial \phi} \right) \phi, \Omega \text{ const} / a_1 a_3 - a_0 / a_1 \)
\[ = \frac{ir}{2} \sin(\phi) \cos(\Omega/2) \left[ \frac{3}{\partial \phi} \sin(\phi) \cos(\Omega/2) \right] / \left[ r \cos(\phi) \right] \]
There are three points of interest

i) \[ \sin(\pi - \phi) = \sin(\phi) \]
so for all \( \omega \) there are two corresponding values of \( \phi \) given by the dispersion relation,
\[ \phi_1 \text{ satisfying } -\pi/2 < \Re(\phi_1) < \pi/2 \]
and \( \phi_2 = \pi - \phi_1 \)

ii) For real \( \omega \) in the range
\[ 0 < \omega < 2 \tan^{-1}(r/2) \]
\[ 0 < \tan(\omega/2) < r/2 \]
so \[ 0 < \sin(\phi) < 1 \]
Thus \( \phi_1 \) and \( \phi_2 \) are both real and
\[ 0 < \phi_1 < \pi/2 \]
so \( r_g(\phi_1) > 0 \)
and \( \pi/2 < \phi_2 < \pi \)
so \( r_g(\phi_2) < 0 \)

Hence for every frequency in the given range there is one forward travelling wave, travelling in the same direction as the physical waves being modelled, and one backward travelling wave with wavelength less than \( 4 \Delta x \).

iii) For real \( \omega \) in the range
\[ 2 \tan^{-1}(r/2) < \omega < \pi \]
\[ \sin(\phi) > 1 \]
so \( \phi_1 \) and \( \phi_2 \) are complex

\[ - \frac{1}{\frac{3}{2} \sin^2(\phi) \cos^2(\omega/2)} / \cos(\phi) \quad (3.48) \]
Let $\phi_1 = \pi/2 + i\phi_I$

Then $\sin(\phi_1) = \cosh(\phi_I)$

so $\phi_I$ is real and satisfies

$$\tan(\phi/2) = \frac{\Gamma}{2} \cosh(\phi_I)$$

$$\phi_2 = \pi - \phi_1$$

$$= \pi/2 - i\phi_I$$

These are evanescent waves. If there are boundaries at $j = 0, J$ and the boundary conditions force a steady oscillation with a frequency in the given range one wave will decay in amplitude exponentially away from the boundary at $j=0$, while the other will decay exponentially away from the boundary at $j=J$. 
3.3.2 Box Scheme

The box scheme is

\[
\frac{1}{\Delta t} \left[ (U_j^{n+1} + U_{j+1}^{n+1}) - (U_j^n + U_{j+1}^n) \right] + \\
\frac{C_j}{\Delta x_j} \left[ (U_j^n + U_{j+1}^{n+1}) - (U_j^n + U_{j+1}^n) \right] = 0
\]  
(3.49)

which may be written in operator notation as

\[
\frac{1}{\Delta t} \left[ \mu x \delta_t + \beta \left( \mu t \delta_x \right) \right] U_{j+1}^{n+1} = 0
\]  
(3.50)

\[a_z = -2i \cos(\phi/2) \sin(\Omega/2) + 2ir \cos(\Omega/2) \sin(\phi/2)
\]  
(3.51)

The dispersion relation is

\[\tan(\Omega/2) = r \tan(\phi/2)
\]  
(3.52)

\[a_1 = i \frac{3a_2}{3\Omega}
\]

\[= \cos(\phi/2) \cos(\Omega/2) + r \sin(\Omega/2) \sin(\phi/2)
\]  
(3.53)

\[a_2 = -i \frac{3a_1}{3\phi}
\]

\[= \sin(\phi/2) \sin(\Omega/2) + r \cos(\Omega/2) \cos(\phi/2)
\]  
(3.54)

\[a_3 = i \frac{3^2 a_2}{3\phi^2}
\]

\[= \frac{1}{4} \cos(\phi/2) \sin(\Omega/2) - \frac{1}{4} r \cos(\Omega/2) \sin(\phi/2)
\]

\[= - \frac{i}{8} a_z
\]

\[= 0
\]  
(3.55)

Thus \(r_0 = a_z / a_1\)

\[= \frac{\sin(\phi/2) \sin(\Omega/2) + r \cos(\Omega/2) \sin(\phi/2)}{\cos(\phi/2) \cos(\Omega/2) + r \sin(\Omega/2) \sin(\phi/2)}
\]
\[
\frac{\tan(\phi/2) \tan(\Omega/2) + r}{1 + r \tan(\phi/2) \tan(\Omega/2)} = r \frac{1 + \tan^2(\phi/2)}{1 + r^2 \tan^2(\phi/2)}
\]

and \( \epsilon = 0 \) \hspace{1cm} (3.57)

There are two points of interest

i) For each real value of \( \Omega \) there is one corresponding real value of \( \phi \) given by the dispersion relation and the group CFL number \( r_g \) is real and positive.

ii) When \( r=1 \), \( r_g=r \), so waves of all frequencies travel at the same velocity as the physical waves being modelled. This is because when \( r=1 \) the Box scheme reduces to,

\[
U_j^{n+1} = U_j^n
\]

which agrees exactly with the solution of the partial differential equation,

\[
u(x+ct, t) = u(x, 0)
\]
3.3.3 Backward Euler Scheme

The backward Euler scheme is,

\[
\frac{1}{\Delta t} \left( U_{j}^{n+1} - U_{j}^{n} \right) + \frac{c_{i}}{2\Delta x} \left( U_{j+1}^{n+1} - U_{j-1}^{n+1} \right) = 0 \tag{3.60}
\]

which may be written using operator notation as

\[
\frac{1}{\Delta t} \left( \delta_{t} \left( \frac{1}{2} \delta_{x} \right) \right) U_{j}^{n+1} = 0 \tag{3.61}
\]

\[
a_{s} = 1 - \exp(i\Omega) + ir \sin(\phi) \tag{3.62}
\]

The dispersion relation is

\[
\exp[i\Omega] - 1 = ir \sin(\phi) \tag{3.63}
\]

\[
a_{1} = \frac{3a_{s}}{3\Omega}\tag{3.64}
\]

\[
a_{1} = -i \frac{3a_{s}}{3\phi}\tag{3.65}
\]

\[
a_{2} = -\frac{1}{2} i \frac{3a_{s}}{3\phi^{2}}\tag{3.66}
\]

so \( r = a_{1} / a_{1} \)

\[
= r \cos(\phi) \exp(-i\Omega) \tag{3.67}
\]

and \( \varepsilon = -i a_{1} \left( \frac{3a_{s}}{3\phi} \right) \Omega \text{ const} / a_{1} a_{1} - a_{2} / a_{1} \)

\[
= \frac{i r}{2} \sin(\phi) \left[ i \frac{3r}{3\phi} \sin(\phi) \right] / \left[ \exp(i\Omega) r \cos(\phi) \right] \tag{3.68}
\]

\[
= -\frac{1}{2} \frac{3r}{3\phi} \sin^{2}(\phi) \exp(-i\Omega) / \cos(\phi) \tag{3.68}
\]
### 3.4 Asymptotic Boundary Conditions

The general solution of

\[ L_j U^n_j = 0 \]  

(3.1)

is a sum of waves with different constant frequencies \( \Omega \) and slowly varying wavenumber \( \phi \) and amplitude \( A \)

\[
U^n_j = \sum_\Omega \sum_{m=1}^M A_m(j,n) \exp\left[\imath\left(\int_0^j \varphi_m(\xi) d\xi - n\Omega\right)\right] \tag{3.69}
\]

The outer summation is over different values of \( \Omega \), and the inner summation is over the \( M \) different values of \( \phi \) which satisfy the dispersion relation for each \( \Omega \).

For each \( \Omega,m \) the amplitude \( A \) satisfies its asymptotic amplitude equation on the interior of the computational domain independent of all the other waves. All the waves of each frequency are however coupled by boundary conditions.

Suppose a finite difference boundary condition at \( j=J \) is

\[
B U^n_J = F^n \tag{3.70}
\]

where \( B \) is a constant finite difference operator which can be expressed in operator polynomial form as

\[
B \equiv P_B(E_x, \delta x, \mu_x, E_t, \delta t, \mu_t) \tag{3.71}
\]

and \( F^n \) is a forcing function which can be expressed as a sum of inputs of different frequencies.

\[
F^n = \sum_\Omega f(\Omega) \exp(-\imath \Omega) \tag{3.72}
\]
Performing exactly the same asymptotic expansion as in the derivation of the asymptotic amplitude equation the boundary condition becomes,

$$\sum_{m=1}^{M} \sum_{n=1}^{M} \left( b A_m + i \frac{3b}{3\Omega} \frac{3A_m}{3n} - i \frac{3b}{3\phi} \frac{3A_m}{3j} - i \left( \frac{3b}{2} \frac{3\phi}{3j} A_m \frac{3\phi}{3j} \right) \right).$$

$$\exp[i( \int_{0}^{J} \phi_m d\xi - n\Omega)] = \sum_{n} f(\Omega) \exp(-in\Omega) + \text{H.O.T.} \quad (3.73)$$

where $b(\Omega, \phi_m) = P_B \{ \exp(i\phi_m), 2i \sin(\phi_m/2), \cos(\phi_m/2), \exp(-i\Omega), -2i \sin(\Omega/2), \cos(\Omega/2) \} \quad (3.74)$

The coefficients of $\exp(-in\Omega)$ in (3.73) must be asymptotically equal to zero for each $\Omega$ so,

$$\sum_{m=1}^{M} \left( b A_m + i \frac{3b}{3\Omega} \frac{3A_m}{3n} - i \frac{3b}{3\phi} \frac{3A_m}{3j} - i \left( \frac{3b}{2} \frac{3\phi}{3j} A_m \frac{3\phi}{3j} \right) \right).$$

$$\exp[i( \int_{0}^{J} \phi_m d\xi )] = f(\Omega) + \text{H.O.T.} \quad (3.75)$$

This paper is primarily concerned with stability and convergence rates. When analysing perturbations from a steady state or constant amplitude oscillation the boundary condition for the perturbation has

$$f(\Omega) = 0 \quad (3.76)$$

Because the zero order terms will usually dominate the normal form of the asymptotic boundary conditions is,

$$\sum_{m=1}^{M} b(\Omega, \phi_m) A_m(J) \exp[i( \int_{0}^{J} \phi_m d\xi )] = 0 \quad (3.77)$$
The first order terms \( \frac{3A_m}{\partial n} \), \( \frac{3A_m}{\partial j} \), and \( \frac{3\phi_m}{\partial j} \) are only important when,

\[
b(\Omega, \phi_m) = O \left( T_A^{-1}, L_A^{-1}, L_\phi^{-1} \right)
\]

As explained in §3.1 if the finite difference operator \( L \) in the interior scheme spans \( M+1 \) spatial levels there will be \( M \) values of \( \phi \) given by the dispersion relation for a given value of \( \Omega \). If the computational domain is \( 0 < j < J \) the interior scheme gives finite difference equations at \( J-M+1 \) nodes, so to complete the set of finite difference equations there must be \( M \) finite difference boundary conditions. Hence for each \( \Omega \) the asymptotic amplitude analysis gives \( M \) independent amplitude differential equations on the interior coupled at the boundaries by \( M \) boundary conditions.
3.5 Examples

The same model problem as in §3.3 is considered,

\[ \frac{\partial u}{\partial t} + c \frac{\partial u}{\partial x} = 0 \]  \hspace{1cm} (3.34)

\( 0 < x < x_f \)

\( c(x) > 0 \)

The analytic boundary condition is,

\[ u(0,t) = F(t) \] \hspace{1cm} (3.78)

For perturbation analysis

\[ u(0,t) = 0 \] \hspace{1cm} (3.79)

The finite difference scheme using the trapezoidal or backward Euler methods on the interior requires two finite difference boundary conditions. For perturbations the boundary condition at \( j=0 \) is,

\[ U^0_0 = 0 \] \hspace{1cm} (3.80)

The boundary condition at \( j=J \) is some form of extrapolation. Four of the most commonly used are analyzed.

3.5.1 Upstream Boundary

\[ U^0_0 = 0 \] \hspace{1cm} (3.80)

\[ B = 1 \] \hspace{1cm} (3.81)

so \( b = 1 \) \hspace{1cm} (3.82)

Hence \( A_1(0,n) + A_2(0,n) = 0 \) \hspace{1cm} (3.83)

In preparation for the theory developed in chapters 4 and 5 it is useful to define \( R_0 \), the amplitude reflection coefficient as
\[ R_0 = \frac{A_1(0,n)}{A_1(0,n)} \quad (3.84) \]

so in this example

\[ R_0 = -1 \quad (3.85) \]

### 3.5.2 Downstream Boundary: Space Extrapolation

The space extrapolation boundary condition is

\[ U^n_J = U^n_{J-1} \quad (3.86) \]

\[ B = 1 - e^{-\xi} = e^{-\frac{\xi}{2}} e^{\frac{\xi}{2}} \quad (3.87) \]

so \[ b = 1 - \exp(-i\phi) \]

\[ = 2i \exp(-i\phi/2) \sin(\phi/2) \quad (3.88) \]

Hence

\[ \sum_{m=1}^{2} \sin(\phi/2) \exp[i \int_0^J \phi_m d\xi - i \phi_m(J)/2] A_m(J, n) = 0 \quad (3.89) \]

The amplitude reflection coefficient \( R_J \) is defined as,

\[ R_J = \frac{A_1(J, n)}{A_1(J, n)} \quad (3.90) \]

so in this example

\[ R_J = -\frac{\sin(\phi_1/2)}{\sin(\phi_1/2)} \exp \left[ i \int_0^J (\phi_1 - \phi_1) d\xi - \frac{1}{2}(\phi_1(J) - \phi_1(J)) \right] \quad (3.91) \]
3.5.3 Downstream Boundary: Space-time Extrapolation

The space-time extrapolation boundary condition is

\[ U^n_J = U^{n-1}_J \] (3.92)

\[ B = 1 - E^{-x} E^{-t} \] (3.93)

\[ b = 1 - \exp(-i\phi + i\Omega) \]
\[ = 2i \exp[i(\Omega-\phi)/2] \sin[(\phi-\Omega)/2] \] (3.94)

Hence,

\[ \sum_{m=1}^{J} \sin\left(\frac{\phi_m - \Omega}{2}\right) \exp\left[i \int_{0}^{J} \phi_m d\xi - i\phi_m(J)/2\right] A_m(J,n) = 0 \] (3.95)

\[ R_J = \frac{\sin\left(\frac{\phi_1 - \Omega}{2}\right)}{\sin\left(\frac{\phi_J - \Omega}{2}\right)} \exp\left[i \int_{0}^{J} (\phi_1 - \phi_1) d\xi - \frac{i}{2}(\phi_1(J) - \phi_1(J))\right] \] (3.96)

3.5.4 Downstream Boundary: Box Method

In this example the Box method which was discussed in §3.3.2 as an interior scheme is now considered as a downstream boundary condition.

\[ \left[ \mu x \delta_t + r \mu t \delta_x \right] u^{n+1}_J = 0 \] (3.97)

\[ B = E^{-x} E^{-t} \left[ \mu x \delta_t + r \mu t \delta_x \right] \] (3.98)

so \[ b = \exp[i(\Omega-\phi)/2] \{-2i \cos(\phi/2) \sin(\Omega/2) + 2i r \cos(\Omega/2) \sin(\phi/2)\} \] (3.99)

Hence,
\[
\sum_{m=1}^{2} \left( r \sin(\phi_m/2) - \tan(\Omega/2) \cos(\phi_m/2) \right) \cdot \\
\exp\left[i \int_{0}^{J} \phi_m \, d\xi - i \phi_m(J)/2 \right] A_m(J,n) = 0 \quad (3.100)
\]

\[
R_J = \frac{r \sin(\phi_J/2) - \tan(\Omega/2) \cos(\phi_J/2)}{r \sin(\phi_1/2) - \tan(\Omega/2) \cos(\phi_1/2)} \cdot \\
\exp\left(i \int_{0}^{J} (\phi_1 - \phi_2) \, d\xi - \frac{i}{2}(\phi_1(J) - \phi_2(J)) \right) \quad (3.101)
\]
4. Ray Theory and Wavepacket-Particle Duality

4.1 Ray Theory

In addition to the asymptotic approximations made in chapter 3, this chapter assumes that for all real wavenumbers \( \phi \), the frequency \( \Omega \) is real for all \( j \) and hence the group CFL number \( r_g \) is real.

\[
\frac{\partial}{\partial t} r_g = \left( \frac{\partial^2}{\partial \phi^2} \right) j \text{ const} \quad (3.32)
\]

A Lagrangian-type total time derivative in computational space is defined by,

\[
\frac{d}{dt} \equiv \frac{3}{3n} + r \frac{3}{g \partial j} \quad (4.1)
\]

so

\[
\frac{dJ}{dn} = \frac{3}{3n} + r \frac{3}{g \partial j} = r_g \quad (4.2)
\]

From the asymptotic amplitude equation (3.25),

\[
\frac{dA}{dt} = \frac{3A}{3n} + r \frac{3A}{g \partial j} = cA \quad (4.3)
\]

and using (3.26) and (3.29),

\[
\frac{ds}{dt} = \frac{3s}{3n} + r \frac{3s}{g \partial j} = r \frac{3s}{g \partial j} = a_i \frac{a_j}{a_i} i(\frac{3a_j}{\partial j}) \phi, \Omega \text{ const} / a_i
\]

\[
= i \frac{a_j}{a_i} \left( \frac{3a_j}{\partial j} \right) \phi, \Omega \text{ const} \quad (4.4)
\]
A general initial value problem for a wave of frequency $\Omega$ and wavenumber $\phi(Q,j)$ can be solved by integrating these equations (4.2)-(4.4) with initial conditions

\begin{align}
    j(0) &= j_0 \quad (4.5a) \\
    A(0) &= A(j_0,0) \quad (4.5b) \\
    \phi(0) &= \phi(Q,j_0) \quad (4.5c)
\end{align}

Each value of $j$ generates a ray and all of the rays together cover the entire domain for $n > 0$. Figure 2 shows the motion of some typical rays in computational space.

**Figure 2. Rays in Computational Space**
\( r \) is a function of \( j \) so at a particular \( j \) all the rays have the same slope \( \frac{dj}{dn} \). Hence the time separation \( T \) of two rays, illustrated in figure 2 for rays 1 and 2, remains constant but the spatial separation \( L \) varies as \( r \) varies.

As explained in chapter 3 if the finite difference operator spans \( M+1 \) spatial nodes then for a particular value of \( Q \) there are \( M \) values of \( \phi \) which satisfy the dispersion relation. Define \( M_+ \) to be the number of solutions \( \phi \) for which the group CFL number is positive, and similarly define \( M_- \) to be the number of solutions \( \phi \) for which the group CFL number is negative. Let the computational domain be \( 0 < j < J \) as usual. At \( j=J \) there are \( M_+ \) rays leaving the domain and \( M_- \) entering it. The amplitudes are related through the asymptotic boundary conditions each of which has the form,

\[
\sum_{m=1}^{M_+} b(m, \phi_m) \exp\int_{0}^{J} \phi_m d\xi A_m(J,n) = 0 \quad (3.37)
\]

Since the \( M_+ \) amplitudes of the rays leaving the domain are known and the \( M_- \) amplitudes of the rays entering the domain are unknown there must be \( M_- \) boundary conditions to uniquely determine the amplitudes of the rays entering domain. Similarly at \( j=0 \) there must be \( M_+ \) boundary conditions to uniquely determine the amplitudes of the rays entering the domain.
4.2 Wavepacket-Particle Theory

In terms of ray theory a wavepacket is a ray tube, a group of rays, along which the amplitude is non-zero. From the discussion in the last section the time length $T_A$ of the wavepacket remains constant but its spatial length $L_A$ will vary whenever $r_g$ has different values at the two ends of the wavepacket. Provided $L_A \ll L_g$ all the rays in the ray tube have approximately the same value for $\psi(\Omega, j)$ so the motion of the wavepacket is given by,

$$\frac{dj}{dn} = r_g(\Omega, \psi(j), j)$$

and

$$\frac{d\psi}{dn} = \frac{i}{\Omega} \left( \frac{\partial \psi}{\partial j} \right) \psi, \Omega \text{ const}$$

The energy, in physical space, of the wavepacket is defined as,

$$E(n) = \int_x^x |A(x, t_n)|^2 \, dx$$

$$= \int_0^J |A(j, n)|^2 \frac{dx}{dj} \, dj$$

Hence the wave energy density in computational space is defined to be,

$$\rho(j, n) = \alpha(j) |A(j, n)|^2$$

where

$$\alpha(j) = \frac{dx}{dj}$$

Using (4.3) and the notation that $\bar{A}$ is the complex conjugate of $A$ it follows that

$$\frac{\partial}{\partial n} + \frac{\partial}{\partial j} (r_g \rho) = \frac{\partial}{\partial n} (\alpha \bar{A}) + \frac{\partial}{\partial j} (r_g \alpha \bar{A})$$
\[
\frac{dE}{dn} = J \int_0^\rho \frac{\partial \rho}{\partial n} \, dj \\
= J \int_0^\rho - \frac{\partial}{\partial j}(r g \rho) + \left( \bar{\epsilon} + \bar{\bar{\epsilon}} + \frac{1}{a} \frac{\partial}{\partial j}(r g \rho) \right) \rho \, dj \\
= -r g \rho \bigg|_0^J + \int_0^J \left( \bar{\epsilon} + \bar{\bar{\epsilon}} + \frac{1}{a} \frac{\partial}{\partial j}(r g \rho) \right) \rho \, dj \\
\text{ (4.9)}
\]

Hence,

\[
\frac{dE}{dn} = \left( \bar{\epsilon} + \bar{\bar{\epsilon}} + \frac{1}{a} \frac{\partial}{\partial j}(r g \rho) \right) \rho
\]

If the wavepacket is in the interior of the domain away from the boundaries the energy flux \( r g \rho \) at the boundaries \( j=0,J \) is zero. Also assuming as before that \( L_A \ll L_C \) then \( \bar{\epsilon} + \bar{\bar{\epsilon}} + \frac{1}{a} \frac{\partial}{\partial j}(r g \rho) \) is approximately constant over the length of the wavepacket, so

\[
\frac{dE}{dn} = \left( \bar{\epsilon} + \bar{\bar{\epsilon}} + \frac{1}{a} \frac{\partial}{\partial j}(r g \rho) \right) \rho \bigg|_0^J \int_0^J \rho \, dj = \left( \bar{\epsilon} + \bar{\bar{\epsilon}} + \frac{1}{a} \frac{\partial}{\partial j}(r g \rho) \right) \rho \, dj \\
\text{ (4.10)}
\]

Thus equations (4.2), (4.9), and (4.11) completely describe the motion of the wavepacket particle in the interior of the computational domain.
When the wavepacket reaches the boundary it interacts with the boundary conditions to produce one or more reflected wavepackets with the same frequency but different wavenumbers. The only case for which it is easy to incorporate boundary conditions is when $M=2$ and
\[
    r_g(\beta_1, j) > 0
\]
\[
    r_g(\beta_1, j) < 0
\]

An example of a scheme satisfying this condition is the trapezoidal method which was applied to the model convection problem in the introduction.

An additional assumption is that
\[
    |r_g(\beta_1, j)|, |r_g(\beta_1, j)| \ll J
\]
so that it takes much more than one time step for a wavepacket to travel from one boundary to the other.

Suppose that initially there is one wavepacket with wavenumber $\beta_1$ as in the introductory example. The wavepacket travels to the right with position and energy determined by the equations of motion previously derived (4.2), (4.4) and (4.11). When the wavepacket reaches the boundary at $j=J$ a proportion of the energy $E_1$ is reflected into a left travelling wavepacket of frequency $\alpha$, wavenumber $\beta_1$ and energy $E_1$. Figure 1 illustrates this interaction.

Equation (4.10) is
\[
    \frac{dE}{dn} = -r_g \left[ \int_0^J \left( \Sigma + C + \frac{1}{\alpha} \sum_j (r_g) \right) p \, dj \right]
\]

The outgoing energy flux is
The incoming energy flux is
\[ r_g(\phi_1, J) \varphi_1(J,n) = r_g(\psi_1, J) a(J) |A_1(J,n)|^2 \] (4.12)

The amplitude reflection coefficient \( R_J \) defined by
\[ R_J = \frac{A_2(J,n)}{A_1(J,n)} \] (4.14)
is a function of \( R, \phi_1, \phi_2 \) determined by the asymptotic boundary condition.

The energy flux entering the reflected wavepacket is a factor
\[ \left| \frac{r_g(\phi_2, J)}{r_g(\phi_1, J)} \right| R_J^2 \]
greater, or less, than the energy flux leaving the incident wavepacket and so the total energy of the reflected wavepacket is given by,
\[ E_1 = \left| \frac{r_g(\phi_2, J)}{r_g(\phi_1, J)} \right| R_J^2 E_1 \] (4.15)

The reflected wavepacket travels left according to the equations of motion for a wave 2 wavepacket until it reaches \( j=0 \) where it is reflected into a right travelling wave 1 wavepacket. The reflected energy \( E_1 \) is given by,
\[ E_1 = \left| \frac{r_g(\phi_1, 0)}{r_g(\phi_2, 0)} \right| R_0^2 E_1 \] (4.16)

where \( R_0 = \frac{A_1(0,n)}{A_2(0,n)} \) (4.17)
is determined by the asymptotic boundary condition.
Figure 3 below shows the particle-like path of the wavepacket in computational space.

\[ \frac{dj}{dn} = r_j(\phi_1, j) \]  \hspace{1cm} (4.2)

\[ \frac{d\phi_i}{dn} = \frac{i}{\hbar} \left( \frac{\partial g}{\partial j} \right) \phi_i, \Phi \text{ const} \]  \hspace{1cm} (4.4)

\[ \frac{dE_1}{dn} = \left( \epsilon + \bar{\epsilon} + \frac{1}{\hbar} \frac{\partial g}{\partial j}(\alpha, \beta) \right) E_1 \]  \hspace{1cm} (4.11)
(b) \[ E_2 = \left| \frac{r(g, \Phi_2, J)}{r(g, \Phi_1, J)} \right|^2 |R_J|^2 E_1 \] (4.15)

(c) 
\[ \frac{d \Phi_2}{d \eta} = r(g, \Phi_2, J) \] (4.2)
\[ \frac{d \Phi_1}{d \eta} = \frac{1}{\delta_1} \left( \frac{\partial \Phi_2}{\partial J} \right) \phi, \text{ const} \] (4.4)
\[ \frac{d E_2}{d \eta} = \left( \epsilon + \overline{\epsilon} + \frac{1}{\delta_1} \frac{3}{\partial \eta} (r \alpha) \right) E_2 \] (4.11)

(d) \[ E_1 = \left| \frac{r(g, \Phi_2, 0)}{r(g, \Phi_1, 0)} \right|^2 |R_0|^2 E_2 \] (4.16)

In (a) and (c) the dispersion relation can be used as a check on the accuracy of the numerical integration of the equations or can replace the equation for the variation of \( \phi \).

The total number of time steps for a round trip from 0 to J and back again to 0 is
\[ N = \int_0^J \left[ \frac{r(g, \Phi_1, J)}{r(g, \Phi_1, J)} \right]^{-1} - \left[ \frac{r(g, \Phi_1, J)}{r(g, \Phi_1, J)} \right]^{-1} dJ \] (4.18)

The energy growth of a wavepacket travelling from 0 to J is given by
\[ \frac{d}{d \eta} \ln(E_1) = \frac{1}{E} \frac{d E_1}{d \eta} \]
\[ = \epsilon + \overline{\epsilon} + \frac{1}{\delta_1} \frac{3}{\partial \eta} (r \alpha) \] (4.19)

so \[ \frac{d}{d \eta} \ln(E_1) = \frac{d}{d \eta} \ln(E_1) / \frac{d \eta}{d \eta} \]
\[ = \frac{\epsilon + \overline{\epsilon}}{\delta_1} + \frac{1}{\delta_1} \frac{3}{\partial \eta} (r \alpha) \]
\[ \frac{\epsilon}{rg} + \frac{3}{3} \sum_j \ln(r_j a) \] (4.20)

Hence,
\[ \ln[E_1(J)] = \ln[E_1(0)] + \int_0^J \frac{\epsilon + \bar{\epsilon}}{rg} \, dj + \ln(r_j a) \] (4.21)

so
\[ E_1(J) = \left| \frac{r_g(\phi_1, J)}{r_g(\phi_1, 0)} \right| \exp \int_0^J \frac{\epsilon + \bar{\epsilon}}{rg} \, dj \, E_1(0) \] (4.22)

Similarly the energy growth of the reflected wavepacket as it travels from \( J \) to \( 0 \) is
\[ E_2(0) = \left| \frac{r_g(\phi_1, 0)}{r_g(\phi_1, J)} \right| \exp \int_0^J -\frac{\epsilon + \bar{\epsilon}}{rg} \, dj \, E_2(J) \] (4.23)

Combining (4.15), (4.16), (4.22) and (4.23) the round trip energy amplification factor \( \lambda \) is
\[ \lambda = \left| \frac{r_g(\phi_1, J)}{r_g(\phi_1, 0)} \right| \exp \int_0^J \left( \frac{\epsilon + \bar{\epsilon}}{rg} \right)_1 \, dj \cdot \left| \frac{r_g(\phi_2, J)}{r_g(\phi_1, J)} \right| \left| R_J \right|^2 \]

\[ \cdot \left| \frac{r_g(\phi_1, 0)}{r_g(\phi_2, 0)} \right| \exp \int_0^J -\left( \frac{\epsilon + \bar{\epsilon}}{rg} \right)_2 \, dj \cdot \left| \frac{r_g(\phi_1, 0)}{r_g(\phi_1, 0)} \right| \left| R_0 \right|^2 \]

\[ = \left| R_0 R_J \right|^2 \exp \int_0^J \left( \frac{\epsilon + \bar{\epsilon}}{rg} \right)_1 - \left( \frac{\epsilon + \bar{\epsilon}}{rg} \right)_2 \, dj \] (4.24)

where \( \left( \frac{\epsilon + \bar{\epsilon}}{rg} \right)_1 \) is evaluated at \( \phi_1, j \)

and \( \left( \frac{\epsilon + \bar{\epsilon}}{rg} \right)_2 \) is evaluated at \( \phi_1, j \)

The condition for stability is
\[ \lambda < 1 \]
The equivalent average decay rate $\sigma$ is

$$\sigma = -\frac{1}{N} \ln(\lambda) \quad (4.25)$$

When $M>2$ and there are $M_+$ waves with positive $r_g$ and $M_-$ waves with negative $r_g$, one wavepacket with positive $r_g$ reaching $j=J$ produces $M_+$ reflected wavepackets with negative $r_g$, and one wavepacket with negative $r_g$ reaching $j=0$ produces $M_-$ reflected wavepackets with positive $r_g$. Thus the total number of wavepackets increases with time exponentially. Since each wavepacket has finite length this ultimately leads to the problem of determining the effect of interference between overlapping wavepackets. In general the sum of the energies of two wavepackets is not equal to the energy of the sum of the wavepackets. If the wavepackets are identical the latter is twice the former while if the second wavepacket has opposite sign to the first the latter is zero.
5. Asymptotic Stability and Convergence Analysis I

5.1 Theory

In addition to the asymptotic approximations in chapter 3 this chapter assumes that \( M=2 \) and there is one boundary condition at both \( j=0 \) and \( j=J \) and if \( \phi_1 \) is real at \( j=0 \) then \( \phi_1 \) and \( \phi_2 \) are real over the whole domain.

Examples of methods satisfying these conditions are the trapezoidal method applied to the model convective problem with variable CFL number \( r \), and the backward Euler method applied to the model convective problem with constant CFL number. Methods which do not satisfy these conditions include Lax-Wendroff and Runge-Kutta type schemes. For these methods the general stability analysis of chapter 6 is required.

As explained in §3.1 a standard Fourier series analysis of the problem with constant coefficients and periodic boundary conditions shows that the eigenfrequencies are \( \omega(\phi) \) where \( \phi \) is a real wavenumber satisfying the periodic boundary conditions and \( \omega(\phi) \) is the corresponding frequency given by the dispersion relation.

The common use of a Fourier series analysis to predict the stability of problems with non-periodic boundary conditions implicitly assumes that for real wavenumber \( \phi \), \( \omega(\phi) \) is a close approximation to an actual eigenfrequency. This chapter follows that assumption, calculates a correction \( \omega' \) to this \( \omega(\phi) \) due to the boundary conditions, and then determines the validity of the assumption for this particular class of methods based on the asymptotic errors.
For real $\phi_1, \phi_2$ and the corresponding complex $\Omega$ the general solution is,

$$U_j^n = A_1(j,n) \exp \left( i \int_0^j \phi_1 \, d\xi - n\Omega \right) + A_2(j,n) \exp \left( i \int_0^j \phi_1 \, d\xi - n\Omega \right)$$

(5.1)

where the amplitudes $A_1$ and $A_2$ satisfy the asymptotic amplitude equations

$$\frac{3A_m}{\nu_n} + (r_q \nu_m) \frac{3A_m}{\nu_j} = \epsilon_m A_m \quad m=1,2$$

(5.2)

and boundary conditions

$$b_1(Q, \phi_1) A_1(0,n) + b_1(Q, \phi_1) A_1(0,n) = 0$$

(5.3)

$$b_2(Q, \phi_1) \exp \left( i \int_0^J \phi_1 \, d\xi \right) A_1(J,n)$$

$$+ b_2(Q, \phi_1) \exp \left( i \int_0^J \phi_2 \, d\xi \right) A_2(J,n) = 0$$

(5.4)

A linear system of finite difference equations with time-independent coefficients and boundary conditions has eigenmode solutions of the form,

$$U_j^n = (U_\beta)_j \exp(-in\Omega_\beta)$$

(5.5)

where $\Omega_\beta$ is the complex eigenfrequency and $U_\beta$ is time-independent.

Suppose the frequency $\Omega$ in (5.1) is close to $\Omega_\beta$. Define $\Omega'$ by

$$\Omega_\beta = \Omega + \Omega'$$

(5.6)

Thus equating (5.1) and (5.5)
\[(U_{\beta})_{j}\exp(-i\Omega') = \]
\[A_1(j,n)\exp\left(i \int_0^j \phi_1 \, d\xi\right) + A_2(j,n)\exp\left(i \int_0^j \phi_2 \, d\xi\right) \quad (5.7)\]

so \[A_1(j,n) = \exp(-i\Omega') A_1(j,0) \quad (5.8)\]
\[A_2(j,n) = \exp(-i\Omega') A_2(j,0) \quad (5.9)\]

and
\[(U_{\beta})_{j} = A_1(j,0)\exp\left(i \int_0^j \phi_1 \, d\xi\right) + A_2(j,0)\exp\left(i \int_0^j \phi_2 \, d\xi\right) \quad (5.10)\]

Substituting (5.8), (5.9) into (5.2) gives
\[
\frac{\partial^2}{\partial j^2}[A_m(j,0)] = \left(\frac{\varepsilon + i\Omega'}{rg}\right)_m A_m(j,0) \quad m=1,2 \quad (5.11)\]

which can be integrated to give
\[
A_m(j,0) = A_m(0,0) \exp\left(\int_0^j \left(\frac{\varepsilon + i\Omega'}{rg}\right)_m \, dj\right) \quad (5.12)\]

The boundary conditions (5.3), (5.4) then become in matrix form
\[
\frac{\partial}{\partial j}\begin{bmatrix} A_1(0,0) \\ A_2(0,0) \end{bmatrix} = 0 \quad (5.13)\]

where
\[A = \begin{bmatrix} A_1(0,0) \\ A_2(0,0) \end{bmatrix} \quad (5.14)\]

and
\[\begin{bmatrix} B_{11} & B_{12} \\ B_{21} & B_{22} \end{bmatrix} = \begin{bmatrix} B_1(0,\phi_1) \\ B_2(0,\phi_1) \end{bmatrix} \quad (5.15a)\]

\[B_{11} = b_1(\Omega,\phi_1) \quad (5.15b)\]
61.

\[ B_{11} = b_1(\Omega, \phi_1) \quad (5.15c) \]

\[ B_{11} = b_2(\Omega, \phi_1) \exp\left( i \int_0^J \phi_1 \, dj \right) \exp\left( \int_0^J \left( \frac{\epsilon + i \Omega}{r g} \right) \, dj \right) \quad (5.15d) \]

\[ B_{11} = b_2(\Omega, \phi_1) \exp\left( i \int_0^J \phi_1 \, dj \right) \exp\left( \int_0^J \left( \frac{\epsilon + i \Omega}{r g} \right) \, dj \right) \quad (5.15e) \]

A non-zero solution \( \tilde{A} \) of (5.13) exists if, and only if,

\[ \det B = 0 \quad (5.16) \]

Hence

\[ \exp\left( i \Omega \int_0^J \left[ r g(\phi_1, j) \right]^{-1} \, dj \right) = \frac{b_2(\Omega, \phi_1) \ b_1(\Omega, \phi_1)}{b_2(\Omega, \phi_1) \ b_1(\Omega, \phi_1)} \exp\left( i \int_0^J \phi_2 - \phi_1 \, dj \right) \exp\left( \int_0^J \left( \frac{\epsilon}{r g} \right) - \left( \frac{\epsilon}{r g} \right) \, dj \right) \quad (5.17) \]

the right hand side of (5.17) can be expressed as its magnitude

\[ \left| \frac{b_2(\Omega, \phi_1) \ b_1(\Omega, \phi_1)}{b_2(\Omega, \phi_1) \ b_1(\Omega, \phi_1)} \right| \exp\left( \text{Re} \int_0^J \left( \frac{\epsilon}{r g} \right) - \left( \frac{\epsilon}{r g} \right) \, dj \right) \]

multiplied by a phase factor \( \exp(i \gamma) \) where

\[ \gamma = \text{arg} \left( \frac{b_2(\Omega, \phi_1) \ b_1(\Omega, \phi_1)}{b_2(\Omega, \phi_1) \ b_1(\Omega, \phi_1)} \right) + \int_0^J \phi_2 - \phi_1 \, dj + \text{Im} \left( \int_0^J \left( \frac{\epsilon}{r g} \right) - \left( \frac{\epsilon}{r g} \right) \, dj \right) \quad (5.18) \]

If \( \phi_1, \phi_2 \) are chosen so that \( \gamma/2\pi \) is an integer then (5.17) reduces to
\[ \Omega' = -\frac{1}{N} \ln \left| \frac{b_2(\Omega, \phi_1) b_1(\Omega, \phi_2)}{b_1(\Omega, \phi_1) b_1(\Omega, \phi_2)} \right| + \text{Re} \left( \int_0^J \left( \frac{\mathcal{E}(r)}{r} \right) \mathcal{E} \left( \frac{r}{r_j} \right) \, dj \right) \]

where as defined in chapter 4,

\[ N = \int_0^J \left[ \mathcal{E}(\phi_1, j) \right]^{-1} - \left[ \mathcal{E}(\phi_2, j) \right]^{-1} \, dj \quad (4.18) \]

The stability criterion is

\[ \text{Im}(\Omega_3) = \text{Im}(\Omega + \Omega') < 0 \quad (5.20) \]

Thus the frequency \( \Omega \) resulting from a normal Von Neumann analysis is corrected by an amount \( \Omega' \) due to boundary conditions and variable coefficients. This approach, using \( \Omega \) as an initial approximation to \( \Omega_3 \) the actual eigenfrequency, is valid provided the asymptotic errors are small compared to \( \Omega' \).

The asymptotic error is \( O \left( L_{\infty}^{-2}, T_{\infty}^{-2} \right) = O \left( L_{\infty}^{-2}, \Omega'^{-2} \right) \)

Now \( N = O \left( \frac{J}{rg} \right) \)

so if \( rg \ll J \) then \( N \gg 1 \)

and hence \( \Omega' \ll 1 \) except near frequencies for which

\[ \left| \frac{b_2(\Omega, \phi_1) b_1(\Omega, \phi_2)}{b_1(\Omega, \phi_1) b_1(\Omega, \phi_2)} \right| \]

is zero, or infinite, which usually occurs at \( \Omega = 0 \). However, these frequencies are heavily damped by the boundary conditions and so an accurate estimate of their eigenfrequencies is not essential. This method gives accurate asymptotic values near the critical frequencies which are least damped and which therefore determine the
overall spectral radius of the scheme.
5.2 Example

This example is the Backward Euler method applied to the model convective problem with constant CFL number \( r \) and space extrapolation at the downstream boundary.

The dispersion relation is

\[ \exp(i\Omega) - 1 = ir \sin(\phi) \]  

so if \( \phi_1 \) is real, \( \phi = \pi - \phi_1 \) is also real

\[ b_1(\Omega, \phi) = 1 \]  

\[ b_2(\Omega, \phi) = 2i \exp(-i\phi/2) \sin(\phi/2) \]  

so

\[ \frac{b_2(\Omega, \phi_1)}{b_1(\Omega, \phi_1)} \frac{b_1(\Omega, \phi_2)}{b_1(\Omega, \phi_1)} = \exp[-i(\phi_2 - \phi_1)/2] \frac{\sin(\phi_2/2)}{\sin(\phi_1/2)} \]

\[ = \exp[-i(\phi_2 - \phi_1)/2] \frac{\cos(\phi_1/2)}{\sin(\phi_1/2)} \]

\[ = \exp[-i(\phi_2 - \phi_1)/2] \cot(\phi_1/2) \]  

(5.21)

Since \( \frac{3\pi}{2^j} = 0 \), \( \epsilon = 0 \)

Hence \( \tau = -(\phi_2 - \phi_1)/2 + J(\phi_2 - \phi_1) \)

\[ = (J - 1/2) (\pi - 2\phi_1) \]  

(5.22)

\( \tau/2\pi = n \), where \( n \) is an integer, implies

\[ \phi_1 = \pi/2 - 2\pi n / (2J - 1) \]  

(5.23)

The group CFL numbers are

\[ r_g(\phi_1) = r \cos(\phi_1) \exp(-i\Omega) \]

\[ = r \cos(\phi_1) / (1 + ir \sin(\phi_1)) \]
\[
= r \cos(\phi_1)(1 - ir \sin(\phi_1)) / (1 + r^2 \sin^2(\phi_1)) \quad (5.24)
\]

\[
\begin{align*}
rg(\phi_1) &= -r \cos(\phi_1)(1 - ir \sin(\phi_1))/ (1 + r^2 \sin^2(\phi_1)) \quad (5.25) \\
\end{align*}
\]

Hence,
\[
\begin{align*}
\Omega &= - \frac{ir \cos(\phi_1)(1 - ir \sin(\phi_1))}{2J(1 + r^2 \sin^2(\phi_1))} \ln \left( \cot(\phi_1/2) \right) \quad (5.26) \\
\exp[-2 \Im(\Omega)] &= |\exp(i\Omega)|^2 \\
&= |1 + ir \sin(\phi_1/2)|^2 \\
&= 1 + r^2 \sin^2(\phi_1/2) \quad (5.27)
\end{align*}
\]

so
\[
\begin{align*}
\Im(\Omega) &= -\frac{1}{2} \ln \left[ 1 + r^2 \sin^2(\phi_1/2) \right] \quad (5.28)
\end{align*}
\]

Hence,
\[
\begin{align*}
\Im(\Omega + \Omega') &= -\frac{1}{2} \ln \left[ 1 + r^2 \sin^2(\phi_1/2) \right] - \\
&\frac{r \cos(\phi_1/2)}{2J(1 + r^2 \sin^2(\phi_1/2))} \ln \left[ \cot(\phi_1/2) \right] \quad (5.29)
\end{align*}
\]

Define the decay rate \( \sigma \) to be
\[
\begin{align*}
\sigma &= -\Im(\Omega + \Omega') \quad (5.30)
\end{align*}
\]

For small \( \phi \ll 1 \)
\[
\begin{align*}
\sigma &= \frac{1}{2} r^2 \phi^2 + \frac{r}{2J} \ln(2/\phi) \quad (5.31) \\
\frac{d\sigma}{d\phi} &= r^2 \phi - \frac{r}{2J} \phi^{-1} \quad (5.32)
\end{align*}
\]

Thus
\[
\frac{d\sigma}{d\phi} = 0 \text{ at } \phi = (2rJ)^{-\frac{1}{2}} \quad (5.33)
\]

so
\[
\begin{align*}
\min \sigma(\phi) &= \frac{r}{4J} + \frac{r}{4J} \ln(8rJ) \quad (5.34)
\end{align*}
\]

The spectral radius \( \lambda \) is
\[ \lambda = \max \exp(-\sigma) \]
\[ = \max (1 - \sigma) \]
\[ = 1 - \frac{\sqrt{r}}{4J} \left[ 1 + \ln(8rJ) \right] \quad (5.35) \]

§6.2 continues this example proving rigorously that every eigenmode is stable, and deriving an asymptotic expression for the decay rate of the eigenmodes near \( \sigma_i = 0 \), showing as expected that the decay rate is greater than the minimum decay rate obtained above and so the above analysis is valid in calculating the spectral radius.
6. Asymptotic Stability and Convergence Analysis II

6.1 Theory

This chapter continues the analysis of chapter 3 without any additional assumptions or approximations. The eigenmodes of a linear system of finite difference equations with time-independent coefficients and boundary conditions vary exponentially with time so a general eigenmode can be written as

\[ U_j^n = \exp(-i\Omega) \sum_{m=1}^{M} A_m(j) \exp\left(i \int_0^j \phi_m \, df\right) \quad (6.1) \]

Note that the amplitudes \( A_m \) are independent of \( n \).

The time evolution of the eigenmode is contained solely in the term \( \exp(-i\Omega) \). The complex amplitudes \( A_m \) each satisfy their asymptotic amplitude equation,

\[ r \frac{\partial A_m}{\partial j} = \varepsilon A_m \quad (6.2) \]

so

\[ A_m(j) = A_m(0) \exp\left(\int_0^j \left(\frac{\varepsilon}{rg} \right) \, dj\right) \quad (6.3) \]

\( \left(\frac{\varepsilon}{rg}\right) \) denotes \( \frac{\varepsilon}{rg} \) evaluated at \( \phi_{m,j} \).

Now that \( A_m(j) \) is related to \( A_m(0) \) the \( M \) asymptotic boundary conditions can be written in tensor summation form as

\[ B_{km} A_m = 0 \quad (6.4) \]

where \( A_m = A_m(0) \quad (6.5) \)

and
\[ b_k(\Omega, \phi_m) \quad \text{if the } k^{\text{th}} \text{ boundary condition is applied} \]

\[ B_{km} = b_k(\Omega, \phi_m) \exp \left( \int_0^J \left( \frac{\xi}{r^2} \right)_m \, dj \right) \]

\[ \text{if the } k^{\text{th}} \text{ boundary condition is applied} \]

\[ \text{at } j=0 \]

\[ \text{at } j=J \]

The term \( b_k(\Omega, \phi_m) \exp \left( \int_0^J i \phi_m \, dj \right) \) comes from (3.77)

and the term \( \exp \left( \int_0^J \left( \frac{\xi}{r^2} \right)_m \, dj \right) \) is the factor relating \( A_m(J) \) to \( A_m(0) \) in (6.3).

A non-zero solution to (6.4) exists if, and only if,

\[ \det(B) = 0 \]

Since all the elements of \( B \) are implicit functions of \( \Omega \) this is the equation which determines the eigenfrequencies.

If the coefficients are constant all of the \( A_m \) are constant and so there are no asymptotic errors. The theory is then exact and is identical to the P-stability analysis of Beam, Warming and Yee [5]. If the coefficients are variable the asymptotic error is of order \( O(L_C^{-1}, J^{-1}L_C^{-1}) \).

The \( O(L_C^{-1}) \) comes from neglecting second derivatives of \( A_m \) and \( \phi_m \) in the asymptotic amplitude equations. The \( O(J^{-1}L_C^{-1}) \) comes from neglecting the first derivatives of \( A_m \) and \( \phi_m \) in the asymptotic boundary conditions.

For all but the very simplest problems it will be
impossible to solve (6.7) analytically to obtain the
eigenfrequencies. Three possible numerical approaches are
outlined below.

6.1.1 Iterative Solution

Suppose $\Omega^n$ is a good approximation to an
eigenfrequency $\Omega$ and

$$\Omega^{n+1} = \Omega^n + \Delta\Omega^n \quad (6.8)$$

is to be a better approximation.

The terms in the definition of $B_{km}$ which change most
rapidly with variations in $\Omega$ are $\exp \left( j \phi_m \right)$ since these
are oscillatory functions because $\phi_m$ usually has a real
component of order $O(1)$.

$$\frac{3\phi}{3\Omega} = \left( \frac{3\Omega}{3\phi} \right)_m$$

$$= (rg)^{-1} \quad (6.9)$$

Hence

$$\phi_m^{n+1} = \phi_m^n + (rg)^{-1} \Delta\Omega \quad (6.10)$$

Subscript $m$ means evaluated at $\phi_{m,j}$

Superscript $n$ means evaluated at $\Omega^n$

Thus

$$\exp \left( \int_0^J i\phi_m^{n+1} \, dj \right) = \exp \left( \int_0^J i\phi_m^n \, dj \right) \exp \left( \int_0^J i\Delta\Omega (rg)^{-1} \, dj \right) \quad (6.11)$$

Define
\[ b_k(\Omega^n, \phi_m^n) \text{ if the } k^{th} \text{ boundary condition is applied at } j=0 \]

\[ b_{km}^n = b_k(\Omega^n, \phi_m^n) \exp \left( \int_0^J \left( \frac{\xi}{r_g m} + i\phi_m^n \right) dj \right) \exp \left( i\Delta \Omega \int_0^J \left( r_g m \right)^{n-1} dj \right) \]

\[ \text{if the } k^{th} \text{ boundary condition is at } j=J \] (6.12)

Then choose \( \Delta \Omega \) to be the smallest root of

\[ \text{det}(B^n) = 0 \] (6.13)

The method in chapter 5 performs one step in this iterative procedure. As explained in chapter 5 the asymptotic error remaining after a correction \( \Delta \Omega \) is \( O(\Delta \Omega^{-2}, L_C^{-2}) \). For constant coefficients this gives quadratic convergence to the true eigenfrequency. For variable coefficients it will converge to a frequency which differs from the true eigenfrequency by an asymptotic error of order \( O(L_C^{-2}) \).

The solution procedure will fail as described in chapter 5 near frequencies for which \( b_k(\Omega, \phi_m) \) is zero since the fractional variation in \( b_k(\Omega, \phi_m) \) is comparable to, or may exceed, the fractional variation in \( \exp \left( \int_0^J i\phi_m dj \right) \).
6.1.2 Newton-Raphson Solution

The Newton-Raphson solution procedure is

\[ u^{n+1} = u^n - \frac{\det(B(u^n))}{\frac{3}{\partial u} \det(B(u^n))} \]  

(6.14)

Although this seems straightforward there will be problems in practice because \( \det(B) = 0 \) has many roots and so \( \frac{3}{\partial u} \det(B(u^n)) \) has many zeros near which the Newton-Raphson iterative procedure is badly behaved.

6.1.3 Stability Domain Method

If \( z \) is defined as

\[ z = \exp(i\Omega) \]  

(6.15)

then the condition for stability is that \( \det(B) \) has no zeros in \( |z| < 1 \). In very simple cases this criterion can be tested analytically (an example is given in §6.2). In more complicated cases because \( \det(B(z)) \) is an analytic function of \( z \) the 'Principle of the Argument' method outlined in appendix A.2 can be used to find whether \( \det(B(z)) \) has any zeros in \( |z| < 1 \). To find the spectral radius \( \lambda \) the same method can be used to find the largest \( \lambda \) for which there are no zeros in \( |z| < \lambda \).
6.2 Example

The example is the Trapezoidal method applied to the model convective problem with constant CFL number \( r \) and space extrapolation at the downstream boundary.

The dispersion relation is

\[
\tan(\Omega/2) = \frac{K}{2} \sin(\phi) \quad (3.41)
\]

Define

\[
K = \exp(i\phi) \quad (6.16)
\]

\[
z = \exp(-i\Omega) \quad (6.17)
\]

Then

\[
\tan(\Omega/2) = \frac{1}{i} \frac{\exp(i\Omega/2) - \exp(-i\Omega/2)}{\exp(i\Omega/2) + \exp(-i\Omega/2)}
\]

\[
= \frac{1}{i} \frac{1 - \exp(-i\Omega)}{1 + \exp(-i\Omega)}
\]

\[
= \frac{1}{i} \frac{1 - z}{1 + z} \quad (6.18)
\]

\[
\sin(\phi) = \frac{1}{2i} [ \exp(i\phi) - \exp(-i\phi) ]
\]

\[
= \frac{1}{2i} (K - K^{-1}) \quad (6.19)
\]

Thus the dispersion relation becomes

\[
\frac{1 - z}{1 + z} = \frac{K}{4} \left( K - K^{-1} \right) \quad (6.20)
\]

Note that if \( K_1 \) is one solution then \( K_2 = -K_1^{-1} \) is the other solution. The condition for stability is that \(|z| < 1\) for all eigenmodes.

Let \( z = R \exp(i\theta) \) \( R, \theta \) real, \( R > 0 \) \( (6.21) \)

Then

\[
\frac{1 - z}{1 + z} = \frac{1 - R \exp(i\theta)}{1 + R \exp(i\theta)}
\]

\[
= \frac{[1 - R \exp(i\theta)] [1 + R \exp(-i\theta)]}{[1 + R \exp(i\theta)] [1 + R \exp(-i\theta)]}
\]
i) Stability domain for $z$

ii) Stability domain for $\frac{1-z}{1+z}$

iii) Stability domain for $\kappa$

FIGURE 4. STABILITY DOMAINS: SHADED REGIONS ARE STABLE
\[
\frac{1 - 2iR \sin(\theta) - R^2}{1 + 2R \cos(\theta) + R^2} = \frac{(1 - R^2) - 2iR \sin(\theta)}{[1 + R \cos(\theta)]^2 + [R \sin(\theta)]^2}\tag{6.22}
\]

Hence \( R < 1 \implies \text{Re} \frac{1-z}{1+z} > 0 \)

\( R > 1 \implies \text{Re} \frac{1-z}{1+z} < 0 \)

Thus if \( r \) is positive then \( R \equiv |z| < 1 \) if, and only if, \( \text{Re} \frac{1-z}{1+z} > 0 \iff \text{Re}[\kappa - \kappa^{-1}] > 0 \)

Now let \( \kappa = R \exp(i\theta) \) \quad (6.23)

\[
\kappa - \kappa^{-1} = R \cos(\theta) + iR \sin(\theta) - R^{-1} \cos(\theta) - iR \sin(\theta)
= (R - R^{-1}) \cos(\theta) + i(R + R^{-1}) \sin(\theta) \tag{6.24}
\]

so \( |z| < 1 \iff \text{Re}[\kappa - \kappa^{-1}] > 0 \)

\( \iff \) either \( R > 1 \), \(-\pi/2 < \theta < \pi/2\) or \( R < 1 \), \( \pi/2 < \theta < 3\pi/2\)

Figure 4 shows the stability domains for the different variables.

The upstream boundary condition has

\( b_1 = 1 \) \quad (3.82)

The downstream space extrapolation has

\( b_1 = 1 - \exp(-i\theta) \) \quad (3.88)

Hence \( B = \begin{pmatrix}
\frac{1}{\exp(i\theta_1)(1-\exp(-i\theta_1))} & \frac{1}{\exp(i\theta_1)(1-\exp(-i\theta_1))}
\end{pmatrix} \)

\[
= \begin{pmatrix}
1 & 1 \\
\kappa^J(1 - \kappa^{-1}) & (-\kappa^{-1})^J(1 + \kappa)
\end{pmatrix} \tag{6.25}
\]
\begin{align}
\text{det}(B) = 0 & \implies \\
\kappa^{2J-1}(\kappa - 1) - (-1)^J(\kappa + 1) = 0 \\
\implies \frac{\kappa+1}{\kappa-1} &= (-1)^J \kappa^{2J-1} \\
\end{align}

Consider the two instability regions I and II marked in figure 4 iii).

In region I \(|\kappa + 1| > |\kappa - 1|\) and \(|\kappa| > 1\)

so \(|\frac{\kappa+1}{\kappa-1}| > |(-1)^J \kappa^{2J-1}|\)

In region II \(|\kappa + 1| < |\kappa - 1|\) and \(|\kappa| < 1\)

so \(|\frac{\kappa+1}{\kappa-1}| < |(-1)^J \kappa^{2J-1}|\)

Hence there are no possible solutions of (6.32) in the two regions of instability. Every eigenmode is stable and so the method is stable. This example is a special example taken from a more general result, proved by Beam, Warming and Yee [5], that the class of A-stable Beam-Warming multistep methods with \(q\) th order space extrapolation at the downstream boundary is stable.

Continuing this example asymptotic decay rates for small \(\phi_1\) can be derived.

\(\phi_1 = 0 \implies \kappa = 1\)

Let \(\kappa = 1 + \delta\)

Equation (6.31) becomes

\((1 + \delta)^{2J-1} \delta - (-1)^J(2 + \delta) = 0\)

Now \(\lim_{J \to \infty} \left(1 + \frac{x}{J}\right)^J = \exp(x)\)

so provided \(J \gg 1 \gg \delta\)
\[(1 + \delta)^{2J} = \exp(2J\delta)\]  
\[\text{Hence } \exp(2J\delta) = 2 (-1)^J \delta^{-1} (2 + \delta)(1 + \delta)\]  
\[= 2 (-1)^J \delta^{-1}\]  
\[\text{If } J \text{ is even this has a solution for real } \delta\]  
\[2J\delta = \ln(2/\delta)\]  
\[\text{so } \delta = \frac{1}{2J} \ln(2/\delta)\]  
\[= \frac{1}{2J} \ln \left( \frac{4J}{\ln(2/\delta)} \right)\]  
\[= \frac{\ln(J)}{2J} + \text{terms of order } O\left( \frac{\ln[\ln(J)]}{J} \right)\]  
\[\text{Since } k = \exp(i\phi_1)\]  
\[= 1 + i\phi_1\]  
\[\phi_1 = -i\delta\]  
\[= -i \frac{\ln(J)}{2J}\]  
\[\text{Linearising the dispersion relation about } \phi = 0 \text{ gives}\]  
\[\Omega = r \phi_1\]  
\[= -ir \frac{\ln(J)}{2J}\]  
\[\text{The asymptotic decay rate is}\]  
\[\sigma = r \frac{\ln(J)}{2J}\]  
\[\text{If } J \text{ is odd the smallest } \delta \text{ solutions are}\]  
\[\delta = \frac{r \ln(J)}{2J} \pm \frac{\pi}{2J}\]  
\[\text{and the decay rate is the same.}\]
7. Assorted Examples and Further Developments

7.1 Instability of Backward Euler with Spacetime Extrapolation

Consider the Backward Euler method applied to the model convective problem with constant CFL number \( r \) on domain \( 0 < j < J \) with space-time extrapolation at the downstream boundary and \( J \gg r \gg 1 \).

The dispersion relation is

\[
\exp(i\Omega) - 1 = ir \sin(\phi) \tag{3.63}
\]

The upstream boundary has

\[
b_1 = 1 \tag{3.82}
\]

The downstream boundary with space-time extrapolation has

\[
b_2 = 1 - \exp[i(\Omega - \phi)] \tag{3.94}
\]

The eigenfrequency equation, \( \text{det}(B) = 0 \) reduces to

\[
\exp(iJ\phi_1)(1 - \exp[i(\Omega - \phi_1)]) = \exp(iJ\phi_1)(1 - \exp[i(\Omega - \phi_1)])
\]

Because \( \phi_1 = \pi - \phi_1 \) this can be written as

\[
\exp(2iJ\phi_1)\left\{1 - \exp[i(\Omega - \phi_1)]\right\} - (-1)^J \left\{1 + \exp[i(\Omega + \phi_1)]\right\} = 0 \tag{7.1}
\]

This and the dispersion relation form two equations in the two unknowns \( \Omega \) and \( \phi_1 \). Considering only the case in which \( J \) is even one eigenmode is given by,

\[
\Omega = \pi + \Omega' \quad |\Omega'| < \pi
\]

so \( ir \sin(\phi_1) = -2 - i\Omega' + O(\Omega'^2) \tag{7.4} \)
\[ \phi_1 = \frac{2i}{r} - \frac{\Omega'}{r} + \text{H.O.T.} \] (7.5)

Substituting into (7.3) with \( \Omega' = 0 \) gives

\[ \exp(-4J/r) \left( 1 + \exp(2/r) \right) - 1 + \exp(-2/r) = 0 + \text{H.O.T.} \] (7.6)

Expanding the exponentials under the approximation \( r >> 1 \) this reduces to,

\[ J = \frac{r}{4} \ln(r) + \text{H.O.T.} \] (7.7)

For a particular even value of \( J \) the value of \( r \) satisfying (7.7) makes this eigenmode asymptotically neutrally stable. To find whether increasing \( r \) makes it unstable or not (7.2) is differentiated by \( r \).

\[ 2iJ \frac{d\phi_1}{dr} \exp(2iJ\phi_1) \left\{ 1 - \exp\left[i(\Omega - \phi)\right] \right\} \]

\[ + \exp(2iJ\phi_1) \left\{ i \frac{d\phi_1}{dr} - i \frac{d\Omega}{dr} \exp[i(\Omega - \phi)] \right\} \]

\[ - \left( i \frac{d\phi_1}{dr} + i \frac{\Omega}{dr} \right) \exp[i(\Omega + \phi)] = 0 \] (7.8)

This is evaluated at \( \Omega' = 0 \), \( J = \frac{r}{4} \ln(r) \) so

\[ \ln(r) \frac{d\phi_1}{dr} - \frac{i}{r} \left\{ \frac{d\phi_1}{dr} - \frac{d\Omega}{dr} \right\} + \left\{ \frac{d\phi_1}{dr} + \frac{d\Omega}{dr} \right\} = 0 + \text{H.O.T.} \] (7.9)

Hence \( \frac{d\Omega}{dr} = \ln(r) \frac{d\phi_1}{dr} + \text{H.O.T.} \)

\[ = - \frac{2i \ln(r)}{r^2} + \text{H.O.T.} \] (7.10)

As \( r \) increases from the neutrally stable value, \( \text{Im}(\Omega) \) becomes negative so the eigenmode becomes unstable. Thus this eigenmode is stable only if

\[ \frac{r}{4} \ln(r) < J \]

In numerical experiments it is found that this is
the least stable eigenmode and so this condition is both necessary and sufficient. The condition is asymptotically equal to an exact stability condition derived by Beam, Warming and Yee [5].
7.2 Optimum CFL Number For Trapezoidal Method

Consider the Trapezoidal method applied to the model convective problem with constant CFL number \( r \) on domain \( 0 < j < J \) with space extrapolation at the downstream boundary.

The dispersion relation is

\[
\tan(\alpha/2) = \frac{r}{2} \sin(\phi) \quad (3.52)
\]

The upstream boundary condition has

\[ b_1 = 1 \quad (3.82) \]

The downstream boundary has

\[ b_1 = 2i \exp(-i\phi/2) \sin(\phi/2) \quad (3.88) \]

Following the stability analysis of chapter 5, \( \epsilon = 0 \) since \( r \) is constant, and the group CFL numbers are given by,

\[ r_{g_1} = r \cos(\phi_1) \cos^2(\alpha/2) \]

\[ r_{g_1} = r \cos(\phi_1) \cos^2(\alpha/2) \]

\[ = -r \cos(\phi_1) \cos^2(\alpha/2) \quad (7.11) \]

so \( \gamma = \arg \left( \frac{b_2(\alpha, \phi_2)}{b_1(\alpha, \phi_1)} \frac{b_1(\alpha, \phi_1)}{b_1(\alpha, \phi_1)} \right) + \int_0^J \phi_2 - \phi_1 \, dj \)

\[ + \text{Im} \left( \int_0^J \left( \frac{\epsilon}{r_{g_2}^2} - \frac{\epsilon}{r_{g_1}^2} \right) \, dj \right) \quad (5.18) \]

\[ = (J-1/2) \left( \phi_2 - \phi_1 \right) \]

\[ = (J-1/2) \left( \gamma - 2\phi_1 \right) \quad (7.12) \]

\[ \gamma/2\pi = n \text{ where } n \text{ is an integer implies} \]
\[ \phi_1 = \frac{\pi}{2} - \frac{2\pi n}{2J-1} \]  

(7.13)

\[ \Omega' = -\frac{i}{N} \left( \ln \left| \frac{b_2(Q, \phi_2) b_1(Q, \phi_1)}{b_2(Q, \phi_1) b_1(Q, \phi_1)} \right| + \text{Re} \left( \int_0^J \left( \frac{r_2}{r_1} - \frac{r_1}{r_2} \right) dj \right) \right) \]

(7.14)

where \( N = \int_0^J [r_g(Q_1, j)]^{-1} - [r_g(Q_2, j)]^{-1} \, dj \)  

(5.20)

\[ = \frac{2J}{r \cos(\phi_1) \cos^2(\alpha/2)} \]

(7.15)

The decay rate \( \sigma \) was defined as

\[ \sigma = -\text{Im}(\Omega + \Omega') \]  

(5.30)

\[ \sigma = \frac{r}{2J} \cos(\phi_1) \cos^2(\alpha/2) \ln[\cot(\phi_1/2)] \]

\[ = \frac{r \cos(\phi_1) \ln[\cot(\phi_1/2)]}{2J \left[ 1 + \tan^2(\alpha/2) \right]} \]

\[ = \frac{2r \cos(\phi_1) \ln[\cot(\phi_1/2)]}{J \left[ 4 + r^2 \sin^2(\phi_1) \right]} \]  

(7.16)

Figure 5 shows the decay rate \( \sigma \) as a function of \( r \) for various values of \( \phi \).

When a system of finite difference equations is solved using a time-independent approach to a steady state solution, usually the initial conditions and the final solution are smooth so the initial error is smooth i.e. the error is predominantly in the low wavenumber, long wavelength eigenmodes. For this problem suppose that the
FIGURE 5. LOG-LOG PLOT OF DECAY RATE AGAINST CFL NO.
initial error is in the wavenumber range $0 < \phi < \phi$, where $\phi$ is a constant, $\phi < \pi/2$

$$\frac{\partial \sigma}{\partial \phi} = - \frac{2r}{J} \left[ \frac{\sin(\phi)}{4 + r^2 \sin^2(\phi)} + \frac{2r^2 \sin(\phi) \cos^2(\phi)}{[4 + r^2 \sin^2(\phi)]^2} \ln[\cot(\phi/2)] \right]
+ \frac{\cos(\phi)}{\sin(\phi); [4 + r^2 \sin^2(\phi)]} < 0 \quad (7.17)$$

so over the range given above $\sigma$ has a minimum at $\phi$. To maximise the overall rate of convergence the CFL number $r$ can be changed by altering $\Delta t$.

$$\frac{\partial \sigma}{\partial r} = \frac{\cos(\phi)}{2J \left[ 4 + r^2 \sin^2(\phi) \right]} \ln[\cot(\phi/2)] \quad (7.18)$$

so $\sigma(\phi)$ is maximised by choosing

$$r = \frac{2}{\sin(\phi)} \quad (7.19)$$

The smoother the initial error the lower the value of $\phi$ and the higher the optimum CFL number. If the initial error is not at all smooth with $\phi$ approaching $\pi/2$, the optimum CFL number drops down towards 2.
7.3 Discontinuous CFL Number In Trapezoidal Method

Consider the following Trapezoidal method applied to the model convective problem.

\[
\left[ \delta_t + \frac{r_{j-1} + r_{j+1}}{2} \mu_t \frac{\partial}{\partial x} + \frac{r_{j+1}}{2} \mu_t \Delta_x \right] U_{j}^{n+\frac{1}{2}} = 0 \quad (7.20)
\]

Suppose that \( r \) is discontinuous

\[
r_j = \begin{cases} 
  r_-, & j < 0 \\
  r_+, & j > 0 
\end{cases}
\]

On the two sides of the discontinuity a general solution of frequency \( \Omega \) can be written as,

\[
U_j^n = \begin{cases} 
  A_1(j, n)\exp[i(j\phi_1 - n\Omega)] + A_1(j, n)\exp[i(j\phi_1 - n\Omega)] & j < 0 \\
  A_1(j, n)\exp[i(j\phi_1 - n\Omega)] + A_1(j, n)\exp[i(j\phi_1 - n\Omega)] & j > 0 
\end{cases}
\]

\( \phi_1 \) and \( \phi_2 \) satisfy the dispersion relation

\[
\tan(\Omega/2) = \frac{r_-}{2} \sin(\phi) \quad (3.52)
\]

with \( \phi_2 = \pi - \phi_1 \)

and \( 0 < \text{Re}(\phi_1) < \pi/2 \)

\( \phi_1 \) and \( \phi_2 \) satisfy the dispersion relation

\[
\tan(\Omega/2) = \frac{r_+}{2} \sin(\phi) \quad (3.52)
\]

with \( \phi_2 = \pi - \phi_1 \)

and \( 0 < \text{Re}(\phi_2) < \pi/2 \)
The amplitudes $A_1$, $A_2$ are related to $A_3$, $A_4$ at $j=0$ by two equations. The first comes from the requirement that the two expressions for $U_j^n$ are equivalent at $j=0$.

Thus

$$A_1 + A_2 = A_3 + A_4 \quad (7.22)$$

The second requirement is that

$$[ \delta t + \frac{1}{2} r_{j-}\mu_{c\chi} x + \frac{1}{2} r_{j+}\mu_{c\chi} \Delta x ] U_0^{n+1} = 0 \quad (7.23)$$

which implies

$$[ \delta t + r_- \mu_{c\chi} ] U_0^{n+1} = -[ \delta t + r_+ \mu_{c\chi} ] U_0^{n+1} \quad (7.24)$$

The left hand side involves $U_j^n$ at $j=0,-1$ so the first expression for $U_j^n$ is used. The right hand side involves $U_j^n$ at $j=0,1$ so the second expression is used. Neglecting derivatives of the amplitudes the resulting equation is,

$$A_1 \{-2i \sin(\frac{\alpha}{2}) + r_-\cos(\frac{\alpha}{2})[1-\exp(-i\phi)]\} + A_2 \{-2i \sin(\frac{\alpha}{2}) + r_-\cos(\frac{\alpha}{2})[1-\exp(-i\phi)]\}$$

$$= -A_3 \{-2i \sin(\frac{\alpha}{2}) + r_+\cos(\frac{\alpha}{2})[1-\exp(-i\phi)]\}$$

$$-A_4 \{-2i \sin(\frac{\alpha}{2}) + r_+\cos(\frac{\alpha}{2})[1-\exp(-i\phi)]\} \quad (7.25)$$

Substituting for $\tan(\frac{\alpha}{2})$ using the dispersion relations and using

$$\exp(i\phi) = \cos(\phi) + i \sin(\phi) \quad (7.26)$$

this reduces to

$$r_-\{ A_1 [1-\cos(\phi_1)] + A_2 [1-\cos(\phi_2)] \}$$

$$= r_+\{ A_3 [1-\cos(\phi_3)] + A_4 [1-\cos(\phi_4)] \} \quad (7.27)$$
In the general problem the two equations relate the amplitudes on either side of the discontinuity at \( j=0 \). Now consider the particular problem in which \( \phi_1, \phi_2, \phi_3, \phi_4 \) are all real and \( A_1 \) is zero. This is the situation when a wavepacket with wavenumber \( \phi_1 \), and positive group CFL number travels from \( j<0 \) to the interface at \( j=0 \) producing a transmitted wavepacket with wavenumber \( \phi_2 \), and positive group CFL number and a reflected wavepacket with wavenumber \( \phi_3 \) and negative group CFL number. The reflection coefficient \( R \) and transmission coefficient \( T \) are defined by,

\[
R = \frac{A_1}{A_1} \tag{7.28}
\]

\[
T = \frac{A_1}{A_1} \tag{7.29}
\]

Since \( A_1 = 0 \)

\[
A_1 + A_2 = A_1 \tag{7.30}
\]

so

\[
r_+(A_1[1-\cos(\phi_1)] + A_2[1-\cos(\phi_3)]) = r_+[A_1+A_2][1-\cos(\phi_1)]
\]

\[
(7.31)
\]

Hence

\[
R = -\frac{r_-[1-\cos(\phi_1)] - r_+[1-\cos(\phi_1)]}{r_-[1-\cos(\phi_2)] - r_+[1-\cos(\phi_2)]} \tag{7.32}
\]

and

\[
T = 1 + R
\]

\[
= \frac{r_-[1-\cos(\phi_2)] - r_+[1-\cos(\phi_1)]}{r_-[1-\cos(\phi_2)] - r_+[1-\cos(\phi_2)]} \tag{7.33}
\]
8. Assorted Loose Ends

8.1 Degeneracy

So far in this paper it has been implicitly assumed that no two eigenmodes have the same frequency \( \Omega \) and wavenumber \( \Omega \). This section considers the degenerate case in which this happens. An example is the Trapezoidal method. The dispersion relation is

\[
\tan(\phi/2) = \frac{r}{2} \sin(\phi)
\]

which has wavenumber solutions \( \phi_1 \) and \( \phi_2 = \pi - \phi_1 \). These are identical when

\[
\phi_1' = \phi_2' = \pi/2
\]

which occurs at the degenerate frequency \( \Omega' \) given by,

\[
\tan(\phi/2) = \frac{r}{2}
\]

Note that

\[
\frac{r'}{r} = \left( \frac{3\Omega}{3\phi} \right) \text{ const}
\]

\[
= r \cos(\phi') \cos^2(\Omega'/2)
\]

\[
= 0
\]

This is characteristic of degeneracy because in the neighbourhood of the double zero

\[
\Omega - \Omega' = a(\phi - \phi')^2, \quad a = \text{constant}
\]

so

\[
\frac{r'}{r} = \frac{\partial \Omega}{\partial \phi}
\]

\[
= 2a(\phi - \phi')
\]

\[
= 0 \quad \text{ at } \phi = \phi'
\]

For \( \Omega \neq \Omega' \) the general solution for constant \( r \) is
\[ U_j^n = A_1 \exp[i(j\phi_1 - n\Omega)] + A_2 \exp[i(j\phi_1 - n\Omega)] \]  (8.6)

Consider the limit as \( \Omega \) approaches \( \Omega' \)
\[ \phi - \phi' = \pm \left( \frac{\Omega - \Omega'}{a} \right) \]  (8.7)

so \( \phi_1 - \phi' = - (\phi_1 - \phi') \)  (8.8)

Hence \( A_1 \exp[ij\phi_1] + A_2 [ij\phi_1] \)
\[ = \exp[ij\phi'] \{ A_1 \exp[ij(\phi_1 - \phi')] + A_2 \exp[ij(\phi_2 - \phi')] \} \]
\[ = \exp[ij\phi'] \{ A_1 \exp[ij(\phi_1 - \phi')] + A_2 \exp[ij(\phi_2 - \phi')] \} \]
\[ = \exp[ij\phi'] \{ (A_1 + A_2) \cos[j(\phi_1 - \phi')] + i(A_1 - A_2) \sin[j(\phi_1 - \phi')] \} \]
\[ = \exp[ij\phi'] \{ A_1 + A_2 \} \]  (8.9)

where \( A_3 = A_1 + A_2 \)  (8.10)

and \( A_4 = i(A_1 - A_2) (\phi_1 - \phi') \)  (8.11)

If \( A_3 \) and \( A_4 \) are now considered to be constants in the limiting process the general form of the degenerate eigenfunction is,
\[ U_j^n = (A_3 + A_4 j ) \exp[i(j\phi' - n\Omega')] \]  (8.12)

Another way of deriving this result is through the asymptotic amplitude equation. With the amplitude \( A \) time-independent, \( r \) constant, and \( q \) equal to zero the largest term is the second order derivative of \( A \) so,
\[ \frac{\partial^2 A}{\partial j^2} = 0 \]  (8.13)

which implies \( A = A_3 + A_4 j \)  (8.14)

In all the examples I have analysed I have not yet
found a degenerate eigenfunction which satisfies the asymptotic boundary conditions and so is a degenerate eigenmode. The degenerate frequency does however satisfy the determinant condition
\[ \text{det}(B) = 0 \] (6.7)
because two of the wavenumbers are equal so their columns are identical and B is singular. This is not a problem in the stability analysis because the separation of eigenfrequencies, using the result from chapter 5, is approximately,
\[
\frac{2\pi}{N} = 2\pi \left( \int_0^J \left[ r_g(\phi_1,j) \right]^{-1} - \left[ r_g(\phi_2,j) \right]^{-1} \, dj \right)^{-1}
\]
+ 0 as \( \Omega \to \Omega' \)
so there is usually a true eigenfrequency which differs from the degenerate frequency by less than the overall asymptotic error.
8.2 Eigenmodes and Eigenfrequencies

In chapters 5 and 6 it was stated that the eigenmodes of a linear system of finite difference equations with time-independent coefficients and boundary conditions vary exponentially with time. This section outlines the proof.

Let \( U_j^n = z^n v_j \) \hspace{1cm} (8.15)

If the domain is \( 0 < j < J \) then there must be \( J+1 \) finite difference equations so \( v_j \) satisfy

\[
\begin{aligned}
z v_j &= 0 \\
C v_j &= 0
\end{aligned}
\] \hspace{1cm} (8.16)

where \( v \) is the \( J+1 \) vector of \( v_j \) elements and \( C \) is a \( (J+1)^2 \) matrix whose elements are polynomials of \( z \).

For there to be a non-zero solution requires

\[
\text{det}(C) = 0
\] \hspace{1cm} (8.17)

This is the equation that determines the eigenvalues \( z \) of the eigenmodes. Apart from the problem of possible degeneracy the only remaining difficulty is to show that the number of eigenmodes equals the number of independent initial conditions needed to start a numerical solution. For the Backward Euler method with space extrapolation at the downstream boundary there are \( J-1 \) independent initial conditions since

\[
U_0^0 = 0 \hspace{1cm} (8.18)
\]

and

\[
U_J^0 = U_{J-1}^0 \hspace{1cm} (8.19)
\]
so \( \det(C) \) is a polynomial in \( z \) of degree \( J-1 \) giving \( J-1 \) eigenmodes. Thus any solution can be expressed as a sum of eigenmodes which vary exponentially with time.
8.3 Other Asymptotic Approaches

One approach which can be used when the variation in coefficients is extremely small is to let,

\[ U_j^n = A(j, n) \exp[i(j\phi - n\Omega)] \]  \hspace{1cm} (8.21)

where \( \Omega \) and \( \phi \) are both constant and satisfy

\[ a_0(\Omega, \phi, j) = 0 \]  \hspace{1cm} (8.22)

at some point \( j \).

The asymptotic amplitude equation is then

\[ a_0A + a_1 \frac{3A}{3n} + a_2 \frac{3A}{3j} = 0 \]  \hspace{1cm} (8.23)

where \( a_0, a_1 \) and \( a_2 \) are defined and calculated as before.

\[ L_A = \min \left( \frac{A}{3} / \frac{3A}{3j} \right) \]

\[ = O \left( \frac{a_1}{a_0} \right) \]  \hspace{1cm} (8.24)

so the fractional error using this method is \( O \left( \frac{a_1}{a_0} \right)^2 \).

If the variations in the coefficients are small this is fine but if the variations are \( O(1) \) the fractional error is \( O(1) \) i.e. the method fails to give accurate asymptotic approximations. The asymptotic approach used in this paper allows total variations in the coefficients of \( O(1) \) and only requires that the length scale of those variations is much greater than 1.

Another approach is to set

\[ U_j^n = A(j, n) \exp[i\psi(j, n)] \]  \hspace{1cm} (8.25)

with \( \frac{3\psi}{3j} = \phi \)  \hspace{1cm} (8.26)
and $A, \Omega, \phi$ are all real and slowly varying. This approach is used extensively in the analysis of water waves and other partial differential equations with dispersion and very little dissipation. This approach applied to finite difference equations would give poor results because dissipation over one time step is $O(1)$ so if $\Omega$ is real $A$ reflects this dissipation and so $T_A = O(1)$. The method presented in this paper is able to use constant complex $\Omega$ rather than variable real $\Omega$ as in the above method because the eigenmodes have constant complex eigenfrequencies provided the finite difference equations are time-independent.

\[ \frac{\partial \psi}{\partial \nu} = -\Omega \quad (8.27) \]
9. Wavepacket Test Program

9.1 Program Description

The program solves the model convective problem,

\[ \frac{3u}{3t} + c \frac{3u}{3x} = 0 \]  \hspace{1cm} (9.1)

using a choice of Box or Trapezoidal methods on the domain,

\[ 0 < j < 200 \]  \hspace{1cm} (9.2)

and time step range,

\[ 0 < n < 400 \]  \hspace{1cm} (9.3)

The CFL number

\[ r_j = \frac{c_j \Delta t}{\Delta x_j} \]  \hspace{1cm} (9.4)

is specified by the user at \( j=0,200 \) and the program interpolates for intermediate values by fitting an exponential curve through \( r_0 \) and \( r_{200} \).

\[ r(j) = r_0 \exp\left( \frac{j}{200} \ln\left( \frac{r_{200}}{r_0} \right) \right) \]  \hspace{1cm} (9.5)

Methods 1-3 are different Trapezoidal methods which are identical if \( r \) is constant. For these methods the program offers a choice of space extrapolation, space-time extrapolation or box condition as the downstream boundary condition. Method 4 is the Box method. The wavepacket theory for each of these methods is derived in the next section.

The upstream boundary condition is,

\[ u^n_0 = 0 \]  \hspace{1cm} (9.6)

The initial conditions are given by,
\[ u_j^n = A(j,n) \exp[i\phi(j,n)] \quad (9.7) \]

where \[ A(j,n) = \exp[-(j-100)^2/200] \quad (9.8) \]

and \[ \phi(j,n) = \sum_{k=0}^{j-1} \phi_k(n,j) \quad (9.9) \]

This produces a wavepacket about 40 mesh points long. The user specifies \( \Omega \) by specifying the critical CFL number which is defined as,

\[ r_{\text{crit}} = 2 \tan(\Omega/2) \quad (9.10) \]

so \[ \Omega = 2 \tan^{-1}(r_{\text{crit}}/2) \quad (9.11) \]

The significance of the critical CFL number is that when,

\[ r = r_{\text{crit}} \quad (9.12) \]

the group CFL number for the Trapezoidal methods is zero.

Wave propagation can only occur for \( r > r_{\text{crit}} \).

At each time step the program calculates 'experimental' values for the position \( X(n) \) and energy \( E(n) \) of the wavepacket. If \( U \) was continuous \( X \) and \( E \) would be defined as,

\[ E(n) = \int_{x_0}^{x_{200}} |U(x,t_n)|^2 \, dx \]

\[ = \int_{0}^{200} |U(j,n)|^2 \frac{dx}{dj} \, dj \quad (9.13) \]
and \[ X(n) = \frac{1}{E(n)} \int_{x_0}^{x_{200}} |U(x, t_n)|^2 x \, dx \]

\[ = \frac{1}{E(n)} \int_{0}^{200} |U(j, n)|^2 x(j) \, dx \, dj \]  \hspace{1cm} (9.14)

so since \( U \) is discrete \( X(n) \) and \( E(n) \) are defined as,

\[ E(n) = \sum_{j=0}^{200} |U_j^n|^2 a_j \]  \hspace{1cm} (9.15)

\[ X(n) = \frac{1}{E(n)} \sum_{j=0}^{200} |U_j^n|^2 x_j a_j \]  \hspace{1cm} (9.16)

where \[ a_j = \frac{1}{2}(x_{j+1}-x_{j-1}) \]  \hspace{1cm} (9.17)

In the program \( c \) is taken to be constant so variations in \( r \) are due to variations in \( \Delta x \).

\[ \Delta x = \frac{c\Delta t}{r} \]  \hspace{1cm} (9.18)

so \[ x_{j+1} - x_{j-1} = \left(\frac{r_{j+\frac{1}{2}}}{r_{j-\frac{1}{2}}}\right)^{-1} \]

A physical domain \( 0 < x < 1 \) is used so,

\[ x_j = \sum_{k=1}^{j} \left(\frac{r_{j-\frac{1}{2}}}{r_{j-\frac{1}{2}}}\right)^{-1} \left/ \sum_{k=1}^{200} \left(\frac{r_{j-\frac{1}{2}}}{r_{j-\frac{1}{2}}}\right)^{-1} \right. \]  \hspace{1cm} (9.19)

After completing the 400 time steps the program calculates predicted values for \( X(n) \) and \( E(n) \) using the wavepacket equations derived in the next section with the experimental values at \( n=1 \) as initial conditions.
9.2 Theory

Method 1 is a Trapezoidal method which is second order accurate in \( \Delta x \) only when \( \Delta x \) is constant.

\[
\begin{align*}
\frac{\partial}{\partial t} + \frac{\mu}{\Delta x} \frac{\partial}{\partial x} \bigg|^{n+\frac{1}{2}} = 0
\end{align*}
\]  
(9.20)

\[
\begin{align*}
\frac{2 \Delta t}{x_{j+1} - x_{j-1}}
\end{align*}
\]  
(9.21)

Following the analyses of chapters 3 and 4,

\[
\begin{align*}
a_0 &= -2i \sin(\phi/2) + ir \cos(\phi/2) \sin(\phi) \\
a_1 &= \cos(\phi/2) + \frac{r}{2} \sin(\phi/2) \sin(\phi) \\
a_2 &= r \cos(\phi/2) \cos(\phi) \\
a_3 &= -\frac{r}{2} \cos(\phi/2) \sin(\phi)
\end{align*}
\]  
(9.22-9.25)

The dispersion relation is

\[
\tan(\phi/2) = \frac{r}{2} \sin(\phi)
\]  
(9.26)

so \( a_3 = 0 \)  
(9.27)

and \( a_1 = \cos(\phi/2) + \sin(\phi/2) \tan(\phi/2) \)

\[
= (\cos^2(\phi/2) + \sin^2(\phi/2)) / \cos(\phi/2) \\
= \sec(\phi/2)
\]  
(9.28)

\[
\begin{align*}
r &= a_2 / a_1
\end{align*}
\]  
(9.29)

\[
\frac{d\theta}{dn} = i \frac{3a_1}{\delta j} \Omega, \phi \text{ const} / a_1
\]  
(4.4)
\[ c^* \]

\[ \begin{align*}
\delta (r) - \frac{3r}{2j} \sin(\phi) \cos^2(\Omega/2) &= 0 \\
\epsilon &= -ia_i \left( \frac{3a}{3j} \right) \Omega, \phi \text{ const } / a_1 a_1 - a_2 / a_1 \\
&= -\frac{1}{2} \frac{3r}{3j} \cos^2(\Omega/2) \sin(\phi) \tan(\phi)
\end{align*} \] (9.30)

\[ \begin{align*}
\frac{1}{a} \frac{3a}{3j} &= -\frac{1}{r} \frac{3r}{3j} \\
\text{so } \frac{1}{a} \frac{3a}{3j} (r a) &= r \frac{3a}{3j} (r / r) \\
&= -r \sin(\phi) \cos^2(\Omega/2) \frac{3\phi}{3j} \\
&= -r \sin(\phi) \cos^2(\Omega/2) i \frac{3a}{3j} / a_1 \\
&= \frac{3r}{3j} \cos^2(\Omega/2) \sin(\phi) \tan(\phi)
\end{align*} \] (9.32)

Hence the equations of motion for the wavepacket for real \( \Omega \) and \( \phi \) are,

\[ \frac{dj}{dn} = r \cos(\phi) \cos^2(\Omega/2) \] (9.34)

\[ \frac{d\phi}{dn} = -\frac{3r}{3j} \sin(\phi) \cos^2(\Omega/2) \] (9.30)

\[ \frac{d}{dn} \ln(E) = 0 \] (9.35)

Method 2 is also a Trapezoidal method which is second order accurate in \( \Delta x \) only when \( \Delta x \) is constant.

\[ \left[ \delta_t + \frac{r_{j+1} \mu^t}{2} + \frac{r_{j-1} \mu^t}{2} \right] u^{n+\frac{1}{2}} = 0 \] (9.36)
\[ \begin{align*}
\mathbf{r}_{j+1} &= \frac{\mathbf{c} \mathbf{a} \mathbf{t}}{x_{j+1} - x_j} \tag{9.37} \\

a_2 &= -2i \sin(\Omega/2) + \frac{1}{2} \cos(\Omega/2) \left( r_{j+1} \left[ \exp(i\phi) - 1 \right] + r_{j-1} \left[ 1 - \exp(-i\phi) \right] \right) \\
&= -2i \sin(\Omega/2) + \frac{1}{2} \cos(\Omega/2) \left( (r_j + \frac{1}{2} \frac{3r}{3j}) \left[ \exp(i\phi) - 1 \right] + (r_j - \frac{1}{2} \frac{3r}{3j}) \left[ 1 - \exp(-i\phi) \right] \right) + \text{H.O.T.} \\
&= -2i \sin(\Omega/2) + ir \cos(\Omega/2) \sin(\phi) + \frac{1}{2} \frac{3r}{3j} \cos(\Omega/2) \left[ \cos(\phi) - 1 \right] + \text{H.O.T.} \tag{9.38}
\end{align*} \]

The H.O.T. are neglected because they are of the same order of magnitude as other terms already neglected in the derivation of the asymptotic amplitude equation. To this same level of asymptotic accuracy \( a_1, a_2 \) and \( a_3 \) are exactly the same as in the analysis of method 1.

The dispersion relation remains,
\[ \tan(\Omega/2) = \frac{r}{2} \sin(\phi) \tag{9.26} \]
so now \( a_3 = \frac{1}{2} \frac{3r}{3j} \cos(\Omega/2) \left[ \cos(\phi) - 1 \right] \tag{9.39} \)

After some algebra it follows that the equations of motion are,
\[ \begin{align*}
\frac{dj}{dn} &= r \cos(\phi) \cos^2(\Omega/2) \tag{9.40} \\
\frac{ds}{dn} &= -\frac{1}{2} \frac{3r}{3j} \sin(\phi) \cos^2(\Omega/2) \tag{9.41} \\
\frac{d}{dn} \ln(E) &= \frac{3r}{3j} \left[ 1 - \cos(\phi) \right] \cos^2(\Omega/2) \tag{9.42}
\end{align*} \]

Method 3 is a Trapezoidal method which is second
order accurate in \( \Delta x \) for cases with smoothly varying \( \Delta x \).

\[
\delta t + \frac{(r_{j+\frac{1}{2}})^2}{r_{j+\frac{1}{2}}+r_{j-\frac{1}{2}}} \mu_x \Delta x + \frac{(r_{j-\frac{1}{2}})^2}{r_{j+\frac{1}{2}}+r_{j-\frac{1}{2}}} \mu_x \Delta x \] \( J_{j}^{n+\frac{1}{2}} = 0 \) (9.43)

The dispersion relation is the same as for methods 1 and 2 so after some algebra,

\[
a_j = \frac{3}{2} \cos(\Omega/2) [\cos(\phi)-1] \] (9.44)

and the equations of motion are,

\[
d \frac{dI}{dn} = r \cos(\phi) \cos^3(\Omega/2) \] (9.45)

\[
d \frac{dE}{dn} = -\frac{3r}{2j} \sin(\phi) \cos^3(\Omega/2) \] (9.46)

\[
d \frac{d \ln(E)}{dn} = 2 \frac{3r}{2j} [1-\cos(\phi)] \cos^2(\Omega/2) \] (9.47)

When the wavepackets of methods 1-3 reach the downstream boundary at \( j=200 \) they are reflected into backward travelling wavepackets. The energy \( E_1 \) and the wavenumber \( \phi_1 \) of the reflected wavepacket are related to the energy \( E_1 \) and wavenumber \( \phi_1 \) of the incident wavepacket by the equations,

\[
\phi_2 = \pi - \phi_1 \] (9.48)

\[
\ln(E_2) = \ln(E_1) + 2 \ln|R_j| \] (9.49)

where \( R_j \) is the amplitude reflection coefficient.

For space extrapolation (see \( \S3.5.2 \))

\[
|R_j| = \frac{\sin(\phi_1/2)}{\sin(\phi_1/2)} \]

\[
= \tan(\phi_1/2) \] (9.50)
For space-time extrapolation (see §3.5.3)

\[ |R_j| = \left| \frac{\sin((\phi_1 - \Omega)/2)}{\sin((\phi_1 - \Omega)/2)} \right| \]  
(9.51)

For the box boundary condition (see §3.5.4)

\[ |R_j| = \left| \frac{\cos(\phi_1/2) \tan(\Omega/2) - r \sin(\phi_1/2)}{\cos(\phi_2/2) \tan(\Omega/2) - r \sin(\phi_2/2)} \right| \]

\[ = \tan^2(\phi_1/2) \]  
(9.52)

after substituting for \( \tan(\Omega/2) \) using the dispersion relation and replacing \( \phi_1 \) by \( \pi - \phi_1 \).

The reflection relations at the upstream boundary are,

\[ \phi_1 = \pi - \phi_2 \]  
(9.53)

\[ \ln(E_1) = \ln(E_2) \]  
(9.54)

since \( R_0 = -1 \) (see §3.5.1)

Method 4 is the Box method discussed in §3.3.2

\[ [ \mu \delta t + r_j \mu \delta x ] U_{n+\frac{1}{2}}^{j+\frac{1}{2}} = 0 \]  
(9.55)

The dispersion relation is

\[ \tan(\Omega/2) = r \tan(\phi/2) \]  
(9.56)

and the equations of motion for the wavepacket are,

\[ \frac{d\phi}{dn} = r \left[ 1 + \tan^2(\phi/2) \right] \cos^2(\Omega/2) \]  
(9.57)

\[ \frac{d\phi}{dn} = -2 \frac{d_r}{\partial j} \tan(\phi/2) \cos^2(\Omega/2) \]  
(9.58)
\[
\frac{d}{dn} \ln(E) = -2 \frac{\partial}{\partial \phi} \frac{\partial}{\partial \Omega} \tan^2(\phi/2) \cos^2(\Omega/2)
\] (9.59)
9.3 Numerical Results

9.3.1 Trapezoidal Method with Variable CFL Number

This example uses,

Method type = 2 ; one of the Trapezoidal methods
Boundary type = 1 ; space extrapolation
\( r_0 = 0.05 \quad r_{200} = 0.2 \quad r_{crit} = 0.04 \)

Figure 6 shows \( X(n) \) and \( \ln[E(n)] \) both predicted and experimental. This example shows the movement of a wavepacket and the change in its energy due to the variation in the CFL number. The agreement between the predicted and experimental values is excellent. The energy of the analytic solution is constant so the wavepacket theory has successfully predicted almost all of change in the numerical energy due to variable \( \Delta x \).
Figure 6, Example 9.3.1 Trapezoidal Method 2
9.3.2 Box Method with Variable CFL Number

This example uses,

Method type = 4 ; Box method

\[ r_0 = 0.05 \quad r_{200} = 0.2 \quad r_{crit} = 0.04 \]

Figure 7 shows \( X(n) \) and \( \ln[E(n)] \). As in §9.3.1 the agreement between experiment and theory is excellent.
9.3.3 Trapezoidal Method with Space Extrapolation

This example uses,

Method type = 1 ; one of the Trapezoidal methods
Boundary type = 1 ; space extrapolation
\( r_0 = 1.0 \quad r_{200} = 1.0 \quad r_{\text{crit}} = 0.3 \)

Figure 8 shows \( X(n) \) and \( \ln(E(n)) \). This example illustrates the effect of the downstream boundary reflecting a wavepacket with reduced energy. Because of the finite length of the wavepacket the drop in energy is smeared and \( X(n) \) does not quite reach 1.0.
FIGURE 8: EXAMPLE 9.3.3 TRAPEZOIDAL METHOD 1 WITH SPACE EXTRAPOLATION
9.3.4 Trapezoidal Method with Space-time Extrapolation

This example is the same as §9.3.3 except that

Boundary type = 2 ; space-time extrapolation

Figure 9 shows $X(n)$ and $\ln(E(n))$. The energy of the reflected wavepacket is less than in §9.3.3. As a consequence the first order terms which are neglected in the asymptotic boundary conditions are more significant and so the energy decrease is more smeared and there is a larger discrepancy between the experimental and predicted values.
FIGURE 9. EXAMPLE 9.3.4 TRAPEZOIDAL METHOD 1 WITH SPACE-TIME EXTRAPOLATION
9.3.5 Trapezoidal Method with Box Boundary Condition

This example is the same as §9.3.3 except that,

Boundary type = 3 ; box boundary condition

Figure 10 shows X(n) and ln[E(n)]. The energy drop in this example is three times that in §9.3.3 because,

\[ \ln(E_2) = \ln(E_1) + 2 \ln(|R_J|) \tag{9.49} \]

and

\[ |R_J| = \begin{cases} \tan(\phi_1/2) & \text{space extrapolation} \tag{9.50} \\ \tan'(\phi_1/2) & \text{space-time extrapolation} \tag{9.52} \end{cases} \]

Thus the box boundary condition increases the overall convergence rate by factor 3 with minimal extra computational effort.
Figure 10. Example 9.3.5 Trapezoidal Method 1 with Box Boundary Condition
9.3.6 Wavepacket Outflow in Box Method

This example uses,

Method type = 4 ; Box method
\[ r_0 = 0.4 \quad r_{200} = 0.4 \quad r_{crit} = 0.2 \]

Figure 11 shows \( X(n) \) and \( \ln[E(n)] \). Note that when the wavepacket reaches the downstream boundary the experimental value for \( X(n) \) remains near 1.0 and \( \ln(E) \) decreases rapidly towards \(-\infty\).
Figure 11. Example 9.3.6 Box Method
9.3.7 Instability of Trapezoidal Method with Space-time Extrapolation

This example uses,

- Method type = 1 ; one of the Trapezoidal methods
- Boundary.type = 2 ; space-time extrapolation
- \( r_0 = 3.0 \)  \( r_{200} = 3.0 \)  \( r_{crit} = 2.1 \)

Figure 12 shows \( X(n) \) and \( \ln[E(n)] \). Both the theoretical prediction and the numerical result show that the energy increases every time the wavepacket reflects off the downstream boundary and so the numerical scheme is unstable. The CFL stability condition for the case with constant CFL number is obtained by considering the amplitude reflection coefficient.

\[
|R_J| = \left| \frac{\sin \left( \frac{\phi_1 - \Omega}{2} \right)}{\sin \left( \frac{\phi_1 - \Omega}{2} \right)} \right| \tag{9.52}
\]

The dispersion relation is

\[
\tan(\Omega/2) = \frac{r}{2} \sin(\phi) \tag{9.26}
\]

Now consider the two cases \( r < 2 \) and \( r > 2 \).

a) \( r < 2 \)

\[ 0 < \phi_1 < \pi/2 \implies \tan(\Omega/2) < 1 \]

\[ \implies \Omega < \pi/2 \]

\[ \implies (\pi/2 - \Omega) > 0 \quad \text{and} \quad (\pi/2 - \phi_1) > 0 \]

\[ \implies \pi > |(\pi/2 - \Omega) + (\pi/2 - \phi_1)| > |(\pi/2 - \Omega) - (\pi/2 - \phi_1)| > 0 \]

\[ \implies \left| \sin \left( \frac{\phi_1 - \Omega}{2} \right) \right| > \left| \sin \left( \frac{\phi_1 - \Omega}{2} \right) \right| \]
Figure 12. Example 9.3.7: Trapezoidal Method 1 with Space-Time Extrapolation
b) \( r > 2 \)

For \( \phi = \pi/2 \), \( \tan(\Omega/2) > 1 \implies \Omega > \pi/2 \implies \Omega > \phi \)

For \( \phi = \pi \), \( \tan(\Omega/2) = 0 \implies \Omega < \phi \)

As \( \phi_i \) varies from \( \pi/2 \) to \( \pi \), \( \Omega - \phi_i \) varies continuously so at some intermediate value,

\[ \Omega = \phi_i \]

and hence \( |R_j| = \infty \)

The numerical scheme is thus stable if, and only if, the CFL number is less than 2. This stability condition has previously been derived by Beam, Warming and Yee [5].

In a numerical experiment an infinite amplitude reflection coefficient does not occur because the first order derivatives of the amplitude which are neglected in the asymptotic boundary conditions become significant. In fact in all the unstable cases I have tried the agreement between experiment and prediction is poor because of the neglected first order terms in the boundary condition and the neglected second order terms in the amplitude equation. The example given is one of the best. The qualitative effects of these neglected terms can be understood as follows;

Since \( \frac{3A}{3n} = r \frac{3A}{3j} \) all the second order terms in the amplitude equation \( \frac{3^2A}{3n^2}, \frac{3^2A}{3n3j}, \frac{3^2A}{3j^2} \) can be expressed in terms of \( \frac{3^2A}{3j^2} \). Thus the amplitude equation including second order terms has the form,

\[ \frac{3A}{3n} + r \frac{3A}{3j} = \nu \frac{3^2A}{3j^2} \]  (9.61)
where \( v \) is a function of \( \Omega, \phi \) and corresponds to an artificial viscosity. The effect of this artificial viscosity is to smear the wavepacket increasing its length and decreasing its maximum amplitude. This has the largest effect on \( X(n) \) since the longer the wavepacket the further \( X(n) \) must be from the ends of the domain. \( X(n) \) still oscillates approximately in phase with the predictions but the amplitude of the oscillations decreases steadily. The effect on the energy is much smaller.

The downstream boundary condition including first order terms can be written as,

\[
A_2(j,n) + \tau_2 \frac{\partial A_1}{\partial n}(J,n) = R_J \left[ A_1(j,n) + \tau_1 \frac{\partial A_1}{\partial n}(J,n) \right] \tag{9.62}
\]

where \( \tau_1, \tau_2 \) are functions of \( \Omega, \phi \). If \( \tau_1 \) and \( \tau_2 \) are both small compared to \( T_A \) then (9.62) is approximately equal to

\[
A_1(J,n+\tau_1) = R_J A_1(j,n+\tau_1) \tag{9.63}
\]

Thus the amplitude is reflected with a delay of \( \tau_2 - \tau_1 \). This explains the fact that in almost all the examples in this chapter the reflected wavepacket lags behind the position predicted by wavepacket theory.
9.3.8 Instability of Trapezoidal Methods Due to Varying Mesh

This example uses,

Method type = 3; one of the Trapezoidal methods
Boundary type = 1; space extrapolation
\[ r_0 = 1.0 \quad r_{200} = 10.0 \quad r_{\text{crit}} = 0.8 \]

Figure 13 shows \( X(n) \) and \( \ln[E(n)] \). The agreement between experiment and prediction is good for the energy but as in §9.3.7 the agreement is poor for \( X(n) \) because of the effect of the second order terms which are neglected in the asymptotic amplitude equation. The significance of this example is that this numerical scheme is stable for uniform meshes which give constant CFL number \( r \) but if the mesh, and hence \( r \), varies sufficiently as in this example the scheme becomes unstable. This instability is best understood by expanding the finite difference equation in computational space.

\[
\left[ \delta_t + \frac{\left( r_{j+\frac{1}{2}} \right)^2}{r_{j+\frac{1}{2}} + r_{j-\frac{1}{2}}} \mu t \delta_x^2 + \frac{\left( r_{j-\frac{1}{2}} \right)^2}{r_{j+\frac{1}{2}} + r_{j-\frac{1}{2}}} \mu t \delta_x \right] U_j^{n+\frac{1}{2}} = 0 \quad (9.43)
\]

so

\[
\left[ \delta_t + \frac{r_j}{2} \mu t \delta_x^2 + \frac{3r}{3j} \mu t \delta_x^2 + \text{H.O.T.} \right] U_j^{n+\frac{1}{2}} = 0 \quad (9.64)
\]

The term \( \frac{3r}{3j} \mu t \delta_x^2 \) corresponds to a viscous term in computational space. If \( \frac{3r}{3j} \) is positive it corresponds to negative artificial viscosity and so causes the instability in the above example.

10. Conclusions

The validity of the asymptotic approach developed in this paper is demonstrated by the numerical results in chapter 9. The limitations of the wavepacket theory are due to the asymptotic approximations involved in treating the wavepacket as a particle. The stability analyses in chapters 5 and 6 use fewer approximations and so the asymptotic errors will be substantially smaller. In particular when the coefficients are constant the analysis in chapter 6 reduces to the P-stability analysis of Beam, Warming and Yee [5].

The calculation of the asymptotic amplitude equation and asymptotic boundary conditions for a particular case is no more difficult than a normal Von Neumann analysis. For applicable cases the wavepacket theory and the stability analysis of chapter 5 are straightforward. The general stability analysis of chapter 6 will usually require numerical computation. In the more complex cases the main benefit from this theory will be the insight given by the asymptotic amplitude equation and boundary conditions. The amplitude equation gives the group velocities of the different wavenumbers and the effect of varying coefficients, which is of great interest since in 2-D cascade geometries cell lengths can vary by factors of up to 100 in inviscid calculations and 1000 in viscous calculations. The asymptotic boundary conditions give the amplitude reflection coefficients which provide a practical criterion for choosing the best numerical boundary conditions.

There are various possibilities for future research
in this area. Further applications to relatively simple problems can be done to gain insight into understanding harder problems and improving boundary conditions. Numerical procedures, such as those suggested in §6.1.1-6.1.3, can be developed to solve the equations given by the stability analysis in chapter 6. Finally the asymptotic amplitude equation and boundary conditions can be extended to 2-D and 3-D.

A.1 Finite Difference Operator Notation

An operator notation for finite difference equations simplifies the analysis of finite difference schemes and is a necessity for making any general statements and proving them.

The principal operators are $\delta_x$, central difference, $\mu_x$, central averaging $E_x$, shift operator, $\Delta_x$, forward difference and $\nabla_x$, backward difference. Their definitions are;

\[
\delta_{mx} U_j = U_{j+m/2} - U_{j-m/2} \quad (A.1(a))
\]
\[
\mu_{mx} U_j = \frac{1}{2} (U_{j+m/2} + U_{j-m/2}) \quad (A.1(b))
\]
\[
E_{mx} U_j = U_{j+m} \quad (A.1(c))
\]
\[
\Delta_{mx} U_j = U_{j+m} - U_j \quad (A.1(d))
\]
\[
\nabla_{mx} U_j = U_{j} - U_{j-m} \quad (A.1(e))
\]

Usually these definitions will be used with $m=1$. The main exceptions are $\delta_{2x}$ which is a node-centered central difference,

\[
\delta_{2x} U_j = U_{j+1} - U_{j-1} \quad (A.2)
\]

and $E_{mx}$ which can be used to define a general linear operator,

\[
L_j U_j = \sum_{m=1}^{M} a_{jm} U_{j+m} \quad (A.3)
\]
When there are several independent variables the subscript on the finite operator denotes the direction of the shift, differencing or averaging. For example if,

$$u_j^n = u(x_j, t_n)$$  \hspace{1cm} (A.5)

then

$$\delta_x u_j^{n+\frac{1}{2}} = u_j^{n+1} - u_j^n$$  \hspace{1cm} (A.6)

and

$$\delta_t u_j^{n+\frac{1}{2}} = u_j^{n+1} - u_j^n$$  \hspace{1cm} (A.7)

The general shift operator expression for a finite operator in 2-D is

$$L_j = \sum_{m,p} \sum_{m,p} C_{mp}(j) E_{mx} E_{pt}$$  \hspace{1cm} (A.8)

In applications however this expression can be very complicated and it is usually simpler to express $L$ as a polynomial in the finite operators. As an example the operator in §3.3.2 has the polynomial form

$$L_j = u(x_j, t_n)$$ \hspace{1cm} (A.9)

but in the shift operator form it is,

$$L_j = \frac{1+r}{2} E_{x/2} E_{t/2} + \frac{1-r}{2} E_{-x/2} E_{t/2} - \frac{1-r}{2} E_{x/2} E_{-t/2}$$

$$- \frac{1+r}{2} E_{-x/2} E_{-t/2}$$  \hspace{1cm} (A.10)

Part of the advantage in using operator notation when analysing finite difference schemes arises because all of the finite operators have the same eigenfunction which in 2-D is $\exp[i(j\sigma - n\Omega)]$. 

$\text{L}_j = \sum_{m=1}^{M} a_j^{m} E^{mx}$  \hspace{1cm} (A.4)
\[ \delta_x \exp[i(j\phi-n\Omega)] = \exp[i((j+\frac{1}{2})\phi-n\Omega)] - \exp[i((j-\frac{1}{2})\phi-n\Omega)] \]
\[ = 2i \sin(\phi/2) \exp[i(j\phi-n\Omega)] \quad (A.11(a)) \]

\[ \mu_x \exp[i(j\phi-n\Omega)] = \frac{1}{2} \left[ \exp[i((j+\frac{1}{2})\phi-n\Omega)] + \exp[i((j-\frac{1}{2})\phi-n\Omega)] \right] \]
\[ = \cos(\phi/2) \exp[i(j\phi-n\Omega)] \quad (A.11(b)) \]

\[ \xi_x \exp[i(j\phi-n\Omega)] = \exp[i((j+1)\phi-n\Omega)] \]
\[ = \exp(i\phi) \exp[i(j\phi-n\Omega)] \quad (A.11(c)) \]

\[ \Delta_x \exp[i(j\phi-n\Omega)] = \exp[i((j+1)\phi-n\Omega)] - \exp[i(j\phi-n\Omega)] \]
\[ = \{ \exp(i\phi) - 1 \} \exp[i(j\phi-n\Omega)] \quad (A.11(d)) \]

\[ \gamma_x \exp[i(j\phi-n\Omega)] = \exp[i(j\phi-n\Omega)] - \exp[i((j-1)\phi-n\Omega)] \]
\[ = \{ 1 - \exp(-i\phi) \} \exp[i(j\phi-n\Omega)] \quad (A.11(e)) \]

and similarly,

\[ \delta_t \exp[i(j\phi-n\Omega)] = -2i \sin(\Omega/2) \exp[i(j\phi-n\Omega)] \quad (A.11(f)) \]

\[ \mu_t \exp[i(j\phi-n\Omega)] = \cos(\Omega/2) \exp[i(j\phi-n\Omega)] \quad (A.11(g)) \]

\[ \xi_t \exp[i(j\phi-n\Omega)] = \exp(-i\Omega) \exp[i(j\phi-n\Omega)] \quad (A.11(h)) \]

\[ \Delta_t \exp[i(j\phi-n\Omega)] = \{ \exp(-i\Omega) - 1 \} \exp[i(j\phi-n\Omega)] \quad (A.11(i)) \]

\[ \gamma_t \exp[i(j\phi-n\Omega)] = \{ 1 - \exp(i\Omega) \} \exp[i(j\phi-n\Omega)] \quad (A.11(j)) \]
A.2 Principle of the Argument

Let \( f(z) \) be an analytic complex function with simple poles in a region of the complex \( z \)-plane and let \( C \) be a closed curve in the region. Then the number of zeros of \( F \) minus the number of poles of \( f \) lying inside \( C \) is equal to,

\[
\frac{1}{2\pi i} \int_C \frac{f'(z)}{f(z)} \, dz
\]

\[= \frac{1}{2\pi i} \left[ \ln(f) \right]_C \]

\[= \frac{1}{2\pi} \left[ \arg(f) \right]_C \] \hspace{1cm} (A.12)

\([\;]_C\) denotes the change as \( z \) goes round \( C \) anticlockwise.

\( \arg(f) \) is defined by,

\[ f(z) = R \exp(i\theta) \quad \text{R,}\theta \text{ real } \quad \text{R}>0 \] \hspace{1cm} (A.13)

\[ \arg(f) = \theta \] \hspace{1cm} (A.14)

with the restriction that \( \theta \) must vary continuously as \( z \) goes round \( C \).

The proof is given in many standard texts on complex analysis, e.g. [6]. This provides a very simple test when considering stability problems in which it is sufficient to know whether there are any zeros in a critical region without knowing their exact position. This is the basis of the Nyquist criterion in control theory stability analysis. The test can also be performed numerically relatively easily. The step size \( \Delta z \) in going round \( C \) is decreased, if
necessary, until $|\Delta \arg(f)| < \varepsilon$. Since $\frac{1}{2\pi} \lfloor \arg(f) \rfloor$ is an integer there is no rounding error. The only possible error is if the magnitude of $\Delta \arg(f)$ over one step lies in the range $2n\pi - \varepsilon < \Delta \arg(f) < 2n\pi + \varepsilon$ for some integer $n$ other than zero. Decreasing $\varepsilon$ reduces the chance of an error at the expense of increased computation. $\varepsilon = \pi/6$ should be adequate in most cases.
The norms used in this paper are generalised $L_1$ norms. For a continuous function $u(x,t)$ defined on $0 < x < X$ the norm $||u(t)||$ is defined by,

$$||u(t)||^2 = \int_0^X |u(x,t)|^2 a(x) \, dx$$  \hspace{1cm} (A.15)

where $a(x)$ is a positive non-zero function.

For a discrete function $U^n_j$ defined on $0 < j < J$ the norm $||U^n||$ which is a function of $n$ is defined by,

$$||U^n||^2 = \sum_{j=0}^{J-1} |U^n_j|^2 a_j$$  \hspace{1cm} (A.16)

where $a_j$ is a positive non-zero function.

The stability used in this paper is asymptotic Liapounov stability which is defined as,

Given $\delta > 0$ there exists $\epsilon > 0$ such that

$$||u(0)|| < \epsilon \implies$$

\hspace{1cm} a) $||u(t)|| < \delta$

\hspace{1cm} and b) $||u(t)|| \to 0$ as $t \to \infty$

Condition a) is Liapounov stability which limits how large an initially small disturbance can become. Condition b) is asymptotic stability which specifies that a sufficiently small initial disturbance must ultimately tend to zero.

For linear systems of equations an equivalent definition is

a) There exists $M > 0$ such that $||u(t)|| < M ||u(0)||$
and \hspace{1em} \text{b)} \ |u(t)| \to 0 \text{ as } t \to \infty \\

The corresponding definitions for a discrete function are,

Given \( \delta > 0 \) there exists \( \epsilon > 0 \) such that
\[
|U^0| < \epsilon \implies \|U^n\| < \delta
\]
and \hspace{1em} \text{b)} \ \|U^n\| \to 0 \text{ as } n \to \infty

and for linear discrete systems,

\hspace{1em} \text{a)} \text{ There exists } M > 0 \text{ such that } \|U^n\| < M \|U^0\| \\
and \hspace{1em} \text{b)} \ |U^n| \to 0 \text{ as } n \to \infty
