ABSTRACT

Ethynyl and substituted ethynyl-terminated polysulfones and a process for preparing the same are disclosed. These polysulfones are thermally cured to induce cross-linking and chain extension, producing a polymer system with improved solvent resistance and use temperatures. Also disclosed are substituted 4-ethynylbenzoyl chlorides as precursors to the substituted ethynyl-terminated polysulfones and a process for preparing the same.

6 Claims, No Drawings
ETHYNYL AND SUBSTITUTED ETHYNYL-TERMINATED POLYSULFONES

ORIGIN OF THE INVENTION

The invention described herein was made by an employee of the U.S. Government and may be manufactured and used by or for the Government for governmental purposes without the payment of any royalties thereon or therefor.

FIELD OF THE INVENTION

The present invention relates to a new class of sulfone polymers and oligomers. More particularly, it relates to a group of ethynyl and substituted ethynyl-terminated sulfone polymers and oligomers which cross-link and chain extend upon heating, and then exhibit excellent solvent resistance and thermal stability.

BACKGROUND OF THE INVENTION

Polysulfones are commercially available thermoplastics which are widely used in a variety of applications such as adhesives, composites, or molds for use in automobiles, household appliances and other applications. As thermoplastics, they are generally amorphous and creep under load at elevated temperatures. A more important use limitation is their sensitivity to various solvents, especially when the polymer is in a stressed condition. Because of this solvent sensitivity, conventional polysulfones cannot be used in many applications such as adhesives or composite matrices for use on commercial airplanes, which may be exposed to numerous solvents such as hydraulic and deicing fluids, fuel, and paint strippers. Composites from polysulfones, especially under load, exhibit pronounced crazing and cracking upon exposure to solvents, with loss of mechanical properties.

Various routes have been employed in an attempt to overcome the two major use limitations of polysulfones, creep at elevated temperature and solvent sensitivity. Each such attempt has not been entirely successful because either new difficulties were introduced or the original problem was not entirely solved. In one such application, polysulfones containing crystalline regions which serve as cross-links were employed to increase solvent resistance. The problem with using crystallinity to attain solvent resistance is that the material is more difficult to process and the physical properties of the polymer depend upon the amount or degree of crystallinity which is introduced into the polymer. The degree to which the polymer crystallizes is difficult to control and maintain, and when the degree of crystallinity changes, the physical properties change accordingly. This makes polymers of this type undesirable in certain applications, as in the design of airplane components which must be capable of performing for more than 50,000 hours in hostile environments.

An ethynyl-terminated sulfone monomer has been previously prepared and thermally polymerized to yield a brittle resin (elongation of approximately 6%) (see M. G. Maximovich, S. C. Lockerby, F. E. Arnold, and G. A. Loughran, Science of Advanced Material and Process Engineering Series, vol. 23, p. 490 (1978)). The present invention differs from this in that higher molecular weight materials are used to retain toughness and the chemistry involved is entirely different (i.e., the synthesis is easier and less expensive). Propargyl terminated sulfone monomers and resins therefrom have also been disclosed. See U.S. Pat. No. 4,226,800 to Picklesimer. Once again, the chemistry involved is entirely different; propargyl (HC≡C—CH2—) groups are used to introduce cross-linking versus the ethynyl and substituted ethynyl groups (—C≡C—X), employed in the present invention. The polymers in Picklesimer are thermosets, whereas the polymers of the present invention, depending on the molecular weight of the precursor polysulfone, are thermoplastics. Thermosets are generally high strength, brittle materials with low impact strength. Thermoplastics are relatively high strength, tough materials with high impact strength. Furthermore, thermosets cannot be reformed once they have cured whereas thermoplastics can be reformed as necessary. This feature makes thermoplastics commercially more attractive because scraps and faulted moldings can be reprocessed, thus reducing waste. There is thus a definite need in the art for a thermoplastic polysulfone exhibiting improved resistance to solvents and creep at elevated temperatures.

Accordingly, it is an object of this invention to provide a new thermoplastic composition produced from polysulfones and containing various degrees of cross-linking.

Another object of the present invention is to provide a new thermoplastic composition that will chain extend upon curing.

It is yet another object of the present invention to provide novel thermoplastic polysulfones which exhibit improved use temperatures and solvent resistance.

It is a further object of the present invention to provide a high yield process for preparing thermoplastic polysulfones which exhibit improved use temperatures and solvent resistance.

SUMMARY OF THE INVENTION

According to the present invention, the foregoing and additional objects are attained by producing a class of polysulfones containing ethynyl and substituted ethynyl groups, which upon application of heat will cross-link and chain extend to produce highly solvent resistant and thermally stable polymer systems. The polymers are synthesized from the reaction of an hydroxy-terminated polysulfone with bromobenzoyl chloride to yield an intermediate which is then reacted with a substituted ethynyl compound to yield the produce as shown in the following representative scheme:
where PS is a polysulfone with a molecular weight between 1000 and 50,000 and X is selected from the group consisting of:

Si(CH₃)₄; straight or branched organic radicals having 4 to 10 carbon atoms; substituted aromatic groups of the formula:

where R is selected from the group consisting of: straight or branched organic radicals having 1 to 12 carbon atoms, H, and halogenated derivatives of all of the above.

As an alternative route, an ethynyl-substituted benzoyl chloride may be reacted directly with a hydroxy-terminated polysulfone to yield the product as represented in the following scheme:

The cross-linked polysulfones of the present invention also exhibit superior mechanical stability at elevated temperatures. As shown in Table II, the ethynyl-terminated polysulfone loses only 2.5% of the flexural strength as the temperature is increased from ambient to 93°C; this is a 60% improvement over the loss of strength in UDEL®, and a similar improvement is realized in the flexural modulus. While the improvement in shear strength is not as dramatic, it remains significant. The polymer of the present invention exhibits an 8.5% improvement over UDEL® in loss of shear strength as the temperature rises from ambient to 93°C.

3Thermoplastic failure

Having generally described the invention, a more complete understanding thereof can be obtained by reference to the following specific examples which are provided herein for purposes of illustration only and are not to be limiting on the invention.

EXAMPLE I

Trimethylsilylethylenebenzoate-Terminated Polysulfones

The hydroxy-terminated PS of various molecular weights were converted to trimethylsilylethylenebenzoate-terminated PS as shown in Eq. (1) by the following representative procedure. Hydroxy-terminated PS (30 g, Mn = 12000, Tg = 183°C) was dissolved in a mixture of chloroform (250 ml) and triethylamine (20 ml). A solution of excess 4-bromobenzoic chloride (11 g) in chloroform (50 ml) was added dropwise over a period of 20 minutes at ambient temperature to the stirred PS solution. After stirring for three hours, the solution was poured into methanol in a blender to precipitate 4-bromobenzoate-terminated PS as shown in Eq. (2). The 4-ethynylbenzoyl chloride (11.0 g, 0.055 mole; source, Aldrich Chemical Company), dichlorobis(triphenylphosphine) palladium (0.3 g; source, Strem Chemical, Inc.), pyridine (60 ml), triethylamine (40 ml), and trimethylsilylacetylene (13 g, 0.085 mole; source, Silar Laboratories Inc.) were stirred under nitrogen at 70°-74°C for six hours. The yellow solution turned brown and a precipitate appeared. The reaction mixture was poured into cold dilute aqueous hydrochloric acid (10°C-20°C) to yield 4-trimethylsilylethylenebenzoic acid as a crude tan solid (11.0 g), m.p. 175°-185°C. [lit. m.p. 181°-182.5°C]. The tan solid was dissolved in dilute aqueous sodium hydroxide solution, filtered, and the filtrate acidified to yield a light tan solid (9.6 g). Recrystallization twice from toluene provided 4-ethynylbenzoic acid as golden needles (4.3 g), m.p. 175°-185°C. (MS), molecular ion (M+) at 146.  

EXAMPLE II

Ethynylbenzoate-Terminated Polysulfones

Trimethylsilylethylenebenzoate-terminated PS (12.0 g from the preceding procedure) was dissolved in DMAC (100 ml) and powdered potassium carbonate (1.5 g) was added. The light brown reaction mixture was vigorously stirred at 40°C for two hours and subsequently poured into dilute aqueous hydrochloric acid in a blender. The light tan precipitate was thoroughly washed successively with water and twice with hot methanol to yield 4-ethynylbenzoate-terminated PS as a light tan solid (11.7 g) (IR essentially identical to that of the 4-bromobenzoate-terminated PS except for a weak sharp band at 3300 cm⁻¹ attributed to H—C=C stretch).
hour followed by quenching in methanol (300 ml) in a blender. The resultant off-white solid was boiled in methanol and dried at 90°C to yield the ethynylbenzoate-terminated PS (1.7 g) [IR, essentially identical to the 4-bromobenzoyl-terminated PS except for a weak sharp band at 3300 cm⁻¹ (H-C=C)]. The yields of these syntheses were greater than 90%, a significant increase over yields of other cross-linked polymers reported in prior art.

Once the substituted ethynyl-terminated polysulfone has been prepared, it can, for example, be dissolved in a suitable solvent, such as cyclohexanone, DMAC, or chloroform, and cast into films, or used to impregnate reinforcing material and subsequently used to form a composite. The film or composite can then be heated to induce the reaction of the end groups to cause cross-linking and chain-lengthening. The resulting polymeric system will then exhibit improved solvent resistance and a higher use temperature.

Alternatively, powder samples of the substituted ethynyl-terminated polysulfone can be molded in suitable molds introduced into a press preheated to approximately 316°C and pressure applied for 15 minutes. The degree of flow exhibited by the polymer will depend upon the molecular weight of the starting polysulfone, i.e., normally the higher the molecular weight, the better the flow characteristics. The press temperature is more than sufficient to induce the ethynyl groups to react, thus the molded product need not be further cured to exhibit the superior solvent and thermal qualities.

The above specific examples are considered illustrative of the invention and there may be variations in the substituted acetylene or substituted ethynylbenzoyl chloride that will be apparent to those skilled in the art without departing from the spirit and scope of the invention as set forth herein.

It is recognized, for instance, that where chloroform has been used in the examples, other chlorinated organic solvents such as methylene chloride, symmetric tetrachloroethane and possibly others, could also be used. Likewise, where triethylamine has been used in the examples, other organic bases such as diethylamine, tripropylamine and possibly others could be used as well. Similarly, where methanol has been employed as a precipitating agent, it is recognized that other non-solvents such as ethanol, propanol, and possibly other liquids in which the precipitate would not be soluble could also be employed. Also, other highly polar solvents which could be substituted for 
N,N-dimethylacetamide include hexamethylphosphoramide, N,N-dimethylformamide, and possibly others.

What is claimed as new and desired to be secured by Letters Patent of the United States is:

1. The class of ethynyl or substituted ethynyl-terminated polysulfones of the general formula:

   ![Formula 1](image1)

   where PS is a polysulfone with a molecular weight between 1000 and 50,000 g/mole, and X is selected from the group consisting of:

   - Si(CH₃)₃
   - straight or branched organic radicals having 4 to 10 carbon atoms; substituted aromatic groups of the formula:

   ![Formula 2](image2)

   where R is selected from the group consisting of: straight or branched organic radicals having from 1 to 12 carbon atoms, H, and

   and halogenated derivatives of all of the above.

2. The cross-linked polymer recovered by thermally treating a polysulfone of claim 1.

3. The polymer of claim 2 wherein the thermal treatment consists of heating to temperatures from 150°-400°C for times ranging from 5 minutes to 4 hours.

4. A process for preparing ethynyl and substituted ethynyl-terminated polysulfones comprised of:

   - dissolving a polysulfone, having a molecular weight between 1000 and 50,000 g/mole, in a mixture of chlorinated organic solvent and an organic base, adding dropwise with stirring a solution of 4-bromobenzoyl chloride in a chlorinated organic solvent at temperatures ranging from 10°-50°C, and allowing this mixture to stir 3 hours, precipitating the 4-bromobenzoyl-terminated polymer with a non-solvent, drying the precipitate, and dissolving it in a highly polar solvent, adding an organic base, dichlorobis(triphenylphosphine)palladium, and a substituted acetylene under an inert atmosphere, stirring the mixture for 0.5 to 4 hours at 50°-100°C, and precipitating the resulting substituted ethynyl-terminated polymer with cold dilute aqueous acid.

5. The process of claim 4 wherein the substituted acetylene is of the formula HC≡C—X, where X is selected from the group consisting of:

   - Si(CH₃)₃
   - straight or branched organic radical having 4 to 10 carbon atoms; substituted aromatic groups of the formula:

   ![Formula 3](image3)

   where R is selected from the group consisting of: straight or branched organic radicals having from 1 to 12 carbon atoms, H, and

   and halogenated derivatives of all of the above.

6. A process for preparing ethynyl and substituted ethynyl-terminated polysulfones comprising dissolving
a polysulfone, having a molecular weight between 1000 and 50,000 g/mole, in a mixture of a chlorinated organic solvent and an organic base, adding a substituted 4-ethynylbenzoyl chloride of the formula:

\[ \text{Z} \equiv \text{C} \equiv \text{C} \]

stirring for 0.5 to 4 hours and quenching in a non-solvent to precipitate the resulting substituted ethynyl-terminated polysulfone;

where Z is selected from the group consisting of:

- Si(CH₃)₃
- H straight or branched organic radicals
- halogenated derivatives of all of the above.
