INTRODUCTION

Numerous approaches have been documented for combining optimization techniques with an analysis capability (e.g., refs. 1 to 3). The approach documented in this paper is a particular implementation of the method for combining analysis and optimization techniques with applications to structures (ref. 4). This method, called the programming structural synthesis system (PROSSS), combines a large, general purpose, finite element program for structural analysis, SPAR (ref. 5), with a large, general purpose, optimization program, CONMIN (ref. 6) and several, small, problem-dependent FORTRAN programs and subroutines which must be written by the user to interface the analysis and optimization programs. All of the programs are connected by a network of control cards in the standard, Control Data Corporation CYBER Control Language (CCL), documented in reference 7. Familiarity with the theory behind this method (ref. 4) and with the software (documented in refs. 5 to 7) is a prerequisite for understanding the remainder of this document.

This particular implementation of PROSSS is only the first step in a series of implementations. Other implementations are intended to give the user easier access to intermediate results and more control over the flow of the problem, as well as a capability for interactive modeling and data generation (ref. 8). Another implementation includes incorporating PROSSS entirely within the Engineering Analysis Language (EAL, ref. 9) computer program to simplify the maintenance, control, and data management aspects.

This paper describes a particular implementation of PROSSS. First, an overview is given which explains PROSSS in general with respect to this implementation. The second section describes how the input data are prepared. Next, each component of the system is explained in detail. These components include options, procedures, programs and subroutines, and data files used in this implementation. Finally, an example exercise for each option is given to allow the user to anticipate the type of results which might be expected. The appendixes contain annotated listings and flowcharts to clarify the descriptions of the components of the system presented within the body of this paper.

The purpose of this paper is to demonstrate one method for implementing a flexible software system combining large, complex programs with control language and small, user-supplied, problem-dependent programs. It is not intended to be a self-contained user's guide for PROSSS.

Identification of commercial products in this report is used to adequately describe the model. The identification of these commercial products does not constitute official endorsement, expressed or implied, of such products or manufacturers by the National Aeronautics and Space Administration.

OVERVIEW OF THIS IMPLEMENTATION OF PROSSS

This implementation of the programming structural synthesis system (PROSSS) combines a general purpose, finite element computer program for structural analysis (SPAR), a state-of-the-art optimization program (CONMIN), and several user-supplied,
problem-dependent computer programs. All of the programs are connected by the standard CCL. The results are flexibility of the optimization procedure organization and versatility of the formulation of constraints and design variables.

A flowchart of the analysis-optimization process for this implementation is shown in figure 1. The process results in a minimized objective function, typically

![Flowchart of the analysis-optimization process for PROSSS.]

Figure 1.- Basic flow of PROSSS.

the mass defined in terms of a set of design variables, such as cross-sectional dimension of a structural member. This member is subject to a set of constraints such that stress must be less than some allowable value. Notice that the analysis and optimization programs are executed repeatedly by looping through the system until the process is stopped by a user-defined termination criterion. This part of the system is referred to as the repeatable part of PROSSS. However, some of the analysis, such as model definition, need only be done one time and the results saved for future use. This analysis is performed outside of the loop and referred to as the nonrepeatable part of PROSSS. The user must write some small FORTRAN programs (e.g.,
front processor and end processor) to interface between the analysis and optimization programs. The front processor converts the design variables output from the optimizer into a suitable format for input into the analyzer. The end processor retrieves the behavior variables (i.e., stresses or deflections due to loads) from the analysis program, evaluates the objective function and constraints, and optionally retrieves and evaluates their gradients. These quantities are output in a format suitable for input into the optimizer. These user-supplied programs are problem dependent, because they depend primarily upon the finite elements being used in the model.

Five options for organizing optimization procedures by combining nonlinear or piecewise linear programming methods with analytical or finite difference gradients are shown in table I. Each option is controlled by a complex CCL sequence of commands. These commands are modularized in the form of procedure files and perform the functions of executing programs in certain sequences, such as if-test branching, looping, and manipulating permanent and temporary files. Each procedure file is written using structured programming techniques to aid in readability.

Although presented in the context of structural analysis, the same system concept could be used for aerodynamic optimization of a wing, if SPAR were replaced by an analyzer with a capability for computational aerodynamics. The system is intended to be used in the following three basic ways:

(1) as a research tool for the development of optimization techniques that will interface with an efficient analysis program

(2) as a research tool for testing new analysis techniques that will interface with an efficient optimization program

(3) as an application tool that can be adapted to a wide range of problem types

for use as a research test bed. The following step-by-step description explains how to start a new implementation using SPAR as the analyzer and CONMIN as the optimizer. (Details of the files discussed are given in sec 4.)

1. Write a SPAR runstream (see sec 4.4.2) for the entire problem, execute it, and verify the results. Save the SPARLA (see sec 4.4.3) as a permanent file.

2. Divide the SPAR runstream into the nonrepeatable and repeatable parts. The nonrepeatable part contains the TAB (ref. 5) and ELD processors while the repeatable part contains the rest. Execute the nonrepeatable part and save its SPARLA as a permanent file with a different name than the one used in step 1.

3. Write a front processor and its input file CNMNIO. The input file contains the design variables yielding the same structural parameters (behavior variables) as those used as SPAR input in step 1. The front processor reads these design variables and outputs them in a form suitable for input into the SPAR TAB processor. Execute the front processor by using the procedure file PRCFPXX and verify the output file SPFPOUT.

4. Execute the procedure files PRCFPXX and PRCANAL in this order. SPAR output should agree with that obtained in step 1. Save the SPARLA from this execution as a permanent file with name different from those used in steps 1 and 2.

5. Write an end processor and its input data file ENDN. The end processor converts data output by SPAR on SPARLA in step 4 into objective function and constraint data for input into CONMIN. Execute the end processor by using the procedure file PRCEPXX and the SPARLA from step 4 as input. Verify the results on output file CNMNIO.

6. Execute the procedure files PRCFPXX, PRCANAL, PRCEPXX in this order. Verify that the CNMNIO file is the same as that obtained in step 5.

7. If the gradients are to be computed analytically, perform the following additional steps:

   (a) Write input files INPT and, if needed, CONS required by the procedure file PRCGRDS, and rerun step 2 by using these files.

   (b) Execute the procedure file PRCGRDS using the SPARLA saved in step 4, as input. Save the SPARLD as a permanent file. Verify the SPAR output containing the desired gradient values.

   (c) Expand the end processor written in step 5 to handle the gradients available in the SPARLD saved in step 7(b). Execute the end processor and verify its output file CNMNIO to see that its contents are augmented by the gradient values.

   (d) Execute the procedure files PRCFPXX, PRCANAL, PRCGRDS, and PRCEPXX in this order and verify that file CNMNIO is the same as that obtained in step 7(c).

8. Write an input file PCNPR containing the CONMIN control parameters. Set ITMAX = 1 (Maximum iterations = 1).
9. Write a file PSTRT containing the starting values of the design variables (same as those used in step 3). Save this file as a permanent file.

10. Select an execution option.

11. In program CONMS1 or CONMS2 (EVALS and FSDS, if applicable), change the dimension statements as required and recompile the program.

12. Write an input file for PROSCRS to convert the general names in the option files (app. A) to specific, problem-dependent names.

13. Execute PROSCRS and verify that the output file CNMNIO is the same as that obtained in step 6 or 7(d).

14. Relax the ITMAX = 1 restriction in the CONMIN control parameter file PCNPR. Proceed with optimization. If option 2.2 or 2.3 (table I) is chosen, allow completion of one linear stage and verify its results before continuing.

15. When the optimization is underway, periodically inspect the CONOUT file for acceptability of the direction the process is taking.

After step 15 has been completed, only the input data files should be changed for a different application to a problem of the same class. In this way, PROSSS is executed like a "black box" because PROSSS is set up and debugged for a specific type of application. All of its components, except the problem-dependent input data files, are protected from unauthorized access. The user thus retains the freedom to change input data as he studies a class of problems, but he cannot change the inner workings of the system. Such restricted use is desirable in production applications, because it facilitates the separation of responsibilities of a support staff specialist from those of the engineer user.

Using PROSSS as a black box is very simple. The user must create an input file PROSSIN for a small program called PROSCRS. (See step 12.) This input file contains the specific names and numbers to replace the general names in the option files (app. A) to solve a particular problem (see sec 4.1). The first column of names, each beginning in column 1, are the general names and the second column of names and numbers, each beginning in column 11, are the specific names and numbers supplied by the user. The first name in the input file must be the option number, thereafter the order is not important. The following are the general names that are to be replaced:

POPT  option number (11, 12, 13, 22, or 23)

NONREPT  1, if nonrepeatable part to be executed; 0, otherwise

NRRS  name of runstream input to SPAR for nonrepeatable part, can be omitted if NONREPT is 0

FUSD  1, if fully stressed design is to be used for optimization program; 0, otherwise

FSDSUB  file containing fully stressed design subroutines to be appended to main program, can be omitted if FUSD is 0

CONMIN  file containing main program for optimization
The following names can be omitted if options 1.3 or 2.3 (use of analytical gradients) are not chosen:

**SUBS**  
\( n \), the number of subroutines supplied by the user to calculate analytical gradients; one subroutine is needed for each element type containing more than one design variable.

**BINDEPB**  
file containing \( 2n \) subroutines supplied by the user for calculating analytical gradients; can be omitted if \( n = 0 \).

**INPT**  
input file of control parameters for calculating analytical gradients.

Once the input file, PROSSIN, has been created, it is input into the PROSCRS program. PROSCRS creates three output files: a file of control cards; a file of Text Editor commands (ref. 10) to replace the general names with the specific names; and a file of Text Editor commands (ref. 10) to remove unwanted blanks in the preceding file. The control file is rewound and executed after PROSCRS has completed. The control file performs the following four functions: gets the PROSOPT file (see sec 4.1) and copies the correct option onto file OPTION; edits the file containing edit commands to remove the blanks; edits the OPTION file to change general names to specific names; and starts the option executing.
The program header card for PROSCRS is as follows:

PROGRAM PROSCRS (TAPE8, TAPE9, TAPE10, TAPE11)

where

TAPE8 is the input file of general and specific names

TAPE9 is the output file of control cards

TAPE10 is the output file of edit commands to change from general names to specific names

TAPE11 is the output file of edit commands to remove blanks

Listings of PROSCRS, the input files, the control card file, and the edit file also are presented in appendix A.

4 COMPONENTS OF THE SYSTEM

PROSSS is composed of a system of files consisting of four primary components: option files, procedure files, program files, and data files. Each file is explained in detail with annotated examples listed in the appendixes. For those files which are problem dependent and supplied by the user, the descriptions are given with emphasis on the way the files interface with each other.

4.1 Option Files

There are five option files in PROSSS (table I): options 1.1, 1.2, 1.3, 2.2, and 2.3. Options 1.1, 1.2, and 1.3 use nonlinear mathematical programming, while options 2.2 and 2.3 use piecewise linear programming. Option 1.1 uses gradients calculated inside CONMIN. Options 1.2 and 2.2 use gradients calculated by the finite difference method, while options 1.3 and 2.3 use analytically computed gradients. Five procedure files, one for each of the five options, exist on file PROSOPT. These procedure files consist of a sequence of control cards in CCL (ref. 7). Listings and flowcharts of each option are shown in appendix B. The BEGIN cards in these procedure files control the sequence of execution of the procedure files described in section 4.2. No option procedures have any key words associated with them. Each procedure does, however, have many general names within it. These general names are replaced by specific names (using the Text Editor (ref. 10)) before the option begins executing. These names are described in detail in sections 4.2 to 4.4, and the replacement process was previously explained in section 3. This process was chosen over key word substitution because one BEGIN card (ref. 7) would not hold all the necessary key words and no continuation card is allowed.

4.2 Procedure Files

PROSSS is controlled by nine procedure files, all of which are located on a file named PROSPRC. The specific functions performed by the procedures are (1) nonrepeatable model definition (PRCNRPT), (2) and (3) initialization (PRCINIT and PRCGETF), (4) front processing (PRCFPXX), (5) optimization (PRCOPTM), (6) analysis
(PRCANAL), (7) analytical gradient calculation (PRCGRDS), (8) end processing (PRCEPXX), and (9) printing output (PRCEND). Each procedure consists of a sequence of control cards in CCL (ref. 7). A procedure is called by a BEGIN statement.

Commented listings of each of the nine procedure files are shown in appendix C. Each procedure begins with a header card containing a list of key words, if needed. Key word substitution allows the user to substitute key words in the procedure body with parameters specified on the BEGIN statement. Table II provides a quick reference for each procedure file by giving the file name, the purpose, and the calling sequence.

</table>

4.2.1 Nonrepeatable Model Definition: PRCNRPT

This procedure PRCNRPT creates a SPAR library of the joint and element information for the finite element model (app. C). If analytical gradients are required, the derivatives of the stiffness and mass matrices with respect to the design variables are also computed and stored on the library. The procedure header card is as follows:

```
.PROC,PRCNRPT,NROPT,NRRS,FLX,I,NRLA.
```

where PRCNRPT is the name of procedure file, with key words:

- **NROPT**: option number
- **NRRS**: nonrepeatable SPAR runstream
- **FLX**: field length (octal)
input file for analytical gradient calculation (see INPT)

SPAR library

4.2.2 Initialization: PRCINIT,PRCGETF

Two procedure files, PRCINIT and PRCGETF, are used in the initialization process. The first, PRCINIT, gets the programs required for a particular option (app. C). Some programs must be assembled using various user-supplied main programs and/or subroutines, the names of which are passed through the header card. The procedure header card is as follows:

```
.PROC,PRCINIT,OP,A,B,BB,NSUB,C,FSD,FSUB.
```

where PRCINIT is the name of procedure file, with key words:

OP  option number
A  main program for optimization
B  main program for end processor with no gradients
BB main program for end processor with gradients
NSUB number of user-supplied subroutines for analytical gradient calculation
C  file containing all user-supplied subroutines for analytical gradient calculation. The first NSUB subroutines are combined with program GNGRDRS. The second NSUB subroutines are combined with program DRVSTRS. Each program is a physical record (not needed if NSUB is zero)
FSD 1, implies fully stressed design is required; 0, implies no fully stressed design is required
FSUB file containing fully stressed design subroutines (not needed if FSD is zero)

The second procedure file PRCGETF, used in the initialization process retrieves the remainder of the files required for executing a particular option (app. C). The procedure header card is as follows:

```
.PROC,PRCGETF,OP,F,E,CN,S,I,C,CT,RS,RGS.
```

where PRCGETF is the name of procedure file, with key words:

OP  option number
F front processor program (see FPROC)
E input file to end processor (see ENDN)
CN input file to optimization program (see PCNPR,CONPAR)
input files to optimization program (see PSTRT, STARTX)

input file for analytical gradient calculation (see INPT)

input file of constants for analytical gradient calculation (see CONS)

input file of constants for optimization program (see CNT)

SPAR runstream (no gradients, see NGRS)

SPAR runstream (gradients, see RGS)

4.2.3 Front Processing: PRCFPXX

The procedure file PRCFPXX executes the front processor (app. C). The procedure header card is as follows:

.PROC,PRCFPXX.

where PRCFPXX is the name of procedure file. There are no key words.

4.2.4 Optimization: PROCOPTM

The procedure file PROCOPTM executes the optimization program (app. C). The procedure header card is as follows:

.PROC,PROCOPTM,C,D,F.

where PROCOPTM is the name of procedure file, with key words:

C restart data for optimization program (see PCONRST)

D transfer data to/from optimization program (see PCNMNIO)

F cumulative output from optimization program (see SAVCOUT)

4.2.5 Analysis: PRCANAL

The procedure file PRCANAL merges the output file (SPFPOUT) from the front processor into the SPAR runstream file (SPARRS) and executes the SPAR analysis program. (See app. C.) The initial SPAR input and output are saved for later listing. The procedure header card is as follows:

.PROC,PRCANAL,NRLA,FLX,SAVELD.

where PRCANAL is the name of procedure file, with key words:

NRLA SPAR library from nonrepeatable part

FLX field length (octal)

SAVELD SPAR library for use by end processor
4.2.6 Analytical Gradient Calculations: PRCGRDS

This procedure file, PRCGRDS, creates a SPAR runstream and then uses SPAR and a postprocessor (see sec 4.3.6.3) to SPAR to calculate stress derivatives when forces and moments and derivatives of forces and moments must be converted to stresses and stress derivatives. (See app. C.) The procedure header card is as follows:

```
.PROC,PRCGRDS,NSUB,SAVELD.
```

where PRCGRDS is the name of procedure file, with key words:

- **NSUB** number of user-supplied subroutines for analytical gradient calculations
- **SAVELD** SPAR library for use by end processor

4.2.7 End Processing: PRCEPXX

This procedure file, PRCEPXX, executes the end processor. (See app. C.) The procedure header card is as follows:

```
.PROC,PRCEPXX,BLK.
```

where PRCEPXX is the name of procedure file, with key word:

- **BLK** transfer data file (see BLOCK)

4.2.8 Printing Output: PRCEND

This procedure file, PRCEND, prints CONMIN and SPAR output files and SPAR runstreams. (See app. C.) The procedure header card is as follows:

```
.PROC,PRCEND.
```

where PRCEND is the name of procedure file. There are no key words.

4.3 Program and Subroutine Files

PROSSS uses the following six types of programs during the analysis-optimization process: analysis (SPAR), optimization (CONMIN), front processor (FPROC), end processor (EPROC), control programs, and analytical gradient programs. The analysis program SPAR and the CONMIN subroutine library are not given in the appendixes because they are standard for the system and are documented in references 5 and 6. The user does not have to create either SPAR or the CONMIN subroutine library. Sample listings for all other programs, including the main driver program for the CONMIN subroutine library, are shown in appendix D. Table III provides a quick reference for each of the programs by giving the options and procedures in which the program is used, whether or not the program must be created by the user, and a brief comment about the function of the program.

4.3.1 Analysis Program: SPAR

4.3.1.1 Overall characteristics.—SPAR is a system of processors which perform linear, finite element, structural analysis (ref. 5). It can compute static deflections, stresses, vibration frequencies and modes, dynamic responses, buckling loads, and mode shapes. Shown in figure 2 is the organization of the SPAR processors and data flow. The individual processors communicate with a central body of information known as the data complex. The data complex consists of one or more libraries, which contain the data sets output from the different processors. Each data set has a specific identifying name by which any processor can access it whenever it is required as input for particular computations. A list of the SPAR processors and their functions is given in table IV. The numeral next to the processor names refers to the rows of table V. In table V certain operations performed in SPAR are defined and the operation is broken down according to the type of variable and whether or not the operation occurs in the repeatable or nonrepeatable part of PROSSS. Taken together, tables IV and V show a division of the SPAR processors between nonrepeatable and repeatable parts. Processors without numerals are utilities for functions such as plotting, printing, eigenvalue extraction, etc.

SPAR executes on a processor-by-processor basis. Each processor is executed by a separate explicit command. A runstream consisting of a string of such commands interlaced with the numerical input data is written by the user for a specific problem. Runstreams are described in section 4.4.2. This modularity of SPAR organization and execution makes it well suited for optimization applications.

#### 4.3.1.2 Analytical calculation of gradients.-
Gradients can be calculated in SPAR by using runstreams established specifically for this purpose. The general analysis capability of SPAR is augmented by this runstream to calculate structural response derivatives for static displacements and stresses. The runstream is dependent upon the types of elements used to model the structure. This method of calculating gradients for static analysis is represented in PROSSS by procedure files discussed in section 4.2.6.

#### 4.3.1.3 SPAR data storage and retrieval.-
A unique feature of SPAR relevant to PROSSS organization is its set of data libraries. A group of data sets can be assembled to form a named library. Subroutines documented in reference 11 are available to store and retrieve the SPAR library data sets. These subroutines can be executed by FORTRAN CALL statements and, hence, can be used to make the SPAR data storage accessible to non-SPAR FORTRAN programs.

### 4.3.2 Optimization Program: CONMIN

#### 4.3.2.1 Overall characteristics.-
CONMIN is a general purpose, optimization subroutine library capable of solving linear or nonlinear constrained optimization problems. The basic optimization algorithm is the method of feasible directions. A user's manual describing the program and its execution options (ref. 6) explains all the control parameters used by CONMIN and the CONMIN execution modes.

In CONMIN, the objective function and the constraint functions must be continuous functions of the design variables. The design variables must also be continuous. Therefore, only these two types of optimization problems can be handled by CONMIN and, consequently, by PROSSS.
The CONMIN program organization, shown in figure 3, consists of a main program and the CONMIN subroutine library. The main program reads the initial values of design variables and CONMIN control parameters. The computation of the constraints, the objective function, and the gradients of both can be carried out in the main program if the problem is computationally small. In PROSSS, this mode of operation is used for options 2.2 and 2.3 (table I) by taking advantage of the simplicity and speed of the linear extrapolation procedure. If the problem is large, the computation of objective function, constraints, and gradients is executed externally by stopping the main program, performing the external analysis, and restarting the main program. This mode of operation is used in all other options.

Actual optimization is carried out by the CONMIN subroutine library and is controlled by a set of parameters input through the main program. The CONMIN subroutine library also contains a set of the termination criteria. The user can select a criterion from that set, and establish the numerical values associated with that criterion by means of the input control parameters.

In PROSSS, the optimizer CONMIN appears in the form of

1. subroutine CONMIN and a set of associated subroutines

2. two versions of CONMIN main programs
   (a) CONMS1, to be used with options 1.1, 1.2, 1.3
   (b) CONMS2, to be used with options 2.2, 2.3

4.3.2.2 Program: CONMS1.- The program is problem independent except for the blank common statement. (See app. D.) For a new application, the arrays in this statement must be inspected and adjusted according to reference 6, if necessary, to accommodate the problem size. The source CONMS1 must then be recompiled by the user, and the binary code is used in execution.

The program functions are

1. read CONMIN control parameters from PCNPR the first time CONMS1 is executed
2. read analyzer output in the second and subsequent executions for file CNMNIO

3. call subroutine CONMIN

4. output new vector of design variables for the optimizer on file CNMNIO

5. stop itself to permit the external analysis

6. write and save all data needed for subsequent restarts on file PCONRST

7. generate a message on file GONOGO to indicate that the nonlinear programming (NLP) be stopped when subroutine CONMIN detects satisfaction of its termination criteria

The program card is as follows:

```
PROGRAM CONMS1 (INPUT,OUTPUT,TAPE8,TAPE7,TAPE9,TAPE11,TAPE10,TAPE5 = INPUT, TAPE6 = OUTPUT)
```

where

```
INPUT   PCNPR
OUTPUT  SAVCOUT
TAPE7   PCONRST
TAPE8   PSTRT
TAPE9   CNMNIO
TAPE10  PASS
TAPE11  GONOGO
```

4.3.2.3 Program: CONMS2.- The foregoing description of the program CONMS1 applies to CONMS2 with the following differences. (See app. D.)

The program functions are

1. read CONMIN control parameters from file PCNPR

2. read data for linear extrapolation analysis from file BLOCK

3. call subroutine CONMIN

4. execute the linear extrapolation analysis

5. repeat functions 3 and 4 until two changes in the objective function, obtained by comparing results of three consecutive linear stages, are smaller than a prescribed limit and generate a message to CCL that the piecewise linear programming (PLP) outer loop should be stopped
The program card is as follows:

PROGRAM CONMS2 (INPUT, OUTPUT, TAPE7, TAPE8, TAPE9, TAPE10, TAPE11, TAPE5 = INPUT, TAPE6 = OUTPUT)

where

\[
\begin{align*}
\text{INPUT} & \quad \text{PCNPR} \quad \{ \quad \text{Same as CONMS1} \} \\
\text{OUTPUT} & \quad \text{SAVCOUT} \\
\text{TAPE7} & \quad \text{PSTRT} \\
\text{TAPE8} & \quad \text{BLOCK} \\
\text{TAPE9} & \quad \text{CNT} \\
\text{TAPE10} & \quad \text{PASS} \quad \{ \quad \text{Same as CONMS1} \} \\
\text{TAPE11} & \quad \text{GONOGO}
\end{align*}
\]

4.3.3 Front Processor Program: FPROC

This program does not exist in the PROSSS until it is coded by the user for a specific problem. The front processor program must be compiled by the user, and the binary code must be stored to be used in the PROSSS execution. The name of the binary file must be supplied in the input file to PROSCRS. (See app. D for an example of a front processor program.)

The program functions are

1. read the design variables output by CONMIN from file CNMNIO
2. calculate behavior variables using the design variables on file CNMNIO
3. output these behavior variables in a format meaningful for SPAR. (See SPFPOUT in sec 4.4.3.)

The program card is as follows:

PROGRAM FPROC (INPUT, OUTPUT, TAPE7, TAPE5 = INPUT, TAPE6 = OUTPUT)

where

\[
\begin{align*}
\text{FPROC} & \quad \text{program name} \\
\text{INPUT} & \quad \text{CNMINIO} \\
\text{OUTPUT} & \quad \text{SPFPOUT} \\
\text{TAPE7} & \quad \text{CONS}
\end{align*}
\]
4.3.4 End Processor Program: EPROC

This program must also be coded by the user. (See app. D.) The end processor program must be compiled by the user, and the binary code must be stored to be used in the PROSSS execution. The name of the binary file must be supplied in the input file to PROSCRS.

The program functions are

1. read user-supplied constants defining limits imposed on the behavior variables from file ENDN; these limits are to be used for the constraint function evaluations

2. retrieve the SPAR output data sets (behavior variables and, optionally, their gradients) from the SPAR libraries and store them in arrays

3. extract from these arrays the design variables to be used for the constraint function evaluations and for computing the objective function

4. evaluate the constraints and the objective function and, optionally, their gradients

5. output these quantities in NAMELIST form on file CNMNIO to be read by CONMS1 or CONMS2 main programs (see the LINKE NAMELIST in app. D)

The SPAR libraries are in a special binary format accessible only by two FORTRAN callable subroutines, DAL and FIN, which are used as standard parts of the end processor code to carry out program function 2. These subroutines are documented in reference 11. Both routines are used in SPAR and must be retrieved from the SPAR relocatable subroutines and loaded with the end processor.

The end processor program card is as follows:

PROGRAM EPROC (INPUT,TAPE6,TAPE8,TAPE5 = INPUT)

where

EPROC program name
TAPE5 ENDN
TAPE6 CNMNIO
TAPE8 BLK

4.3.5 Control Programs

There are four problem independent control codes: EVALS, evaluates the finite difference gradients; FSDS, incorporates the fully stressed design technique; SELECTS, selects active or violated constraints; and RERITES, rewrites the design variables to a new file.
4.3.5.1 Program to compute the finite difference gradients: EVALS.- Its functions are

1. read CONMIN control parameters supplied by user from file PCNPR
2. read the design variables from file PSTRT
3. Stop itself to allow execution of the front processor/SPAR/end processor sequence
4. restart - read (from file CNMNIO) and store the objective function and constraint values
5. increment one design variable
6. restart - reset the design variable incremented in step 5 to its original value
7. using the stored objective function and constraint values, compute the finite difference gradients of these functions for the design variable
8. repeat steps 4 to 7 until all variables have been incremented

The program card is as follows:

```
PROGRAM EVALS (INPUT,OUTPUT,TAPE5 = INPUT,TAPE7,TAPE8,TAPE9,TAPE10,TAPE11)
where

TAPE5   PCNPR
TAPE7   PASS
TAPE8   PSTRT
TAPE9   CNMNIO
TAPE10  BLOCK
TAPE11  CHECK
```

See appendix D for a sample listing.

4.3.5.2 Fully stressed design (FSD) program: FSDS.- The program uses a fully stressed design technique to modify the initial design variables. The program functions are

1. read control parameters supplied by user from file PCNPR
2. read the design variables from file PSTRT
3. stop itself to allow execution of the front processor/SPAR/end processor sequence
4. restart - read values of the stress constraints from file BLOCK

5. change the design variables by FSD technique using the constraint values

6. repeat from 3

The program card is as follows:

PROGRAM FSDS (INPUT,OUTPUT,TAPE8,TAPE7,TAPE9,TAPE11,TAPE10,TAPE5 = INPUT, TAPE6 = OUTPUT)

All files are defined exactly the same as in the program CONMS1. (See app. D for a sample listing.) The program calls a problem independent subroutine FSDSUBS (also in app. D) that carries out FSDS function 5.

4.3.5.3 Program to select the active or violated constraints: SELECTS.- The program functions are

1. read the constraints from file BLOCK

2. determine if the constraint is less than the constraint thickness parameter for linear and side constraints and, thus, active or violated

3. if the constraint is active or violated, the analytical gradient of that constraint is stored and a pointer is set in an array to denote whether or not the constraint is active or violated

The program card is as follows:

PROGRAM SELECTS (INPUT,OUTPUT,TAPE5 = INPUT,TAPE6 = OUTPUT)

where

TAPE5 BLOCK

TAPE6 CONREST

See appendix D for a sample listing.

4.3.5.4 Program to rewrite the design variables to a different file: RERITES.- The program RERITES copies the design variables from CNMNIO to SO.

The program card is as follows:

PROGRAM RERITES (INPUT,TAPE5 = INPUT,TAPE6)

where

TAPE5 CNMNIO

TAPE6 SO

See appendix D for a sample listing.
4.3.6 Gradient Programs

There are three problem independent programs, BLDELDS, GNGRDRS, and DRVSTRS, that aid in calculating analytical gradients. The first, BLDELDS, builds a file for input into the analysis program to calculate the derivatives for the mass and stiffness matrices with respect to the design variables in the nonrepeatable part of PROSSS. The second, GNGRDRS, builds a file in the repeatable part for input into the analysis program to compute the derivatives of the stresses and of the forces and moments with respect to the design variables. The third, DRVSTRS, converts the forces and moments and the derivatives of the forces and moments into stresses and derivatives of stresses.

4.3.6.1 Program to create input file for computing gradients in the analysis program in the nonrepeatable part: BLDELDS.- BLDELDS performs the following functions:

1. Read control parameters supplied by the user from file INPT.
2. Read the input model data file for the analysis program from file NRRS.
3. Change all design variables in the file NRRS to unity and place on file RSOUT.
4. Create remainder of file RSOUT to calculate the derivative of the stiffness and mass matrices with respect to the different design variables.

The program card is as follows:

PROGRAM BLDELDS (TAPES,TAPE23,TAPE20,TAPE21,TAPE22,OUTPUT)

where

  TAPES
  TAPE23
  TAPE20
  TAPE21
  TAPE22
  OUTPUT

  INPT
  NRRS (after editing)
  RSOUT
  Scratch file
  Scratch file
  Output file for error messages

See appendix D for a sample listing.

4.3.6.2 Program to create input file for computing gradients in the analysis program in the repeatable part: GNGRDRS.- GNGRDRS performs the following functions:

1. Reads control parameters supplied by user from file INPT.
2. Creates the runstream to calculate the derivatives of the stiffness and the mass matrices with respect to the design variables when an element (such as a beam or plate) has more than one contributing factor. The program calls user-supplied subroutine(s) with any of the following names DKDVE21, DKDVE22, DKDVE33, and/or
DKDVE43. These subroutines compute the derivatives of the stiffness matrix with respect to a design variable for a particular element type in SPAR (e.g., E21 or E43). The name(s) used depends upon the elements used in the finite element model. If a subroutine is not used, it remains unsatisfied. Two integer parameters used in naming the created data sets are passed to each subroutine. The first is the counter for the design variable and the second is the number of unconstrained degrees of freedom (from 1 to 6). A listing of a sample DKDVE21 subroutine is shown in appendix D.

The subroutine card for DKDVE21 is as follows:

SUBROUTINE DKDVE21(NDVJIM,NDF)

where

NDVJIM the number of the design variables (first, second, third, etc.) for which the derivative of the stiffness and mass matrices with respect to the design variable is being calculated

NDF number of degrees of freedom per joint squared

3. Create the remainder of the runstream and place on file RSOUT.

The program card is as follows:

PROGRAM GNGRDRS (INPUT,TAPE30,TAPE31,TAPE10,TAPE5 = INPUT,OUTPUT)

where

TAPE5 INPT
TAPE30 CONS Used in user-supplied subroutine
TAPE31 CNMNIO
TAPE10 RSOUT

OUTPUT Output file for error messages

See appendix D for listing of GNGRDRS.

4.3.6.3 Program to convert forces and moments and the derivatives of forces and moments to stresses and stress derivatives: DRVSTRS.- DRVSTRS performs the following functions:

1. Reads control parameters supplied by user from file INPT.

2. Reads forces and moments and the derivatives of forces and moments from file SPARLD, a library created by SPAR.

3. Computes stresses and stress derivatives using a user-supplied subroutine named BMSTRS (for beams) or PLTSTRS (for plates). As before, if a name is not used, it remains unsatisfied. Four integer parameters are passed to BMSTRS. They are (1) a switch and (2) a counter, so certain computations can be skipped if they are not needed; (3) a block counter for accessing an array; and (4) another switch to
determine if the beam is the contributing factor to the stress derivative. The first three parameters are also passed to PLTSTRS. A listing of a sample BMSTRS subroutine is provided in appendix D.

The subroutine card for BMSTRS is as follows:

\[
\text{SUBROUTINE BMSTRS (ISW,KCNT,JCNT,IBEAM)}
\]

where

- **ISW, KCNT** a switch and a counter used to store certain beam data (e.g., moments of inertia) and make certain computations only on the first time BMSTRS is called from DRVSTRS.
- **JCNT** a counter to find the location in blank common for various data items, depends on the number of beam elements.
- **IBEAM** 1, if beam is a contributing factor to stress derivatives; 0, otherwise.

4. The stress and stress derivatives are written on SPARLD for processing by the end processor EPROC (sec 4.3.4).

The program card is as follows:

\[
\text{PROGRAM DRVSTRS (INPUT,TAPE30,TAPE31,TAPE5 = INPUT,TAPE15,TAPE16,OUTPUT, TAPE6 = OUTPUT)}
\]

where

- **TAPE5** INPT
- **TAPE30** CONS
- **TAPE31** CNMNIO
- **TAPE15** Scratch file
- **TAPE16** Scratch file
- **OUTPUT** Output file for error messages

See appendix D for a sample listing of DRVSTRS.

4.4 Data Files

There are five types of data files in PROSSS: input, model, transfer, edit, and save. Sample annotated listings of each file are shown in appendix E. Table VI

</tbody>
</table>
provides a quick reference for each data file by providing the following information about each file:

1. the name of the file
2. the type of file (e.g., input or model)
3. whether the file is created by the user, program, or external to PROSSS; files created external to PROSSS, are created one time, stored on a permanent file, and then accessed by any user independent of the application
4. whether the file is local or permanent
5. whether the file is problem dependent or independent
6. the programs that use this file
7. a brief comment about the file's function

4.4.1 Input Data Files

There are seven input files that primarily provide initialization data to the various programs in PROSSS. (See app. E for sample listings.) These files are as follows:

1. PCNPR (CONPAR) initializes variables used in the optimization program. (Note: PCNPR is the name used in the generalized input files. See app. A.) It is replaced by the specific problem dependent file name before the option is used. CONPAR is the local file name into which the specific file is stored. It is in NAMELIST format with the NAMELIST name CONPAR. A description of the variables can be found in reference 6.

2. PSTRT (STARTX) is also read by the optimization program to initialize the design variables. (See note about PCNPR and CONPAR.) It, too, is in NAMELIST format with the NAMELIST name STARTX.

3. PASS contains one number. In the initialization process, the number is set to 1 using the EDPASS1 file in section 4.4.4, signifying the first pass through the system. After the first pass, the value is changed to 2 and different paths are taken in the programs using PASS as an input variable. Options 1.2 and 2.2 (table I) reset the value to 1 within the system using the EDPASS2 file also described in section 4.4.4. PASS is also in NAMELIST format with the NAMELIST name PASSAGE.

4. INPT defines values used in analytical gradient calculation. INPT has two card types. The first type has the format (6(1X,I4),1X,A4), consists of one card, and contains the following variables:

<table>
<thead>
<tr>
<th>Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NOLC</td>
<td>number of load cases</td>
</tr>
<tr>
<td>NODV</td>
<td>number of design variables</td>
</tr>
<tr>
<td>ISNOLC</td>
<td>new starting number for load cases with derivatives</td>
</tr>
<tr>
<td>JOINTS</td>
<td>number of joints in the model</td>
</tr>
</tbody>
</table>
NDF  number of degrees of freedom
NOEL  number of different element types in the model
VORB  a four character word to determine the type of analysis (e.g., STAT,VIBR,BUCK)

The second type has the format (6(1X,A3,1X,I3,1X,I3»), consists of one or more cards, and contains the following variables (one set for each element):

- \text{EL(I)}: element type (e.g., E21,E43)
- \text{NSEC(I)}: largest section property number used for that element type
- \text{NODVPE(I)}: number of design variables per element type

5. CNT is a file that initializes parameters for terminating the optimization process. CNT is in NAMELIST form with the NAMELIST name CNT.

6. ENDN is a file that defines limits imposed on the design variables in the end processor. ENDN is in NAMELIST format with the NAMELIST name EPIN.

7. CONS is a file supplied by the user to define certain constants such as the cross-sectional dimensions of a beam used in analytical gradient calculation. Since the file is only read by user-supplied subroutines, the format is also defined by the user. See section 4.3.6 for more information.

4.4.2 Model Data Files

Model data files contain finite-element-model input data for the analysis program SPAR. Two model data files, called SPAR runstreams, are used in PROSSS. The first, NRRS, defines the model in terms of nodes and elements connecting those nodes. This file is only used in the nonrepeatable part of PROSSS. The second model file, NGRS (no gradients) or RGS (gradients), updates the data for elements used as design variables and contains data for performing the analysis in the repeatable part of PROSSS. Sample listings of NRRS, NGRS, and RGS are contained in appendix E.

4.4.3 Transfer Data Files

Transfer data files pass data among the various programs in PROSSS. These are local files created within the system, and they are returned when the analysis-optimization process is completed. The following transfer files exist in PROSSS:

1. PCONRST is a file in NAMELIST format with the NAMELIST name SAVE that takes initial data from PCNPR and updates these data in each new pass through the optimization program. In two options from table I (2.2 and 2.3), the BLOCK file (described next) is used in place of PCONRST.

2. BLOCK or BLK is a file in NAMELIST format with the NAMELIST name BLK and contains objective function and constraint data.
3. PCNMNIO or TCNMNIO, CNMNIO (see note on PCNPR in section 4.4.1) is a file in NAMELIST format with two NAMELIST names. Name LINKE contains the number of design variables and their values. It is written by the end processor and read by the optimization program. Name LINKF contains objective function and gradient information. It is written by the optimization program and read by the front and end processors. Two options (2.2 and 2.3) replace PCNMNIO with CNT file discussed in section 4.4.1.

4. CHECK is created in options 1.2 and 2.2 when analysis has been performed for each design variable and their combination, if this file exists (i.e., local), then the optimization program is executed.

5. GONOGO is created when the objective function has not changed more than a specified tolerance (see CNT file in section 4.4.1) in three passes. If this file exists (i.e., local), the process is terminated.

6. SPFPOUT is created by the front processor and contains the updated design variables. This file is merged into the NGRS or RGS file using the MERGFP files described in section 4.4.4. The NGRS and RGS files are described in section 4.4.2.

7. RSOUT is an input file (runstream) for the analysis program similar to those found in section 4.4.2. RSOUT is created twice in each of two options (2.2 and 2.3), once in the nonrepeatable part and once in the repeatable part, and is used in calculating the analytical gradients.

8. SO is identical to the PSTRT file discussed in section 4.4.1.

9. SPARLA, SPARLB, SPARLC, SPARLD are data libraries created by the analysis program.

Sample listings of the transfer files are presented in appendix E. Files CHECK, GONOGO, SO, SPARLA, SPARLB, SPARLC, and SPARLD are not listed, either because of their length or because of their binary format.

4.4.4 Edit Data Files

Edit data files contain Text Editor (ref. 10) commands primarily for editing files input to the analysis program. None are created by the user. The following edit data files exist in PROSSS:

1. EDPASS1 creates the PASS file described in section 4.4.1 and initializes the variable to 1.

2. EDPASS2 reinitializes the number in the PASS file to 1.

3. EDIT1 edits the NRRS file described in section 4.4.2 to remove all but the element connection data.

4. EDIT2 edits the RSOUT file in the nonrepeatable part described in section 4.4.3 to prepare it for input to the analysis program.

5. MERGFP merges the SPFPOUT file described in section 4.4.3 into the NGRS or RGS files described in section 4.4.2.
6. EDGRDS edits the RSOUT file in the repeatable part described in section 4.4.3 to prepare it for input to the analysis program.

Sample listings of edit data files are contained in appendix E.

4.4.5 Saved Data Files

Three files are automatically saved for listing (SAVCOUT) and postprocessing or restart purposes (NRLA, SAVSPLD). File SAVCOUT contains a cumulative list of all the information output from the optimization program. File NRLA is a library of data output by the analysis program in the nonrepeatable part of the process. File SAVSPLD is a library of objective function, stress, and/or stress derivative information output by the analysis program in the nonrepeatable part of the process. File SAVSPLD is a library of objective function, stress, and/or stress derivative information output by the analysis program in the repeatable part of the process. These files are either too long or in a binary format and, therefore, are not listed in appendix E.

5 SAMPLE EXECUTIONS OF PROSSS

Each option was executed, using the input files shown in appendix A, to determine the final objective function (min. mass, kg) of the finite element model of the fuselage shown in figure 4. The model is composed of 80 joints, 58 rods, 76 beams, and 56 membranes. There are 352 degrees of freedom. The three design variables are the cross-sectional area of the transverse stringers (beams), the

![Fuselage model diagram](image)

Figure 4.- Fuselage model used for testing.
cross-sectional area of the longitudinal stringers (rods), and the thickness of the panels (membranes). The design variables are handled by the optimizer in reciprocal form to improve the convergence. Their initial reciprocal starting values are 0.05 cm$^2$, 1.0 cm$^2$, and 4.0 cm, respectively. The initial objective function is 5460.12 kg. Shown in table VII is a comparison of actual results (not reciprocals)

EDIT DATA FILES

EDPASS1

A
> $PASSAGE
NPASS=1,
$END>

Creates PASS file, setting NPASS to 1 for first pass

EDPASS2

RS:1/2/;1/
END

Changes NPASS from 2 to 1 when restarting

EDIT1

F:/$XQT ELD/
F:/$XQT/;2
D;*
R
F:/$XQT ELD/
E;*
R
D;*
R
ADD
END

Edits out all information from NRSS file except ELD input in nonrepeatable part

EDIT2

RS:  / / ; *
RS:  / / ; *
A: /TOPO/;*
>RESET MAXSUB=2500>
END

Removes blanks from RSOUT file in nonrepeatable part
APPENDIX E

MERGFP

SPFPOUT file is merged into SPARS. E+ and E- are changed to + and - because SPAR does not accept E's in input.

EDGRDS

Remove blanks from RSOUT in repeatable part

(See ref. 10 for more detail on edit commands.)
REFERENCES

This paper describes a particular implementation of the programming structural synthesis system (PROSSS). This software system combines a state-of-the-art optimization program, a production-level structural analysis program, and user-supplied, problem-dependent interface programs. These programs are combined using standard command language features existing in modern computer operating systems. PROSSS is explained in general with respect to this implementation along with the steps for the preparation of the programs and input data. Each component of the system is described in detail with annotated listings for clarification. The components include options, procedures, programs and subroutines, and data files as they pertain to this implementation. The paper concludes with an example exercising each option in this implementation to allow the user to anticipate the type of results that might be expected.
