Produced by the NASA Center for Aerospace Information (CASI)
The invention disclosed in this document resulted from research in aeronautical and space activities performed under programs of the National Aeronautics and Space Administration. The invention is owned by NASA and is, therefore, available for licensing in accordance with the NASA Patent Licensing Regulation (14 Code of Federal Regulations 1245.2).

To encourage commercial utilization of NASA-owned inventions, it is NASA policy to grant licenses to commercial concerns. Although NASA encourages nonexclusive licensing to promote competition and achieve the widest possible utilization, NASA will consider the granting of a limited exclusive license, pursuant to the NASA Patent Licensing Regulations, when such a license will provide the necessary incentive to the licensee to achieve early practical application of the invention.

Address inquiries and all applications for license for this invention to NASA Patent Counsel, Langley Research Center, Mail Code 279, Langley Station, Hampton, VA 23665. Approved NASA forms for application for nonexclusive or exclusive license are available from the above address.
A SYSTEM FOR CONTROLLING THE OXYGEN CONTENT OF A GAS PRODUCED BY COMBUSTION

The invention relates to a method and apparatus for controlling the oxygen content of a gas produced by combustion.

The invention consists essentially of a combustion chamber 10 into which air, CH, and O flow. The gas produced by the combustion in chamber 10 flows into a test section 17. The partial pressure of O in the gas in test section 17 is compared to the partial pressure of O in reference air by means of an O sensor 22. If there is a difference in partial pressure an error signal is produced at the output of control circuit 25. The error signal is applied to a solenoid valve 15 which regulates the flow of O in chamber 10 to thereby reduce the error signal to zero. When the error signal is zero the oxygen content in test section 17 is the same as the oxygen content of air. The calibration air supplied through valve 27 and the voltmeter 28 are for the purpose of measuring the cell constant of sensor 22 when air is applied to both sides of the sensor. This measured cell constant is set into a potentiometer 29 and subtracted from the output of sensor 22 to produce the error signal when the gas from test section 17 is applied to sensor 22.

The details of sensor 22 are shown in FIG. 2. The chamber 35 was modified such that the gas from the test section is flushed out of the chamber immediately after arriving thereby making the response time of the sensor extremely short.

The novel feature of the invention appears to lie in the overall combination of elements to provide a device for controlling the oxygen content of a combustion gas such that it is the same as that of air. Also, the modification of the O sensor to make it have a fast response time appears to be novel.

A SYSTEM FOR CONTROLLING THE OXYGEN CONTENT OF A GAS PRODUCED BY COMBUSTION

ORIGIN OF THE INVENTION

The invention described herein was made by employees of the United States Government and may be manufactured and used by the Government for governmental purposes without the payment of any royalties thereon or therefor.

BACKGROUND OF THE INVENTION

The invention relates to the control of the amount of a specific gas in a combustion product gas and more specifically concerns the control of the amount of oxygen in a combustion product gas.

At Langley Research Center in Hampton, Virginia, there is an 8-Foot High Temperature Tunnel for testing aircraft engines. In this facility methane gas is burned in air under pressure and the products of the combustion are expanded through an axisymmetric, conical contoured nozzle with an exit diameter of 8-feet to produce a nominal Mach 7 flow in the test section. However, because of the reduced oxygen content in the test medium, the facility is not suitable for air-breathing-propulsion testing. If the oxygen content in the test medium were to be increased to accommodate air-breathing-propulsion testing, it is very important that the oxygen content be equivalent to the oxygen content of air. Too much oxygen may damage the engine, and too little oxygen will result in reduced impulse. Also, because of limited run time of the facility (as little as 20 seconds for some conditions), a fast-response (response time of less than one percent of the tunnel run time) oxygen monitoring and control system is required.

It is an object of this invention to maintain the oxygen content of a test medium equal to the oxygen content of a selected gas.

Another object of this invention is to maintain the oxygen content of gases produced by combustion equal to that of air.
A further object of this invention is to compare the oxygen content of the gas products of combustion with the oxygen content of air and to reduce the difference to zero.

Still another object of this invention is to provide a device having an extremely short response time for comparing the oxygen contents of two gases.

Other objects and advantages of this invention will become apparent hereinafter in the specification and drawings.

SUMMARY OF THE INVENTION

The invention includes a combustion chamber into which a mixture of gases including O₂ flows. The mixture of gases is burned in the combustion chamber to produce a product gas. The purpose of this invention is to regulate the flow of O₂ into the mixture so that content of O₂ in the product gas is equal to the content of O₂ in air. This is done by comparing the partial pressure of O₂ in the product gas with the partial pressure of O₂ in air to produce an error signal. This error signal is used to regulate the flow of O₂ into the combustion chamber to make the error signal equal to zero thereby keeping the O₂ content of the product gas equal to the O₂ content of air.

BRIEF DESCRIPTION OF THE DRAWINGS

FIG. 1 is a block diagram of the invention; and FIG. 2 is a schematic drawing of the O₂ sensor shown in FIG. 1.

DETAILED DESCRIPTION OF THE INVENTION

Turning now to the embodiment of the invention selected for illustration the number 10 in FIG. 1 of the drawings designates a combustion chamber. Air under pressure flows through a valve 11 and a flowmeter 12 into combustion chamber 10; CH₄ under pressure flows through a valve 13 and a flowmeter 14 into combustion chamber 10; and oxygen under pressure flows through a solenoid controlled valve 16 and a flowmeter 16 into combustion chamber 10. The mixture of gas flowing into combustion chamber 10 is burned and the product gas of the combustion flows into a test section 17. A sample of the gas in test section 17 flows through a valve 18, a compressor 19, a flowmeter 20 and a heater 21 into one
side of an O₂ sensor 22. Compressor 19 is required to pressurize the sample of gas from test section 17. Reference air under pressure flows through a valve 23 and a flowmeter 24 to the other side of the O₂ sensor 22. If there is a difference in the oxygen contents of the gas from the test section and reference air, O₂ sensor 22 will produce a signal that is adjusted by a control circuit 25 and then applied to solenoid valve 15. This adjusted signal called an error signal will change the flow of O₂ into the combustion chamber 11 which in turn will change the oxygen content of the gas in test section 17. When the oxygen contents of the gas in test section 17 and air become equal the adjusted signal at the output of control circuit 25 becomes zero. Hence, if the response of the system is fast the oxygen content of the gas in the test section 17 will be the same as that of air. If the difference in the oxygen contents of the gas in test section 17 and air exceeds a predetermined amount, visual and audio alarms are given by a visual audio alarm device 26 to signal that the system should be shut down.

The O₂ sensor 22 is shown in more detail in FIG. 2. The sensor includes a high temperature, Y₂O₃ stabilized ZrO₂ ceramic electrolyte disc 30 coated with porous platinum electrodes 31 and 32. The platinum electrodes 31 and 32 are porous enough to permit ready diffusion of gases through them. A practical relationship between the sensor voltage output E across electrodes 31 and 32 is given by the following equation:

\[ E = AT \ln \left( \frac{P_1}{P_2} \right) + C(P) \]  

(1)

where A is a mathematical constant, T is the ZrO₂ disc temperature, \( P_1 \) is the partial pressure of oxygen on electrode 31, \( P_2 \) is the partial pressure of oxygen on electrode 32 and C(P) is the cell constant determined by calibration with known gas mixtures at known pressures.

The ZrO₂ disc 30 and electrodes 31 and 32 are enclosed in a cylindrical enclosure 33 with disc 30 dividing enclosure 33 into two cavities 34 and 35. Electrode 31 is exposed to the gas inside cavity 34 and electrode 32 is
exposed to the gas inside cavity 35. The gas from test section 17 is introduced into cavity 35 and reference air is introduced into cavity 34 through valve 23. The test section gas in cavity 35 is pumped out through a flowmeter 36 by means of a pump 37 to keep the test section gas moving through cavity 35. Cavity 35 has a volume of less than 1 cm³ with a 0.5 mm circumferential slot opening 38 approximately 0.5 mm from disc 30. Consequently, the gas in cavity 35 is flushed out of the cavity almost immediately after entering the cavity by the gas entering the cavity. The test section gas in cavity 35 is pumped out through a flowmeter 36 by means of a pump 37 to keep the test section gas moving through cavity 35. As a result, the response time of the system is greatly decreased.

The voltage $E$ produced across electrodes 31 and 32 is extremely sensitive to disc 30 temperature. Hence, it is important that the temperature of disc 30 be maintained at a high level of approximately 843°C. To maintain the temperature at 843°C, a NiCr/NiAl thermocouple 39 monitors the temperature of disc 30. The output of thermocouple 39 is compared with a set voltage in a voltage controller 40 to produce an error signal which is used by voltage controller 40 to produce a voltage across a heating coil 41 to maintain disc 30 at a temperature of approximately 843°C. In order to avoid an increase in sensor response time caused by the cooling effect of the lower temperature gas from test section 17, the gas is heated to about 843°C by heater 21 before it reaches the $O_2$ sensor 22.

It is apparent from equation (1) that when the partial pressures of the gas from test section 17 and reference air are compared the output $E$ of $O_2$ sensor 22 will not be directly proportional to the difference of the two partial pressures. The reason is that the cell constant $C(P)$ is not equal to zero. Hence, $C(P)$ must be determined. To do this valve 18 is closed and calibration air under pressure is applied through a valve 27, flowmeter 20, and heater 21 to $O_2$ sensor 22. Consequently, the partial pressure of calibration air is compared to the partial pressure of reference air and if the flow rates of flowmeters 20 and 24...
are the same the output $E$ of $O_2$ sensor 22 will be $C(P)$. This output is measured by a voltmeter 28. Then the slider of a potentiometer 29, with a voltage $V$ applied to it, is adjusted to apply $C(P)$ to control circuit 25. Control circuit 25 subtracts the output of potentiometer 29 from the output of $O_2$ sensor 22 and then amplifies the difference to produce an error signal that is applied to solenoid valve 15 to change the flow of oxygen into chamber 10, thereby forcing the error signal to zero. This ensures that the oxygen content of the gas in test section 17 is the same as the oxygen content of air.

The advantages of this invention are that it provides a fast response, simple straightforward means for maintaining the oxygen content of a combustion product gas the same as the oxygen content of a different gas, for example, air.

It is to be understood that the form of the invention herewith shown and described is to be taken as a preferred embodiment. Various changes may be made without departing from the invention. For example, if an $O_2$ sensor can be found in which $C(P) = 0$, valve 27, voltmeter 28 and potentiometer 29 can be eliminated; or if $C(P)$ is known this value can be set into potentiometer 29 and valve 27 and voltmeter 28 can be eliminated. Also, the combustion gas can be different from that shown and the gas to which the combustion product gas is compared can be a gas other than air.

What is claimed is:
A SYSTEM FOR CONTROLLING THE OXYGEN CONTENT OF A GAS PRODUCED BY COMBUSTION

ABSTRACT OF THE DISCLOSURE

A mixture of air, CH₄ and O₂ is burned in a combustion chamber 10 to produce a product gas in test section 17. The O₂ content of the product gas is compared with the O₂ content of reference air in an O₂ sensor 22. If there is a difference an error signal is produced at the output of control circuit 25 which by the means of a solenoid valve 15 regulates the flow of O₂ into combustion chamber 10 to make the error signal zero. Hence, the product gas in test section 17 has the same oxygen content as air.
