COMPONENTS DESORBING FROM THE SPACE SHUTTLE TILES

Bertha L. Proctor and John Blair
Graduate Program in Environmental Sciences & Engineering
University of Texas at Dallas
The purpose of this project was to determine the chemicals desorbing from the space shuttle heat protection tiles. The original protocol for this project involved direct insertion probe mass spectrometry (DIPMS) analysis of the outgassing products from the tiles. This procedure allowed us to examine the desorbing chemicals for the tile material subjected to temperatures ranging between ambient temperature to 500°C at a pressure of 10^{-3} torr. However, this method proved unsatisfactory due to the large number of compounds desorbing from the tiles. Analysis by DIPMS does not allow for separation of compounds with the same volatility (1). The large number of compounds desorbing from the tile material resulted in unresolved complex organic mixture.

A purge and trap technique (2) was then employed to collect and separate the chemicals desorbing from the tiles. The maximum temperature in this analysis was 280°C which is the gas chromatograph fused silica capillary column's temperature limit. The desorption was also carried out at atmospheric pressure with helium as the purge gas. A description of the modified protocol is given below. All compounds are tentatively identified and have not been confirmed.

Material and Methods
Sample Collection
Interior Tile Material: A tared, preconditioned (1 hour at 550°C) quartz tube (3 mm I.D. × 5 cm) was inserted directly into the tiles to a depth ranging between 3-4.5 cm. The
black protective skin on the surface of the tiles was removed prior to insertion of the quartz sample tube. Care was also taken to avoid the adhesive material on the bottom of the tiles. Samples represented a vertical profile of the upper half of most tiles tested. Aliquots of the tile material ranged between 0.8-1.1 grams. After collection of tile material the samples were placed in the purge and trap chamber for analysis.

**Exterior Tile Materials:** The black protective skin (0.3-0.5 mm thick) or the surface of the tiles was carefully removed and quantitatively transferred to the quartz desorption tubes. Aliquots of this material weighed between 0.3-0.45 grams. It should be noted that it was virtually impossible to separate all of the black skin from the white subsurface tile material.

**Method**

**Purge:** The quartz tube containing the tile material was heated to 280°C and held at that temperature for 15 minutes. There was a constant flow of helium through the purge chamber to sweep the desorbing
compounds into the gas chromatograph where they were cryogenically trapped onto the fused silica capillary column. The inlet of the column was held at \(-30^\circ\text{C}\) throughout the desorption phase. After desorption the purge chamber was cooled to room temperature and the trapped compounds separated and analyzed by gas chromatography-mass spectrometry (GC-MS).
