Nomenclature

\( a \) subscript represents aileron mode
\( an \) accelerometer signal
\( A,G,H \) control law matrices
\( b \) semi-span of the wing
\( b_a \) aileron mode damping (from control law)
\( b_a \) ii element of generalized damping matrix
\( \bar{b} \) generalized damping matrix
\( \bar{d} \) damping factor of \( i \)th mode
\( \bar{d} \) modal accelerometer deflection matrix
\( g(s) \) portion of control law used for aileron mode
\( g(s) \) entire control law
\( g'(s) \) portion of control law not used for aileron mode
\( I \) identity matrix
\( \bar{I} \) reduced frequency
\( k_a \) aileron mode stiffness (from control law)
\( k_i \) ii element of generalized stiffness matrix
\( K \) generalized stiffness matrix
\( L \) generalized force matrix
\( L(s) \) generalized force matrix in Laplace form
\( m \) mass of the aileron
\( m_i \) ii element of generalized mass matrix
\[ m_{ij} \] element of generalized mass matrix
\[ M \] generalized mass matrix
\[ P_{1,2}, P_{3,0} \] matrices representing aerodynamic influence
\[ P'_{1,2}, P'_{3,0} \] coefficients
\[ P_{1',2',} P_{3',0'} \] nondimensional matrices representing aerodynamic influence coefficients
\[ q \] dynamic pressure
\[ Q(s) \] aerodynamic influence coefficient matrix in Laplace form
\[ Q(s') \] nondimensional aerodynamic influence coefficient matrices in Laplace form
\[ r_{i}(x,y) \] deflection at point \((x,y)\) for the \(i\)'th mode
\[ r_{i,l} \] leading edge deflection of aileron for \(i\)'th mode
\[ r_{i,t} \] trailing edge deflection of aileron for \(i\)'th mode
\[ r_{k} \] modal deflection at accelerometer location
\[ u_{i} \] \(i\)'th mode displacement vector
\[ u'_{i} \] first derivative of \(i\)'th mode displacement vector
\[ u''_{i} \] second derivative of \(i\)'th mode displacement vector
\[ U \] displacement vector matrix
\[ U' \] first derivative of displacement vector matrix
\[ U'' \] second derivative of displacement vector matrix
\[ v \] free stream velocity
\[ w \] frequency of oscillation
\[ w_{i} \] natural frequency of \(i\)'th vibration mode
\[ y_{i} \] \(i\)'th control law state vector
\[ Y \] control law state vector matrix
\[ X \] generalized force state vector matrix
\[ P(x,y) \] density of aircraft at point \((x,y)\)
CHAPTER 1
INTRODUCTION

The ability to predict the aeroelastic response of aircraft wings is of increasing importance as attempts are made to reduce the weight of aircraft wings. One of the methods presently being explored to reduce weight is the use of a flutter suppression system (FSS) to reduce the required structural stiffness of the wing. The wing must be stiff enough to remain vibrationally stable (positive damping) throughout its flight envelope. If the wing is not vibrationally stable, it will flutter and possibly cause the loss of the aircraft.

This paper explains a method for predicting the vibrational stability of an aircraft with an analog active aileron FSS. Active aileron refers to the use of an active control system connected to the aileron to damp vibrations. Wing vibrations are sensed by accelerometers and the information is used to deflect the aileron. Aerodynamic forces caused by the aileron deflection oppose wing vibrations and effectively add additional damping to the system.

An assumed mode vibrational analysis approach is used with additional terms added to include the unsteady aerodynamics of a vibrating wing and the control system feedback. The assumed modes used are the actual vibration modes of the aircraft plus an aileron mode. The unsteady aerodynamic effects, modeled by the third order pade approximation method suggested by Edwards in the paper

1
"Applications of Laplace Transform Methods to Airfoil Motion and Stability Calculations", are used as the forcing functions for the vibration.

A computer program called "SAFSS" was written to determine the vibrational stability of an aircraft wing using the method described above. The input information needed to use 'SAFSS' consists of: the natural frequencies of vibration, the generalized mass for each mode, the generalized force matrices for the mach number of interest, the control law matrices and the aileron deflections for each mode. "SAFSS" produces a root locus plot from a CalComp plotter and a listing of the frequencies and damping.

A comparison between predicted and flight test data for the DAST ARW-1 vehicle is made. DAST stands for drones for aerodynamic and structural testing. ARW-1 stands for aerelastic research wing number one. The DAST ARW-1 is a modified Firebee II target drone fuselage mated to the ARW-1 wing (see figure 1). ARW-1 is a supercritical, sweptback, transport-type wing with an aspect ratio of 6.8 and a performance design point of mach 0.98 at 45,000 feet. The ARW-1 wing is designed to be susceptible to flutter and is equipped with an active aileron flutter suppression system (FSS).
CHAPTER 2

VIBRATION MODEL OF WING IN STILL AIR

Since flutter is a vibration problem, it would seem to be a reasonable idea to start with a basic vibrational approach and work up to the harder aspects one at a time. This section will review the basic equations of the “assumed modes” method (sometimes called Rayleigh-Ritz method) used to solve vibration problems.

An aircraft wing can be treated as a normal beam if no air is flowing over it. Because the aircraft is symmetrical, two types of vibration are possible: the symmetric case where both wings vibrate 180 degrees out of phase. The symmetric and asymmetric vibrations do not couple with each other so two separate analyses will be run. The equations used to determine the frequencies and damping of the system are identical so no distinction is made between the symmetric and asymmetric cases.

Using the orthogonal normal modes (vibration modes) of the wing and generalized terms, each vibration mode can be written as a function of one variable and its derivatives. The equations of motion are represented by

\[(m_i) \dddot{u}_i + (b_i) \dot{u}_i + (k_i) u_i = 0\]

Where \(m_i\) is the generalized mass, \(b_i\) is the generalized damping, \(k_i\) is the generalized stiffness with \(i\) representing the \(i\)th mode. Using the matrix notion:
The vibration equations can be written as one matrix equation

$$[M][U'''] + [B][U'] = [K][U'] = 0$$

Using the fact that $[U']$ is equal to $[U''']$, and reordering the above equation, the vibration equations can be written as:

$$\begin{bmatrix} I & 0 \\ 0 & m \end{bmatrix}\begin{bmatrix} I \\ U'' \end{bmatrix} = \begin{bmatrix} 0 & I \\ -K & -B \end{bmatrix}\begin{bmatrix} I \\ U'' \end{bmatrix}$$

The left side of the above equations can be simplified by multiplying by the inverse of the left hand square matrix.

The inverse is

$$\begin{bmatrix} I & 0 \\ 0 & M \end{bmatrix}^{-1} = \begin{bmatrix} I & 0 \\ 0 & M \end{bmatrix}^{-1} = \begin{bmatrix} I & 0 \\ 0 & M^{-1} \end{bmatrix}$$
Since \([M] \) is a diagonal matrix, \([M]^{-1} \) is a diagonal matrix with terms equal to the inverse of the terms in \([M] \).

\[
\begin{bmatrix}
m & 0 & \cdots & 0 \\
1 & 0 & \cdots & 0 \\
0 & m & \cdots & 0 \\
\vdots & \vdots & \ddots & \vdots \\
0 & 0 & \cdots & m
\end{bmatrix}^{-1} =
\begin{bmatrix}
1/m & 0 & \cdots & 0 \\
1 & 0 & \cdots & 0 \\
0 & 1/m & \cdots & 0 \\
\vdots & \vdots & \ddots & \vdots \\
0 & 0 & \cdots & 1/m
\end{bmatrix}
\]

Multiplying both sides by the inverse solves the equations for the derivatives of "\(U\)".

\[
\begin{align*}
\begin{bmatrix}
U' \\
U''
\end{bmatrix} &=
\begin{bmatrix}
0 & I & 0 \\
-M & -M & B
\end{bmatrix}
\begin{bmatrix}
U' \\
U''
\end{bmatrix}^{-1}
\end{align*}
\]

Because both \([M] \) and \([K] \) are diagonal matrices, their product will also be a diagonal matrix.

\[
[M][K] =
\begin{bmatrix}
k/m & 0 & \cdots & 0 \\
1 & 1 & 0 & \cdots & 0 \\
0 & k/m & 0 & \cdots & 0 \\
2 & 2 & k/m & \cdots & 0 \\
0 & 0 & 3 & \cdots & 0 \\
\vdots & \vdots & \vdots & \ddots & \vdots \\
0 & 0 & 0 & \cdots & k/m \\
0 & 0 & 0 & 0 & k/m
\end{bmatrix}^{-1}
\]

The same statement holds true for the product of \([M]^{-1} \) and \([B] \).
Two relationships that are helpful in solving vibration problems are

\[
k/m = w^2
\]

\[
b/m = 2d \cdot w
\]

where "w" is the natural frequency and "d" is the damping factor. Substituting these relationships into the matrices

\[
[M]^{-1} [B] = \begin{bmatrix}
  b/m & 0 & 0 & \cdots & 0 \\
 0 & 1 & 1 & b/m & 0 & \cdots & 0 \\
0 & 0 & 2 & 2 & b/m & \cdots & 0 \\
0 & 0 & 0 & 3 & 3 & \cdots & 0 \\
\vdots & \vdots & \vdots & \ddots & \ddots & \ddots & \vdots \\
0 & 0 & 0 & 0 & 0 & \cdots & b/m
\end{bmatrix}
\]

\[
[M]^{-1} [K] = \begin{bmatrix}
  w^2 & 0 & 0 & \cdots & 0 \\
0 & w^2 & 0 & \cdots & 0 \\
0 & 2 & w^2 & 0 & \cdots & 0 \\
0 & 0 & 3 & 3 & \cdots & 0 \\
\vdots & \vdots & \vdots & \ddots & \ddots & \ddots & \vdots \\
0 & 0 & 0 & 0 & 0 & w^2 \\
\end{bmatrix}
\]

\[
[M]^{-1} [B] = \begin{bmatrix}
  2d \cdot w & 0 & 0 & \cdots & 0 \\
0 & 2d \cdot w & 0 & \cdots & 0 \\
0 & 2 & 2 & 2d \cdot w & \cdots & 0 \\
0 & 0 & 3 & 3 & \cdots & 0 \\
\vdots & \vdots & \vdots & \ddots & \ddots & \ddots & \vdots \\
0 & 0 & 0 & 0 & 0 & 2d \cdot w \\
\end{bmatrix}
\]
The natural frequency for a structure can be obtained from any program that does vibrational analysis such as "NASiRAN" or from a ground vibration test (a test in which the structure is shaken). Damping factors are harder to come by theoretically so a value is usually assumed. The wing provides only a small amount of damping so a small value, such as 0.005, can be assumed.
CHAPTER 3
AERODYNAMIC INFLUENCE COEFFICIENTS

The oscillatory motion of an aircraft wing in flight will produce oscillatory forces on the wing. As the wing oscillates up and down, the deflection and its derivatives cause an effective angle of attack which changes the lifting forces on the wing. Likewise, as the wing oscillates torsionally, the changes in pitch and its derivatives will produce changes in the lift.

The oscillation of the lift on the wing acts as a forcing function to the wing vibration and must be included in the vibration equations. The lift can be included in the following manner

\[
[M] \ddot{U} + [B] \dot{U} + [K] \ddot{U} = [F] \dot{U}
\]

where \([F] \dot{U}\) represents the oscillatory aerodynamic loads (generalized forces). The aerodynamic loads can be defined in the Laplace form to be

\[
L(s) = q \cdot [Q(s)] \cdot \dot{U}
\]

where "q" is the dynamic pressure and \([Q(s)]\) represents the aerodynamic influence coefficients.

The \([Q(s)]\) matrix is determined by curve fitting the aerodynamic influence coefficients (AICs) calculated at several vibrational frequencies. AICs for several reduced frequencies can be calculated by using a doublet lattice routine or some other unsteady aerodynamics routine. The
AICs are a function of the reduced frequency and the mach number. The reduced frequency \( k \) is defined as

\[
k = \frac{b \omega}{\nu}
\]

where "b" is the semi-span, "\( \omega \)" is the frequency of oscillation and "\( \nu \)" is the free stream velocity. A nondimensional form of \([Q(s)]\) can be assumed to be

\[
[Q(s')] = \left( s' \right)^{-1} \left[ \left[ P1' \right](s')^2 + \left[ P2' \right] s' + \left[ P3' \right] \right]
\]

where \([P1']\), \([P2']\), \([P3']\) and \([R0']\) are constants determined by performing a least squares curve fit on the AICs calculated at the different reduced frequencies. The "s'" is used to indicate a function of reduced frequency instead of oscillatory frequency.

Rewriting this equation as a function of the oscillation frequency results in

\[
[Q(s)] = \left( s \right)^{-1} \left[ \left[ P1 \right](s)^2 + \left[ P2 \right] s + \left[ P3 \right] \right]
\]

Multiplying \([Q(s)]\) by \( \nu \) and labeling the product \( \hat{X} \)

\[
\hat{X} = [Q(s)] \nu
\]

The above equations can be rewritten by substituting in for \([Q(s)]\) and rearranging

\[
(sI + [R0']\nu/b) \hat{X} = \left( \left[ P1 \right](s)^2 + b/\nu + \left[ P2 \right] s + \left[ P3 \right] \right) \nu \hat{U}^2
\]

for the ease of writing and to agree with the nomenclature used by other authors the following notation will be used:
$\{R0\} = v/b\{R0'\}$

$\{P1\} = b/v\{P1'\}$

$\{P2\} = \{P2'\}$

$\{P3\} = v/b\{P3'\}$

Note that $\{P1\}$, $\{P2\}$, $\{P3\}$ and $\{R0\}$ must be recalculated for each different mach number. Using the above notion and taking the previous equation out of Laplace form,

$$\{1\}(X') - \{P1\}(U') = -[R0](X) + [P3](U) + [P2](U')$$

Remembering that

$$[M](U'') + [B](U') + [K](U) = [L]$$

and

$$[L] = q * (X)$$

the vibration equations can be written as

$$\begin{bmatrix} I & 0 & 0 \\ 0 & M & 0 \\ 0 & -P1 & I \end{bmatrix} \{U'\} = \begin{bmatrix} 0 & I & 0 \\ 0 & -B \ q1 \\ P3 & P2 & -R0 \end{bmatrix} \{U'\}$$

Taking the inverse of the left hand side

$$\begin{bmatrix} I & 0 & 0 \\ 0 & M & 0 \\ 0 & -P1 & I \end{bmatrix}^{-1} = \begin{bmatrix} I \quad 0 \quad 0 \\ 0 \quad M^{-1} \quad 0 \\ 0 \quad P1\#M^{-1} \quad I \end{bmatrix}$$

and multiplying both sides by the inverse
the vibration equations can be written as

\[
\begin{pmatrix}
  U' \\
  U'' \\
  x'
\end{pmatrix} =
\begin{bmatrix}
  I & 0 & 0 \\
  0 & -M & 0 \\
  0 & P1*M & I
\end{bmatrix}
\begin{bmatrix}
  0 & I & 0 \\
  -K & -B & qI \\
  P3 & P2 & -R0
\end{bmatrix}
\begin{pmatrix}
  U' \\
  U'' \\
  x'
\end{pmatrix}
\]

The above equation can be used to solve for the frequency and damping of the open loop aircraft wing vibration.
CHAPTER 4

CONTROL LAW

Although the procedure for putting a control law into matrix form is fairly standard, a few steps can be taken to simplify the solution of the vibration equations. In addition, part of the control law must be used elsewhere in the analysis (see chapter 5).

A control law is defined as the output of a system divided by the input of a system. The input signal for this analysis is an accelerometer signal and the output is the deflection of the aileron. The numerator and denominator of the control law are generally written as the product of several first and second order Laplace polynomials (see figure 6). Part of the control law, a second order polynomial from the denominator and a constant from the numerator

\[ g(s) = \frac{k}{(s + c^2s + k)} \]

where "k" and "c" are constants, must be used for the aileron vibration mode (see chapter 5). The entire control law is equal to the product of its parts so

\[ G(s) = G'(s) \times g(s) \]

where \( G(s) \) is the entire control law, \( G'(s) \) is the control law without the aileron term and \( g(s) \) is the aileron term.

The portion of the control law that needs to be put into matrix form is \( G'(s) \). Keeping in mind that the input to
\( G'(s) \) is the accelerometer signal and the output is a state space vector. The following equation can be written

\[ G'(s) = V(s)/an(s) \]

where "an" is the accelerometer signal and "V" is a state space vector. Taking \( G'(s) \) out of the Laplace form and putting it into state vector differential equation form results in the following equation

\[
\begin{align*}
\{Y\}' &= \{A\} Y + [G][an] \\
\{V\}' &= \{H\}\{Y\}
\end{align*}
\]

where the matrices \([A]\), \([G]\) and \([H]\) have no unique solution but depend on the state vectors \([Y]\).

In order to keep the vibration equations as simple as possible, it is desirable to have \([G]\) and \([H]\) contain as many zeros as possible. If the denominator of \( G'(s) \) is at least 3 orders larger than the numerator, \([G]\) and \([H]\) can be constructed to each contain only one non-zero term.

\( G'(s) \) can be broken up into the product of its second order (or smaller) polynomials of the form

\[ g_n'(s) = (s + a\delta + b) / (s + c\delta + d) \]

where \( g_n'(s) \) is a portion of \( G'(s) \), "a", "b", "c" and "d" are constants.

Assuming that \( g_1'(s) \) is of the form

\[ g_1'(s) = 1 / (s + d) \]

and \( g_2'(s) \) is of the form
\[ G_2'(s) = \frac{1}{(s^2 + cs + d)} \]

\([G]\) and \([H]\) can be forced to have a minimum of terms. By assigning the state vectors \(Y\) to be the unlabeled inputs and outputs to each portion of the control law

\[ g_1'(s) = y_1/\text{an} \]
\[ g_2'(s) = y_1/y_1 \]

the following equations can be written

\[ y_1' = d^2y_1 + \text{an} \]
\[ y_2' = y_3 \]
\[ y_3' = y_1 \cdot d^2y_2 - c^2y_3 \]

Note that the accelerometer signal, "an" is used only once, meaning that \([G]\) contains only one non-zero value. Assigning the state vectors \(Y\) in this manner also causes \([H]\) to contain only one non-zero value.
CHAPTER 5

INCLUDING CONTROL LAW IN VIBRATION EQUATIONS

The movement of the aileron will have two effects on the vibration equations. The first will be the addition of a mode shape (the aileron mode) and the calculation of AICs for the mode. The second will be the introduction of nondiagonal terms to \([M]\) due to the addition of non-orthogonal aileron mode.

In order to include the aileron as a vibration mode, terms for the generalized mass, generalized stiffness, and damping term must be used. In the previous chapter the control law was divided up into two parts

\[ G(s) + G'(s) = g(s) \]

where \( G'(s) \) was put into state vector differential form and \( g(s) \) was of the form

\[ g(s) = k_1 (s^2 + s^2 + k) \]

As stated in the last chapter the output of \( G'(s) \) is \( \frac{1}{s+1} \). Since the output of \( g(s) \) is the aileron deflection, the following equation must be true

\[ \frac{1}{s+1} \cdot u = \dot{u} \]

where \( u \) is the aileron deflection. Substituting for \( g(s) \), to obtain

\[ k = \frac{1}{s+1} \quad u'' + u + u' + k \]

\[ k_a u \]
Solving the above equation for \( u_a'' \)

\[
  u_a'' = -k_a u_a - b_a u_a' + k_a V
\]

The vibration mode for the aileron can then be defined as having a
generalized mass of 1.0, a generalized stiffness of \( k_a \), and a
generalized damping term of \( b_a \).

The input to the control law was described in the previous
chapter as the signal from the accelerometer. The accelerometer
signal is the acceleration at the accelerometer location. Since
the vibration model is based on superposition, the acceleration
at any point, due to the \( k \)'th vibration mode, is equal to the
acceleration state vector for the \( k \)'th vibration mode multiplied
by the deflection \( k \)'th mode shape at that point. Therefore,

\[
  a_n = \sum_r r_k u_k''
\]

where \( a_n \) is the accelerometer signal, \( u_k'' \) is the acceleration
of the \( k \)'th vibration mode and \( r_k \) is the deflection at the
accelerometer location for the \( k \)'th mode shape. Expressing \( a_n \)
in matrix notation:

\[
  \{a_n\} = [D] \{u_k''\}
\]

where \([D]\) is a row matrix containing the modal vibration deflections
at the accelerometer location.
A conversion factor may be needed between the units of the analysis and the units of the control law. If the control law is designed to convert a signal from g's (acceleration of gravity) to degrees deflection of the aileron, and the units being used in the analysis are inches and seconds, a conversion between the model and the real system must be made. Using the above example, the control law would have the units

$$G(s) = AD \text{(degrees)} / \text{an (gravities)},$$

and the analysis would require the units:

$$G(s) = u\text{a (modal deflection)} \times c / \text{an (in/sec^2)}$$

where $G(s)$ is the control law, "AD" is the aileron deflection, "u" is the state space notation for the aileron mode and "c" is the conversion factor. The conversion from g's to in/sec$^2$ is simply

$$1 \text{g} = (32.2 \text{ ft/sec}^2) \times (12 \text{ in/ft}) = 368.4 \text{ in/sec}^2$$

and assuming that a 10 degree deflection of the aileron is equivalent to the aileron mode

$$1 \text{ degree} = 1/10 \text{ deflection mode}$$

Therefore, the conversion factor is determined to be

$$c = (1/368.4) \times (1/10)$$
The equations related to the aileron mode and control law are

\[ \dddot{\mathbf{y}} = [A]\dot{\mathbf{y}} + [G]\ddot{\mathbf{u}} \]
\[ \dddot{\mathbf{y}} = [H]\dot{\mathbf{y}} \]
\[ \dddot{\mathbf{u}} = [D]\dot{\mathbf{u}} \]

\[ u'' = -k * u - b * u' + k * c * \dot{\mathbf{y}} \]

Combining the above equations, the following state vector equations can be obtained:

\[ \dddot{\mathbf{y}} = [A]\dot{\mathbf{y}} + [G][D]\dot{\mathbf{u}} + [H]\dot{\mathbf{y}} \]
\[ u'' = -k * u - b * u' + k * c * \dot{\mathbf{y}} \]

The aileron mode is not orthogonal to the other vibration modes so nondiagonal terms will be introduced into \([M]\) and/or \([K]\). In the case being examined here, there is no coupling between modes in \([K]\) but there is coupling in \([M]\). The terms in \([M]\) are defined as

\[ m_{ij} = \iint (r_i(x,y) * r_j(x,y) * \rho(x,y)) \, dx \, dy \]

where "\(m_{ij}\)" is the element \(ij\) of the generalized mass matrix "\(r_i\)" and "\(r_j\)" are deflections at the point \((x,y)\) due to the \(i\)th and \(j\)th mode shapes, and "\(\rho\)" is the density of the wing at point \((x,y)\). Because the deflection of the aileron mode is zero everywhere except the aileron, the integral will only be non-zero over the aileron. Assuming the aileron is rectangular and has a constant mass distribution, the generalized mass terms due to the aileron mode are
\[ m_{i} = -m \times r \times (r /3 + (r - r_{il})/2) \]

Where \( m_{i} \) is the generalized mass of \( i \)'th row and the column representing the aileron mode; \( m \) is the mass of the aileron; \( r \) is the deflection of the trailing edge of the aileron for the aileron mode shape; \( r_{il} \) is the deflection of leading edge of the aileron for the \( i \)'th mode shape; and \( r_{it} \) is the deflection of the trailing edge of the aileron for the \( i \)'th mode shape. Assuming that the aileron mode is placed last, \([M]\) would then be written as

\[
[M] = \begin{bmatrix}
1 & 0 & 0 & \ldots & 0 & m_{1a} \\
0 & m & 0 & \ldots & 0 & m_{2a} \\
0 & 0 & m & \ldots & 0 & m_{3a} \\
\vdots & \vdots & \vdots & \ddots & \vdots & \vdots \\
0 & 0 & 0 & \ldots & m & m_{na} \\
0 & 0 & 0 & \ldots & 0 & 0 \\
\end{bmatrix}
\]

Putting the problem into state vector differential notation

\[
\begin{bmatrix}
U' \\
U'' \\
X' \\
Y'
\end{bmatrix} = \begin{bmatrix}
0 & I & 0 & 0 \\
-K-B & q_{I} & k_{H} & e_{a} \\
P_{3} & P_{2} & R_{0} & 0 \\
0 & 0 & 0 & A
\end{bmatrix} \begin{bmatrix}
U' \\
U'' \\
X \\
Y
\end{bmatrix}
\]

The inverse of the square matrix on the left is
\[ \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & M & 0 & 0 \\ 0 & -P1 & I & 0 \\ 0 & -GD & 0 & I \end{bmatrix}^{-1} = \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & M & 0 & 0 \\ 0 & P1M & I & 0 \\ 0 & -GDM & 0 & I \end{bmatrix} \]

Multiplying both sides by the inverse and simplifying

\[
\begin{array}{c}
\{U\}' \\
\{U''\} \\
\{X\}' \\
\{Y\}'
\end{array} =
\begin{bmatrix}
-1 & 0 & 0 & 0 \\
-M & K & -M & B \\
-P3 & -P1M & K & P2 & -RO & +P1M \\
-GDM & K & -GDM & B & GDM & q & A & +GDM & k & a
\end{bmatrix}
\begin{array}{c}
\{U\}' \\
\{U''\} \\
\{X\}' \\
\{Y\}'
\end{array}
\]

Because of the aileron mode, the \([M \ K]\), \([M \ B]\) and \([M \ q]\) are no longer diagonal. Assuming that the aileron mode is placed last

\[-1 \begin{array}{c}
M \ K =
\begin{bmatrix}
k \ / m & 0 & 0 & \. & k \ & m \ / m \\
1 & 1 & a & 1 & a & 1 \\
0 & k \ / m & 0 & \. & k \ & m \ / m \\
2 & 2 & a & 2 & a & 2 \\
0 & 0 & k \ / m & \. & k \ & m \ / m \\
3 & 3 & a & 3 & a & 3 \\
\ldots & \ldots & \ldots & \ldots & \ldots & \ldots & \ldots & \ldots & \ldots & \ldots \\
0 & 0 & 0 & \. & k \ & a
\end{bmatrix}
\end{array} \]

\[-1 \begin{array}{c}
M \ B =
\begin{bmatrix}
b \ / m & 0 & 0 & \. & b \ & m \ / m \\
1 & 1 & a & 1 & a & 1 \\
0 & b \ / m & 0 & \. & b \ & m \ / m \\
2 & 2 & a & 2 & a & 2 \\
0 & 0 & b \ / m & \. & b \ & m \ / m \\
3 & 3 & a & 3 & a & 3 \\
\ldots & \ldots & \ldots & \ldots & \ldots & \ldots & \ldots & \ldots & \ldots & \ldots \\
0 & 0 & 0 & \. & b \ & a
\end{bmatrix}
\end{array} \]
\[
M^{-1} q = \begin{bmatrix}
q/m & 0 & 0 & \cdots & 0 & 0 \\
0 & q/m & 0 & \cdots & 0 & 0 \\
0 & 0 & 2q/m & \cdots & 0 & 0 \\
\vdots & \vdots & \vdots & \ddots & \vdots & \vdots \\
0 & 0 & 0 & \cdots & q/m & 0 \\
0 & 0 & 0 & \cdots & 0 & n \\
\end{bmatrix}
\]

This is the form of the vibration equations that will be used to solve for the frequency and damping of an aircraft wing.
CHAPTER 6

ANALYSIS OF DAST ARW-1

The computer program "SAFSS" (Stability Analysis of Flutter Suppression Systems) was written to implement the analysis approach presented in chapters 2-5 (see figures 2 and 3). The input information to "SAFSS" consists of the generalized force matrices, the control law matrices, the generalized mass, natural frequency, and the aileron deflections for each mode. In order to obtain the input information, other computer programs were used.

The finite element analysis portion of the computer program "NASTRAN" and an input file provided by NASA Langley were used to calculate the first ten natural frequencies and mode shapes of the DAST ARW-1. The aileron mode shape was then substituted for one of the rigid body modes calculated by "NASTRAN". The mode shapes were then input to the double lattice portion of "NASTRAN" and used to calculate the aerodynamic influence coefficients (AICs) at fifteen reduced frequencies (see figure 4). The pade approximate curve fitting routine "QUEFIT" used the AICs at the reduced frequencies to calculate the generalized force matrices (see figure 5).

The control law for the third test flight of DAST ARW-1 was obtained from NASA Langley and is shown in figure 6. The portion of the control law used for the aileron mode was

\[ g(s) = \frac{2}{1256.6} \div (s = 502.7s + 1256.6)^2 \]
Therefore, the aileron mode had a natural frequency of 1256.6 hertz and a damping factor of 0.2. The remaining terms of the control law were put into matrices by the program "CONTRL".

The input file documentation needed to use the computer program "SAFSS" is presented in appendix B and a listing of the program is in appendix C. A sample input file for the DAST ARW-1 symmetric, .825 mach number, 15,000 feet altitude case is presented in appendix D. The output for the sample case is contained in appendix E.
CHAPTER 7
FLIGHT TEST DATA

Data from the third test flight of the DAST ARW-1 test vehicle was collected by the NASA Dryden Flight Test Research Center. The DAST was launched from a B-52 aircraft and remotely piloted to an altitude of 15,000 ft. Testing was performed at the following mach numbers; 0.70, 0.75, 0.775, 0.80 and 0.825.

The wing was vibrationally excited at each mach number to determine the vibrational stability. Excitation of the wing was produced by oscillating the aileron in a continuous frequency sweep from 10 to 40 hertz. Excitation sweeps were performed with the flutter suppression system (FSS) on and/or off (depending on the predicted stability at the test point) for both symmetric and asymmetric cases.

The FSS used for the DAST ARW-1 is active aileron control which operates in the following manner. Electrical signals from four accelerometers (two located in the fuselage and one in each wing) are sent to a compensator. The compensator separates the symmetric, asymmetric, and rigid body motions then signals the actuators to hydraulically move the ailerons. A time history of the accelerometer signals is used to calculate the frequencies of vibration and damping factors.

Because of an error in the implementation of the control law, the FSS was operated at one-half of the designed gain. This error caused test data for a gain factor...
of one-half to be compared with predictions for a gain factor of one. As a result, the DAST ARW-1 with the FSS on entered a flutter region near Mach 0.825 at 15,000 ft. and was lost.
CHAPTER 8
RESULTS

The natural frequencies for the symmetric case of DAST ARW-1 obtained from the program "NASTRAN" and from a ground vibrations test (GVT), are presented in Table 1. For the frequency range of interest (10-40 hertz), the predicted and actual frequencies agree to within 0.5 hertz. The first wing bending mode is of special importance because the aircraft fluttered in that mode. "NASTRAN" predicted the first bending mode to have a natural frequency of 9.1 hertz. The actual value was 9.6 hertz. The mode shapes and natural frequency were used to calculate the generalized force matrices therefore a 5% error could be considered large.

The data taken at mach 0.755 is believed to be unreliable because the wing showed uninitiated oscillations, possible due to atmospheric turbulence. The FSS (flutter suppression system) was left on for velocities of mach 0.755 and above. The FSS off data for mach 0.755 and above was calculated from FSS on information. Due to an error in the implementation of the control law, the FSS on condition was operating at one-half the desired gain (K=.5) for the test flight.

Table 2 shows the relationship between the predicted and experimental vibrational frequencies with the FSS off and Table 3 shows the relationship with the FSS on. The average error in frequency for the FSS off condition is 5% while the error for the FSS on condition is 8%.
The FSS increased the vibrational frequency from 13.91 hertz to 19.93 hertz. The analysis predicted the effect of the FSS quite well as an increase from 14.54 to 21.58 hertz.

A graph of root locus versus mach number for the 15,000 ft. altitude case for the first wing bending mode is shown in Figure 7. Three gain factors are plotted: full gain (K=1, the designed gain factor), half gain (K=.5, the actual FSS on gain) and no gain (K=0, the FSS off gain). The root locus plot is interpreted by noting that as the real term approaches the imaginary axis from the negative real side, the system becomes less stable. As the imaginary axis is crossed from the negative real to the positive real, the system goes from stable (no flutter) to unstable (flutter). The experimental results are shown to be consistently less damped and of a lower frequency than the predicted values. Trends seem to be predicted well, however more data is needed to draw any conclusions.

The predictions presented here are not the outcome of a single analysis, but rely on finite element, unsteady aerodynamics and vibrational analysis which tend to reduce the accuracy. The small difference which resulted can be caused by the inaccuracy (5%) of the finite element analysis alone.
CHAPTER 8
CONCLUSIONS

A method for analysis of an active aileron control flutter suppression system has been explained and compared with flight data. The method was shown to produce reasonable results but relies heavily on finite element and unsteady aerodynamic analysis. The ability of the finite element routine to match the mode shapes and natural frequencies of the ground vibration test will have a large affect on the accuracy of the flutter analysis.

Future work in this area will move toward digital instead of analog control systems. Digital systems will reduce space and weight requirements as well as make possible the use of dynamic control laws.

APPENDIX B

This appendix contains a description of the input file for the computer program "SAFSS" (Stability Analysis of Flutter Suppression System). This program is designed to use the output of an aerodynamic influence coefficient curve fitting routine has outlined by Edwards in "Applications of Laplace Transform Methods to Airfoil Motion and Stability Calculations".

The input information includes the aerodynamics, the control law, and information about each mode, such generalized mass, frequency of oscillation in still air and physical information about the wing. The input is grouped into four blocks. The first block contains information about the analysis options and the size of the problem. The second has all the information about the control law. The third block contains all the aerodynamic matrices and mach number. The last block contains the wing vibration and mode shape information.

The term "card" means that all the information is contained on one card. The term "card set" will refer to a group of cards that contain the stated information. Card sets usually contain matrices. Matrices will be read in by rows (first row, second row etc.). The last value in a row of a matrix will be the last value read from that card. As an example, a ten by ten matrix to be input with only eight values read from each card, will need two cards for each row. The first card for each row will contain eight values with the second card containing the
last two.

Variable Name   Column #   Format
Description
CARD BLOCK 1

CARD 1:---------------------------

TITLE(s)  1-46  6AB
The title and/or description desired on the data output and the root locus plot. The time and date will be supplied by the computer.

CARD 2:---------------------------

NGASE 1-5  IS
The number of different altitudes that calculations are to be performed at.

MODE 17 IS
The number of vibration modes being used for the calculations. Must include the aileron mode.

MALERN 11-15 IS
The number of the vibration mode that contains the aileron mode. Usually the first or the last.

NGAINT 16-20 IS
The type of arithmetic progression desired for the gain factor, (1=linear, 2=geometric).
Example: linear (0, .25, .5, .75, 1.0, 1.25, 1.5)
geometric (0., .25, .5, 1.0, 2.0, 4.0, 8.0)

NGAINS

The number of gain factors to be analyzed including zero. In the example above, both linear and geometric have 7 gain factors.

GAINUP

The desired value of the first gain factor after the pole (0.0).
Both the linear and geometric series in the above example have a value of .25.

IEGVEC

If the eigenvectors are to be printed, use the number "1". If any other number is used, the eigenvectors will not be printed.

CLEN

The span of the wing. It is used in the doublet lattice routine as the reference length to calculate the reduced frequency.

PLLT

If a root locus plot is desired, set equal to "1". If any other number is used, no plot will be made.

YMAX

The maximum frequency (rad/sec) that is of interest. This value is used in plotting only, and does not effect the calculations.
CARD SET 3:---------------------------------------------------------

ALT(I) 1-80 8F10.6

This card(s) contains the altitudes to be used in the calculations. The maximum number of altitudes that can fit on one card is 8. If more than 8 altitudes are desired additional cards must be used.

CARD Block 2

This set of cards is obtained from the "Ctrl" program as output. The entire block of cards is produced and order ready to be inserted into this data card deck.

CARD 4:---------------------------------------------------------

NCONTR 1-5 15

The size of the control matrix.

CARD Set 5:---------------------------------------------------------

AC(I,J) 1-80 4E20.13

This set of cards contains the "A" matrix of the control law. It is a square matrix with dimensions N x N, wherein the order of the control matrix (does not include the terms used as the aileron mode).

CARD Set 6:---------------------------------------------------------

GC(I,I) 1-80 4E20.13

This set of cards contains the "G" matrix of the control law. It is a row matrix with 1 x N dimensions, where N
is the order of the control matrix.

CARD SET 7:---------------------------------------------------------------

HC(1,J) 1-80 4E20.13

This set of cards contains the "H" matrix of the control law. It is a column matrix with Nx1 dimensions, where N is the order of the control matrix.

CARD BLOCK 3:******************************************

This block of cards contains the P1', P2', P3', and RO' matrices as described by Edwards (ref. 1, 2, 3 and 4). This block of cards is designed to be used as a unit. There is no need to separate the information in this block at any time.

CARD 8:---------------------------------------------------------------

MACH 1-10 F10.6

The mach number at which the calculations of the unsteady aerodynamics were performed are included here. The unsteady aerodynamic data is only valid for one Mach number.

CARD 9:---------------------------------------------------------------

ISYM 1-5 L5

This states whether the analysis is for a symmetric or asymmetric case, where "T" is for the symmetric and "F" is for the asymmetric case. These parameters have no effect on the problem, but does label the type of problem being solved.

CARD SET:---------------------------------------------------------------
This set of cards contain the PI' matrix. This matrix is square of dimension MxM, where M is the number of mode shapes. One card is needed for every 8 elements in a row and there are M rows.

CARD SET 11:-----------------------------------------------
P2(K,L) 1-80 4E20.13

Same as card set 10 except that it is the P2' matrix

CARD SET 12:-----------------------------------------------
P3(K,L) 1-80 4E20.13

Same as card set 10 except that it is the P3' matrix.

CARD SET 13:-----------------------------------------------
RO(K,L) 1-80 4E20.13

Same as card set 10 except that it is the RO' matrix.

CARD BLOCK 4 *********************************************

This card block contains the physical characteristics of the wing and should remain the same throughout the analysis.

CARD SET 14:-----------------------------------------------
OMEGA(I) 1-80 8F10.6

This card contains the vibrational frequency of each mode shape. It is important that the order of the mode shapes is the same as the order for the doublet lattice routine. The frequency
for the aileron mode is obtained from the 2'nd order term of the control law and was not input in the "Control" program.

CARD SET 15:-----------------------------------------------------------------------------------------------------------------

ZETA(I) 1-80 SF10.6

This card contains the damping factor for each vibration mode. The modal damping term for the aileron mode is obtained from the 2'nd order term of the control law that was not input into the "Control" program. The modal damping term for the other modes were hard to obtain therefore, a small value of approximately .005, was assumed.

CARD SET 16:-----------------------------------------------------------------------------------------------------------------

GMASS(I) 1-80 SF10.6

This card contains the generalized mass terms for each mode. The value for the generalized mass term of the aileron has a value of 1.0000. If the user does not set the aileron term to 1.0000, the program will do so.

CARD SET 17:-----------------------------------------------------------------------------------------------------------------

DEFLECT(I) 1-80 SF10.6

The deflection of the wing at the accelerometer location for each mode shape. The deflection for the aileron mode should be zero.

CARD SET 18:-----------------------------------------------------------------------------------------------------------------
The mass of the aileron in consistent units. If the problem has been done in units of inches, seconds, and pounds (as is usually the case) the mass should be of such units as to be consistent with the rest of the problem. The consistent units for the above example are the mass of the aileron in slugs divided by 12 in/ft. The program does not do this type of conversion so that other system of units can be used.

This card contains the conversion factor for the units of the input and output of the control law used in this analysis. If the control law input is in g's (gravities) and the analysis is in inches and seconds a conversion must be made. Likewise, the output of the control law output may be in degrees and the mode shape deflection may be one inch. For this example, the input portion of the conversion is \((1g)/(32.2 \text{ ft/sec}^2 \times 12 \text{ in/ft})\). The output portion would be \((1 \text{ degree})/(\text{the angle due to the one inch deflection})\). The proper conversion is obtained by multiplying the two terms.

The information below is required for each mode shape. The aileron mode will have a hinge line deflection of zero. Each card contains the information for one mode.
PHIIII  1-10  F10.6
The average deflection at leading edge of the aileron.

SIGIII  21-22  F10.6
The average deflection at the trailing edge of the aileron.

C
THIS SUBROUTINE IS A TRANSLATION OF THE ALGOL
PROCEDURE ELMHES, NUM. MATH. 12, 349-358(1966) BY
MARTIN AND WILKINSON,
APPLIED MATHEMATICS DIVISION, ARGONNE NATIONAL
LABORATORY
GIVEN A REAL GENERAL MATRIX, THIS SUBROUTINE
REDUCES A SUBMATRIX SITUATED IN ROWS AND COLUMNS
LOW THROUGH IGH TO UPPER HESENBERG FORM BY
STABILIZED ELEMENTARY SIMILARITY TRANSFORMATIONS.

ON INPUT:

NM must be set to the row dimension of two-dimensional array parameters as declared in the calling program dimension statement;

N is the order of the matrix;

LOW and IGH are integers determined by the balancing subroutine BALANC. If BALANC has not been used, set LOW=1, IGH=N;

A contains the input matrix.

ON OUTPUT:

A contains the Hessenberg matrix. The multipliers which were used in the reduction are stored in the remaining triangle under the Hessenberg matrix;

INT contains information on the rows and columns interchanged in the reduction.

Only elements LOW through IGH are used;

Questions and comments should be directed to B. S. Garbow.

LA = IGH - 1
KP1 = LOW + 1
IF (LA .LT. KP1) GO TO 200

K subroutine eltran(nm,n,low,igh,a,aint,z)

integer i,j,n,kl,mm,mp,nm,igh,low,mpi
real a(nm,igh),z(nm,n)
integer int(igh)

this subroutine is a translation of the algol procedure elmtrans,

this subroutine accumulates the stabilized elementary
similarity transformations used in the reduction of a
real general matrix to upper hessenberg form by elmhess.

on input:

nm must be set to the row dimension of two-dimensional
array parameters as declared in the calling program
dimension statement;

n is the order of the matrix;

low and igh are integers determined by the balancing
subroutine balanc. if balanc has not been used,
SET LOW=1, IGH=N;

A contains the multipliers which were used in the
reduction by ELMHES in its lower triangle
below the subdiagonal;

INT contains information on the rows and columns
interchanged in the reduction by ELMHES.
Only elements low through IGH are used.

ON OUTPUT:

Z contains the transformation matrix produced in the
reduction by ELMHES.

Questions and comments should be directed to B. S. Garbow,
Applied Mathematics Division, Argonne National Laboratory

SUBROUTINE HGR2(NM,N,LOW,IGH,H,WR,HI,Z,IERR,INUM)

INTEGER I,J,H,L,M,N,EN,II,II,LL,MM,NA,NM,NN,
X
IGH,ITS,LOW,MP2,ENM2,IERR
REAL H(NM,N),WR(N),HI(N),Z(NM,N)
INTEGER MNO
LOGICAL NOTLAS
COMPLEX 23
COMPLEX CMPXL
REAL T3(2)
EQUIVALENCE (23,T3(1))
C
THIS SUBROUTINE IS A TRANSLATION OF THE ALGOL PROCEDURE HGR2,
NUM. MATH. 16, 101-204(1970) BY PETERS AND WILKINSON.
THIS SUBROUTINE FINDS THE EIGENVALUES AND EIGENVECTORS
OF A REAL UPPER HESSENBERG MATRIX BY THE QR METHOD. THE
EIGENVECTORS OF A REAL GENERAL MATRIX CAN ALSO BE FOUND
IF ELMHES AND ELTRAN OR ORTHES AND ORTRAN HAVE
BEEN USED TO REDUCE THIS GENERAL MATRIX TO HESSENBERG FORM
AND TO ACCUMULATE THE SIMILARITY TRANSFORMATIONS.

ON INPUT:

NM MUST BE SET TO THE ROW DIMENSION OF TWO-DIMENSIONAL
ARRAY PARAMETERS AS DECLARED IN THE CALLING PROGRAM
DIMENSION STATEMENT;

N IS THE ORDER OF THE MATRIX;

LOW AND IGH ARE INTEGERS DETERMINED BY THE BALANCING
SUBROUTINE BALANC. IF BALANC HAS NOT BEEN USED,
SET LOW=1, IGH=N;

H CONTAINS THE UPPER HESSENBERG MATRIX;

Z CONTAINS THE TRANSFORMATION MATRIX PRODUCED BY ELTRAN
AFTER THE REDUCTION BY ELMHES, OR BY ORTRAN AFTER THE
REDUCTION BY ORTHES, IF PERFORMED. IF THE EIGENVECTORS
OF THE HESSENBERG MATRIX ARE DESIRED, Z MUST CONTAIN THE
IDENTITY MATRIX.

ON OUTPUT:

H HAS BEEN DESTROYED;

WR AND WI CONTAIN THE REAL AND IMAGINARY PARTS,
RESPECTIVELY, OF THE EIGENVALUES. THE EIGENVALUES
ARE UNORDERED EXCEPT THAT COMPLEX CONJUGATE PAIRS
OF VALUES APPEAR CONSECUTIVELY WITH THE EIGENVALUE
HAVING THE POSITIVE IMAGINARY PART FIRST. IF AN
ERROR EXIT IS MADE. THE EIGENVALUES SHOULD BE CORRECT
FOR INDICES IERR+1,...,N:

Z CONTAINS THE REAL AND IMAGINARY PARTS OF THE EIGENVECTORS.
IF THE I-TH EIGENVALUE IS REAL, THE I-TH COLUMN OF Z
CONTAINS ITS EIGENVECTOR. IF THE I-TH EIGENVALUE IS COMPLEX
WITH POSITIVE IMAGINARY PART, THE I-TH AND (I+1)-TH
COLUMNS OF Z CONTAIN THE REAL AND IMAGINARY PARTS OF ITS
EIGENVECTOR. THE EIGENVECTORS ARE UNNORMALIZED. IF AN
ERROR EXIT IS MADE, NONE OF THE EIGENVECTORS HAS BEEN FOUND:

IERR IS SET TO
ZERO FOR NORMAL RETURN.
J IF THE J-TH EIGENVALUE HAS NOT BEEN
DETERMINED AFTER 30 ITERATIONS.

ARITHMETIC IS REAL EXCEPT FOR THE REPLACEMENT OF THE ALGOL
PROCEDURE CDIV BY COMPLEX DIVISION.

QUESTIONS AND COMMENTS SHOULD BE DIRECTED TO B. S. GARROW,
APPLIED MATHEMATICS DIVISION, ARGONNE NATIONAL LABORATORY
