This paper describes and discusses a general method of solutions for treating effects of Doppler-broadened Rayleigh backscattering in H_2O DIAL measurements. Errors in vertical DIAL measurements caused by this laser line broadening effect can be very large (Ansmann, 1) and, therefore, this effect has to be accounted for accurately.

To analyze and correct effects of Doppler-broadened Rayleigh backscattering in DIAL experiments, a generalized DIAL approximation was derived starting from a lidar equation, which includes Doppler broadening:

\[
N(\bar{R}) = \frac{1}{2(\sigma_1(\bar{R}) - \sigma_2(\bar{R}))DR} \left[ \ln \left( \frac{P_1(R_1) \cdot P_2(R_2)}{P_1(R_2) \cdot P_2(R_1)} \right) + D_1(\bar{R}) - D_2(\bar{R}) \right]
\]

where \(N(\bar{R})\) is the water vapor number density averaged over the range cell DR centered at \(\bar{R} = (R_1 + R_2)/2\) and \(P_1(R)\) and \(P_2(R)\) are the on- and off-line laser signals backscattered from the range cell at \(R\), respectively. The absorption cross section for wave number \(v_i (i = 1: \text{on-line}, i = 2: \text{off-line})\) averaged over the range cell DR centered at \(\bar{R}\) is given by

\[
\sigma_i(\bar{R}) = \frac{1}{2} \int_{-\infty}^{\infty} \sigma_i(v, \bar{R}) \cdot \left[ \left( 1 + \frac{\beta_M(R_2)}{\beta(R_2)} \right) h_i(v) + \frac{\beta_R(R_2)}{\beta(R_2)} g_i(v, R_2) \right] dv
\]

and the Doppler broadening correction term \(D_i\) for wave number \(v_i\) is given by

\[
D_i(\bar{R}) = \ln \left[ \int_{-\infty}^{\infty} \frac{\beta_M(R_2)}{\beta(R_2)} h_i(v) + \frac{\beta_R(R_2)}{\beta(R_2)} g_i(v, R_2) \cdot \exp \left( - \int_{R_0}^{R_1} N(r) \cdot \sigma_i(r, v) dr \right) dv \right] - \ln \left[ \int_{-\infty}^{\infty} \frac{\beta_M(R_1)}{\beta(R_1)} h_i(v) + \frac{\beta_R(R_1)}{\beta(R_1)} g_i(v, R_1) \cdot \exp \left( - \int_{R_0}^{R_1} N(r) \cdot \sigma_i(r, v) dr \right) dv \right]
\]

where \(\beta(R)\) is the total backscattering coefficient for range \(R\), \(\beta_M(R)\) and \(\beta_R(R)\) are the Mie and Rayleigh backscattering coefficients for range \(R\), \(h_i(v)\) is the normalized laser line shape for wave number \(v_i\), and \(g_i(v, R)\) is the convolution of the incident laser profile \(h_i(v)\) and the intensity distribution of an incident monochromatic frequency \(v_i\) backscattered by air molecules in the range cell at \(R\).

The calculation of water vapor density \(N(\bar{R})\) with Eqs. (1)-(3) includes the correction of Doppler broadened Rayleigh backscattering effects. For using this calculation scheme, laser and H_2O absorption line parameters, temperature and pressure have to be known as usual for H_2O DIAL retrieval. In addition, for the correction of effects of Doppler broadening, backscattering properties of molecules and aerosols have to be known. The backscattering properties of molecules can be determined from measured temperature and pressure pro-
files or approximated from model atmosphere data. The aerosol backscattering properties can be obtained from range normalized off-line signals $P_2(R) - R^2$ using a numerical integration scheme (Fernald, Z; Sasano et al., 3). Here, in addition, Rayleigh backscattering coefficients, aerosol extinction/backscattering ratio and aerosol backscattering coefficient at calibration range $R_c$ have to be known. To yield generally stable solutions of this integration scheme for $\beta_m(R)$ with respect to uncertainties in the signals and the other input parameters, backward integration mode with boundary value $\beta_m(R_c)$ for maximum range $R_c = R_{\text{max}}$ should be used (Klett, 4). For the evaluation of the integral in Eq. (3) giving the water vapor optical thickness up to the range $R_1$, values for $N(r)$ calculated in the preceding steps $R_0 < R < R_1$ can be used. The off-line Doppler broadening correction term $D_2$ can be neglected, if off-line absorption is approximately constant over the transmitted spectrum.

To evaluate the accuracy of H$_2$O DIAL measurements using Eqs. (1)-(3), computer simulations were performed using Gaussian laser line shape with HWHM of 0.0125 cm$^{-1}$, Voigt-H$_2$O absorption lines with Lorentz halfwidth of 0.09 cm$^{-1}$, profiles of temperature, pressure and H$_2$O density (5.9 g m$^{-3}$ at ground level) for standard atmospheric conditions, aerosol scattering coefficients for clear atmosphere conditions (McClatchey, 5), ground level visibility of 23 km with additional layers of enhanced aerosol backscattering, and realistic lidar and receiver parameters. Lidar signals needed for the determination of H$_2$O and aerosol backscattering were calculated with a lidar equation considering Doppler broadened Rayleigh backscattering. H$_2$O-DIAL number densities were calculated with Eqs. (1)-(3). To analyze only Doppler broadening effects, no errors in the profile $\ln(P_1(R)/P_2(R))$ used for solving the DIAL approximation (1) were assumed. The difference between the retrieved and the true or input H$_2$O is shown in the figures.

In Fig. 1 examples of error profiles to be expected in ground based H$_2$O DIAL experiments due to realistic uncertainties in input parameters for backscattering retrieval are shown. It can be seen that correction of Doppler broadening effects is generally necessary. The accuracy of this correction mainly depends on the accurate determination of aerosol backscattering coefficients. Analysis of the influence of each input parameter for aerosol backscattering retrieval shows that it is especially important to have a proper estimate of the boundary value $\beta_m(R_c)$ at $R_c = R_{\text{max}}$ as a starting value for iterative aerosol backscattering retrieval. Error peaks at the upper layer boundaries in Fig. 1 are mainly due to errors in $\beta_m(R_c)$. The influence of errors in backscattering calculation is most important, when Mie and Rayleigh backscattering coefficients are of the same order of magnitude and, in addition, layers with steep gradients of aerosol backscattering are present. This is the case in the figures for the layer regions in the middle and upper troposphere. The relative water vapor error due to uncertainties in Doppler broadening correction is proportional to $\text{DR}^{-1}$ so that the shown effects decrease with increasing DR.

In conclusion, correction of Doppler broadened Rayleigh backscattering is possible with good accuracy in most cases of tropospheric H$_2$O DIAL measurements, but great care has to be taken when layers with steep gradients of Mie backscattering like clouds or inversion layers are present.
