SUMMARY

An analytical method to predict the shift of the contact ellipse between the meshing teeth in a spiral bevel gear set is presented in this report. The contact ellipse shift of interest is the motion of the nominal tooth contact location on each tooth from the ideal pitch point to the point of contact between the two teeth considering the elastic motions of the gears and their supporting shafts. This is the shift of the pitch point from the ideal, unloaded position on each tooth to the nominal contact location on the tooth when the gears are fully loaded. It is assumed that the major contributors of this motion are the elastic deflections of the gear shafts, the slopes of the shafts under load and the radial deflections of the four gear shaft bearings. The motions of the two pitch point locations on the pinion and the gear tooth surfaces are calculated in a Fortran program which also calculates the size and orientation of the Hertzian contact ellipse on the tooth faces. Based on the curvatures of the two spiral bevel gear teeth and the size of the contact ellipse, the program also predicts the basic dynamic capacity of the tooth pair. A complete numerical example is given to illustrate the use of the program.
INTRODUCTION

Spiral bevel gears are important elements for transmitting power. The design of an efficient gear box consisting of spiral bevel gears is based on gear geometry, bearing and shaft sizing, applied loading, and material properties. The gear tooth interaction is considerably more complex than that found in spur or helical gears. The loaded region of the gear mesh shifts due to the deflections and rotations of the gear and the pinion. A primary cause of these error inducing motions is the flexibility of the gear support shaft and bearings. If this shift is sufficiently large, the dynamic capacity of the gear mesh may be significantly reduced from the capacity based on the tooth curvature at the ideal pitch point.

In this report, a method to predict the shift of the loaded region on the tooth as a result of the gear tooth load and the elastic deflections of the gear support shafting and bearings is developed. The calculation of the gear mesh dynamic capacity based on the tooth curvatures, material strength and the applied load is presented also. A Fortran computer program to calculate this shift and the mesh dynamic capacity assuming constant tooth curvature is presented as well.

The gear box is modeled as a single output reduction such as those found in the OH-58 light duty helicopter. This geometry is shown in figure 1a, and is composed of a single spiral bevel gear drive with a spiral bevel pinion input and the shafts and bearings that support the gear and pinion. The analysis is based on the assumption that the transmission gear box is adequately lubricated and well designed.
Figure 1a. Spiral Bevel Gear Unit.
Due to the interactions of the deflections of the component parts of the reduction, the analysis is performed in a modular form. In the first stage, the gear geometry and loading is defined. In the second stage, the elastic deflections of the bearings and shafts and the slopes of the shafts at the gears are determined. In the third stage, the motions of the gear teeth caused by each elastic deflection are determined. The total deflections of the gear teeth are the algebraic sum of these motions. In the fourth stage, the interaction between the tooth geometry and motion is studied to determine the prediction for the influence of these elastic motions on the gear teeth contact.

Two separate analyses are presented in this fourth stage. In the first, a relative motion vector analysis is performed to model the relative displacement of the unloaded pitch points and the change in the shaft angle at the point of contact between the two gears due to these elastic deflections. These quantities are required for the Tooth Contact Analysis [1-3] of the mesh performed by a major bevel gear manufacturer. In the second, the geometry and curvatures of the gear and pinion teeth are combined with the separate elastic motions of the two gear teeth to predict the shift of the contact ellipse under load. In this analysis, it is assumed that the curvatures are constant over the surfaces of the teeth.

Finally, the basic dynamic capacity of the mesh is calculated from the loading, tooth curvatures and material properties. The computer program can simulate a number of different support geometries with the gear and pinion separately supported either between two bearings or overhung from a bearing quill behind the gear. Several different roller and ball bearing types can also be simulated with and without preload.
When working with spiral bevel gears, it is necessary to have a thorough understanding of the basic terms that define these gears and the kinematic properties that govern the meshing of the two gears. In the classic work on spiral bevel gears, Wildhaber [1] presents much of this information. Additional papers by Baxter [2] and Coleman [3] expand on this fundamental theory and describe the basis of a Tooth Contact Analysis program which is used to analyze the kinematic action of the two spiral bevel gears in mesh, based on their manufacture.

Litvin and Coy [4] have also completed works dealing with the theory of spiral bevel gear generation, and design. They have presented two types of spiral bevel geometry, and the line of action along the bearing contact can be determined. A significant result of this work is the ability to estimate the kinematic errors induced in the transmission by errors in gear manufacturing and assembly. Litvin Rahman, and Goldrich [5] have extended this work to obtain general mathematical models for the synthesis and optimization of spiral bevel gears. In this work the tooth surface is described as a conjugate envelope of the cutter surface in its generating positions. It is possible to have two different cutters for the gear and the pinion. Their generating surfaces may both be conical or one may be conical while the second is a more general surface of revolution.

The tooth curvature analysis presented in this report is built directly upon this work of Litvin [4,5]. Direct relationships have been presented between the principal curvatures and the directions of the tool generating surfaces and the generated curvatures and directions on the bevel gear teeth. Using these relationships, the model for the contact point shift was made possible. In addition, the Hertzian contact ellipse
and the mesh dynamic capacity can be found, once the tooth curvatures and directions are known. The conjugate analysis of Litvin [5] has made this possible.

Taha, Ettles, and MacPherson [6] have presented the interaction of the structural rigidity and performance for a helicopter reduction gear box. Their study used finite element models for the housing and presented the influence of deflections on bearing roller load distribution, bearing fatigue life and absolute deflections of the gear and pinion for the unloaded pitch point. This work demonstrated the importance of rigidity to minimize bearing life in a transmission.

In preliminary work to this effort, Savage, Brikmanis, Lewicki and Coy [7], and Savage, Knorr and Coy [8] have presented system reliability models for bevel gear reductions and helicopter transmissions. Both works describe analytical reliability simulations of transmission systems based on the reliabilities of the bearings and gears in the transmissions. Both works assume that the loaded geometry of the transmission is identical to the ideal unloaded geometry. This work concerns itself with predicting the change in gear mesh geometry due to loading.

The reliability model for gear teeth is based on the research of Coy, Townsend, and Zaretsky [9-12] and Lewicki [13]. In this model, the gears are assumed to be sufficiently well designed that bending failure at the tooth root is not a factor in the gear tooth life. The mode of failure which cannot be avoided is that of pitting near the pitch point on the gear teeth.
SPIRAL BEVEL GEAR GEOMETRY

Recently there has been extensive interest in determining the effects of loading and small profile changes on the kinematic efficiency, wear and life of spiral bevel gears. The interest originates from the desire to improve operating and maintenance procedures in high performance transmissions of helicopters and other aircraft.

In order to model the service life of these gears, a quantitative understanding of the geometrical characteristics is required.

These gears are called "spiral bevel" because the tooth face is constructed in a spiral on the pitch cone of the gear. This is done to obtain gradual engagement and disengagement of successive teeth in the mesh. The spiral angle, $\psi$, is nearly constant along the tooth and is generated by the circular cutter location. Spiral bevel gears are used in high performance transmissions because their curved teeth provide smoother and quieter operation.

A schematic representation of a single input bevel gear is shown in figure 1b. The pitch cone center distance, $A_0$, is a distance from the apex of the bevel cones to the back edge of the tooth face.
Figure 1b. Spiral Bevel Gear Geometry.
The pitch cone distance is measured along the pitch line of the two pitch cones and it is used as the major measure of the bevel size. The face width, \( f \), is also measured along the pitch line.

The following parameters define the pitch cone geometry: The number of the gear and pinion teeth, \( N_g \) and \( N_p \) respectively, the shaft angle, \( \Sigma \). The shaft angle is defined as the angle between the gear and pinion shaft. The shafts may or may not be perpendicular to each other. The pitch angles are half of the cone angle and are directly related to the above parameters in the following equations:

\[
\tan \Gamma_g = \frac{\sin \Sigma}{(N_p/N_g) + \cos \Sigma} \quad (1)
\]

\[
\tan \Gamma_p = \frac{\sin \Sigma}{(N_g/N_p) + \cos \Sigma} \quad (2)
\]

Throughout this analysis, the pitch point is considered to be the contact point of the gear mesh. The pitch point is located on the pitch ray at the midpoint of the tooth face. The distance from the cone apex to the pitch point is:

\[
D_0 = A_0 - \frac{f}{2} \quad (3)
\]

The pitch diameters of the equivalent spur gears for the spiral bevel gear and pinion are defined accordingly:

\[
D_g = 2D_0 \sin \Gamma_g \quad (4)
\]

\[
D_p = 2D_0 \sin \Gamma_p \quad (5)
\]
Beside the size and the shape of the pitch surface, the geometry of the meshing gear is also defined. In figure 2, the spiral bevel gear is shown at the pitch plane, which is tangent to the pitch cones at the line of contact. In the same figure, the spiral angle, $\psi$, is also shown. The spiral angle is defined as the angle between the pitch ray and the tangent to the circular cutter at the midpoint of the tooth, and it is measured at the mean radius of the gear.

A right-handed advance of the spiral along the axis of the gear toward the cone apex is defined as positive. The figure shows a right-hand spiral. The spiral angle is of the same magnitude in both the gear and the pinion but of opposite hands. The diametral pitch of the gear and the pinion is defined at the mean radius by the following equation:

\[
P_d = \frac{N_g}{2D_0 \sin \gamma_g}\]

Equation 6 shows that the diametral pitch is a direct function of the number of the gear teeth and the pitch cone geometry.

As shown in figure 3 the normal tooth is defined at the midplane of the tooth which corresponds to the section A-A in figure 2. The geometry also includes the normal pressure angle $\phi_n$, and the addendum and dedendum distances as well. The addendum and dedendum distances are defined as:

\[
a_d = \frac{a}{P_d}\]
Figure 2. Spiral Angle.
Figure 3. Normal Tooth.
The constants $a$ and $b$ in equations 7 and 8, respectively, are functions of the gear type. Dudley [15] provides equations for the calculation of the gear tooth dimensions of many bevel gear types.

In this study, the teeth at the pitch point are modeled as spur gear teeth. Figure 4 shows in a drawing the correlation of the bevel and the reference spur gear. As can be seen, the radius of the reference spur gear is equal to the midcone distance. The midcone distance is defined as the perpendicular distance from the centerline of the gear shaft to the midpoint of the gear face at the pitch point. From the geometry of figure 4, the midcone distance for the gear and the pinion are defined by using the distance from the cone apex to the midpoint of the gear face, $D_0$, and the respective pitch angle.

\[
BC_g = D_0 \tan \gamma_g \tag{9}
\]

\[
BC_p = D_0 \tan \gamma_p \tag{10}
\]

In order to define the loads transmitted at the point of the gear contact, the direction of rotation is required. In this study, a rotation of the gear is positive for clockwise rotation when looking at the cone apex from the back of the gear at the gear shaft.

The gear assembly includes the support system of bearings and their location. The support system is defined by the position of the gear with respect to the bearing locations. Two bearing
Figure 4. Composite Spiral Bevel Gear and Reference Spur Gear.
configurations are commonly used, straddle and overhung. In the first case, the bearings straddle the bevel gear, while in the second, the gear is overhung from the two bearing quill. Both configurations are shown in figure 5. In both cases, distance A is defined from the gear to the right bearing, while distance B is defined from the gear to the left bearing. The distances are measured from the midpoint of the gear to the midpoint of the bearing. It should be noted that for a straddle mounted gear, distance A is considered positive. In the overhung configuration, distance A is considered to be negative. The axial thrust loads produced by the gear mesh are carried by the bearing which is identified as the thrust bearing.
Figure 5. Bearing Mount Configurations.
LOADING ANALYSIS

The load components may be calculated from the applied input torque and the spiral bevel gear geometry.

The total force acting normal to the gear tooth is assumed to be concentrated at the average radius of the pitch cone. This force is divided into three orthogonal components, which are aligned relative to the axis of the gear alone [16]. The three components shown in figure 6 are: The transmitted or tangential load, \( W_t \), which produces the torque transmitted to the gear; the axial, or the thrust load, \( W_a \); and the radial load, \( W_r \). The axial and the radial load components are directly related to geometry of the gear teeth that transmit the tangential load. According to Shigley [16], the loads for the output gear are computed as:

\[
W_t = \frac{T_g}{2(A_0 - f/2)\sin \Gamma_g} \tag{11}
\]

\[
W_a = \frac{W_t}{\cos \psi} (\tan \phi_n \sin \Gamma_g - \sin \psi \cos \Gamma_g) \tag{12}
\]

\[
W_r = \frac{W_t}{\cos \psi} (\tan \phi_n \cos \Gamma_g + \sin \psi \sin \Gamma_g) \tag{13}
\]
Figure 6. Spiral Bevel Gear Forces.
where $T_g$ is the torque to the output gear. A positive sign for an axial or radial load indicates that it is directed towards the cone center.

The sign of the last term in equations 12 and 13 depends on the direction of rotation and the hand of the spiral and whether the gear is driving or being driven. There are four possible cases to be considered. These equations are valid for a right-hand spiral driving gear rotating clockwise, or a left-hand spiral rotating counterclockwise. For a driven gear, these equations are also valid for a right-hand spiral gear rotating counterclockwise or a left-hand spiral rotating clockwise. For the other four conditions with power flow in the opposite direction, the signs of the last terms in these equations are switched. The rotation is figured by looking at the gear from the side opposite the apex.

Only for right angle drives are all the force components exerted by the gear on the pinion equal and opposite. The opposite of a radial pinion load is an axial gear load, and the opposite of an axial pinion load is a radial gear load.

In all cases, however, the tangential and the total resultant tooth load of one gear must be equal and opposite to the corresponding force on the mating gear. The thrust load which acts in the axial direction of the shaft is equal to the gear axial force and is carried by the thrust bearing.

$$F_t = W_a$$

(14)
The normal tooth load which is the resultant of the three components is given by:

\[ W_n = \sqrt{W_t^2 + W_a^2 + W_r^2} \] \hspace{1cm} (15)

The radial forces on the two bearings are the resultants of the radial and tangential components of the reactions acting on each bearing as shown in figure 6. By taking moments with respect to the points where the bearings are located, the bearing load components can be calculated from the gear force components of equations 11 through 13. As shown in figure 7, the bearing load in each station is resolved in two planes which are perpendicular to each other. The gear tangential component acts on the horizontal plane, while the gear radial and axial components are on the vertical plane. The development of the bearing loads is the same for both support configurations.

STRADDLE CONFIGURATION

Figure 7 shows the straddle configuration modeled as a single span, simply supported beam with a concentrated load acting on it.

Tangential Plane

Taking the sum of moments with respect to the left bearing to be equal to zero:

\[ \sum M_A = 0 = F_{t2}(A + B) - W_t B \] \hspace{1cm} (16)

or \[ F_{t2} = \frac{W_t B}{A + B} \] \hspace{1cm} (17)
Figure 7. Force Analysis - Straddle Configuration.
Similarly, take moments with respect to the right bearing in figure 7.

\[ \sum M_B = 0 = F_{t1} (A + B) - W_t A \]  

(18)

or \[ F_{t1} = \frac{W_t A}{A + B} \]  

(19)

By rewriting the equation of diametral pitch (6) as:

\[ D_o \sin \gamma = \frac{Ng}{2P_d} = R_{avg} \]  

(20)

Equation 20 yields the average radius of the gear. The average radius is defined at the midpoint of the gear face, and is used as the moment arm of the axial load, \( W_a \), that causes a moment load in the radial direction.

Radial Plane

In the same way the loads in the radial plane are derived:

Sum of moments with respect to left bearing:

\[ \sum M_A = 0 \]

\[ = F_{r2} (A + B) + \left( \frac{W_a Ng}{2P_d} \right) - W_r B \]  

(21)

or \[ F_{r2} = \frac{- \left( \frac{W_a Ng}{2P_d} \right) + W_r B}{A + B} \]  

(22)
And with respect to the right bearing:

\[ \sum M_B = 0 \]

\[ = F_{r_1}(A + B) - (W_a N_g/(2 P_d)) - W_r A \]  

(23)

or \[ F_{r_1} = \frac{(W_a N_g/(2 P_d)) + W_r A}{A + B} \]  

(24)

OVERHUNG CONFIGURATIONS

The equations for overhung configurations can be found in a similar way. Figure 8 shows the gear shaft as a single span, simply supported beam with an overhang at the right end. The beam is loaded with a concentrated load at the outer end. As mentioned in the spiral bevel gear geometry section, distance \( A \) is considered to be negative for the overhung configurations.

Tangential Plane

Moments with respect to the left bearing:

\[ \sum M_A = 0 = F_{t_2}(B - A) - W_t B \]  

(25)

or \[ F_{t_2} = \frac{W_t B}{B - A} \]  

(26)

Moments with respect to the right bearing:

\[ \sum M_B = 0 = F_{t_1}(B - A) - W_t A \]  

(27)
Figure 8. Force Analysis - Overhung Configuration.
or \( F_{t1} = \frac{W_t A}{B - A} \) \hspace{1cm} (28)

Radial Plane

Similarly:

\[ \sum M_A = 0 \]
\[ = F_{r2}(B - A) + \left( \frac{W_a N_g}{2 P_d} \right) - W_r B \] \hspace{1cm} (29)

or \( F_{r2} = \frac{-\left( \frac{W_a N_g}{2 P_d} \right) + W_r B}{B - A} \) \hspace{1cm} (30)

\[ \sum M_B = 0 \]
\[ = F_{r1}(B - A) + \left( \frac{W_a N_g}{2 P_d} \right) - W_r A \] \hspace{1cm} (31)

or \( F_{r1} = \frac{-\left( \frac{W_a N_g}{2 P_d} \right) + W_r A}{B - A} \) \hspace{1cm} (32)

The following equations give the combined load for each bearing station. It should be noted that these equations hold true for both bearing configurations.

Combined Left Bearing Load

\[ F_{b1} = \sqrt{F_{t1}^2 + F_{r1}^2} \] \hspace{1cm} (33)

Combined Right Bearing Load

\[ F_{b2} = \sqrt{F_{t2}^2 + F_{r2}^2} \] \hspace{1cm} (34)
These equations are valid for any gear loaded by a single pinion.
DEFLECTIONS AND SLOPES

The motion of a gear assembly may be considered to be composed of three components. These components are the shaft motion, gear body motion, and bearing motion. The first two will be analyzed in this section, while the last will be treated along with the bearing analysis.

Using simple beam theory, the equations for the deflections and the slopes due to the three loading components are derived [16]. Due to the nature of the load application, the three load components may be classified as two different types of load. The tangential and the radial loads are considered as concentrated loads acting on the gear shaft. The axial load is treated as a moment load, since it acts parallel to the shaft.

STRADDLE CONFIGURATION

As shown in figure 9a the gear shaft is assumed to be a simply supported beam with a concentrated load acting on it. This load may be the tangential or the radial component. According to Shigley [16], the deflection equation for this case is given by:

\[ y_i = \frac{F_A x}{6 E I L} \left( x^2 + A^2 - L^2 \right) \]  

(35)
Figure 9. Straddle Configuration Loading Conditions.
Substituting \( x = B \) and \( L = A + B \) yields:

\[
y_i = \frac{F B^2 A^2}{3 EI(A + B)}
\]  

(36)

where \( F = W_t \) for tangential load
\( F = W_r \) for radial load
\( Y_i = Y_t \) for tangential load
\( Y_i = Y_r \) for radial load

The slope equation can be found by differentiating the deflection equation 35 with respect to distance \( x \). The same slope equation is used for both tangential and radial loads.

\[
\theta_i = \frac{F A[(x^2 + A^2 - L^2) + 2x^2]}{6 EIL}
\]  

(37)

for a tangential load:

\[
\theta_t = \frac{W_t A B(B - A)}{3 EI(A + B)}
\]  

(38)

and for a radial load:

\[
\theta_r = \frac{W_r A B(B - A)}{3 EI(A + B)}
\]  

(39)

Similarly, the deflection equation due to axial load is derived using equation 40 as given by Shigley [16]. The axial load in figure 9b acts along the gear shaft direction, thus creating a moment load at the
point of application with a moment arm equal to the average radius of the gear at the midpoint of the face width.

$$Y_a = \frac{M x}{6 \ E I L} (x^2 + 3B^2 - 6BL + 2L^2)$$  \hspace{1cm} (40)

Substituting \( x = B \) and \( L = A + B \) and \( M = W_a \cdot R_{avg} \) yields

$$Y_a = \frac{W_a \cdot R_{avg} \cdot A(B - A)}{3EI(A + B)}$$ \hspace{1cm} (41)

The equation giving the slope due a moment load is calculated from the derivative of equation 40 with respect to \( x \) as:

$$\theta_a = \frac{M(2x^2 + 3B^2 - 6BL + 2L^2 + 2x^2)}{6\ E I L}$$ \hspace{1cm} (42)

where \( x = B \) and \( L = A + B \) and \( M = W_a \cdot R_{avg} \),

$$\theta_a = \frac{W_a \cdot R_{avg}(A^2 + B^2 - AB)}{3EI(A + B)}$$ \hspace{1cm} (43)

**OVERHUNG CONFIGURATION**

The analysis for the overhung configuration is similar to the straddle case. However, the loading conditions are different and therefore the approach to derive the deflection and slope equations varies as well.

The gear shaft is treated as a cantilever beam with two types of loads at the free end. One concentrated load for the tangential
and radial components and one moment load for the axial component. The following analysis is the same for both types of loads.

As shown in figure 10, the gear shaft is modeled as a single span, simply supported beam with overhang, and is loaded by a concentrated load at the outer end. The portion of the beam which is outside the bearing quill is considered as a cantilever beam. The total deflection at the free end is the algebraic sum of two discrete deflections.

The first deflection is given by equation 44, and it represents a pure deflection of a cantilever beam with a moment load at the free end.

\[ D_1 = \frac{FA^3}{3EI} \]  

The slope is found by differentiating equation 44, and is

\[ S_1 = \frac{FA^2}{EI} \]  

As shown in figure 10, the load acting at the free end also creates a rotation at the end of the cantilever. This rotation contributes to the total deflection by creating a slope to the whole beam, and is shown in equation 46.

\[ S_2 = \frac{ML}{3EI} \]  

where \( M = FA \) and \( L = B - A \).
Figure 10. Overhung Configuration Concentrated Load Analysis
Figure 11. Overhung Configuration Moment Load Analysis

\[ M = W_a R_{avg} \]

\[ M = B - A \]

\[ M = \]
Multiplying this slope by the cantilever length yields the second deflection:

\[ D_2 = \frac{FA^2B}{3EI} \]  

(47)

By adding the deflections given in equations 44 and 47, the total deflection is given by equation 48. Similarly, by adding the slopes in equations 43 and 46, the total slope is given by equation 49.

\[ Y_0 = D_1 + D_2 = \frac{FA^2B}{3EI} \]  

(48)

\[ \theta_0 = S_1 + S_2 = \frac{FA(3A + 2(B - A))}{3EI} \]  

(49)

Equations 48 and 49 are valid for tangential and radial loads. The load, F, can be either a tangential load, \( W_t \), or a radial load, \( W_r \).

Working in a similar manner, the equations for a moment load are derived.

\[ D_3 = \frac{MA^2}{2EI} \]  

(50)

By differentiating equation 50, the slope is:

\[ S_3 = \frac{MA}{EI} \]  

(51)

Figure 11 shows the moment load acting at the free end that creates a rotation at the end of the cantilever which contributes to the total
deflection by creating a slope to the whole beam as shown in equation 52:

\[ S_4 = \frac{M(B - A)}{3EI} \]  

(52)

where \( M = FA \).

This slope is multiplied by the cantilever length results in the second deflection:

\[ D_4 = \frac{MA(B - A)}{3EI} \]  

(53)

The deflections given in equations 50 and 53 are added to give the total deflection of equation 54. Similarly, by adding the slopes in equations 51 and 52, the total slope is given in equation 55.

\[ Y_0 = D_3 + D_4 = \frac{M(3A + 2(B - A))}{6EI} \]  

(54)

\[ \theta_0 = S_3 + S_4 = \frac{M(3A + (B - A))}{6EI} \]  

(55)

where \( M = Wa \cdot Ra_{avg} \).

According to the axis system established in figure 12, the gear tooth deflection can be derived. The origin of this axis system is located at the midpoint of the gear face. Based on the loads exerted on the gear tooth, the new position may be found by considering the effect of these loads on the gear shaft. Equations 56-61

35
Figure 12. Reference Axis System.
describe the new position for any translation and/or rotation with respect to the axis system of figure 12. In the direction tangent to the gear tooth, \( Y_1 \), carries the deflection \( Y_t \), which is caused by the tangential load \( W_t \). The slope about \( Y_1 \), in equation 57, is equal to the difference of the slopes caused by the axial and radial loads.

\[
Y_1 = Y_t
\]

\[
\theta_1 = \theta_a - \theta_r
\]

As shown in equation 58, the deflection \( Y_2 \) accounts for the new position of the midpoint of the gear tooth, whose slope is equal to \( \theta_1 \). The slope about \( Y_2 \) is found by considering that the gear shaft is subjected to a torsional load equal to the tangential component, \( W_t \), and causes a torsional displacement equal to the slope, \( \theta_2 \). Equation 59 is the slope about \( Y_2 \), where the negative sign is due to the fact that the tangential load is acting in the counterclockwise direction. According to the right-hand rule established in figure 13, the slope about \( Y_2 \) causes a clockwise torsional effect on the gear shaft.

\[
Y_2 = R_{\text{avg}} \sin(\theta_a - \theta_r)
\]

\[
\theta_2 = -\frac{W_t R_{\text{avg}} Z}{JG}
\]
Figure 13. Pitch Point Deflection.
where \( Z = A + B \) for straddle configuration
\( Z = B \) for overhung configuration

\( J = \) polar moment of inertia of the shaft, \( \text{in}^4 \)
\( J = \frac{\pi d^4}{32} \)

\( G = \) modulus of rigidity, \( \text{lbf/in}^2 \)
\( G = \frac{E}{2(1 + \nu)} \)

where \( E \) is the modulus of elasticity, and \( \nu \) is the Poisson's ratio (for steel \( \nu = 0.25 \)).

As mentioned earlier in this chapter, the axial and the radial loads act on the same plane as the radial component; therefore, they contribute to the deflection in the radial direction. This contribution is accounted for in equation 60 along with the new position of the pitch point in the radial direction.

\[
Y_3 = Y_a + Y_r + R_{avg}(1 - \cos(\theta_a - \theta_r)) \tag{60}
\]

As can be seen from figure 12, the slope \( \theta_3 \) is equal to the slope caused by the tangential load.

\[
\theta_3 = \theta_t \tag{61}
\]

The deflections at the gear center for the three directions are given by equations 62 through 64. The axis system is the one of figure 12. The gear is considered to be a disk and the deflections are the ones caused by the external loading components at the disk.
center. It should be noted that these deflections are describing the same gear motion but at a different position.

\[ V_1 = Y_t \quad (62) \]

\[ V_2 = 0 \quad (63) \]

\[ V_3 = Y_r + Y_a \quad (64) \]

These deflections are the vector summations of the superimposed components of the shaft and the gear body motion.
BEARING ANALYSIS

The third component of the gear assembly deflection is due to the deflection of the bearings supporting the spiral bevel gear mesh.

The bearings used in bevel gears are usually ball or roller or tapered roller bearings with one or two rows of rolling elements. In order to determine the deflection in a bearing, the bearing geometry and the load to which the bearing is subjected have to be known.

The deflection of a bearing may be treated as the sum of two major deflections, the motion through the internal clearance of the bearing and the compression between the bearing races and the rolling elements. The deflection due to the motion through the internal clearance can be found by considering the change in the radial clearance, which is half of the diametral clearance. From the geometry of figure 14 the diametral clearance, \( C_d \), is defined:
Figure 14. Ball Bearing Geometry.
\[ C_d = 4(d_o - d_i - 2D) \] (65)

where \( d_o \) and \( d_i \) are the outer and inner race diameters, respectively, and \( D \) is the rolling element diameter.

For most practical bearings, this clearance is either zero or negative in which case the bearing is preloaded at assembly. The negative value of the diametral clearance is one way to describe the amount of preload present in the bearing. This preload affects the stiffness of the bearing because of the nonlinear Hertzian contact and the load-deflection relationship. Each rolling element in the loaded region of the bearing has Hertzian deflections with both the inner and outer bearing races. The equations presented in this section are valid for zero or negative clearance. In the case of positive clearance the bearing deflection is equal to the deflection of the bearing with zero clearance plus the amount of positive clearance.

The deflection due to the compression of the bearing components can not be found with a direct approach. This is because of the nonlinear Hertzian contact and the static indeterminancy among the rolling elements. As a starting point though, the Hertzian analysis for a surface deflection of two bodies may be considered.
Figure 15 shows two bodies of revolution with different radii of curvatures in a pair of intersecting principal planes. These planes pass through the contact point of the two bodies. In figure 15, the upper body is denoted as I, and the lower as II. For reference purposes, the principal planes are denoted as 1 and 2. Therefore, the radius of curvature of body I in plane 2 is designated as $R_{I2}$. The curvature $\kappa$ is defined as the reciprocal of the corresponding radius of curvature $R$, and one may write:

$$\kappa_{I1} = 1/R_{I1} = \text{Body I curvature in the direction of the rolling velocity}$$
$$\kappa_{I2} = 1/R_{I2} = \text{Body I curvature at } 90^\circ \text{ to the direction of the rolling velocity}$$
$$\kappa_{II1} = 1/R_{II1} = \text{Body II curvature in the direction of the rolling velocity}$$
$$\kappa_{II2} = 1/R_{II2} = \text{Body I curvature at } 90^\circ \text{ to the direction of the rolling velocity}$$

These curvatures may be positive or negative. In figure 16a is shown the case in which the center of curvature is inside the surface, known as convex; this curvature is positive. The curvature is negative when the center of curvature is outside the surface as shown for $R_2$ in figure 16b. This curvature is known as concave. The curvatures are used to describe the contact between surfaces of revolution in the following equations:
Figure 15. Contacting Surface Geometry.
Figure 16. Types of Contacting Surfaces.
The curvature sum:

$$\sum \kappa = \kappa_{II} + \kappa_{I2} + \kappa_{III} + \kappa_{II2}$$  \hspace{1cm} (67)$$

The curvature difference $F(\kappa)$:

$$F(\kappa) = \frac{(\kappa_{II} - \kappa_{I2}) + (\kappa_{III} - \kappa_{II2})}{\sum \kappa}$$  \hspace{1cm} (68)$$

In both cases the sign convention of convex and concave curvature is applied, and $F(\kappa)$ should be positive. A complete derivation of these equations is presented by Houghton [17].

The sum and curvature difference can be calculated for the inner and outer raceways. The bearing raceways that are in contact with the rolling element have different radii of curvatures, thus the curvature sum and the curvature difference are also different. Harris [18] provides equations for ball and roller bearings which are shown in equations 69-76.

BALL BEARINGS

a. Inner Raceway

$$\sum \kappa_i = \frac{1}{D} \left( 4 - \frac{1}{f_i} + \frac{2 \gamma}{1 - \gamma} \right)$$  \hspace{1cm} (69)$$

$$F(\kappa)_i = \frac{\frac{1}{f_i} + \frac{2 \gamma}{1 - \gamma}}{4 - \frac{1}{f_i} + \frac{2 \gamma}{1 - \gamma}}$$  \hspace{1cm} (70)$$
b. Outer raceway

\[ \Sigma \kappa_0 = \frac{1}{D} \left[ 4 - \frac{1}{f_0} + \frac{2 \gamma}{1 - \gamma} \right] \]  

\[ F(\kappa)_0 = \frac{\frac{1}{f_0} + \frac{2 \gamma}{1 - \gamma}}{4 - \frac{1}{f_0} + \frac{2 \gamma}{1 - \gamma}} \]  

ROLLER BEARINGS

a. Inner Raceway

\[ \Sigma \kappa_i = \frac{1}{D} \left[ \frac{2 \gamma}{1 - \gamma} + D \left( \frac{1}{R} - \frac{1}{r_i} \right) \right] \]  

\[ F(\kappa)_i = \frac{\frac{2 \gamma}{1 - \gamma} - D \left( \frac{1}{R} - \frac{1}{r_i} \right)}{\frac{2 \gamma}{1 - \gamma} + D \left( \frac{1}{R} - \frac{1}{r_i} \right)} \]

b. Outer raceway

\[ \Sigma \kappa_0 = \frac{1}{D} \left[ \frac{2 \gamma}{1 - \gamma} + D \left( \frac{1}{R} - \frac{1}{r_0} \right) \right] \]  

\[ F(\kappa)_0 = \frac{\frac{2 \gamma}{1 - \gamma} - D \left( \frac{1}{R} - \frac{1}{r_0} \right)}{\frac{2 \gamma}{1 - \gamma} + D \left( \frac{1}{R} - \frac{1}{r_0} \right)} \]

where

\[ \gamma = \frac{D \cos a}{d_m} \]
the bearing pitch diameter is given by:

\[ d_m = \frac{d_i + d_0}{2} \]  \hspace{1cm} (78)

In these equations, \( D \) is the ball or roller diameter, \( \alpha \) is the contact angle, and \( r_i, r_o \) are the raceway groove curvature radii. In the same equations, \( f_i \) and \( f_o \) designate the ratio \( r/D \) of the inner and outer raceway groove radii to the ball or roller element diameter, and \( R \) is the roller contour radius, for roller bearings.

The curvature difference equation is considered to be an auxiliary function of the elliptical parameters \( a \) and \( b \), the semi-major and semi-minor axis of the projected ellipse surface, respectively [18]. This function is described by equation 79.

\[ F(k) = \frac{(q^2 + 1)E - 2F}{(q^2 - 1)E} \]  \hspace{1cm} (79)

where \( E \) and \( F \) are complete elliptic integrals of the first and second kind, respectively, and \( q \) is the elliptical eccentricity. These integrals are given by equations 80 and 81, respectively.

\[ F = \int_0^{\phi/2} [1 - (1 - \frac{1}{q^2})\sin^2\phi]^{1/2} \, d\phi \]  \hspace{1cm} (80)

\[ E = \int_0^{\phi/2} [1 - (1 - \frac{1}{q^2})\sin^2\phi]^{1/2} \, d\phi \]  \hspace{1cm} (81)

in which \( \phi \) is the auxiliary angle.
For bearings whose surfaces have point contact, it has been determined [18] that the ellipse size is given by equations 82 and 83:

\[
a = a^*\left[\frac{3Q}{2\kappa}\left(\frac{1 - v_1^2}{E_1} + \frac{1 - v_2^2}{E_2}\right)\right]^{1/3}
\]

(82)

\[
b = b^*\left[\frac{3Q}{2\kappa}\left(\frac{1 - v_1^2}{E_1} + \frac{1 - v_2^2}{E_2}\right)\right]^{1/3}
\]

(83)

The deflection for the contact of the two bodies is found by:

\[
\delta = \delta^*\left[\frac{3Q}{2\kappa}\left(\frac{1 - v_1^2}{E_1} + \frac{1 - v_2^2}{E_2}\right)\right]^{2/3}\frac{\kappa^2}{2}
\]

(84)

where \(Q\) is the normal load acting on the two bodies in contact. The dimensionless parameters, \(a^*\), \(b^*\), \(\delta^*\), are given by equations 85-87:

\[
a^* = \left(\frac{2G^2}{\pi}\right)^{1/3}
\]

(85)

\[
b^* = \left(\frac{2E}{\pi q}\right)^{1/3}
\]

(86)

\[
\delta^* = \frac{2}{\pi}\frac{F}{\xi q^2 E}\left(\frac{\pi}{\xi q^2 E}\right)^{1/3}
\]

(87)

A complete table giving values of the dimensionless parameters, \(a^*\), \(b^*\), \(\delta^*\), has been developed by Harris [18], to record the evaluation of the integrals of equations 80 and 81, for all possible ball bearing geometries.

50
In the case of bearings with line contact, the equations for deflection can be calculated in a similar way. Palmgren [19] has developed an equation to calculate the deflection between the inner or outer race and the rolling element:

\[ \delta = 0.0003 E_e^{2.7} \frac{Q^{0.9}}{L_w^{0.9}} \]  

(88)

where \( Q \) is the normal load acting on the two bodies, \( L_w \) is the contact length and \( E_e \) is the material constant. The material constant is given by equation 89:

\[ E_e = \sqrt[3]{\frac{11500(E_{01} + E_{02})}{E_{01} E_{02}}} \]  

(89)

\[ E_{01} = \frac{E_1}{1 - \frac{1}{\nu_1^2}} \quad E_{02} = \frac{E_2}{1 - \frac{1}{\nu_2^2}} \]

where \( E_1, E_2 \) are the moduli of elasticity in kg/mm², and \( \nu_1, \nu_2 \) are the Poisson's ratios of the two bodies in contact.

The method previously described could be used to find the contact deflection in bearings. However, due to the assumptions used in the Hertz analysis, it can not be used directly.

The first assumption is that there is only one point of contact between the two bodies, which is not the case in bearings since there is more than one roller element in contact with the inner
and outer races at all times. The second assumption is that the load is acting in the same direction as the deflection. This assumption is only valid for a single rolling element directly under the load in a bearing with a zero contact angle. For all other rolling elements, the assumption is not valid.

Furthermore, the Hertz analysis is for the rolling element in contact with one of the bearing races. However, the rolling element is in contact with both the inner and outer race, thus both contact points contribute to the total bearing deflection. In order to get an accurate value for the total bearing deflection, the Hertzian analysis can still be used, but in a modified version, to account for the above considerations.

By observing equations 84 and 88, it can be seen that they can take the form:

\[ \delta \propto Q^{1/n} \]  

(90)

where \( n = 3/2 \) for ball and spherical bearings, and \( 10/9 \) for roller bearings.

By inverting relation 90 and expressing it in an equation format,

\[ Q = K\delta^n \]  

(91)

where \( K \) is a load-deflection factor.

Solving for \( K \) yields:

\[ K = \frac{Q}{\delta^n} \]  

(92)
By raising equation 84 to \( n=3/2 \) and simplifying:

\[
\delta = 0.530 \frac{Q}{\kappa^{3/2} \left( \frac{1 - v_1^2}{E_1} + \frac{1 - v_2^2}{E_2} \right)}
\]  

(93)

Substituting this into equation 92 produces the load-deflection factor for ball and spherical bearings:

\[
K = \frac{1.886}{\delta^{3/2} \kappa^{1/2} \left( \frac{1 - v_1^2}{E_1} + \frac{1 - v_2^2}{E_2} \right)}
\]  

(94)

Similarly, the load-deflection factor for roller bearings with line contact may be found by using the deflection of equation 88 in equation 92, or:

\[
K = \frac{Q}{[0.0003 \frac{E_e^{2.7} Q^{0.9}}{L_w^{0.8}}]^{10/9}}
\]  

(95)

or

\[
K = \frac{L_w^{8.9}}{0.000122 \ E_e^3}
\]  

(96)

where \( L_w \) is in mm and \( E_e^3 \) in mm²/kg.

Equation 96 can be easily converted in English units yielding:

\[
K = \frac{658665.714 \ L_w^{8.9}}{E_e^3}
\]  

(97)

where \( L_w \) is in inches and \( E_e^3 \) in in²/1b.
The total normal approach-deflection between the raceways under load separated by a rolling element is the sum of approaches between the rolling element and each raceway [18]. Hence,

\[ \delta_t = \delta_i + \delta_0 \]  

(98)

Since the deflection at the inner and outer races of a bearing can be expressed as a relationship of the applied load, \( Q \), and the corresponding load-deflection factor, \( K \), of the contacting bodies, equation 91 can be written as:

\[ Q = K_i \delta_i^n \]  

(99)

\[ Q = K_0 \delta_0^n \]  

(100)

Since the load acting at each of the contact points is the same, it can be expressed as:

\[ Q = K_j \delta_j^n \]  

(101)

Due to the fact that the rolling element acts in series between the two races, the total load-deflection factor, \( K_j \), can be evaluated by equation 102.

\[ K_j = \left[ \frac{1}{(\frac{1}{K_i})^{1/n} + (\frac{1}{K_0})^{1/n}} \right]^n \]  

(102)

To account for load sharing among the rolling elements, Harris [18] has shown that, for a rigidly supported bearing subjected to
radial loading, the radial deflection at any angular position of the rolling element is given by:

\[ \delta_\psi = \delta_r \cos \psi - 0.5 C_d \]  \hspace{1cm} (103)

where \( C_d \) is the diametral clearance and \( \psi \) is the angular position of the roller. The ring radial shift, \( \delta_r \), occurs at \( \psi = 0 \). Figure 17 illustrates a radial bearing with clearance and a radial deflection at an angle \( \psi \). Harris [18] has shown that equation 103 can be rearranged in terms of the maximum deflection.

\[ \delta_\psi = \delta_r (1 - \frac{1}{2e} (1 - \cos \psi)) \]  \hspace{1cm} (104)

in which

\[ e = \frac{1}{2} (1 - \frac{C_d}{\delta_r}) \]  \hspace{1cm} (105)

From equation 91 it is clear that

\[ \frac{Q}{Q_{\text{max}}} = \left( \frac{\delta}{\delta_r} \right)^n \]  \hspace{1cm} (106)

Therefore, from equations 104 and 106:

\[ Q_\psi = Q_{\text{max}} \left[ 1 - \frac{1}{2e} (1 - \cos \psi) \right]^n \]  \hspace{1cm} (107)

If static equilibrium is to exist, the applied radial load must be equal to the sum of the vertical components of the rolling element loads:
Figure 17. Bearing Ring Deflection.
(108) \[ F_r = \sum_{\psi=0}^{\psi=\pm \pi} Q \cos \psi \]

or \( F_r = Q_{\text{max}} \sum_{\psi=0}^{\psi=\pm \pi} \left[ 1 - \frac{1}{2e} \right] \cos \psi \) (109)

which has the following equivalent integral form:

\[ F_r = Z Q_{\text{max}} \frac{1}{2\pi} \int_{-\psi_\ell}^{\psi_\ell} \frac{1}{2e} \left[ 1 - \frac{1}{2e} (1 - \cos \psi) \right] \cos \psi \, dy \] (110)

where \( Z \) is the number of rolling elements in the bearing and \( \psi_\ell \) is the angle over which the load is distributed on the bearing. By defining:

\[ J_r(e) = \frac{1}{2\pi} \int_{-\psi_\ell}^{\psi_\ell} \frac{1}{2e} \left[ 1 - \frac{1}{2e} (1 - \cos \psi) \right] \cos \psi \, dy \] (111)

Harris [18] has evaluated the integral numerically and has tabulated the values as a function of \( e \) for a range of values from 0 to 5. The integral was evaluated for point and line contact. The results were plotted and are shown in figure 18. Using equation 111, equation 110 can then be written in the form:

\[ F_r = Z Q_{\text{max}} J_r(e) \] (112)

The value of \( Q_{\text{max}} \) is found by evaluating equation 103 at \( \psi=0 \).

\[ Q_{\text{max}} = K_j \delta^n = K_j (\delta_r - 0.5 C_d)^n \] (113)
Figure 18. $J_r(e)$ vs. $e$ for Radial Bearings.
or in terms of equation 112:

\[ F_r = Z K_j (\delta_r - 0.5 C_d) n J_r (e) \]  

(114)

Due to the nonlinear relationship of the applied load and the bearing deflection, equation 114 cannot be solved directly. An incremental search method is used to calculate the deflection that corresponds to the externally applied load. In this method, the bearing deflection is the value to be determined that corresponds to a value \( F_r(\delta_r) \), that equals the externally applied load within a small prescribed error range.

The sum and the difference equations 69 through 77 are first calculated. Depending on the bearing type the inner and outer race deflections for zero diametral clearance are calculated per equations 84 or 88, along with the resultant load-deflection factor, \( K_j \), of equation 102. Then \( e \) is calculated in equation 105 which results in a value of \( J_r(e) \). As a first guess for the deflection, equation 98 gives the value for \( \delta_r \) for zero diametral clearance, which is used to calculate \( F_r \) in equation 114. The method compares the difference between the externally applied load and the value found from equation 114, against a small convergence criterion. Should these figures be within the limits of the criterion, the scheme converges to the right value of deflection \( \delta_r \). Otherwise, an increment is added to the previous approximation and the scheme is repeated. The increment is halved and reversed whenever the error changes sign. The process continues until the above mentioned difference is less or equal to the convergence criterion.

In a bearing for which the angle of contact is not equal to zero, the load that is in the direction of the deflection can be found by equation 115:
\[ F_{\text{appl}} = \frac{F_r}{\cos \alpha} \quad (115) \]

where \( F_r \) is the applied load to which the bearing is subjected, and \( \alpha \) is the contact angle. For the case of the bearing that has two rows of rolling elements, the total load applied to the bearing is equally shared by the two rows of elements. For ball bearings that are subjected to pure radial load and zero radial clearance, Strubeck [20] concluded that:

\[ F_{\text{appl}} = \frac{4.37 F_r}{Z \cos \alpha} \quad (116) \]

where \( Z \) is the number of rolling elements.

Based on this transformation, the deflection calculated at an angle equal to the contact angle from the radial direction can be found as:

\[ D_r = \delta_r \cos \alpha \quad (117) \]

According to the Cartesian axis system established in figure 19a, the bearing loads in the tangential and radial directions, \( F_t \) and \( F_r \), respectively, are combined in equation 119, in one resultant load, \( F_{\text{tot}} \) per bearing station. The bearing loads were determined in equations 33 and 34 and are shown in figure 19b.

\[ \beta = \tan^{-1}(F_r/F_t) \quad (118) \]

\[ F_{\text{tot}} = \sqrt{F_t^2 + F_r^2} \quad (119) \]
(a) **RADIAL LOADS**

(b) **RESULTANT LOAD**

(c) **RADIAL DEFLECTIONS**

Figure 19. Bearing Force and Deflection Components.
Based on the information provided for the bearing design parameters, the computer program calculates the bearing deflection, $\delta_r$, for each station on the same shaft. This deflection is then analyzed back into two components in the tangential direction, $Y_{at}$, and radial direction, $Y_{ar}$, of figure 19c.

\[ Y_{at} = \delta_r \cos \beta \]  \hspace{1cm} (120)

\[ Y_{ar} = \delta_r \sin \beta \]  \hspace{1cm} (121)

By designating the left bearing deflection as $Y_1$, and right as $Y_2$, the deflection $Y_b$ due to the tangential load, $W_t$, or the radial load, $W_r$, is determined. Therefore, the left bearing deflection in the tangential direction is designated as $Y_{1t}$, and in the radial direction as $Y_{1r}$. For the straddle configuration of figure 20a, the bearing deflection in the tangential load direction is:

\[ Y_{bwt} = \frac{Y_{1t} A + Y_{2t} B}{A + B} \]  \hspace{1cm} (122)

From the same figure the slope of the deflected shaft is found as:

\[ \theta_{bwt} = \frac{Y_{2t} - Y_{2t}}{A + B} \]  \hspace{1cm} (123)

Due to the fact that the two bearing deflections on the same shaft are not equal, the new position of the shaft is calculated by
(a) BEARING DEFLECTION

(b) CONTACT POINT CORRECTION

Figure 20. Straddle Configuration Bearing Support Deflection.
considering the slope of the shaft with respect to the original undeflected position.

\[ \theta_{bwr} = \frac{Y_{2r} - Y_{1r}}{A + B} \]  

(124)

In the radial load direction, the deflection is similar to the tangential, with an additional term that accounts for the new position of the pitch point in the radial direction, caused by the slope, \( \theta_{bwr} \), as shown in figure 20b.

\[ Y_{bwr} = \frac{Y_{1r} A + Y_{2r} B}{A + B} + R_{avg}(1 - \cos(\theta_{bwr})) \]  

(125)

From the same figure, the deflection in the axial direction changes the position of the pitch point by:

\[ Y_{bwa} = R_{avg} \sin(\theta_{bwr}) \]  

(126)

The axial load does not cause an out-of-plane slope, thus it does not affect the bearing deflection of any bearing station.

Similarly, for an overhung configuration, shown in figure 21a, the deflections in the three directions of the acting loads and the shaft slope are given by equations 127 through 131. The bearing deflection due to the tangential load is given as:

\[ Y_{bwt} = \frac{Y_{2t} B + Y_{1t} A}{B - A} \]  

(127)
Figure 21. Overhung Configuration Bearing Support Deflection.
The unequal deflections of the two bearing stations in the tangential direction create a slope, $\theta_{bwt}$, as:

$$\theta_{bwt} = \frac{Y_{2t} - Y_{1t}}{B - A}$$  \hspace{1cm} (128)

In the radial direction the slope is found by:

$$\theta_{brw} = \frac{Y_{2r} - Y_{1r}}{B - A}$$  \hspace{1cm} (129)

The pitch point's new location, shown in figure 21b, is added to the deflection in the radial deflection:

$$Y_{brw} = \frac{Y_{2r} B + Y_{1r} A}{B - A} + R_{avg}(1 - \cos(\theta_{brw}))$$  \hspace{1cm} (130)

From figure 21b also, the pitch point has moved in the axial direction:

$$Y_{bwa} = R_{avg} \sin(\theta_{brw})$$  \hspace{1cm} (131)

The motion of the gear assembly due to the bearing internal deflection is the third and last of the three motions. The total deflections and slopes due to these three motions is the algebraic sum of all three contributing components. These three motions analyzed in this section, comprise the total absolute motion consisting of three translations and three rotations. The term "absolute" refers to the nominal point of contact at no load, with no relative motion of one gear with respect to the other.
Equations 132 through 137 give the total no-loaded deflections and slopes, shown in figure 22, of the gear or the pinion, in each of the three directions and motions analyzed in the last two sections.

**TOTAL DEFLECTIONS**

- **Tangential component**
  \[ D_{t1} = Y_t + Y_{bwt} \]  
  (132)

- **Axial component**
  \[ D_{t2} = Y_a + Y_2 + Y_{bwa} \]  
  (133)

- **Radial component**
  \[ D_{t3} = Y_r + Y_3 + Y_{bwr} \]  
  (134)

**TOTAL SLOPES**

- **Tangential component**
  \[ \theta_{t1} = \theta_t + \theta_1 + \theta_{bwt} \]  
  (135)

- **Axial component**
  \[ \theta_{t2} = \theta_a + \theta_2 \]  
  (136)

- **Radial component**
  \[ \theta_{t3} = \theta_r + \theta_3 + \theta_{bwr} \]  
  (137)
Figure 22. Total Deflections and Slopes for Spiral Gear and Pinion.
In dealing with the motion of a gear assembly in the previous sections, the motion has been considered and analyzed as an absolute motion of three translations and three rotations at the nominal (no load) point of contact and at the gear center as well.

Another way to estimate the motion of the loaded point of contact and its curvatures on the two gears is by considering the relative motion of the two gears at their nominal point of contact. Based on the gear tooth and assembly geometry, the actual (loaded) point of contact is determined in this section.

Consider the axis system in figure 23, the original of which is located at the midpoint of the tooth face. This coordinate frame can be defined by three axes: $Z_1$, is the common tangential component of the gear and the pinion; $Z_2$ the pinion axial component; and $Z_3$ the gear axial component. Due to the fact that the shaft angle, $\Sigma$, of the gear mesh may not be a right angle, the axis system need not be orthogonal.

The axis system combines the three translational and three rotational relative motions of the gear and the pinion in one coordinate system. The relative translations are indicated by $Z$, while the relative rotations are indicated by $A$. Figure 23 shows these
Figure 23. Relative Motion Coordinate Axis System.
translations and rotations in the positive sense. In the same figure the subscript \( g \) designates the gear parameters, while the subscript \( p \), the pinion's. \( Z_1 \) and \( A_1 \) are in the same direction as the gear's tangential deflection and slope, \( D_{t_1g} \) and \( \theta_{t_1g} \), respectively. \( Z_2 \) and \( A_2 \) are in the direction of the pinion's total axial deflection, \( D_{t_2p} \), and slope, \( \theta_{t_2p} \) and \( Z_3 \) and \( A_3 \) are colinear with the gear's total axial deflection, \( D_{t_2g} \), and slope, \( \theta_{t_2g} \).

The relative rotation can be defined in terms of the projections of the total deflections and slopes of the two gears on the axes of the coordinate frame of figure 23. The total axial and radial deflections and slopes act in the same plane that is defined by \( Z_2 \) and \( Z_3 \). This plane is perpendicular to the plane of the common tangential component in the direction of \( Z_1 \). The projections of these deflections and slopes are the only ones to contribute to the pinion axial, \( Z_2 \) and \( A_2 \), and the gear axial, \( Z_3 \) and \( A_3 \), relative translational and rotational motion components.

Assuming that the pinion is fixed, and the two mating gears have point contact, the following equations give the rotation and translation of the contact point caused by the relative motion of the gear relative to the pinion. In the case of the reverse situation, that is, the motion of the pinion relative to the gear, the deflections and rotations have the same magnitude but the opposite signs. The analysis is also based on the assumption that the finite rotations of the one gear with respect to the other are sufficiently small that they can be treated as vector quantities.
The relative rotation is first analyzed. Along the common tangential axis, \( A_1 \), the relative rotation of the gear with respect to pinion is the algebraic sum of the corresponding total tangential slopes. The relative rotation, which is in the same plane with the total slopes, can be expressed as the algebraic difference of the slopes. By virtue of the right-hand rule, the pinion rotation is in the opposite direction of the gear's. Therefore, the relative rotation can be expressed as:

\[
A_1 = \theta_{t1g} - (-\theta_{t1p}) \tag{138}
\]

The pinion axial, \( A_2 \), and the gear axial, \( A_3 \), components of figure 23 can be seen independently in figure 24. The total axial and radial slopes of the gear and the pinion are projected on the axes of the system yielding the relative rotations in the axial direction. The pinion axial component, \( A_2 \), is comprised of three discrete rotations. These rotations are: the pinion radial, \( \theta_{t3p} \), and axial, \( \theta_{t2p} \), and the gear radial, \( \theta_{t3g} \).

Due to the choice of this coordinate axis system, the projection of the gear axial rotation, \( \theta_{t2g} \), in the direction of \( A_2 \), is equal to zero. Similarly, the pinion axial rotation, \( \theta_{t2p} \), does not contribute to the relative rotation in the direction of \( A_3 \).

As shown in figure 24, the vector of the pinion axial rotation, \( \theta_{t3p} \), is on the diagonal of a parallelogram whose sides are the projections along the \( A_2 \) and \( A_3 \) rotational directions. Similarly, the gear axial rotation, \( \theta_{t3g} \), is along the diagonal of a parallelogram composed of the projections of its respective components along
the same $A_2$ and $A_3$ rotational directions. The gear or pinion rotation in any of these directions is the algebraic difference of the participating components. Therefore, the pinion component, $A_{2p}$, in the pinion axial rotation direction, is written as:

$$A_{2p} = + \frac{\theta_{t3p}}{\tan \Sigma}$$  \hspace{1cm} (139)

and the gear component, $A_{2g}$, in the same direction is:

$$A_{2g} = - \frac{\theta_{t3g}}{\sin \Sigma}$$  \hspace{1cm} (140)

The pinion axial rotation, $A_2$, is the algebraic difference of $A_{2p}$ and $A_{2g}$.

$$A_2 = - A_{2p} + A_{2g}$$  \hspace{1cm} (141)

Similarly, the gear axial component, $A_3$, is the difference of the projections of the same two rotations, but on the gear axial component axis, $A_3$.

The pinion component, $A_{3p}$, along $A_3$ is:

$$A_{3p} = \frac{\theta_{t3p}}{\tan \Sigma}$$  \hspace{1cm} (142)

and the gear component, $A_{3g}$, in the same direction:

$$A_{3g} = + \frac{\theta_{t3g}}{\sin \Sigma}$$  \hspace{1cm} (143)
Figure 24. Relative Rotation Components.
The gear axial rotation, $A_3$, then is:

$$A_3 = -A_{3p} + A_{3y} \quad (144)$$

The relative translational motion of the gear with respect to the pinion can also be seen in figure 23. The common tangential translation, $Z_1$, is in the same plane with the relative rotation, $A_1$. Therefore, equation 145 can be derived in a similar manner.

$$Z_1 = D_{t1g} - (- D_{t1p}) + \Delta Z_1 \quad (145)$$

where $\Delta Z_1$ is the relative motion of the contact points along the pitch ray of the gear and the pinion, given by equations 146 and 147, respectively.

$$\theta_g = R_{avg,g} A_3 \quad (146)$$

$$\theta_p = R_{avg,p} A_2 \quad (147)$$

Therefore,

$$\Delta Z_1 = \theta_g - \theta_p \quad (148)$$

or

$$\Delta Z_1 = R_{avg,g} A_3 - R_{avg,p} A_2 \quad (149)$$

The relative translation along the $Z_2$ and $Z_3$ coordinate axes, shown in figure 25, can be determined in the same way.

The component projections in the pinion axial, $Z_2$ follow.
The pinion components are:

\[ Z_{2p} = + D_{t2p} + \frac{D_{t3p}}{\tan \Sigma} \]  \hspace{1cm} (150)

and the gear components are:

\[ Z_{2g} = - \frac{D_{t3g}}{\sin \Sigma} \]  \hspace{1cm} (151)

Their difference results in the pinion axial translation, \( Z_2 \), which is also adjusted for the relative motion:

\[ Z_2 = - Z_{2p} + Z_{2g} \]  \hspace{1cm} (152)

and along the gear axial direction, the pinion component is:

\[ Z_{3p} = - \frac{D_{t3p}}{\tan \Sigma} \]  \hspace{1cm} (153)

and the gear component:

\[ Z_{3g} = D_{t2g} + \frac{D_{t3g}}{\sin \Sigma} \]  \hspace{1cm} (154)

Their difference yields the gear relative translation, \( Z_3 \):

\[ Z_3 = - Z_{3p} + Z_{3g} \]  \hspace{1cm} (155)
Figure 25. Relative Translation Components.
CONTACT ANALYSIS

The determination of the bearing contact for spiral bevel gears is analyzed in this section. It comprises the last part of the deflection analysis.

By considering the gear and shaft deflection found in the Deflection analysis section, along with the bearing motion of the Bearing analysis section, the total deflection and slope of the gear mesh are determined. Based on this analysis, the contact point deflection can be determined.

Due to the fact that the geometry of the spiral gear tooth surface is very complicated, the determination of the principal curvatures and principal directions along with the Hertzian contact stresses is a difficult problem. Litvin [5] has developed the equations to determine these principal curvatures and directions. The analysis is based on the assumption that there is a direct relationship between the principal curvature and its direction of the gear tooth surface and the gear cutting tool surface. Therefore, the curvature of the gear tooth surface is determined without using the complicated equations of the tooth geometry.

A novel approach to understanding and analyzing the geometry of spiral bevel gears is to consider the fact that one of the generating surfaces of these gears is conical, and the other is a surface
of revolution as shown in figure 26. These surfaces are in linear tangency along a circle of radius, \( r_d \), passing through the pitch point of the gear tooth. They are also in point contact at the same point that moves along the circumference of the circle. In order to approach and solve the Hertzian contact problem, Litvin [5] has used methods of kinematic and analytic geometry and kinematic relations between motions of contact point.

The result of this analysis is the principal curvatures of the two gear teeth in contact. These curvatures are used to determine the size of the contact ellipse, and the maximum developed contact stresses. Finally, the principal curvatures are utilized to calculate the new location of the contact point with respect to the nominal pitch point in the middle of the tooth face. Furthermore, the dynamic capacity of the gear assembly is also determined.

Litvin's analysis is based on the gear and pinion geometry, along with the gear's and pinion's cutter machine settings. The geometry is described by the number of teeth for the gear and the pinion, \( N_g \) and \( N_p \), spiral angle, \( \psi \), pressure angle, \( \phi_n \), pitch angles, \( \Gamma_g \) and \( \Gamma_p \), and the mean cone distance, \( D_0 \). The pitch angles and the mean cone distance are determined by equations 1-3 found in the spiral bevel gear geometry analysis. The gear cutter settings are provided by the cutting machine's manufacturer. Table 1 is a set of manufacturing parameter values which are needed to determine the principal curvatures and their directions for the gear and the pinion.
Figure 26. Generating Surfaces.
CONTACT ELLIPSE SIZE AND COMpressive STRESS

The contact ellipse size can be determined by using equations provided by Roark and Young [21]. The semi-major and semi-minor axis lengths of the contact ellipse are calculated as:

\[ a = \alpha \sqrt[3]{\frac{W_n K_D C_E}{K_D}} \]  
\[ b = \beta \sqrt[3]{\frac{W_n K_D C_E}{K_D}} \]  

The relative motion of approach, \( y \), along the axis of the applied loading is calculated as:

\[ y = \lambda \sqrt[3]{\frac{W_n^2 C_E}{K_D}} \]  

In these equations, \( W_n \) designates the normal tooth load determined by equation 15, \( K_D \) is a curvature constant given by equation 159, and \( C_E \) of equation 160 is a material constant of the two teeth in contact.

\[ K_D = \frac{1.5}{K_{II} + K_{I2} + K_{III} + K_{II2}} \]  

where \( K_{II}, K_{I2}, K_{III}, K_{II2} \) are the principal curvatures of the two bodies as described in Bearing Analysis section and whose equations are given in Litvin's analysis [5].

\[ C_E = \frac{1 - v_1^2}{E_1} + \frac{1 - v_2^2}{E_2} \]

</table>
where \( v_1 \) and \( v_2 \) are the Poisson's ratios and \( E_1 \) and \( E_2 \) are the Young's moduli of elasticity of the contacting teeth. The constants \( \alpha \), \( \beta \), and \( \lambda \) are a function of an auxiliary angle, \( \theta \), given by equation 161, and have been evaluated [21] for a range of 0 to 90 degrees.

\[
\cos \theta = \frac{K_{D}}{1.5} \sqrt{(K_{II1} - K_{II2})^2 + (K_{II1} - K_{II2})^2 + 2[(K_{II1} - K_{II2}) + (K_{II1} - K_{II2})] \cos 2\phi}
\]

where \( \phi \) is the angle between the principal curvatures \( K_{II1} \) and \( K_{II2} \) shown in Figure 27.

The maximum contact stress can be determined as a function of the normal load acting on the gear tooth and the contact ellipse size:

\[
\max \sigma_c = \frac{1.5 W_n}{ab}
\]

(162)

**CONTACT POINT DEFLECTION**

The total axial and radial deflections determined in Bearing analysis section are shown in the \( B_D \) axis system shown in figure 28. To differentiate between the pitch point deflection components and the directions in which they act, let \( \beta_{D_1} \) be the unit vector in the direction of the \( D_{t_1} \) displacement. Then \( \beta_{E_1} \) is a unit vector in the direction of the \( E_{t_1} \) displacement component. The coordinate system has its origin at the pitch point on the gear tooth, with axes extending along the pitch ray and the midcone plane. This coordinate
Figure 27. Contact Angle.
Figure 28. Contact Point Displacement in $\beta_{E_2}$, $\beta_{E_3}$ Direction.
system is the $\beta_{D_1}$ coordinate system rotated through the half cone angle about the $\beta_{D_1}$ axis.

The deflections shown are those of the pitch point. The deflections in the midcone plane direction, $E_{t_3}$, and along the pitch ray, $E_{t_2}$, are described by the following equations.

$$E_{t_2} = D_{t_2} \cos \Gamma - D_{t_3} \sin \Gamma \quad (163)$$

$$E_{t_3} = D_{t_2} \sin \Gamma + D_{t_3} \cos \Gamma \quad (164)$$

These equations are valid for the gear or the pinion.

Since the pitch ray is not tangent to the tooth surface, shown in figure 29, the motion along the pitch ray has to be transformed to a motion tangent to the tooth in the plane tangent to the pitch cone. In order to obtain this tangent direction, one has to rotate the $\beta_{E_2}$ direction through the spiral angle, $\psi$, about the $\beta_{E_3}$ direction.

In figure 29, a complete representation of the $\beta_{E_1}$ coordinate frame and the total deflections in these three directions are shown. From the same figure, the motion in the tangent direction, $H_{t_2}$, can be determined by considering the motion along the pitch ray, $E_{t_2}$, and in the bevel gear tangential deflection, $E_{t_1}$, as a function of the spiral angle where:

$$E_{t_1} = D_{t_1} \quad (165)$$

The tooth tangent displacement, $H_{t_2}$, acts in a direction $\beta_{H_2}$ which is one of the axes of a $\beta_H$ coordinate frame rotated from the $\beta_E$
Figure 29. Displacements on Spiral Bevel Tooth
coordinate frame about the $\beta_E$ axis through the spiral angle, $\psi$. The displacements of the pitch point in this tangent coordinate frame, $\beta_H$, are:

\[ H_{t1} = E_{t2} \sin \psi + E_{t1} \cos \psi \]  
\[ H_{t2} = E_{t2} \cos \psi - E_{t1} \sin \psi \]  
\[ H_{t3} = E_{t3} \]  

(166) (167) (168)

The slope vector components in the $\beta_D$ coordinate frame are the $\theta_{t1}$ vector components. In the $\beta_E$ coordinate frame these slope vector components become:

\[ A_{t1} = \theta_{t1} \]  
\[ A_{t2} = \theta_{t2} \cos \Gamma - \theta_{t3} \sin \Gamma \]  
\[ A_{t3} = \theta_{t2} \sin \Gamma + \theta_{t3} \cos \Gamma \]  

(169) (170) (171)

In order to treat the tangential motion of the contact point, the motion of the unloaded pitch point and the motion of the primary center of curvature will be combined. By this combination, the tangential location of the loaded pitch point on both the gear and the pinion will be estimated. These two points lie in a plane normal to the tooth surface, which makes an angle $\phi_n$ with the pitch plane of the bevel gear which is tangent to the pitch cone. A unit vector, $\lambda$, is shown in figure 29. The components of this unit vector in the $\beta_E$ coordinate frame, as shown in figure 30, are:
Figure 30. Unit Vector $\lambda$ and Its Components.
\[ \lambda_1 = \cos \psi \sin \phi_n \]  \hspace{1cm} (172)

\[ \lambda_2 = \sin \psi \sin \phi_n \]  \hspace{1cm} (173)

\[ \lambda_3 = -\cos \phi_n \]  \hspace{1cm} (174)

The rotation vector components in the direction which acts in the normal plane containing the centers of primary curvature can be found as the dot product of \( \lambda \) with \( A \).

\[ \theta_r = \lambda \cdot A = A_{t1} \cos \psi \sin \phi_n + \]

\[ + A_{t2} \sin \psi \sin \phi_n - A_{t3} \cos \phi_n \]  \hspace{1cm} (175)

Figure 31 shows the normal plane defined by \( \lambda \), which contains the tooth tangent direction, \( \beta_{H2} \), and the primary centers of curvature for both gear and pinion.

The new contact point location can be determined in this plane by using similar triangles. The new position is determined by considering the motion components along the tooth in the plane tangent to the pitch cone, \( H_{t2} \), plus the new positions of the center of curvatures in the same plane due to the angles, \( \theta_r \), of the gear and the pinion.

\[ D_f = H_{t2g} + R_g \sin \theta_{rg} + \]

\[ + \frac{R_g}{R_p + R_g}[(H_{t2p} + R_p \sin \theta_{rp}) - \]

\[ - (H_{t2g} + R_g \sin \theta_{rg}) \]  \hspace{1cm} (176)
Figure 31. Contact Point Motion in $\beta_{H_2}$ Direction.
This equation describes the absolute motion from the unloaded pitch point at the tooth center to the loaded pitch point in the tangent direction, $D_f$. The shift of the contact point on the gear in this direction is the difference between this motion and the absolute motion of the unloaded pitch point:

$$D_{pg} = D_f - H_{t2g} \tag{177}$$

and for the pinion:

$$D_{pp} = D_f - H_{t2p} \tag{178}$$

This is shown in figure 32.

The radial motion of the contact point along the tooth is determined by considering the base circles of a gear system shown in figure 33a. The gear motion in the plane affects the tooth contact by moving the base circles apart, thus increasing the pressure angle, $\phi_n$, and the midcone radii, $R_g$, $R_p$, for the gear and the pinion, respectively.

The midcone plane intersects the pitch circle in an ellipse. Due to the presence of the spiral angle, the shape of the tooth of a spiral bevel gear at the pitch point is nearly the same as the shape of a bevel gear having a midcone distance, $R_e$. The midcone radii for the gear and the pinion are found from analytic geometry [22] as:

$$R_{eg} = \frac{R_g}{\cos^2\psi} \tag{179}$$

$$R_{ep} = \frac{R_p}{\cos^2\psi} \tag{180}$$
Figure 32. Contact Point Motion in Tangential Plane.
Since the sum of the two base circle radii, $R_{bp} + R_{bg}$, is fixed, the distance between the center of the two base circles is:

$$C_m = R_{eg} + R_{ep} = \frac{R_{bg} + R_{bp}}{\cos \phi_n}$$ (181)

Due to the radial displacement of the base circle centers in the midcone plane, the distance between these centers increases to:

$$C'_m = C_m + H_{t3g} + H_{t3p} - R_{eg}(1 - \cos \theta_{r_{mg}}) - R_{ep}(1 - \cos \theta_{r_{mp}})$$ (182)

where $\theta_{r_{rm}}$ is the rotation vector component normal to the midcone plane for the gear and the pinion, and is found from the rotations about $\beta_{E1}$ and $\beta_{E2}$, $A_{t1}$ and $A_{t2}$ found in equations 169 and 170.

$$\theta_{r_{rm}} = A_{t1} \cos \psi + A_{t2} \sin \psi$$ (183)

The new pressure angle, $\phi'_n$, is determined by considering that the sum of the base circle radii remains constant.

$$\phi'_n = \cos^{-1} \left( \frac{C_m \cos \phi_n}{C'_m} \right)$$ (184)

The new midcone radii which are shown in figure 33b for the gear and the pinion can be determined by equations 185 and 186, respectively.

$$R_{g'} = \frac{R_{eg} \cos \phi_n}{\cos \phi'_n}$$ (185)
Figure 33. Contact Point Motion in Midcone Plane.
The gear pitch point moves radially along the tooth by an amount, $D_n$, which is shown in figure 34. This figure shows the unloaded and loaded pitch radii, $R_{eg}$ and $R_g'$, and their two pressure angles, $\phi_n$ and $\phi_n'$. A chordal approximation of the motion is:

$$D_{ng} = \sqrt{R_{eg}^2 + R_g'^2} - \frac{-2 R_{eg} R_g' \cos(\phi_n' - \phi_n)}{}$$

Similarly, for the pinion:

$$D_{np} = \sqrt{R_{ep}^2 + R_p'^2} - \frac{-2 R_{ep} R_p' \cos(\phi_n' - \phi_n)}{}$$

The new position of the contact point on the gear or the pinion, as shown in figure 35, is found by adding the motions along the pitch ray and the midcone plane. The new contact point on the gear is separated from the old by:

$$D_{totg} = \sqrt{D_{pg}^2 + D_{ng}^2}$$

and on the pinion:

$$D_{totp} = \sqrt{D_{pp}^2 + D_{np}^2}$$
Figure 34. Radial Motion of Gear Pitch Point.
Figure 35. Total Contact Point Motion in Gear and Pinion.
DYNAMIC CAPACITY

The dynamic capacity of a gear mesh is defined as the normal load that may be carried with a 90 percent probability of survival for a life of one million cycles. The dynamic capacity of a gear tooth is proportional to the Hertzian contact pressure squared for applications in which the major axis of the contact ellipse is significantly larger than the minor axis. This elliptical contact shape is similar to that found in the case of two cylinders in contact. In this case the ratio of the major to minor axis of the contact ellipse is infinity and the area of contact is a rectangular strip. The contact between two cylinders can then be visualized as a 2-dimensional case.

In dealing with spiral bevel gears, the teeth contact can be seen as a contact of two spheres. Since the contact area is of circular shape, the ratio of the major to minor axis is equal to 1. The spherical contact implies a 3-dimensional relationship, thus the dynamic capacity is proportional to the Hertzian pressure cubed. However, the size and shape of the contact ellipse show that the contact area can be approximated more accurately as a 2-dimensional case, as if it were a contact area between two cylindrical surfaces.

Due to the significant difference in size of the major axis as compared to the minor, the curvature in the direction of the major axis is small. Therefore, the curvature in the direction of the tooth rotation dominates, and provides a more accurate estimate of the
dynamic capacity. Based on these assumptions and definitions the
dynamic capacity of a gear tooth can be calculated as:

\[ C = \frac{2B_1 a}{K_{II1} + K_{II2}} \]  

(191)

where \( B_1 \) is a material constant, \( a \) is the semi-major axis of the
contact ellipse, and \( K_{II1}, K_{II2} \) are the principal curvatures of the two
gears in contact in the direction of the tooth rotation.

The material constant, \( B_1 \), is an experimental factor of
load-stress relationship and is based upon test values. The value for
case-hardened AISI 9310 Vacuum Arc Remelt steel gears can be
determined as \( B_1 = 35,000 \text{ psi} \) [7]. The values for this constant may
be used to calculate the limiting surface loads between two curved
surfaces of the same combination of materials [14].

The gears involved in the reduction have a certain load - the
dynamic capacity - that will cause 10 percent of a large sample of
gears to fail by pitting before or at one million applications of that
load. Once the dynamic capacity is known, it can be used to determine
the 90 percent reliability life in one million cycles for the applied
load on the component [7]. The load-life relation for the gear can
then be used to find the 90 percent reliability life for the actual
gear load.
The computer-aided analysis of a spiral bevel gear assembly is performed using a program written in FORTRAN 77. The program can run in an interactive or in a batch file mode. At any prompt of input data entry, the user has the choice of the mode.

In the interactive mode, the user has to answer a series of prompts to enter the proper information on gear geometry, gear assembly, and bearing specifications. After a large block of data has been entered, an input summary of this block is printed to verify the correctness of the data. A prompt will ask whether any changes on the last set have to be made. In the case of any wrong input(s), the program will return to the beginning of the last section of input and the information is entered again.

In a batch file mode, the information will be read from a data file. At the end of the data entry, a verification is needed to resume the execution. For any incorrect number(s) found in the file, the program prompts the user to enter the data file's entries in the interactive mode described above.

The program was written in a modular form. There is a main program where the introductory information for the geometry of the gear mesh is entered, and the preliminary calculations are performed.
Depending on the bearing support configuration of the gear and/or the pinion, the program branches to two subroutines. The subroutines cover the straddle and the overhung configurations independently. The calculations performed are similar in both subroutines. For proper execution of the subroutines, two additional sets of information are required: The mounting geometry of the gears and bearings and the characteristics of the bearings. The sets of data inputs in the main program and the subroutines are shown in tables 2, 3 and 4.

Inside the subroutines, the deflections discussed and analyzed in the Deflection analysis section are calculated first. The bearing deflection is also calculated within the same subroutine by branching to other subroutines that perform the calculations of the Bearing analysis section.

The output of the two major subroutines is returned to the main program, and the relative motion analysis is performed. The program branches to a subroutine to figure the contact point geometry, principal curvatures and contact ellipse size. These results are used by another subroutine, and the new contact point location and dynamic capacity are determined. A complete flowchart of the program logic is shown in figure 36, and the source code is listed in Appendix A.

In the output of the program, the complete dimensions and the loading components of the gear mesh are displayed. Furthermore, the various deflections and slopes, the contact analysis and the dynamic capacity results are also printed by the program. Table 5 lists the sequence of the transmission analysis results.

</table>

Inputs to Define the Characteristics of the Spiral Bevel Gear Mesh Bearings

The bearings can be of the following types:

1. Single Row Ball Bearings
2. Double Row Ball Bearings
3. Single Row Roller Bearings
4. Double Row Roller Bearings

For all types the inputs required are:

1. Inner raceway diameter (inches)
2. Inner raceway groove radius (inches)
3. Inner raceway elastic modulus (lbs/inch²)
4. Inner raceway Poisson ratio
5. Outer raceway diameter (inches)
6. Outer raceway groove radius (inches)
7. Outer raceway elastic modulus (lbs/inch²)
8. Outer raceway Poisson ratio
9. Rolling element diameter (inches)
10. Rolling element groove radius (inches)
11. Rolling element elastic modulus (lbs/inch²)
12. Rolling element Poisson ratio
13. Number of rolling elements in the bearing
14. Angle of contact between the rolling element and the inner/outer raceway
TABLE 5

Output of the Program

For each gear the output will be as follows:

1. The gear mesh geometry
2. The loading force components on the gear
3. The forces on the bearings
4. The shaft motion deflections and slopes
5. The gear motion deflections and slopes
6. The bearing characteristics
7. The bearing deflection and slope components
8. The total deflection and slopes
9. The deflections at the gear center

For the curvature analysis the following will be the output:

1. The principal curvatures
2. The unit vectors along the principal curvatures
3. The contact ellipse size
4. The contact deformation and maximum stress

For the contact analysis the following will be the output:

1. The deflection along the pitch ray
2. The deflection along the midcone plane
3. The total deflection on the gear and the pinion

A summary of the results is also printed in a tabulated form (optional).
NUMERICAL EXAMPLE

The analysis presented in the previous chapters along with the computer program can be used to analyze the spiral bevel mesh shown in figure 37. In this example, the mesh being analyzed is part of a 320 horsepower single input helicopter transmission. The input speed is 6180 rpm and the output speed is 1654 rpm, producing a gear reduction of 3.736:1. The input torque of 3232 lbs-in will be transferred through 95 degrees from an approximately horizontal input pinion to a vertical output gear shaft. The geometry of the spiral bevel gear unit and the bearing characteristics are listed in table 6. Appendix B shows how the input information is entered into the program. The program was run with the geometry given in table 6 and the output can be found in Appendix C.

The loading on each component in the transmission is first calculated. If the geometry of the transmission changes, the loads on the components will change as well. This change of loading will subsequently affect the deflections of the assembly, the principal curvatures and the contact geometry. The loading analysis results are shown in table 7.

After the intermediate step of loading calculations, the various deflections due to the three motions discussed in the sections
Figure 37. Example Spiral Bevel Mesh.
of Deflection and Bearing Analysis are calculated. These calculations are valuable to the designer since any change in shaft, gear or bearing geometry will affect the final contact analysis. The results are shown in table 8. Finally, the principal curvatures of the gear and pinion teeth are computed and used in calculating the contact geometry, contact point deflection, and the dynamic capacity, shown in table 9. The tooth profile and contact ellipses at the original and new position for the gear and the pinion are shown in figure 38.

The contact point deflection informs the designer whether the new point is on the tooth face or at the edge of it. This will affect the strength and the life of the tooth itself.

Basic dynamic capacity 14900.0 lbs.
DISCUSSION OF RESULTS

The analysis presented in this study is a model of the effect of shaft and bearing design on spiral bevel gear performance. Helicopter transmissions are designed with the objective of transmitting high power in a minimum weight package. In order to achieve this objective, some elastic flexibility must be accepted in the transmission. The purpose of this study is to develop a design tool which can be used by the designer to evaluate the necessary trade off between transmission weight and rigidity. Although all deflections do not adversely affect transmission performance, the deflections inside the bevel gear mesh dramatically reduce transmission performance. These deflections change the kinematic interaction of the gear teeth, increase the kinematic transmission error, increase the transmission noise and reduce the life and dynamic capacity of the bevel gear mesh.

Use of this model should assist the designer in determining transmission configurations which are light in weight but which also support the bevel mesh in such a way as to minimize the gear mesh deflections and the shift of the Hertzian contact ellipse location on the tooth surface.

The model is incorporated in a Fortran computer program which has been written with interactive input modules for ease of use. The program requests the input information in a series of prompts. After a screen of
data has been entered, the program then echoes the given information and requests the designer to verify its accuracy. If any information has been incorrectly read by the computer, the user may correct it and repeat the review. Once the screen of data has been accepted, the user need not re-enter it if later data is corrected. If multiple designs are to be checked at the same session, an input data file may be used to bypass the interactive data entry process and speed the program execution.

Since the model is not specific to a single support geometry configuration or a fixed set of spiral bevel gear parameters, the program may be used to evaluate the contact shift magnitude for many significantly different designs. It is hoped that systematic use of this program can assist the helicopter transmission designer in improving the effective power to weight ratio of his transmission.
A method to predict the shift of the loaded region on the teeth of the gears in a spiral bevel gear reduction is presented in this report. This shift is a result of the gear tooth load and the elastic deflections of the gear support shafting and bearings. The deflections considered are those caused by the radial bearing deflections, the shaft deflections and the shaft slopes.

The modeled gear box is a single output, single input, bevel gear reduction such as found in the OH-58 light duty helicopter. This geometry is composed of a single spiral bevel gear drive with a spiral bevel pinion input and the shafts and bearings that support the gear and pinion. The calculation of the gear mesh dynamic capacity based on the tooth curvatures, material strength and the applied load is presented also. A Fortran computer program to calculate this shift and the mesh dynamic capacity assuming constant tooth curvature is included.

The analysis is performed in a modular fashion. In the first stage, the gear geometry and loading are defined. In the second stage, the elastic deflections of the bearings and shafts and the slopes of the shafts at the gears are determined. In the third stage, the motions of the gear teeth caused by each elastic deflection are determined. The total deflections of the gear teeth are the algebraic sum of these motions. In the fourth stage, the interaction between the tooth geometry and motion is analyzed to obtain a prediction for the effects of these elastic motions on the gear tooth contact. Two separate analyses are presented in this fourth stage. In the first, a relative motion vector analysis is performed to model the relative
displacement of the unloaded pitch points and the change in the shaft angle at the point of contact between the two gears due to these elastic deflections. These quantities are required for the Tooth Contact Analysis of the mesh performed by a major bevel gear manufacturer. In the second analysis, the geometry and curvatures of the gear and the pinion teeth are combined with the separate elastic motions of the two gear teeth to predict the shift of the contact ellipse under load. In this analysis, it is assumed that the curvatures are constant over the surfaces of the teeth.

Finally the basic dynamic capacity of the mesh is calculated from the loading, tooth curvatures and material properties. The computer program can simulate a number of different support geometries with the gear and the pinion separately supported, either between two bearings or overhung from a bearing quill behind the gear. Several different roller and ball bearing types can also be simulated with and without preload.

This report includes the development of theory that supports the computer aided simulation. A listing of the program in Fortran source code is appended. The application of this model and the use of the program are illustrated with an example. A listing of the computer input and output for this example are appended to the report as well.

NOMENCLATURE

Variables

\[ A \] Distance from gear to right bearing in inches
\[ A_1 \] relative rotation in degrees \((i = 1-3)\)
\[ A_0 \] cone distance in inches
\[ A_{ti} \] slope vector components in b coordinate frame \((i = 1-3)\)
\[ a \] semi-major axis length in inches
\[ a_d \] addendum distance in inches
\[ b \] distance from gear to left bearing in inches
\[ b_C \] midcone distance in inches
\[ b_1 \] material constant in psi
\[ b \] semi-minor axis length in inches
\[ C \] dynamic capacity in pounds
\[ C_d \] diametral clearance in inches
\[ C_e \] elasticity constant in inch^{-2}
\[ C_m \] old base circle radii sum in inches
\[ C_m' \] new base circle radii sum in inches
\[ u \] pitch diameter in inches
\[ u_f \] motion of contact point in tangent plane in inches
\[ u_0 \] mean cone distance in inches
\[ u_p \] contact point motion in tangent plane in inches
Variables (continued)

$D_r$  total bearing deflection in inches

$D_n$  contact point motion in normal plane in inches

$D_{ti}$  total deflection in inches ($i = 1-3$)

$D_{tot}$  total contact point motion in inches

$d_b$  dedendum distances in inches

$d_i$  inner race diameter in inches

$d_m$  average race diameter in inches

$d_o$  outer race diameter in inches

$E$  modulus of elasticity in psi

$E_{t2}$  motion in pitch ray plane in inches

$E_{t3}$  motion in midcone plane in inches

$F$  bearing load in pounds

$F(K)$  curvature difference in inch$^{-1}$

$F_r$  radial loading on bearing in pounds

$f$  face width in inches

$G$  shear modulus of elasticity in psi

$H_{ti}$  displacement in tangent coordinate frame ($i = 1-3$)

$I$  area moment of inertia in inch$^4$

$J$  polar moment of inertia in inch$^4$

$K$  load-deflection factor

$K_D$  curvature constant in inches

$K_I$  principal curvature of pinion tooth in inch$^{-1}$

$K_{II}$  principal curvature of pinion tooth in inch$^{-1}$
Variables (continued)

$L_w$ contact length for roller bearings in inches

$P_d$ diametral pitch in in$^{-1}$

$q$ load acting on bearing in pounds

$R, R'$ midcone radii in inches

$R_i$ radius of curvature of body $i$ in inches

$R_{avg}$ average radius in inches

$T$ input torque to output gear in pound inches

$V_i$ deflection at the gear center in inches ($i = 1-3$)

$W$ loading components in pounds

$W_n$ normal loads in pounds

$Y_{bw}$ deflection due to bearing stiffness in inches

$Y_i$ deflection due to gear motion in inches ($i = 1-3$)

$y$ elastic deformation in inches

$Z$ number of rolling elements

$Z_i$ relative translation in inches ($i = 1-3$)

$\Gamma$ pitch angle in degrees

$\delta_r$ internal bearing deflection in inches

$\theta_{DW}$ slope due to bearing stiffness in degrees

$\theta_i$ slope due to gear motion in degrees ($i = 1-3$)

$\theta_r$ rotation vector component in the normal plane

$\theta_{rm}$ rotation vector component normal to midcone plane

$\theta_{ti}$ total slope in degrees ($i = 1-3$)

$k$ curvature in bearing contact in inc$^{-1}$
Variables (continued)

λ_i  unit vector in the β_E coordinate frame (i = 1-3)
ν  poisson ratio
Σ  shaft angle in degrees
Σ_k  curvature sum in inch^{-1}
σ_c  maximum compressive stress in psi
φ_n  pressure angle in degrees
ψ  spiral angle in degrees

Subscripts
a  axial direction
b_1  left bearing
b_2  right bearing
g  gear
p  pinion
r  radial direction
t  tangential direction
1  motion in tangential direction
2  motion in axial direction
3  motion in radial direction
REFERENCES

An analytical method to predict the shift of the contact ellipse between the meshing teeth in a spiral bevel gear set is presented in this report. The contact ellipse shift of interest is the motion of the nominal tooth contact location on each tooth from the ideal pitch point to the point of contact between the two teeth considering the elastic motions of the gears and their supporting shafts. This is the shift of the pitch point from the ideal, unloaded position on each tooth to the nominal contact location on the tooth when the gears are fully loaded. It is assumed that the major contributors of this motion are the elastic deflections of the gear shafts, the slopes of the shafts under load and the radial deflections of the four gear shaft bearings. The motions of the two pitch point locations on the pinion and the gear tooth surfaces are calculated in a Fortran program which also calculates the size and orientation of the Hertzian contact ellipse on the tooth faces. Based on the curvatures of the two spiral bevel gear teeth and the size of the contact ellipse, the program also predicts the basic dynamic capacity of the tooth pair. A complete numerical example is given to illustrate the use of the program.
