The invention disclosed in this document resulted from research in aeronautical and space activities performed under programs of the National Aeronautics and Space Administration. The invention is owned by NASA and is, therefore, available for licensing in accordance with the NASA Patent Licensing Regulation (14 Code of Federal Regulations 1245.2).

To encourage commercial utilization of NASA-owned inventions, it is NASA policy to grant licenses to commercial concerns. Although NASA encourages nonexclusive licensing to promote competition and achieve the widest possible utilization, NASA will consider the granting of a limited exclusive license, pursuant to the NASA Patent Licensing Regulations, when such a license will provide the necessary incentive to the licensee to achieve early practical application to the invention.

Address inquiries and all applications for license for this invention to NASA Patent Counsel, Ames Research Center, Mail Code 200-11A, Moffett Field, California, 94035. Approved NASA forms for application for nonexclusive or exclusive license are available from the above address.
Invention Abstract

The subject invention pertains to a method of producing an improved composite-composite honeycomb structure for aircraft or aerospace use. Specifically, the subject invention relates to a method for the production of a lightweight ceramic-ceramic composite honeycomb structure, which method comprises:

a) pyrolyzing a loosely woven fabric/binder having a honeycomb shape and having a high char yield and geometric integrity after pyrolysis at between about 700 and 1,100 °C;

b) substantially evenly depositing at least one layer of ceramic material on the pyrolyzed fabric/binder of step (a);

c) recovering the coated ceramic honeycomb structure;

d) removing the pyrolyzed fabric/binder of the structure of step (c) by slow pyrolysis at between about 700 and 1,000 °C in between about 2 to 5% by volume oxygen atmosphere for between about 0.5 and 5 hr.; and

e) substantially evenly depositing on and within the rigid hollow honeycomb structure at least one additional layer of the same or a different ceramic material by chemical vapor deposition and chemical vapor infiltration. The honeycomb shaped ceramic articles have enhanced physical properties and are useful in aircraft and aerospace uses.

CERAMIC HONEYCOMB
STRUCTURES AND METHOD THEREOF

BACKGROUND OF THE INVENTION

ORIGIN OF THE INVENTION

The invention described herein was made by employees of the United States Government and may be manufactured and used by or for the government for governmental purposes without payment of any royalties thereon or therefor.

FIELD OF THE INVENTION

The present invention relates to a method of producing an improved composite-composite structure for aircraft or aerospace use. The method and articles produced thereby generally involve pyrolyzing a loosely woven organic or inorganic fabric/binder in the shape of a honeycomb, depositing a ceramic material onto the carbonized fabric, optionally removing the pyrolyzed organic fabric and depositing the same or a different ceramic material onto and within the hollow honeycomb structure.

DESCRIPTION OF THE PRIOR ART

In the present art, polymeric, metallic and ceramic structures have been produced at low temperatures or in situations wherein weight requirements are not of concern. Structures having intricate designs, such as honeycomb structures, have not been described.

In U.S. Patent No. 4,488,920, L.J. Danis discloses a process of making a large scale ceramic heat exchanger by separately forming grooved components and bonding these components together by chemical vapor deposition.

In U.S. Patent No. 4,515,860, R.A. Holzl discloses a method for coating carbon bodies to protect them at elevated temperatures.

In U.S. Patent No. 4,476,178, R.D. Veltri et al., disclose a multilayered coating system for the protection of carbon-carbon composites. Silicon carbide is diffused onto a carbon substrate which successfully protects the carbon-carbon materials from oxidation at temperatures up to 2,500°F and higher. These references individually or collectively do not disclose the present invention.
One approach to produce ceramic honeycomb structures is to extrude ceramic forms having the following shapes:

(X) \[ \text{shape A} \]

and

(Y) \[ \text{shape B} \]

The two shapes are layered one on top of the other so that the flat portions are mated and a regular honeycomb structure is obtained. These points of juncture are then either adhered to each other using ceramic adhesive or are fused together using deposition or simply using elevated temperature. The honeycomb has hexagonal solid sides and hexagon-shaped openings therebetween. This method is long, involved, requires extensive hand labor and is expensive.

Previous attempts to produce ceramic-ceramic honeycomb structures by deposition have used porous substrates with uneven pore size distributions. These configurations have caused slow deposition rates and also pore blockage reducing penetration of the ceramic into the substrate. It is therefore desirable to develop a method to produce ceramic honeycomb based materials which have increased structure stability, improved physical properties, lighter weight properties, better high temperature limits (e.g., between about 700 to 1,800°C) and the like.

It is an object of the present invention to provide a process and articles thereof wherein an organic, inorganic or metallic fabric made rigid in an organic binder or an organic fabric and an inorganic binder is used as a honeycomb form for the chemical vapor deposition/chemical vapor infiltration/deposition of a ceramic material to produce the corresponding ceramic honeycomb.

It is an object of the present invention to provide a process to obtain a ceramic coated pyrolyzed organic polymer/fabric honeycomb structure.

It is another object of the present invention to provide a process to obtain a ceramic honeycomb wherein the carbon-based fabric/binder honeycomb internal structure has been removed.

It is still another object of the present invention to provide a process to obtain a ceramic object which is formed by first depositing
ceramic in all of the holes of the honeycomb fabric and or binder structure left by pyrolyzing and removing the organic components.

It is still another object to provide a process to obtain a ceramic object formed when the ceramic is deposited upon the degradable honeycomb structure, the honeycomb structure is removed and the voids created by removal are filled with more ceramic material.

**SUMMARY OF THE INVENTION**

The present invention relates to a method for the manufacture of a ceramic honeycomb structure, which process comprises:

1. obtaining a loosely woven fabric in a binder wherein the fabric consists essentially of metallic, ceramic or organic fibers and the binder consists essentially of an organic or inorganic material, with the proviso that when the fibers are ceramic or metallic the binder is not an inorganic material, wherein the fabric/binder has and retains a substantially honeycomb shape;

2. substantially evenly depositing at least one layer of a ceramic on the fabric binder of step (a); and

3. recovering the ceramic coated honeycomb structure.

In another aspect, the present invention relates to a method for the manufacture of a light weight ceramic-ceramic composite honeycomb structure, which process comprises:

1. pyrolyzing a loosely woven fabric having a honeycomb shape and exhibiting a high char yield and geometric integrity after pyrolysis at between about 700 and 1,100°C;

2. substantially evenly depositing at least one layer of a ceramic material on the pyrolyzed fabric of step (a); and

3. recovering the coated ceramic honeycomb structure.

In another aspect, the present invention discloses after step (c):

4. a step (d) wherein the pyrolyzed fabric of the structure of step (c) is slowly removed by pyrolysis/oxidation at between 500 and 1000°C, e.g. by using between about a 2 to 5% by volume oxygen atmosphere.

The present invention also comprises, in accordance with the objects and purposes described herein, the articles of manufacture comprising the degradable honeycomb form and the ceramic material,
the ceramic article when the honeycomb form has been removed, and
the ceramic article where the volume of the ceramic article which
originally contained the degradable honeycomb form are filled with a
ceramic material.

BRIEF DESCRIPTION OF THE DRAWINGS

honeycomb structure has been filled by ceramic deposits.

DETAILED DESCRIPTION OF THE
INVENTION AND PREFERRED EMBODIMENTS

As used herein:

"Ceramic-ceramic" describes a structure wherein one ceramic is
deposited in any manner upon a second ceramic material. Additional
layers of ceramic (the same or different) may also be subsequently
deposited.

"Metallic" refers to a metallic fabric having useful high tempera-
ture properties. Typical metallic fabrics include titanium, nickel, or
stainless steel.

"Organic" fibers or fabric includes, for example, aramids,
Nomex® (polyamide), Kevlar®, carbon, and the like. The organic
fibers or fabric have properties that they maintain their shape at
temperatures of between about ambient temperature and 1,300°C, and
when heated in an oxygen free atmosphere do not sag or deform

"Inorganic" fibers or fabrics refers, for example, to fiberglass, alumina borosilicate, silica, silicon carbide, silicon nitride, silicon boride, boron nitride, boron carbide and the like. Alumina borosilicate fabrics are available from Hexcel Corporation of Dublin, California.

"Organic" binder refers, for example, to resins to maintain the structural integrity of the honeycomb shape. Organic binder refers, for example, to phenol resins, epoxy resins, polyimide resins, polyphenylene sulfide, polybenzimidazole, polystrylypyridine (PSP), and the like.

"Inorganic" binder refers to inorganic materials which are useful to retain the structural integrity of the honeycomb shape. Inorganic binder refers to, for example, silica, titania, alumina, zirconia, and the like.

Referring then to Figures 1-8, the broadest embodiment of the present invention may be described by starting with a loosely woven fabric 20 in Figure 2 made up of metallic, organic or inorganic fiber. The fabric is formed in a general honeycomb shape. Preferably, the fabric is set in an organic or inorganic binder which is useful to
maintain the honeycomb shape. The honeycomb form may be fabric/binder of organic/ceramic (i.e. inorganic), organic/organic, metallic/organic, or inorganic/organic.

The honeycomb structure 20 is then placed in reactor 9 as shown in Figure 1. The process for deposition is described below.

Thus it is possible to obtain in a honeycomb shape:

a metallic fabric coated with ceramic, e.g., a titanium–silicon carbide coated honeycomb;

an organic fabric coated with ceramic, e.g., NOMEX coated with alumina from a sol gel; or

a pyrolyzed organic fabric coated with ceramic, e.g., carbon coated with alumina.

A preferred embodiment is a pyrolyzed organic honeycomb form upon which is deposited a ceramic.

Referring to Figures 1–8, the loosely woven fabric 20 is shown in Figure 2. The fabric is formed of any number of suitable reactive organic polymers which can be woven so long as the polymeric fiber generates a high char yield on initial pyrolysis and is then capable of being removed by subsequent pyrolysis or chemical degradation.

Typical organic polymers include aramid, Nomex®, Nomex/phenolic, polyacrylonitrile (PAN) or epoxy polymer. A preferred polymer fiber is polyacrylonitrile. The loosely woven organic polymer fabric woven in the desired honeycomb shaped fabric is available from, or can be woven by the Hexcel Corporation of Dublin, California 94566. The organic fabric usually has an organic resin or binder to maintain the honeycomb shape until the organic fiber (and binder) is pyrolyzed. Typical organic binder resins include, for example, phenols, epoxys, silicones, polyimides, and the like. A preferred polymeric binder is a phenolic resin.

The honeycomb structure 20 is then placed in reactor 9 as shown in Figure 1. Argon enters via value 2A, fluorometer 2B and line 2 through carburetor 1 containing ceramic precursor material and exits through line 3. Liquid precursors for the ceramic deposit in carburetor 1 include, for example trichloromethylsilane, dimethyl dichlorisilane and the like. Trichloromethylsilane is preferred to produce silicon carbide (SiC). A mixture of boron trichloride,
hydrogen, and silicon tetrachloride is preferred to produce silicon boride. A mixture of ammonia and silicon tetrachloride are preferred to produce silicon nitride. A mixture of ammonia and boron trichloride is preferred to produce boron nitride.

Additional argon is controlled by valve 5, flowmeter 5A and enters line 8 via line 5B, optional gas enters line 8 controlled by valve 6 and flowmeter 6A via line 6B and hydrogen may enter line 8, via line 7B controlled by valve 7 and flowmeter 7A. These gases mix in line 8 and enter reactor 9. Reactor 9 is a conventional ceramic deposition chamber and is heated between about 700 and 1,100°C, preferably between about 800 and 1,100°C. Products are removed via line 9A pass through condenser 10 through line 11 to scrubber 12. After the gases are scrubbed they are conveyed through line 13 to filter 14 and into line 15. Vent gas is introduced via line 16A, controlled by needle valve 16 into 17. Needle valve 18 controls the flow of gas to vacuum pump 19. The gases are then vented to the atmosphere.

In reactor 9 the pre-ceramic material, e.g., trichloromethylsilane is thermally decomposed at between about 900 and 1,100°C and the SiC produced is deposited fairly evenly on the loosely woven honeycomb fabric/binder as is shown by structure 30 in Figure 3. Usually between about a 100% to 300% by weight increase is preferred for the coated honeycomb structure 30, when the substrate is to be removed. If a large deposit (greater than 300% by weight) of ceramic material is initially made before the pyrolyzed fabric 21 is removed, the subsequent removal of the pyrolyzed fabric is usually incomplete. Large deposits cause the structure to become too difficult for the oxygen to penetrate to remove the pyrolyzed fabric.

Figure 4 is a cross-section of structure 30 along line 4-4 of Figure 30. It shows honeycomb 21 within ceramic coating 30. The ceramic layer shown in phantom outline 41 indicates that an additional layer of ceramic optionally is deposited. This additional layer of ceramic 41 may be the same or a different ceramic than was originally deposited and found in structure 30.
Figure 5 shows in breakaway view the honeycomb structure of Figure 3 in which all of the honeycomb cells are filled with ceramic deposit - a solid honeycomb 50.

Figure 6 shows the honeycomb structure 30 of Figure 3 in which structure 30 is pyrolyzed at between about 700 and 1,000°C in an restricted atmosphere having between about 2 to 5% oxygen by volume. The organic polymer fabric 20 is degraded and leaves a microstructure (opening, voids), but retains its geometric integrity having a porous structure for subsequent deposition of ceramic. The pyrolysis must be conducted (e.g., about 1 to 5 hrs.) so that no excessive exotherm occurs in a restricted oxygen environment. If an excess of oxygen is present, the carbon material present may burn at a temperature high enough to oxidize the ceramic, e.g., SiC or B₄C of the ceramic, and destroy the desired honeycomb structure.

Figure 7 shows a cross-section 70 of structure 60 along line 7-7. Openings 71 show the voids left in the ceramic when the honeycomb fiber is removed.

Figure 8 shows structure 80 as a monolithic structure wherein all of the voids left by pyrolyzing the fabric have been filled in with additional ceramic. These former voids are shown in phantom line 81. Further the honeycomb cells have been filled completely by the deposited ceramic. A ceramic structure such as 80 has enhanced physical properties such as low convective and radiative heat transfer and high interlaminor shear in comparison to a similar structure which is an open structure.

A more detailed description of the formation of an organic honeycomb/ceramic structure is given below.

A conventional chemical vapor deposition reactor is used to deposit refractory materials on substrates, such as honeycomb, see S. Motozima et al., in Bulletin of the Chemical Science of Japan, Vol. 48(5), pp. 1,463-1,466, published in 1975, which is incorporated herein by reference for the design of a chemical vapor deposition reactor. When the BCl₃, SiCl₄ and H₂ are replaced by the appropriate precursors, the corresponding ceramics, such as silicon carbide, silicon nitride, boron nitride and the like are deposited. This reactor consists of a mullite tube with a heated reaction chamber.
about 2.28 cm I.D. and 30.48 cm long. The reactor is heated in a
resistance furnace in the temperature range of 900 to 1,300°C and
held at pressures from 50 to 760 mm mercury. Reactant gases are
mixed with an inert carrier gas such as argon to obtain different
concentrations. Various substrates in honeycomb form are suspended
in the reactor tube for deposition. In the experimental procedure the
substrate is heated at a programmed heating rate in an inert gas until
a set temperature is obtained or suitable charred substrate was
produced. At this point the reactive gas is included and continued
until the desired deposition had occurred.

Honeycomb structures with the deposit are examined with X-ray
to determine the composition of the deposit and also oxidized at
1000°C to determine the concentration of refractory material.

The following Examples are intended to be illustrative, and not
to be limiting in any way.

EXAMPLE 1
CVD/CVI OF SiC

(a) (Organic/organic Honeycomb) The reaction system shown in
Fig. 1 was used to obtain a SiC deposit from trichloromethylsilane.
The substrate was honeycomb material made of carbon fiber (organic)
coated with phenolic resin (organic). Honeycomb material was 2.54
cm thick and cell walls were 0.32 cm. The honeycomb material was
heated to 275°C at 50°C/min in argon flowing at 230.9 cc/min and
held at this temperature for 5 min followed by continued heating to
950°C. The pressure in the system was 380 mm mercury. At this
point the silane was added to the argon stream. The concentration of
silane was 7.07%. The temperature was increased to 1,000°C and the
reactor held at this temperature for 321 min. Honeycomb cells were
obtained with an optimum yield of SiC of 100%, and a total deposit of
298.2% based on the char yield of the honeycomb.

(b) (Inorganic/Organic) The process described in subpart (a)
above is repeated except that a alumina borosilicate coated with
phenolic resin is used instead of the carbon fiber coated with phenolic
resin. Honeycomb cells are obtained with an optimum yield of SiC of
about 100% and a total deposit of 300% based on the fiberglass in the
honeycomb.
(c) (Metallic/Organic) The process described in Subpart (a) above is repeated except that a titanium fabric coated with a phenolic resin is used instead of the carbon fiber coated with a phenolic resin. Honeycomb cells are expected to be obtained with an optimum yield of SiC of about 100% and a total deposit of 300% based upon the titanium in the honeycomb.

**EXAMPLE 2**

**CVD/CVI OF SiC**

(Organic/Organic Honeycomb) A similar procedure was used as described in Example 1 except that the trichloromethylsilane concentration was 9.84% and hydrogen was added to the reaction system. The hydrogen concentration was 24.6%. The total flow rate was 256.1 cc/min and the deposition time 110.5 min. An optimum yield of SiC of 100% was obtained with a total deposit of 124.6%.

**EXAMPLE 3**

**CVD/CVI OF SiC**

(Inorganic/Organic Honeycomb) A similar procedure was used in Example 1 except 6.85% silane was used as the reactant gas and a NEXTEL (alumina borosilicate)/phenolic substrate was used. The deposit time was 79.3 min. An optimum yield of SiC of 100% was obtained and 83.6% total deposit.

**EXAMPLE 4**

**CVD/CVI OF SiC, B_4Si or BN**

(a) (Organic/Organic Honeycomb) A similar procedure as in Example 3 was used except the concentration of silane was 6.85% and the honeycomb was Nomex/Epoxy 832 with about 0.15 cm wide cell walls. The deposition time was 112.1 min. Instead of 275°C, the intermediate temperature in the program was 500°C. The maximum reactor temperature remained 1,100°C. The optimum SiC yield was 100% and the total deposit was 238.7%.

(b) B_4Si-- The procedure of Example 4 (a) was repeated using an equivalent amount of BCl_3, SiCl_4 and H_2 instead of silane. The corresponding B_4Si ceramic is expect to be deposited on the honeycomb substrate.

(c) BN-- The procedure of Example 4(a) is repeated using an equivalent amount of BCl_3 and ammonia instead of silane. The
corresponding BN ceramic is expected to be deposited on the honeycomb substrate.

**EXAMPLE 5**

**CVD/CVI OF SiC**

(Organic/Organic Honeycomb) A similar procedure was used in Example 1 except the concentration of silane was 6.04% and the pressure 760 mm of mercury. The deposition time was 111.9 min. The optimum yield of SiC was 89.8% and the total deposit 95.3%.

**EXAMPLE 6**

(Organic/Organic Honeycomb) A similar procedure was used as in Example 1 except the silane used was dichlorodimethylsilane. The concentration of silane was 7.07% and the pressure 760 mm mercury. The deposition time was 107.3 min. The optimum yield of SiC was 97.8% and the total deposition 73.1%.

**EXAMPLE 7**

**CVD/CVI of B₄Si**

(Inorganic/Inorganic Honeycomb) A similar procedure as is found in Example 2 above is used, however the honeycomb used in a NOMEX having a SiC binder. The Organic is oxidized in 4% oxygen at 700°C leaving a SiC structure having honeycomb shaped openings and holes in the honeycomb where the organic had been. Subsequently a B₄Si layer is deposited on the honeycomb structure as is described in Example 4(b).

**EXAMPLE 8**

**REMOVAL OF PYROLYZED ORGANIC HONEYCOMB**

The honeycomb structure produced in Example 1(a) above is placed in a chamber at about 900°C in a 4% oxygen atmosphere for 2hr. The SiC honeycomb structure does not have any residue of organic honeycomb.

**EXAMPLE 9**

**DEPOSITION OF CERAMIC INTO THE VOIDS**

The honeycomb structure produced in Example 7 above is placed in the deposition/infiltration chamber as described in Example 1(a) above. SiC is deposited in the holes (or openings) left by pyrolyzing the organic material present, using the conditions described in
Example 1(a) above. SiC is deposited in the voids using the conditions described in Example 1(a). A solid SiC honeycomb is obtained.

While some embodiments of the invention have been shown and described herein, it will become apparent to those skilled in the art that various modifications and changes can be made in the method to produce improved ceramic structures by CVD/CVI of metallic, ceramic or organic honeycomb structures and the structures obtained thereby without departing from the spirit and scope of the present invention. All such modifications and changes coming within the scope of the appended claims are intended to be covered thereby.
CERAMIC-CERAMIC HONEYCOMB
STRUCTURES AND METHOD THEREOF

ABSTRACT OF THE INVENTION

The present invention relates to a method for producing ceramic articles and the articles, the process comprising the chemical vapor deposition (CVD) and/or chemical vapor infiltration (CVI) of a honeycomb structure.

Specifically the present invention relates to a method for the production of a ceramic honeycomb structure, including:

(a) obtaining a loosely woven fabric/binder wherein the fabric consists essentially of metallic, ceramic or organic fiber and the binder consists essentially of an organic or inorganic material wherein the fabric/binder has and retains a honeycomb shape, with the proviso that when the fabric is metallic or ceramic the binder is organic only;

(b) substantially evenly depositing at least one layer of a ceramic on the fabric/binder of step (a); and

(c) recovering the ceramic coated fiber honeycomb structure.

In another aspect, the present invention relates to a method for the manufacture of a lightweight ceramic-ceramic composite honeycomb structure, which process comprises:

(d) pyrolyzing a loosely woven fabric a honeycomb shaped and having a high char yield and geometric integrity after pyrolysis at between about 700 and 1,100°C;

(e) substantially evenly depositing at least one layer of ceramic material on the pyrolyzed fabric of step (a); and

(f) recovering the coated ceramic honeycomb structure. The ceramic articles produced have enhanced physical properties and are useful in aircraft and aerospace uses.
