The subject invention pertains to a novel class of fire- and heat-resistant bisimide resins prepared by thermal polymerization of maleimido or citraconimido substituted 1-[(di(alkoxyphosphonyl)methyl)-2,4- and -2,6-diaminobenzenes. Typical polymer precursors have the chemical structure:

wherein R is alkyl, substituted alkyl or aryl, and R₁ is hydrogen or lower alkyl.

The polymer precursors are prepared by reacting 1-[(di(alkoxyphosphonyl)methyl)-2,4- and -2,6-diaminobenzenes with maleic anhydride or citraconic anhydride in a mole ratio 1:2. Chain extension of the monomers is achieved by reacting the mono-N-maleimido derivatives of 1-[(di(alkoxyphosphonyl)methyl)-2,4- and -2,6-diaminobenzenes with aryl tetracarboxylic dianhydrides, such as benzophenone tetracarboxylic dianhydride, or aryl diisocyanates, such as methylenebis(4-phenylisocyanate), in a mole ratio 2:1. The polymerization of the monomers is studied by differential scanning calorimetry (DSC) and the thermal stability of the polymers is ascertained by thermogravimetric analysis (TGA).

FIRE AND HEAT RESISTANT LAMINATING RESINS BASED ON MALEIMIDO AND CITRACONIMIDO SUBSTITUTED 1-(DIORGANOXYPHOSPHONYL)-METHYL-2,4-AND-2,6-DIAMINOBENZENES

ORIGIN OF THE INVENTION

The invention described herein was made in the performance of work under a NASA contract and is subject to the provisions of Section 305 of the National Aeronautics and Space Act of 1958; Public Law 85-568 (72 Stat. 435;42 U.S.C 2457).

BACKGROUND OF THE INVENTION

Related Applications

This is a division of application Ser. No. 641,147, filed 8/16/84, which is a continuation-in-part of our copending application Ser. No. 522,629, filed Aug. 12, 1983 now abandoned, which is directed to compounds and polymers having

![Chemical Structure](attachment:image.png)

repeating units, and is incorporated herein by reference. This application is also related to the following commonly assigned patent applications: U.S. Ser. No. 641,152 filed Aug. 16, 1984, which is directed to the above compounds and polymers; U.S. Ser. No. 641,142 filed Aug. 16, 1984, which is directed to the above mentioned compounds and polymers; U.S. Ser. No. 641,153 filed Aug. 16, 1984, which is directed to polyimides and copolyimides prepared from the present diaminobenzenes; and U.S. Ser. No. 641,143, now U.S. Pat. No. 4,536,565, filed Aug. 16, 1984, which is directed to polyimides and copolyimides from the present diaminobenzenes.

FIELD OF THE INVENTION

The invention relates to fire- and heat-resistant bisimide resins obtained by thermal polymerization of maleimido or citraconimido derivatives of 1-[diorganoxyphosphonyl]methyl]-2,4- and -2,6-diaminobenzenes.

DESCRIPTION OF THE ART

High temperature resistant polymers are used extensively in advanced aerospace structures in which structural integrity must be retained during continuous use at temperatures of 325° C. and above. The stringent requirements of space technology and of other industrial applications for thermal protective materials have led to the development of several classes of heat- and fire-resistant heterocyclic polymers. Aromatic polyimides have met these requirements to a large extent and are considered heat-resistant. However, these polymers were found to be inherently brittle because of the extensive crosslinking which occurs during polymerization. Several amine-capped liquid elastomeric prepolymers reacted with bismaleimides to produce polymers. See for example, P. Kovacicek, U.S. Pat. No. 2,818,405; Chem. Abstracts, 52, 5018e (1958). However, these polymers could not be considered heat-resistant.

Several investigations concerning flame retardation of polyimide resins prepared from phosphorus-containing prepolymers, end-capped with reactive maleimido rings, have been recently reported. Bismide resins based on bis(m-aminopheny1)methylphosphine oxide as well as bismide and trimide resins based on tris(m-aminopheny1)phosphine oxide have been prepared and tested as a matrix for fiber-reinforced composites. See, for example, U.S. Pat. No. 4,276,344 and I. K. Varma, G. M. Fohlen and J. A. Parker, J. Macromol.Sci-Chem., (1), 39 ff (1983). Some of the polymer precursors show a relatively high curing temperature or yield inherently brittle polymers due to their high cross-linking density. It is desirable to have organic matrix resins with a low curing temperature so as to obtain polymers with reduced brittleness.

Some patents of general interest in this field include the following U.S. Pat. Nos. 3,929,713; 4,269,961; 4,107,153; 4,276,344; 4,283,522; and 4,421,820.

Some references of the inventors, which describe fire resistant compositions of phosphorus-containing polymers and the monomers thereof, include the following:

Initial attempts to overcome these processability problems led to the development of addition polyimides based on short, preimidized segments which polymerize thermally through end groups without loss of volatiles. However, these polymers were found to be inherently brittle because of the extensive crosslinking which occurs during polymerization. Several amine-capped liquid elastomeric prepolymers reacted with bismaleimides to produce polymers. See for example, P. Kovacicek, U.S. Pat. No. 2,818,405; Chem. Abstracts, 52, 5018e (1958). However, these polymers could not be considered heat-resistant.
It is an object of the present invention to provide novel phosphorous- or phosphorous and chlorine-containing maleimido and citraconimido end-capped monomers which have a relatively low melting temperature and can polymerize at moderate temperatures to produce rigid bisimide resins without elimination of volatiles or formation of voids.

It is a further object of the invention to provide polymer precursors soluble in solvents such as methyl ethyl ketone (MEK), dimethyl ketone (acetone), and tetrahydrofuran (THF) which are very suitable and often referred as "varnish" solvents for composite fabrication. Moreover, molten polymer precursors may be used as adhesives without utilization a solvent due to their low melting temperature and the higher polymerization temperature.

It is a further object of the invention to provide bisimide resins obtained by thermal polymerization of monomers which are improved with respect to one or more of the properties limiting oxygen index (LOI), char yield and smoke evolution. They are useful for purposes such as, for example, lamination which combine good fire- and heat-resistance with good mechanical properties, for composites and laminates for use in aircraft structures.

It is a further object of the invention to provide bisimide resins with reduced brittleness. For this purpose the formula weight and the length of the bridge between the two maleimido groups was increased by incorporation of benzophenone tetracarboxylic dianhydride or methylenebis(4-phenylisocyanate) as a building unit of this bridge. The chain extension of monomers is expected to reduce brittleness of the bisimide resins, since larger polymer segments would be available for internal motions after crosslinking.

BRIEF DESCRIPTION OF THE DRAWING

The invention is further described with relevance being made to the accompanying drawing wherein FIG. 1 is a graph illustrating the reduced smoke evolution of some polymers which results from practicing the present invention.

BRIEF SUMMARY OF THE INVENTION

In accordance with the invention various polymer monomers or precursors are based on maleimido or citraconimido substituted 1-[(diorganooxyphosphonyl)methyl]-2,4- and -2,6-diaminobenzenes of the formula:

\[ \text{(RO)}_2P\text{-CH}_2\text{R} \]

wherein \( R \) is an organo group selected from alkyls, substituted alkyls and aryls; and \( R^1 \) is hydrogen or lower alkyl. These monomers are thermally copolymerized with dianhydrides and diisocyanates to produce fire- and heat-resistant polymers which are used as laminating resins, without the elimination of volatiles or formation of voids. The polymers combine one or more properties of heat-resistance low flammability, high char yield, low smoke evolution, reduced brittleness and good mechanical properties.

DETAILED DESCRIPTION OF THE INVENTION

The starting material of the present invention is a mixture of 1-[(diorganooxyphosphonyl)methyl]-2,4 and -2,6-diaminobenzenes 1.

\[ \text{(ClCH}_2\text{CH}_2\text{O})_2\text{P}\text{-CH}_2\text{NH}_2 \]

This mixture is a consequence of the method of synthesis (See Examples 1 to 4 below) and the 2,4-diamino isomer predominates. It is unnecessary for purposes of the present invention to separate the isomers. Compounds 1, though a mixture, will referred to as a compound having the chemical structure of the predominant 2,4-diamino isomer. R is an alkyl, substituted alkyl or aryl group. Examples of R are methyl, ethyl, n- and iso-propyl, higher (e.g., C4 to C10) alkyl, haloalkyl, especially chloroethyl; and aromatic groups, such as phenyl, substituted phenyl, naphthyl, e.g., tolyl, etc. Ethyl and 2-chloroethyl groups are preferred, e.g., Compounds 1a and 1b.

The diamines 1 may be prepared as described in the related application (ARC-11425-2) referred to above. Briefly stated, a 1-[(diorganooxyphosphonyl)methyl]-
benzene, \((\text{RO})_2\text{P(O)CH}_2\text{C}_6\text{H}_5\), is nitrated by a mixture of fuming nitric and sulfuric acid to the corresponding dinitro derivatives which are then reduced by catalytic hydrogenation to the diamino species 1. 1-[(Diethoxyphosphonyl)methyl]benzene and 1-[(di-2-chloroethoxyphosphonyl)methyl]benzene, both of which are known compounds, are used as starting materials for preparing the diamines 1a and 1b respectively.

The subject invention pertains to the synthesis of N-maleimido or N-citraconimido derivatives of diamines 1, which may be thermally polymerized. More particularly, the polymer precursors 2:

\[
\begin{align*}
\text{Ar} & \quad \text{O} \quad \text{O} \\
\text{O} & \quad \text{O} \quad \text{O} \\
\text{N} & \quad \text{N} \quad \text{N}
\end{align*}
\]

where

2a: \(R = \text{CH}_2\text{CH}_3\); \(R_1 = \text{H}\)
2b: \(R = \text{CH}_2\text{CH}_2\text{Cl}; R_1 = \text{H}\)

are synthesized by condensation of diamines 1 (1 mol) with an anhydride, such as maleic anhydride (2 mol), where \(R_1\) is hydrogen. Intermediate bismaleamic acid is cyclodehydrated “in situ” with acetic anhydride using sodium acetate as catalyst in boiling acetone. (Examples 5 and 6).

Similarly, the polymer precursors 3 where Compound 3a (\(R = \text{CH}_2\text{CH}_3\) and \(R_1 = \text{CH}_3\)) and Compound 3b (\(R = \text{CH}_2\text{CH}_2\text{Cl}; R_1 = \text{CH}_3\)) are synthesized by condensation of diamines 1 with an anhydride of the formula:

\[
\begin{align*}
\text{CO} & \quad \text{O} \\
\text{O} & \quad \text{O} \\
\text{R} & \quad \text{R}
\end{align*}
\]

where \(R_1\) is alkyl having one to six carbon atoms, e.g., methyl, where citraconic anhydride is used (See Examples 7 and 8).

The above methods produce a diamine/anhydride combining about one equivalent of diamine with about two equivalents of anhydride. That is to say, more than twice as much anhydride per diamine on an equivalent basis is required to obtain compounds 2, 2a, 2b, 3a and 3b and the like.

If a polymer precursor having a free amine is desired, then a diamine such as 1 and an anhydride are combined in about a 1:1 equivalent ratio. That is to say, 1-[(Diorganooxyphosphonyl)methyl]benzene maleimide of the formula:

\[
\begin{align*}
\text{O} & \quad \text{N} \\
\text{N} & \quad \text{N} \\
\text{O} & \quad \text{O}
\end{align*}
\]

is thus produced, where \(R\) is an organo group selected from alkyls, substituted alkyls and aryls; \(A\) is a \(-\text{NH}_2\) or a

\[
\begin{align*}
\text{N} & \quad \text{O} \\
\text{O} & \quad \text{O}
\end{align*}
\]

group and \(B\) is the other group; where \(R_1\) is hydrogen or lower alkyl, and \(A\) and \(B\) are in the 2,4 or 2,6-positions (See Examples 11 and 12). Preferred embodiments of these monomaleimides are those where \(R\) is ethyl or 2-chloroethyl, and \(R_1\) is hydrogen or methyl.

Chain extension of the phosphonyl group connecting the two maleimido groups is accomplished by reaction with an aryl tetracarboxylic dianhydride

\[
\begin{align*}
\text{Ar} & \quad \text{O} \\
\text{O} & \quad \text{O} \\
\text{CO} & \quad \text{O} \\
\text{O} & \quad \text{O}
\end{align*}
\]

where \(\text{Ar}\) is a tetravalent aromatic group containing from 6 to 20 carbon atoms. Thus, \(\text{Ar}\) may be a substituted aryl group, phenyl, naphthyl, phenanthryl, benzophenonyl and the like. Preferred embodiments of the present invention include benzophenone tetracarboxylic dianhydride and pyromellitic dianhydride. Chain extension also includes aryl, alkylene and aryalkylene diisocyanates of the formula OCN-R2-NCO, where \(R_2\) is a disubstituted aryl, such as phenyl, naphthyl; alkylene such as ethylene, pentylene, hexylene; or aryalkylene, such as methylenebisphenyl and the like. Preferred embodiments of the present invention include 1,3-phenylene disiocyanate, methylene bis(4-phenyl isocyanate), 2,4-toluene disiocyanate and the like.

The polymerization of the dianhydrides may be considered to be a two-stage polycondensation method. The first stage of the condensation is carried out in a solvent. The formation of the bismaleimide acid is exothermic and is carried out at ambient temperature or slightly above. Under these conditions the extent of cyclodehydration is negligible.

Dehydration, the second stage of the imidization process can be carried out by thermal or chemical means. After removal of the solvent the thermal process involves heating the polymer at about 280° C. in a vacuum for 2 hr. The chemical means includes azoetroping the water of cyclization with benzene or refluxing in acetic anhydride with sodium acetate as catalyst. The completion of the cyclization is ensured by heating the polymers at about 200° C. in a vacuum oven for two hours (See Examples 5 and 9).

Specifically, in the first stage the polymer precursors 4:
Overall the polymerization of diisocyanate and Compound 1 may be summarized as is shown in the sequence below having the bracketed recurring unit:

$$OCN-R^2-NCO + 2$$

where R and R^2 are defined hereinabove. "y" is a positive integer. An embodiment of the present invention is "y" between 1 and 1000. A preferred embodiment is "y" between 10 and 100.

In all cases of polymer precursors the diamino moiety is shown as the 2,4-diamino compound (which predominates) but it will be understood that the 2,6-diamino compound is also present.

Bisimide resins are prepared by thermal polymerization of the polymer precursors. The polymerization behavior of the polymer precursors was analyzed and determined by differential scanning calorimetry (DSC) in nitrogen atmosphere. The results are listed in Table 1. In this Table, T1 is the temperature of first energy release (start of polymerization), T2 is the temperature of exothermic peak position, and T3 is the temperature of termination of polymerization. m-Phenylenesimide, which is a conventional polymer precursor, is shown in this table as Experiment Number 6.

The thermal polymerization of the polymer precursors is achieved by heating them into an air draft oven at 180°C for about 20 min until molten and subsequently at 230°C for 2 hr.

The thermal stability of the polymers is ascertained by thermogravimetric analysis (TGA) both in N\textsubscript{2} and air atmosphere. The results are shown in Table 2. The polymers obtained from the precursors 2, 3, 4, 5 and 6 by the thermal process mentioned above are referred to by the numbers 2', 3', 4', 5' and 6' respectively. PDT is the polymer decomposition temperature, PDT\textsubscript{max} is the maximum polymer decomposition temperature, and TCP is the temperature of complete pyrolysis. As is
seen from Table 2, char yield is substantially greater with the phosphorus-containing polymers of the present invention than with conventional polymer (Polymer 6'). Table 3 sets forth data demonstrating superior fire-resistance of some polymers. In this Table, LOI is the limiting oxygen index determined according to the ASTM D 2863-74 method. LOI value indicates resistance to ignition. As is seen in Table 3 the LOI values of polymers of the invention are substantially greater than that of comparable Polymer 6'. The smoke density is determined according to the test method described by National Fire Protection Assoc., Bull. No. NFPA 258-T (1974). FIG. 1 shows the smoke density (Ds) value of smoke evolved from some polymers under flaming conditions (heat flux = 3.3 W/cm²) as a function of the irradiation time. The smoke density value indicates the flammability. As will be seen from Table 3 as well as from FIG. 1, the polymers of the present invention show a substantially lower smoke density than the conventional polymer 6'.

The following examples will serve to illustrate the practice and advantages of the invention, and are not to be construed as limiting the scope of the invention. Examples 1 to 4 illustrate the preparation of diamines 1. Examples 5 to 12 illustrate the preparation of the polymer precursors.

The structure of the polymer precursors is confirmed by elemental analysis, proton magnetic resonance (¹H-NMR) and infrared spectroscopy (IR) and by gas chromatography-mass spectroscopy (GC-MS). Melting temperatures of most of the polymer precursors synthesized were not recorded by the standard test methods because they did not show a clear melting point, probably due to the formation of crossbonds on gradual heating of these compounds.

EXAMPLE 1

1-[(Diethoxyphosphonyl)methyl]-2,4- and 2,6-dinitrobenzenes

1-[(Diethoxyphosphonyl)methyl]benzene (21.76 g, 95 mmol) was added dropwise to a mixture of fuming nitric acid (16.3 g) and fuming sulphuric acid (54.3 g), containing 30% 20%, at 55°C. The addition of the phosphonate lasted 1 hr and subsequently the mixture was heated at the same temperature for another hour. The mixture was poured into 1 liter of ice water and extracted with chloroform. The layer of chloroform was subsequently washed by a 5% sodium bicarbonate solution and with water, dried (sodium sulfate) and concentrated to give a viscous liquid (4.92 g) diluted with about 100 ml of acetone-ether (1:10 vol/vol). Upon cooling of the solution the title product was crystallized (2.80 g, 42%, mp 79°–84°C). Recrystallizations from acetone-ether (1:10 vol/vol) gave an analytical sample: mp 83°–85°C. Structure was confirmed by ¹H-NMR and chemical analysis.

EXAMPLE 3

1-[(Di-2-chloroethoxyphosphonyl)methyl]-2,4- and 2,6-dinitrobenzenes

1-[(Di-2-chloroethoxyphosphonyl)methyl]benzene (5.13 g, 17 mmol) was added dropwise to a mixture of fuming nitric acid (4.0 g) and fuming sulphuric acid (13.0 g), containing 30% SO₃ at 55°C. The addition of the phosphonate lasted 0.5 hour and subsequently the mixture was heated at the same temperature for 4 hours longer. The mixture was poured into 300 ml of ice water and extracted with chloroform (150 ml). The chloroform solution was washed with 5% sodium bicarbonate solution and with water, dried (sodium sulfate) and concentrated to give a viscous liquid (4.92 g) diluted with about 100 ml of acetic-ether (1:10 vol/vol). Upon cooling of the solution the title product was crystallized (2.80 g, 42%, mp 79°–84°C). Recrystallizations from acetone-ether (1:10 vol/vol) gave an analytical sample: mp 83°–85°C. Structure was confirmed by ¹H-NMR and chemical analysis.

EXAMPLE 4

1-[(Di-2-chloroethoxyphosphonyl)methyl]-2,4- and 2,6-diaminobenzenes, 1b

Recrystallized product of Example 3 (2.27 g, 58.6 mmol) was dissolved in 40 ml of absolute ethanol and a small amount of catalyst, 10% palladium on carbon, was added. The hydrogenation was carried out as in Example 2. A solid product was obtained (1.88 g, 98%, mp 105°–109°C). Recrystallizations from benzene gave an analytical sample: mp 116°–119°C. Structure was confirmed by ¹H-NMR and chemical analysis.

EXAMPLE 5

Bismaleimide, 2a

To a vigorously stirred solution of 1a (7.37 g, 28.5 mmol) in acetic anhydride (61.6 g, 62.8 mmol) was added portion-wise so that the temperature was maintained at about 40°C. After stirring at room temperature for about 30 min. the bismaleimide was precipitated as a pale yellow solid. Stirring was continued for 1.5 hr. More to complete the reaction. Cyclodehydration of bismaleimide to bismaleimide was carried out by adding acetic anhydride and fused sodium acetate (300 ml and 27 g respectively per mole of maleic anhydride) to the reaction mixture and refluxing for 2 hr. The suspension became a brown solution during the first 15 min. of refluxing. Most of the acetone was evaporated at the end of the reaction. The mixture was poured into ice water and extracted by chloroform. The layer of chloroform was subsequently washed by a 5% aqueous solution of NaHCO₃, followed by water and then dried, (MgSO₄). The concentrate obtained after removing of volatile components using a rotary evaporator was dried in a vacuum oven at about 50°C overnight. Bismaleimide 2a was obtained as a brown solid (10.96 g, 92%) and purified from tetrahydrofuran/ether.
isolation of the bismaleimide 4b was carried out as in Example 9. The yield of the reaction was 72% (2.46 g).

EXAMPLE 11
Bismaleimide, 5a
Diamine 1a (8.27 g, 32.0 mmol) reacted with maleic anhydride (3.45 g, 35.2 mmol) according to the procedure described in Example 5 to yield the mono-N-maleimido derivative of 1a.

Methylenebis(4-phenylisocyanate) (4.00 g, 16.0 mmol) dissolved in acetone was rapidly added to a vigorously stirred solution of mono-N-maleimido derivative of 1a in acetone under nitrogen atmosphere. After subsiding, the exothermic reaction the mixture was heated to 50°-60° C. for 1 hr. Bismaleimide 5a (12.16 g, 82%) was precipitated by adding ether to the reaction mixture and purified from acetone/ether.

EXAMPLE 12
Bismaleimide, 5b
The mono-N-maleimido derivative of 1b was prepared by reacting diamine 1b (4.25 g, 13.0 mmol) with maleic anhydride (1.40 g, 14.3 mmol) as in Example 5. To a vigorously stirred solution of the mono-N-maleimido derivative of 1b in acetone, methylenebis(4-phenylisocyanate) (1.62 g, 6.5 mmol) was rapidly added portionwise to a stirred Solution Of diamine la (3.89 g, 15.1 mmol) in acetone under nitrogen atmosphere. After the exothermic reaction subsided, the mixture was heated to 50°-60° C. for 1 hr. Bismaleimide 5b (5.95 g, 86%) was precipitated by adding ether to the reaction mixture and purified from acetone/ether.

While the present invention has been described with reference to specific embodiments thereof, it will be understood by those skilled in this art that various changes may be made and that equivalent steps may be substituted without departing from the true spirit and scope of the present invention. All such modifications or changes are intended to be included within the scope of the following claims.

We claim:

1. A method of producing a mono maleimide of the formula:

$$\text{R} = \text{organ group selected from alkyl, halogenated alkyls and aryls;}$$
$$\text{A} = \text{NH}_2$$

B is the other group, wherein R is hydrogen or lower alkyl, and A and B are in the 2,4 and 2,6-positions, which method comprises:

(a) reacting about one equivalent of an amine of the formula:

$$\text{R} = \text{organ group selected from alkyls having from 1 to 10 carbon atoms, halogenated alkyls and aryls;}$$
$$\text{A} = \text{NH}_2$$

with about one equivalent of an anhydride of the formula:

$$\text{R} = \text{organ group selected from alkyls having from 1 to 10 carbon atoms, halogenated alkyls and aryls;}$$
$$\text{A} = \text{NH}_2$$

and

B is the other group, wherein R is hydrogen or lower alkyl, and A and B are in the 2,4 and 2,6-positions, which method comprises:

(a) reacting about one equivalent of an amine of the formula:

$$\text{R} = \text{organ group selected from alkyls having from 1 to 10 carbon atoms, halogenated alkyls and aryls;}$$
$$\text{A} = \text{NH}_2$$

with about one equivalent of an anhydride of the formula:

wherein:

$$\text{R}$$ is an organo group selected from alkyl, halogenated alkyls and aryls;
$$\text{A}$$ is $\text{NH}_2$ or

wherein:

$$\text{R}$$ is an organo group selected from alkyl, halogenated alkyls and aryls;
$$\text{A}$$ is $\text{NH}_2$ or
and
(b) thereafter recovering said maleimide.

8. The method of claim 7 wherein R is ethyl or 2-chloroethyl.
9. The method of claim 7 wherein R¹ is hydrogen or methyl.
10. A mono maleimide of the formula:

\[ (\text{RO})_2P\text{--CH}_2\text{--O} \]

wherein:
R is an organo group selected from alkyl, substituted alkyls and aryls:
A is \(-\text{NH}_2\) or

wherein R¹ is hydrogen or lower alkyl; and
B is the other, and A and B are in the 2,4 or 2,6-positions relative to the (phosphonyl)methyl group.
11. The mono maleimide of claim 10 wherein said maleimido groups are predominantly in the 2 and 4 positions.
12. The mono maleimide of claim 11 wherein R¹ is hydrogen.
13. The mono maleimide of claim 11 wherein R¹ is alkyl.
14. The mono maleimide of claim 10 wherein R¹ is methyl.
15. The mono maleimide of claim 12 wherein R is alkyl.
16. The mono maleimide of claim 15 wherein R is ethyl.
17. The mono maleimide of claim 12 wherein R is halogenated alkyl.
18. The mono maleimide of claim 17 wherein R is 2-chloroethyl.
19. The mono maleimide of claim 11 wherein R is halogenated alkyl.
20. The mono maleimide of claim 19 wherein R is 2-chloroethyl.

...
