Galerkin/Runge-Kutta Discretizations for Parabolic Equations with Time Dependent Coefficients

Stephen L. Keeling*

Abstract. A new class of fully discrete Galerkin/Runge-Kutta methods is constructed and analyzed for linear parabolic initial boundary value problems with time dependent coefficients. Unlike any classical counterpart, this class offers arbitrarily high order convergence while significantly avoiding what has been called order reduction. In support of this claim, error estimates are proved, and computational results are presented. Additionally, since the time stepping equations involve coefficient matrices changing at each time step, a preconditioned iterative technique is used to solve the linear systems only approximately. Nevertheless, the resulting algorithm is shown to preserve the original convergence rate while using only the order of work required by the base scheme applied to a linear parabolic problem with time independent coefficients. Furthermore, it is noted that special Runge-Kutta methods allow computations to be performed in parallel so that the final execution time can be reduced to that of a low order method.

*Supported by the National Aeronautics and Space Administration under NASA Contract No. NAS1-18107 while in residence at the Institute for Computer Applications in Science and Engineering (ICASE), NASA Langley Research Center, Hampton, VA 23665-5225.
1 Introduction.

In this paper, linear parabolic initial boundary value problems with time dependent coefficients are considered. Specifically, the goal is to construct and analyze fully discrete approximations to the unique solution $u(x,t)$ of:

$$\begin{cases}
\frac{\partial u}{\partial t} = -L(t)u & \text{in } \Omega \times [0,t^*] \\
u = 0 & \text{on } \partial \Omega \times [0,t^*] \\
u(x,0) = u_0(x) & \text{in } \Omega,
\end{cases}$$

where:

$$L(t)u \equiv - \sum_{i,j=1}^{N} \partial_{x_i} (\ell_{ij}(x,t) \partial_{x_j} u) + \ell_0(x,t)u.$$

Here, $\Omega$ is a bounded domain in $\mathbb{R}^N$ with $\partial \Omega$ sufficiently smooth. Also, $\ell_{ij}(x,t)$ and $\ell_0(x,t)$ are assumed to be smooth. Further, on $\tilde{\Omega} \times [0,t^*]$, the matrix $\{\ell_{ij}\}_{i,j=1}^{N}$ is symmetric and uniformly positive definite and $\ell_0$ is non-negative. Also, the initial data $u_0$ is assumed to be both sufficiently smooth and compatible, and precise hypotheses on the required smoothness of the solution $u$ are made as needed.

Now, for $1 \leq p \leq \infty$ and integers $s \geq 0$, let $W^{s,p} \equiv W^{s,p}(\Omega)$ represent the well-known Sobolev spaces consisting of functions with (distributional) derivatives of order $\leq s$ in $L_p \equiv L_p(\Omega)$. Also, let $\| \cdot \|_{W^{s,p}}$ denote the usual norm. Then, in particular, take $H^s \equiv W^{s,2}$ and denote its norm by $\| \cdot \|_s$. In addition, let $H^1_0$ be the subspace of $H^1$ consisting of functions vanishing on $\partial \Omega$ in the sense of trace. Further, let the inner product on $L_2$ be denoted by $(\cdot,\cdot)$, and the associated norm by $\| \cdot \|$. Next, given Hilbert spaces $H$, $H_1$, and $H_2$, $B(H_1, H_2)$ represents the Hilbert space of bounded linear operators from $H_1$ into $H_2$, and $B(H) \equiv B(H,H)$. Also, for $t_2 > t_1$, $C^l([t_1, t_2], H)$ denotes the Banach space of operators, continuously differentiable to order $l \geq 0$, from $[t_1, t_2]$ into $H$. See Adams [1] for more details.

Now for each $t \in [0,t^*]$, let $L(t)$ be extended to be $L_2$-selfadjoint with domain $H^2 \cap H_0^1$. Also, assume that for $l \geq 0$ and $m \geq 0$ sufficiently large, $L(t) \in C^l([0, t^*], B(H^{m+2} \cap H_0^1, H^m))$ so that:

$$\|L(t)u\|_m \leq c(l,m)\|u\|_{m+2} \quad \forall u \in H^{m+2} \cap H_0^1$$

where $L(t) \equiv D_1^l L(t)$. Note that here and throughout this work, $c$ (sometimes with a subscript) is used to denote a general positive constant, not necessarily the same in any two places. Moreover, if in a given (in)equality, there is a crucial element upon which $c$ is meant to depend, such dependence is indicated explicitly as in (1.2). Next, introducing the $L_2$-selfadjoint solution operator $T(t)$ for which $T(t)L(t) = I$ on $H^2 \cap H_0^1$ and $L(t)T(t) = I$ on $L_2$, assume that for $l \geq 0$ and $m \geq 0$ sufficiently large, $T(t) \in C^l([0, t^*], B(H^m, H^{m+2} \cap H_0^1))$ so that:

$$\|T(t)u\|_{m+2} \leq c(l,m)\|u\|_m \quad \forall u \in H^m$$

where $T(t) \equiv D_1^l T(t)$. Finally, assume that for sufficiently large $l \geq 0$ and $m \geq 0$, the solution $u$ and the data $u_0$ satisfy:

$$\sup_{0 \leq t \leq t^*} \|\partial_t^l u(t)\|_m \leq c(m,l)\|u_0\|_{m+2l}.$$

For details connected with (1.2)-(1.4), see Sammon [16].
A rough description of the results now follows. For this, let $h$ and $k$ denote spatial and temporal discretization parameters respectively, and suppose that $U^n_h$ is a fully discrete approximation to $u(nk)$ obtained according to the base scheme (1.38) described below. Now, in section 3, the error committed by (1.38), is shown to satisfy:

\[
\max_{0 \leq n \leq n^*} \|U^n_h - u^n\| \leq c(h^r + k^\mu + h^k \mu^{-\frac{1}{2}} + h^2 k^{\mu-1})||u^0||_\alpha
\]

where $\alpha \equiv \max(r + 1, 2\mu + 2)$, $\mu \equiv \min(\nu, q + 1)$, $q$ is the number of Runge-Kutta stages, and $r$ and $\nu$ represent respectively, optimal exponents, characteristic of the Galerkin method and the Runge-Kutta method upon which the fully discrete scheme is based. Note that under the mild condition that either $r \leq 2\mu$ or $h^2 \leq ck$, the above error is $O(h^r + k^\mu)$. Further, it is explained below that the methods which are most easily implemented have the property that $\nu \leq q + 1$ which makes the estimate optimal. It is also worth mentioning that inverse properties (associated with the use of a quasi-uniform triangulation of $\Omega$) are never explicitly assumed, and as explained after Lemma 3.8, the constructions of section 2 are required for this.

Next, section 4 deals with (1.46), a variant of the base scheme which incorporates a preconditioned iterative method (PIM) for the time stepping equations (1.40). Specifically, these equations are solved only approximately at the $n$th time level with say, $l_n$ outer iterations (4.5), and $j_n$ inner (PIM) iterations (4.11), and it is shown that the above convergence rate can be preserved while keeping $\frac{1}{n} \sum_{n=0}^{n^*-1} l_n j_n$ bounded independently of $h$ and $k$. Hence, the order of work is asymptotically as that for a linear parabolic problem with time independent coefficients. Additionally, in [14], semilinear and quasilinear problems are considered, and the latter are treated with methods such as those reported here to obtain comparable results.

It should also be mentioned that the discovery of the methods described below was fortuitous. Note that there are extrapolation options other than (1.35) which are apparently more natural. For example, $D^t$ could be replaced by $T^t$ in (1.35) since the latter is consistent with (1.39). This idea is considered together with (1.39) in a computational section. However, under rather general conditions, (1.5) is proved and demonstrated computationally only for (1.38) and (1.46). In fact, it has been reported by many authors ([7], [13], [8]) that unless the solution to the differential equation satisfies very restrictive conditions, a classical fully discrete scheme fashioned after (1.23) cannot be expected to offer optimal order convergence. Furthermore, with regard to efficiency, (1.39) requires the formation of $q$ new stiffness matrices at every time step. On the other hand, (1.38) and (1.46) require only the formation of a single such matrix and, at the expense of at most $100q^{-1}\%$ more storage, the recall of $\mu - 1$ of its counterparts formed at previous time steps.

In [7], Crouzeix analyzes (1.39), and with Butcher's conditions $C(p - 1)$ and $B(\nu)$, [5] he establishes the $L_2$ estimate:

\[
\max_{0 \leq n \leq n^*} \|U^n_h - u^n\| = O(h^r + k^{\min(p\nu)}).
\]

Since $O(h^r + k^\nu)$ has not generally been observed experimentally, this suboptimal phenomenon has been called order reduction. Note further that this $L_2$ estimate depends upon the assumption that the stages are computed exactly. On the other hand, in [13], Karakashian considers approximating the stages with a PIM, and proves that the above estimate holds while the order of work is kept optimal. Also, he constructs collocation type implicit Runge-Kutta methods (IRKM's) for which $p = \nu = q + 1$. Nevertheless, such methods have limited stability for $q \geq 3$. In fact, there is a general trade-off among IRKM's in the sense that the more stable methods suffer more from order...
reduction while those which do not suffer so, are not as stable. However, when (1.39) is modified as in (1.38), it is possible to achieve high order even for very stable methods. For example, in section 4, an algebraically stable IRKM is used for a problem of the form (1.1), and optimal order convergence is obtained with (1.46) but not with a counterpart based on (1.39).

Douglas, Dupont and Ewing [10] have analyzed Galerkin/Crank-Nicholson fully discrete approximations for a class of quasilinear parabolic problems, proving an optimal \( L_2 \) estimate for a method which is second order in time. Also, this rate was shown to be preserved by an algorithm in which the time stepping equations are solved only approximately with an optimal order of work. Then studying (1.1), Bramble and Sammon [3] have obtained similar results for some Galerkin/Obrechkoff fully discrete approximations, proving optimal \( L_2 \) estimates for methods up to fourth order in time. Finally, note that in [9], Dougalis and Karakashian analyze Galerkin/Runge-Kutta fully discrete approximations for the Korteweg-De Vries equation. In fact, they prove optimal \( L_2 \) estimates for some modified IRKM's which are up to fourth order. Hence, the spirit of their work is similar to that of the present study.

In the remainder of this section, there is a presentation of material relevant to the spatial and temporal discretizations considered here, which concludes with a precise definition of the schemes for which the above claims are made.

Spatial Discretizations

To make the following machinery more definite, consider the Ordinary Galerkin Method for the spatial approximation of the solution to (1.1). Let \( D(t)(\cdot, \cdot) \) be a bilinear form defined by:

\[
D(t)(v, w) \equiv \sum_{i,j=1}^{N} (\ell_{ij}(t) \partial_{x_i} v, \partial_{x_j} w) + (\ell_{0}(t)v, w) \quad v, w \in H_0^1.
\]

Next, let \( S_h \) represent an approximation subspace consisting of continuous, piecewise polynomials of degree \( \leq r - 1 \), vanishing on \( \partial\Omega \). Then, take \( T_h(t) : L_2 \rightarrow S_h \) to be an approximation to the solution operator \( T(t) \) defined by:

\[
D(t)(T_h(t)w, \chi) \equiv (w, \chi) \quad \forall w \in L_2, \quad \forall \chi \in S_h.
\]

For more examples of Galerkin methods satisfying the assumptions enumerated below, see Bramble, Schatz, Thomée, and Wahlbin [4], and Sammon [16], [17].

Depending on the Galerkin method used for the spatial approximation, let \( H_E \) be a linear space equipped with a norm \( \| \cdot \|_E \) and satisfying the following properties. Suppose \( H^2 \cap H_0^1 \subset H_E \) and that:

\[
\begin{align*}
(1.6) \quad & \|v\|_1 \leq c\|v\|_E & \forall v \in H_E, \\
(1.7) \quad & \|v\|_E \leq c\|v\|_2 & \forall v \in H^2.
\end{align*}
\]

For example, for the method described above, take \( H_E = H_0^1 \). Now let \( \{S_h\}_{0<h<1} \) be a family of finite-dimensional subspaces of \( H_E \) satisfying the following for some integer \( r \geq 2 \):

\[
\begin{align*}
(1.8) \quad & \inf_{\chi \in S_h} \{\|v - \chi\| + h\|v - \chi\|_E \leq ch^s\|v\|_s \} \quad \forall v \in H^s \cap H^1_0, \quad 2 \leq s \leq r.
\end{align*}
\]

Then suppose that for each \( t \in [0, t^*] \), a corresponding family of operators \( \{T_h(t)\}_{0<h<1} \) is given satisfying:
i. $T_h(t) : L_2 \rightarrow S_h$ is selfadjoint, positive semidefinite on $L_2$, and positive definite on $S_h$.

ii. For $0 < h < 1$, $T_h(t) \in C^l([0, t^*], B(L_2, S_h))$ for $l \geq 0$ sufficiently large.

iii. For $2 \leq s \leq r$, $0 \leq t \leq t^*$, and $l \geq 0$ as large as required in the sequel:

\begin{equation}
\|[T^{(l)}(t) - T_h^{(l)}(t)]v\| + h\|[T^{(l)}(t) - T_h^{(l)}(t)]v\|_E \leq ch^s\|v\|_{s-2} \quad \forall v \in H^{s-2}.
\end{equation}

Hence, the restriction of $T_h(t)$ to $S_h$ is invertible and its inverse is henceforth denoted by $L_h(t)$. Since $L_h(t)$ is also positive definite and selfadjoint on $S_h$, both $L_h(t)$ and $T_h(t)$ have square roots but it is also assumed that:

\begin{equation}
\sup \{ \|[T^{(l)}(t) - T_h^{(l)}(t)]v\| + h\|[T^{(l)}(t) - T_h^{(l)}(t)]v\|_E \leq ch^s\|v\|_{s-2} \quad \forall v \in H^{s-2}.
\end{equation}

Also $L_h(t) \in C^l([0, t^*], B(S_h))$ for $l \geq 0$ sufficiently large and in fact, Bales [2] has proved that for $0 \leq s, t \leq t^*$, and $l \geq 0$:

\begin{equation}
\|[\frac{1}{2}(t)T_h^{(l)}(s)L_h^{(l)}(t)x]\| \leq c(l)\|x\| \quad \forall x \in S_h,
\end{equation}

\begin{equation}
\|[T_h^{(l)}(s)L_h^{(l)}(t)v]\| \leq c(l)\|v\| \quad \forall v \in L_2.
\end{equation}

Then using the selfadjointness of these operators, the following are straightforward consequences of (1.12) and (1.13). For $0 \leq s, t \leq t^*$:

\begin{equation}
\|[L_h^{(l)}(s)L_h^{(l)}(t)x]\| \leq c(l)\|x\| \quad \forall x \in S_h,
\end{equation}

\begin{equation}
\|[L_h^{(l)}(s)T_h^{(l)}(t)v]\| \leq c(l)\|v\| \quad \forall v \in L_2.
\end{equation}

In addition to (1.16), assume that for $0 \leq t \leq t^*$ and $l \geq 0$:

\begin{equation}
\|(L_h^{(l)}(s)x, x)\| \leq c(l)(L_h(t)x, x) \quad \forall x \in S_h.
\end{equation}

Next, defining the elliptic projection operator as $P_E(t) \equiv T_h(t)L(t)$, it follows from (1.9) and (1.2) that for $0 \leq t \leq t^*$:

\begin{equation}
\|[I - P_E(t)]v\| + h\|[I - P_E(t)]v\|_E \leq ch^s\|v\|_s \quad \forall v \in H^s \cap H_0^1, \quad 2 \leq s \leq r.
\end{equation}

In fact, with $\omega(t) \equiv P_E(t)u(t)$ and $\eta(t) \equiv u(t) - \omega(t)$, (1.2), (1.4), and (1.9) can be used [3] to show that:

\begin{equation}
\sup_{0 \leq t \leq t^*} \{ \|[\eta^{(l)}(t)] + h\|\eta^{(l)}(t)\|_E \} \leq ch^s\|u_0\|_{s+2l} \quad 2 \leq s \leq r, \quad 0 \leq 2l \leq \alpha - s.
\end{equation}

Finally, it can be shown that $P_0 \equiv L_h(t)T_h(t)$ is for every $t \in [0, t^*]$, the orthogonal projection of $L_2$ onto $S_h$ and that $T_h(t) = T_h(t)P_0$. Then, since $I - P_0$ is majorized by $I - P_E$ in $L_2$, it follows from (1.18) that:

\begin{equation}
\|[I - P_0]v\| \leq ch^s\|v\|_s \quad \forall v \in H^s \cap H_0^1, \quad 2 \leq s \leq r.
\end{equation}
Now, (1.1) has the following semidiscrete formulation. Find \( u_h : [0, t^*] \to S_h \) satisfying:

\[
\begin{align*}
\partial_t u_h &= -L_h(t) u_h \\
u_h(0) &= u_h^0,
\end{align*}
\]

(1.21)

where \( u_h^0 \in S_h \) is a suitable approximation to \( u^0 \). In [17], Sammon analyzes approximations of the form (1.21), and with assumptions comparable to those described above, he proves an optimal \( L^2 \) estimate:

\[
\sup_{0 \leq t \leq t^*} ||u(t) - u_h(t)|| \leq ch^r ||u^0||_r.
\]

In the present paper, semidiscrete approximations are not analyzed. Instead, (1.21) serves only as a source of inspiration for fully discrete approximations, and \( u_h \) is not even mentioned in forthcoming proofs.

**Temporal Discretizations**

For the temporal approximation of the solution to (1.21), *Implicit Runge-Kutta Methods* (IRKM's) are now introduced. Given an integer \( q \geq 1 \), a \( q \)-stage IRKM is characterized by a set of constants \( \{a_{ij}\}_{i,j=1}^q \), \( \{b_j\}_{j=1}^q \), and \( \{\tau_i\}_{i=1}^q \), and it is convenient to make the following definitions:

\[
A \equiv \{a_{ij}\}_{i,j=1}^q, \quad b^T \equiv (b_1, b_2, \ldots, b_q), \quad B \equiv \text{diag} \{b_i\},
\]

\[
M \equiv BA + A^T B - bb^T, \quad T \equiv \text{diag} \{\tau_i\}, \quad e^T \equiv (1, 1, \ldots, 1).
\]

For the IRKM formulation used in this work, choose arbitrarily, \( t_0 \in \mathbb{R}, \ y_0 \in \mathbb{R}^n, \ F : \mathbb{R}^{n+1} \to \mathbb{R}^n \) sufficiently smooth, and \( k > 0 \) sufficiently small, so that for \( t_0 \leq t \leq t_0 + k \), smooth functions \( y, \dot{y} : \mathbb{R} \to \mathbb{R}^n \) are well-defined by:

\[
\begin{align*}
D_i y(t) &= F(t, y(t)) \\
y(t_0) &= y_0,
\end{align*}
\]

(1.22)

\[
\begin{align*}
y'^{j}(t) &= y_0 + (t - t_0) \sum_{j=1}^q a_{ij} F(t_0 + \tau_j (t - t_0), y^j(t)), & 1 \leq j \leq q \\
\dot{y}(t) &= y_0 + (t - t_0) \sum_{i=1}^q b_i F(t_0 + \tau_i (t - t_0), \dot{y}(t)).
\end{align*}
\]

(1.23)

The method is described as *explicit* if \( a_{ij} = 0, i \leq j \) and *implicit* if for any \( i, \ a_{ii} \neq 0 \). Also, it is said to have order \( \nu \) if for every \( y \) and \( \dot{y} \) defined as above, \( D^l y(t_0) = D^l \dot{y}(t_0), \ 0 \leq l \leq \nu \). Butcher [5] has developed simple conditions for the above parameters which guarantee a given order; however, only the following is explicitly required in this work:

\[
l!b^T A^{l-1} e = 1 \quad 1 \leq l \leq \nu.
\]

(1.24)

To see the roots of condition (1.24), let (1.22) have \( n = 1, \ t_0 = 0, \ y_0 = 1, \) and \( F(y) = -y \), so that \( y(t) = e^{-t} \). Then, from (1.23), \( \dot{y}(t) = r(t) \) where \( r(z) \) is a rational approximation to the exponential \( e^{-z} \) given by:

\[
r(z) \equiv 1 - z b^T (I + zA)^{-1} e.
\]

(1.25)
Expanding this expression shows that \( r(z) \) is a \( \nu \)th order approximation to the exponential if and only if (1.24) holds. Next, with regard to stability, an IRKM is said to be \( A_0 \)-stable if:

\[
| r(z) | \leq 1 \quad \forall z \geq 0, \tag{1.26}
\]

and strongly \( A_0 \)-stable if:

\[
\sup_{z \geq z_0} | r(z) | < 1 \quad \forall z_0 > 0. \tag{1.27}
\]

Also, a method is called algebraically stable if \( M \) and \( B \) are positive semidefinite. However, if an algebraically stable method is irreducible (not equivalent to a fewer stage method) then:

\[
B \text{ is positive definite, and } M \text{ is positive semidefinite.} \tag{1.28}
\]

One other notion of stability which is useful here is that of dissipativity:

\[
-1 < -1 + \delta \leq r(z) \leq 1 \quad \forall z \geq 0. \tag{1.29}
\]

\( A_0 \)-stability is required of all IRKM's considered in this work. However, in order for the approximations to decay with respect to the time step, strong \( A_0 \)-stability must hold. In fact, to guarantee decay, both (1.27) and (1.28) are assumed. Then in section 4, the iterative scheme (1.46) described below requires at least (1.29) in addition to:

\[
r(z) \leq 1 - c \frac{z}{(1 + z)^3} \quad \forall z \geq 0. \tag{1.30}
\]

This growth condition is extremely mild and this author is unaware of any popular IRKM which fails to satisfy it. Also, requiring (1.29) and (1.30) improves on a related result of Karakashian [13] in which (1.27) is used. Next, note that the spectrum of \( A \), \( \sigma(A) \) is related to the poles of \( r(z) \) and in addition to the above, it is assumed throughout this paper that:

\[
\sigma(A) \subset \{ x \in \mathbb{R} : x > 0 \}. \tag{1.31}
\]

Returning to the temporal discretization of (1.21), let a \( q \)-stage IRKM of order \( \nu \geq 1 \) be given. Assume also that there exists a \( q \times q \) matrix \( D \) satisfying:

\[
D[e; Ae; \ldots; A^{q-1}e] = [Ae; 2A^2e; \ldots; qA^qe]. \tag{1.32}
\]

Again, this author is unaware of any well-known IRKM for which such a \( D \) fails to exist. In fact, the so-called collocation type methods are those for which \( D = T \). Now with \( \mu \equiv \min(\nu, q + 1) \), it follows from (1.32) and (1.24) that:

\[
lAD^{l-1}e = D^l e \quad 1 \leq l \leq \mu - 1, \tag{1.33}
\]

\[
lb^T D^{l-1}e = 1 \quad 1 \leq l \leq \mu. \tag{1.34}
\]

Next, for \( 0 \leq n \leq n^* - 1, n^* k \equiv \tilde{r} \), let the real values \( \{ \delta_m^n \}_{m=0}^{\mu-1} \) be chosen distinctly, so that the \( q \times q \) matrices \( \{ \Gamma_m^n \}_{m=0}^{\mu-1} \) are well-defined by:

\[
\sum_{m=0}^{\mu-1} \Gamma_m^n (\delta_m^n)^l = D^l \quad 0 \leq l \leq \mu - 1. \tag{1.35}
\]
as the computation of their components involves the inversion of the \( \mu \times \mu \) Vandermonde matrix \( \{(\delta_{m}^{n})\}_{m,l=0}^{\mu-1} \). In addition, assume that these parameters are bounded independently of \( n \):

\[
\max_{0 \leq m \leq \mu - 1} \left\{ |\delta_{m}^{n}| + \max_{1 \leq i, j \leq q} |(\Gamma_{m})_{ij}| \right\} \leq c.
\]

Actually, it is clear below that the natural and computationally advantageous choice for (1.35) is:

\[
\delta_{m}^{n} = \begin{cases} 
  m/\mu, & 0 \leq n \leq \mu - 2 \\
  -m, & \mu - 1 \leq n \leq n^{*} - 1.
\end{cases}
\]

In any case, define \( t^{n} \equiv nk \) and \( t_{m}^{n} \equiv t^{n} + \delta_{m}^{n} k \), and for \( 0 \leq n \leq n^{*} - 1, 0 \leq t \leq t^{*}, \) and \( 0 \leq s \leq k \), let the following be defined on \( S_{h} \equiv [S_{h}]^{q} \):

\[
\mathcal{L}_{h}(t) \equiv \text{diag}(L_{h}(t)), \quad \mathcal{L}_{h}^{n} \equiv \mathcal{L}_{h}(t^{n}), \quad \mathcal{L}_{h}^{n}(s) \equiv \sum_{m=0}^{\mu-1} \Gamma_{m}^{n} L_{h}(t^{n} + \delta_{m}^{n} s), \quad \mathcal{L}_{h}^{n} \equiv \mathcal{L}_{h}^{n}(k).
\]

Now with:

\[
U_{h}^{0} = [I + kL_{h}^{0}]^{-1} P_{0}[I + kL_{h}^{0}]u^{0}
\]

suppose that for \( 0 \leq n \leq n^{*} - 1 \), the approximation \( U_{h}^{n} \in S_{h} \) is given, where \( U_{h}^{n} \approx u^{n} \) and \( u^{n} \equiv u(x, t^{n}) \). Then, let \( U_{h}^{n+1} \approx u^{n+1} \) be given by what is henceforth called the base scheme:

\[
\begin{cases}
U_{h}^{n} = eU_{h}^{n} - kA_{h} \mathcal{L}_{h}^{n} U_{h}^{n} \\
U_{h}^{n+1} = (I - bTA^{-1} e)U_{h}^{n} + bTA^{-1} U_{h}^{n}
\end{cases}
\]

where \( U_{h}^{n} \in S_{h} \) is well-defined provided \( [I + kA_{h} \mathcal{L}_{h}^{n}] \) is invertible. Here, \( A_{h} \mathcal{L}_{h}^{n} \) for example, is understood in the sense of composition of operators defined on \( S_{h} \). Note that if the temporal discretization of (1.21) were accomplished as prescribed by (1.22) and (1.23), the following would result:

\[
\begin{cases}
\tilde{U}_{h}^{n} = eU_{h}^{n} - kA_{h} \mathcal{L}_{h}^{n} \tilde{U}_{h}^{n} \\
U_{h}^{n+1} = (I - bTA^{-1} e)U_{h}^{n} + bTA^{-1} \tilde{U}_{h}^{n}
\end{cases}
\]

where \( \tilde{U}_{h}^{n} \equiv \text{diag}\{L_{h}(t^{n} + kr_{i})\} \). However, as discussed in the beginning of the Introduction, (1.38) is designed to improve upon (1.39) with the indicated modification.

Now, with regard to iterative approximations, note that an efficient method is needed for solving the time stepping equations:

\[
[I + kA_{h} \mathcal{L}_{h}^{n}] \tilde{U}_{h}^{n} = eU_{h}^{n}.
\]

According to (1.31), \( A \) can be transformed as follows:

\[
SAS^{-1} = \Lambda \equiv \text{diag}\{\lambda_{i}\} + \text{subdiag}\{\theta_{i}\}; \quad \lambda_{i} > 0, \quad 1 \leq i \leq q; \quad \theta_{i} = 0 \text{ or } 1, \quad 2 \leq i \leq q.
\]

Then \( \tilde{U}_{h}^{n} \approx \tilde{U}_{h}^{n} \) can be obtained by the (outer) iterations:

\[
[I + kA_{h} \mathcal{L}_{h}^{n}](S\tilde{U}_{h}^{n}) = \{SeU^{n} + kSA(\mathcal{L}_{h}^{n} - \tilde{L}_{h}^{n})S\tilde{U}_{h}^{n-1}\} \equiv R_{l}^{n} \quad 1 \leq l \leq l_{n}
\]
where:

\[(1.42) \quad \tilde{V}_0^n \equiv \sum_{m=n-1-\mu_n}^{n-1} (-1)^{n-m-1} \left( \frac{\mu_n + 1}{n-m} \right) \tilde{U}_h^m \quad 1 \leq n \leq n^* - 1, \quad \tilde{V}_0^0 \equiv eU_0^0,\]

\[(1.43) \quad l_n \equiv \begin{cases} \mu, & n = 0 \\ \mu + 1 - n, & 1 \leq n \leq \mu \\ 1, & n - 1 \leq n \leq n^* - 1, \mu \\ n - 1, & 1 \leq n \leq \mu \\ \mu, & \mu + 1 \leq n \leq n^* - 1, \end{cases} \]

and \((1.41)\) is started with \(\tilde{V}_0^n \equiv \tilde{V}_0^n\) provided \(\{\tilde{U}_h^m\}_{m=n-1-\mu_n}^{n-1}\) are computed as indicated below.

Now consider the simple but important observation that if:

\[(1.44) \quad \lambda_i \neq \lambda_j, \quad i \neq j \quad \text{and} \quad \theta_i = 0, \quad 2 \leq i \leq q,\]

then the block system above decouples into the following equations which can be solved in parallel:

\[\left[ I + k\lambda_i L^n_0 \right] (S\tilde{V}_i^n)_i = (R_i^n)_i, \quad 1 \leq i \leq q.\]

Then, to avoid having to factor new coefficient matrices at every time step, a preconditioned iterative method is used to approximate \(\tilde{V}_i^n\) with (inner) iterates, say \(\{\tilde{V}_{i,j}^{n}\}_{0 \leq j \leq J_i}\). Further, it is shown that there exist integers \(\{\bar{j}_n\}_{m=0}^{n^* - 1}\) such that:

\[(1.45) \quad \frac{1}{n^*} \sum_{m=0}^{n^* - 1} l_n \bar{j}_m \leq c\]

while the convergence order \((1.5)\) is preserved for what is henceforth called the iterative scheme:

\[(1.46) \quad \left\{ \begin{array}{l} \tilde{U}_h^n = \tilde{V}_{l_n,j_n} \\ U_h^{n+1} = (I - b^TA^{-1}e)U_h^n + b^TA^{-1}\tilde{U}_h^n. \end{array} \right.\]

Finally, let the initial approximation for this scheme be given by \((1.37)\) also.

2 The Product Space Operators.

In this section, the machinery elaborated between \((1.2)\) and \((1.20)\) is generalized to analogous operators defined on products of spaces on which their precursors are defined. Also, various technical lemmas are proved for later use. Now, in addition to \(S_h\), define the product spaces \(L_2 \equiv [L_2]^q\), \(H_0^1 \equiv [H_0^1]^q\), \(H_E \equiv [H_E]^q\), and \(H^m \equiv [H^m]^q\). Also, denote the natural product space norms by:

\[\|\Phi\|_E \equiv \left\{ \sum_{i=1}^q \|\phi_i\|_E^2 \right\}^{\frac{1}{2}}, \quad \|\Phi\|_{m} \equiv \left\{ \sum_{i=1}^q \|\phi_i\|_m^2 \right\}^{\frac{1}{2}}, \quad \text{and} \quad \|\Phi\| \equiv \|\Phi\|_0.\]

Then, for \(0 \leq n \leq n^* - 1, 0 \leq t \leq t^*\) and \(0 \leq s \leq k\), let the following be defined on \(H^2 \cap H_0^1:\)

\[\mathcal{L}(t) \equiv \text{diag}\{L(t)\}, \quad \mathcal{L}^n \equiv \mathcal{L}(t^n), \quad \mathcal{L}(s) \equiv \sum_{m=0}^{\mu-1} \Gamma_m^n \mathcal{L}(t^n + \delta^n_m s), \quad \mathcal{L}^n \equiv \mathcal{L}(k).\]
The first step is to construct, for $0 \leq n \leq n^* - 1$ and $0 \leq s \leq k$, operators $\mathcal{T}^n(s)$ ($\mathcal{T}^n \equiv \mathcal{T}^n(k)$) satisfying:

$$
\begin{align*}
\mathcal{T}^n(s) \mathcal{T}^n(s) &= I & \text{on } L_2 \\
\mathcal{T}^n(s) \mathcal{L}^n(s) &= I & \text{on } H^2 \cap H^1_0.
\end{align*}
$$

(2.1)

Note that with the following defined on $L_2$ for $0 \leq t \leq t^*$ and $0 \leq n \leq n^* - 1$:

$$
\mathcal{T}(t) \equiv \text{diag} \{ T(t) \}, \quad \mathcal{T}^n \equiv \mathcal{T}(t^n)
$$

$\mathcal{T}^n(s)$ cannot be taken as a combination of such operators unless $D$ is diagonal.

**Lemma 2.1** For $0 \leq n \leq n^* - 1$, $\mathcal{L}^n(s) \in C^1([0,k],B(H^{m+2} \cap H^1_0,H^m))$ where $l,m \geq 0$ are as in (1.2). Also the following hold:

$$
\| \partial_t \mathcal{L}^n(s)v \|_m \leq c(l,m) \| v \|_{m+2}
$$

(2.2)

$$
\| (\mathcal{L}^n(s) - \mathcal{L}^n)v \|_m \leq c(m)k \| v \|_{m+2}
$$

(2.3)

$\forall v \in H^{m+2} \cap H^1_0, \ 0 \leq s \leq k, \ \text{and} \ 0 \leq n \leq n^* - 1.$

**Proof:** The crucial observation is that by (1.35) with $l = 0$:

$$
\mathcal{L}^n(s) - \mathcal{L}^n = \sum_{i=0}^{\mu-1} \Gamma_i \left[ \mathcal{L}(t^n + \delta^n_i s) - \mathcal{L}^n \right] = \sum_{i=0}^{\mu-1} \Gamma_i \int_{t^n}^{t^n+\delta^n_i s} \mathcal{L}^{(1)}(t)dt
$$

and (2.3) follows with (1.36) and (1.2). Also, (2.2) follows using (1.36) and (1.2). $\blacksquare$

**Theorem 2.1** Let $m,l \geq 0$ be as in (1.3). Then for $k$ small enough, and $0 \leq n \leq n^* - 1$, there exist operators $\mathcal{T}^n(s) \in C^1([0,k],B(H^m,H^{m+2} \cap H^1_0))$ satisfying (2.1) and:

$$
\| \partial_t \mathcal{T}^n(s)v \|_{m+2} \leq c(l,m) \| v \|_m \quad \forall v \in H^m.
$$

(2.4)

**Proof:** Let $v \in H^m$ be chosen arbitrarily, and define $\mathcal{F} : H^{m+2} \cap H^1_0 \rightarrow H^{m+2} \cap H^1_0$ by:

$$
\mathcal{F}u \equiv \mathcal{T}^n \{ v + [\mathcal{L}^n - \mathcal{L}^n(s)]u \}.
$$

By (1.3) and (2.3), with $k$ small enough, there is an $\varepsilon \in (0,1)$ such that $\forall u_1, u_2 \in H^{m+2} \cap H^1_0$:

$$
\| \mathcal{F}(u_2 - u_1) \|_{m+2} \leq c(m) \| [\mathcal{L}^n - \mathcal{L}^n(s)](u_2 - u_1) \|_m \leq \varepsilon \| u_2 - u_1 \|_{m+2}.
$$

Hence $\mathcal{F}$ is a global contraction and has a unique fixed point. Thus, for every $v \in H^m$, there exists a unique element $\mathcal{T}^n(s)v \in H^{m+2} \cap H^1_0$ such that $\mathcal{L}^n(s)\mathcal{T}^n(s)v = v$. In particular, the first part of (2.1) holds. Also, if $u \in H^{m+2} \cap H^1_0$ and $w \equiv \mathcal{T}^n(s)[\mathcal{L}^n(s)u - u]$, then by the uniqueness, $\mathcal{L}^n(s)w = 0$ implies that $w = 0$. So, (2.1) follows. Next, the following estimate is well-known:

$$
\| \mathcal{T}^n(s)v - \mathcal{T}^n v \|_{m+2} \leq (1 - \varepsilon)^{-1} \| \mathcal{T}^n v - \mathcal{T}^n v \|_{m+2}.
$$

By (1.3) and (2.3):

$$
\| \mathcal{F} \mathcal{T}^n v - \mathcal{T}^n v \|_{m+2} \leq c(m) \| [\mathcal{L}^n - \mathcal{L}^n(s)]\mathcal{T}^n v \|_m \leq c(m)k \| \mathcal{T}^n v \|_{m+2}.
$$
Then, for the case \( I = 0 \), (2.4) follows from the last two inequalities and (1.3). Now, by estimating difference quotients, it can be shown in a straightforward way that \( \partial_s \mathcal{T} \mathcal{V}(s) = - \mathcal{T} \mathcal{V}(s) \partial_s \mathcal{V}(s) \mathcal{T} \mathcal{V}(s) \) for \( 0 \leq s \leq k \) and the smoothness of \( \mathcal{T} \mathcal{V}(s) \) follows inductively with Lemma 2.1. Finally, after differentiating the first line of (2.1):

\[
\partial_s \mathcal{T} \mathcal{V}(s) = - \sum_{i=0}^{l-1} \left( \frac{l}{i} \right) \mathcal{T} \mathcal{V}(s) \partial_s^{l-i} \mathcal{V}(s) \partial_s^i \mathcal{T} \mathcal{V}(s)
\]

and (2.4) follows inductively using (2.2).

Now with trivial modifications of the above, the following is obtained for the adjoints.

**Lemma 2.2** For \( 0 \leq n \leq n^* - 1 \), \( \mathcal{V} \mathcal{V}(s) * \in C^l([0, k], B(\mathbb{H}^{m+2} \cap \mathbb{H}_0, \mathbb{H}^m)) \) where \( l, m \geq 0 \) are as in (1.2), and:

\[
\| \partial^l_s \mathcal{V} \mathcal{V}(s) * \mathcal{V} \mathcal{V} \|_m \leq c(l, m) \| \mathcal{V} \mathcal{V} \|_{m+2} \quad \forall \mathcal{V} \mathcal{V} \in \mathbb{H}^{m+2} \cap \mathbb{H}_0.
\]

Furthermore, with \( m, l \geq 0 \) as in (1.3), there exist operators \( \mathcal{T} \mathcal{V}(s) \in C^l([0, k], B(\mathbb{H}^m, \mathbb{H}^{m+2} \cap \mathbb{H}_0)) \) satisfying:

\[
\| \partial^l_s \mathcal{T} \mathcal{V}(s) * \mathcal{V} \mathcal{V} \|_{m+2} \leq c(l, m) \| \mathcal{V} \mathcal{V} \|_m \quad \forall \mathcal{V} \mathcal{V} \in \mathbb{H}^m.
\]

and \( \mathcal{V} \mathcal{V}(s) * \mathcal{T} \mathcal{V}(s) * = I \) on \( L_2 \), \( \mathcal{T} \mathcal{V}(s) * \mathcal{V} \mathcal{V}(s) * = I \) on \( \mathbb{H}^2 \cap \mathbb{H}_0 \). □

The next step is to construct for \( 0 \leq n \leq n^* - 1 \) and \( 0 \leq s \leq k \), operators \( \mathcal{T} \mathcal{V}(s) (\mathcal{T} \mathcal{V} = \mathcal{T} \mathcal{V}(m)) \) satisfying:

\[
\begin{cases}
\mathcal{L} \mathcal{V}(s) \mathcal{T} \mathcal{V}(s) = \mathcal{P}_0 & \text{on } L_2 \\
\mathcal{T} \mathcal{V}(s) \mathcal{L} \mathcal{V}(s) = I & \text{on } S_h
\end{cases}
\]

where \( \mathcal{P}_0 \equiv \text{diag}\{P_0\} \). Note that with the following defined on \( L_2 \) for \( 0 \leq t \leq t^* \) and \( 0 \leq n \leq n^* - 1 \):

\[
\mathcal{T} \mathcal{V}(t) \equiv \text{diag}\{\mathcal{T} \mathcal{V}(t)\}, \quad \mathcal{T} \mathcal{V}(m) \equiv \mathcal{T} \mathcal{V}(m)
\]

\( \mathcal{T} \mathcal{V}(s) \) cannot be taken as a combination of such operators unless \( D \) is diagonal.

Now let \( \{D_h(t)(\cdot, \cdot)\}_{0 \leq t \leq t^*} \) be a family of bilinear forms defined on \( H_E \times H_E \) so that:

\[
D_h(t)(\chi, \phi) = (L_h(t)\chi, \phi) \quad \forall \chi, \phi \in S_h.
\]

More specifically, with \( D_h^{(l)}(t)(\cdot, \cdot) \equiv D_h^{(l)}(t)(\cdot, \cdot) \), assume that for \( 0 \leq t \leq t^* \), \( l \geq 0 \), and \( 2 \leq m \leq r \):

\[
\begin{align*}
|D_h^{(l)}(t)(w, w) - (L^{(l)}(t)v, w)| & \leq c(l)h^{m-1}\|w\|_m\|w - u\|_E, \\
& \forall w \in H^m \cap H_0^1, \quad \forall u \in H^2 \cap H_0^1 + S_h, \quad \forall u \in H^2 \cap H_0^1,
\end{align*}
\]

\[
|D_h^{(l)}(t)(w, v)| \leq c(l)\|w\|_E\|v\|_E \quad \forall w, v \in H_E,
\]

\[
|D_h^{(l)}(t)(v, v)| \leq c(l)\|v\|_E^2 \quad \forall v \in H_E.
\]

For example, these assumptions are readily verified for the Ordinary Galerkin Method mentioned in the Introduction. For additional examples, see Sammon [16], [17]. Next, for \( 0 \leq t \leq t^* \), \( 0 \leq n \leq n^* - 1 \) and \( 0 \leq s \leq k \), let the following be defined on \( H_E \times H_E \):

\[
D_h(t)(w, v) \equiv \sum_{i=1}^{q} D_h(t)(w_i, v_i), \quad \bar{D}_h^n(s)(w, v) \equiv \sum_{m=0}^{\mu-1} D_h(t^n + \delta_m s)(\mathcal{T} \mathcal{V}(n)w, v).
\]

10
Lemma 2.3  For $k > 0$ small enough, $l \geq 0$, $0 \leq n \leq n^* - 1$ and $0 \leq s \leq k$:

\begin{equation}
|\partial_s^l \partial_n^a(s)(w, v)| \leq c(l)\|w\|_E\|v\|_E \quad \forall w, v \in H_E
\end{equation}

\begin{equation}
c\|X\|_E^2 \leq \bar{D}_n^a(s)(X, X) \quad \forall X \in S_h.
\end{equation}

Proof: Using (2.10) and (1.36), (2.12) follows in a straightforward way. Then, by (2.12), (2.11) and (1.35) with $l = 0$:

\[ \bar{D}_n^a(s)(X, X) = D_h(t^n)(X, X) + \int_0^s D_n^a(r)(X, X)dr \geq c(1-k)\|X\|_E^2 \quad \forall X \in S_h \]

and (2.13) follows for $k$ small enough.

Discrete counterparts to Lemma 2.1 and Theorem 2.1 appear next.

Lemma 2.4  For $0 \leq n \leq n^* - 1$, $\bar{L}_n^a(s) \in C^l([0, k], B(S_h))$ where $l \geq 0$ is as in (1.13). Also, the following hold:

\begin{equation}
\|T^n_{\frac{1}{2}}(t)\partial_s^l \bar{L}_n^a(s)\| \leq c(l)\|f\|
\end{equation}

\begin{equation}
\|T^n_{\frac{1}{2}}(t)[L_h(t_2) - L_h(t_1)]T^n_{\frac{1}{2}}(t)\| \leq c|t_2 - t_1|\|f\|
\end{equation}

\begin{equation}
\|T^n_{\frac{1}{2}}(t)[L_n^a(s) - L_h]T^n_{\frac{1}{2}}(t)\| \leq ck\|f\|
\end{equation}

$\forall f \in L_2; \ 0 \leq t, t_1, t_2 \leq t^*, \ 0 \leq s \leq k, \ 0 \leq n \leq n^* - 1$.

Proof: The manipulations required are similar to those needed for Lemma 2.1, except that (1.13) is used instead of (1.2).

Theorem 2.2  Let $l \geq 0$ be as in (1.12). Then for $k$ small enough, and $0 \leq n \leq n^* - 1$, there exist operators $\bar{T}_n^a(s) \in C^l([0, k], B(L_2, S_h))$ defined by:

\begin{equation}
\bar{D}_n^a(s)(\bar{T}_n^a(s)f, X) = (f, X) \quad \forall f \in L_2, \ \forall X \in S_h, \ 0 \leq s \leq k
\end{equation}

and satisfying (2.7) in addition to:

\begin{equation}
\|\partial_s^l \bar{T}_n^a(s)f\|_B \leq c(l)\|f\|
\end{equation}

\begin{equation}
\|L_n^a(t)\partial_s^l \bar{T}_n^a(s)L_n^a(t)X\| \leq c(l)\|X\|
\end{equation}

$\forall f \in L_2, \ \forall X \in S_h, \ \theta_1, \theta_2 = 0, \frac{1}{2} \ 0 \leq t \leq t^*, \ 0 \leq s \leq k, \ 0 \leq n \leq n^* - 1$.

Proof: That $\bar{T}_n^a(s)$ is well-defined by (2.17) follows from Lemma 2.3 and the Lax-Milgram Lemma [6]. For (2.7), note first that by (2.8), for $X, \Phi \in S_h$:

\[ \bar{D}_n^a(s)(X, \Phi) \equiv \sum_{m=0}^{\mu-1} D_h(t^n + \delta_m^a)(\Gamma_m^n X, \Phi) = \sum_{m=0}^{\mu-1} (L_h(t^n + \delta_m^a)\Gamma_m^n X, \Phi) = (\bar{L}_n^a(s)X, \Phi). \]

Combining this with (2.17), it follows that $\forall X, \Phi, \Psi \in S_h$ and $\forall f \in L_2$:

\[ (\bar{L}_n^a(s)\bar{T}_n^a(s)f, X) = \bar{D}_n^a(s)(\bar{T}_n^a(s)f, X) = (f, X) = (P_0 f, X), \]
\[ D^m_n(s)(\tau_n^m(s)\mathcal{L}_n^m(s)\psi, \Phi) = (\mathcal{L}_n^m(s)\psi, \Phi) = D^m_n(s)(\psi, \Phi). \]

Then (2.7) follows after setting \( X = [\mathcal{L}_n^m(s)\tau_n^m(s) - \rho_0]f, \Phi = \tau_n^m(s)\mathcal{L}_n^m(s)\psi \) and using (2.13). Next, to obtain (2.19) for the case that \( l = 0 \), set \( E \equiv (\tau_n^m)^{\frac{1}{2}}[\mathcal{L}_n^m - \mathcal{L}_n^m(s)(\tau_n^m)]^{\frac{1}{2}} \) so that by (2.16):

\[
||[I - E]X|| \geq (1 - ck)||X|| \quad \forall X \in S_h.
\]

Hence, for \( k \) small enough:

\[
\mathcal{L}_n^m(t)\tau_n^m(s)\mathcal{L}_n^m(s) = [\mathcal{L}_n^m(t)(\tau_n^m)^{\frac{1}{2}}][I - E]^{-1}[(\tau_n^m)^{\frac{1}{2}}\mathcal{L}_n^m(t)].
\]

If \( \theta_1 = \theta_2 = \frac{1}{2} \), the first case of (2.19) follows with (1.14) and (1.15). Otherwise, (1.10) is used. Now by estimating difference quotients, it can be shown in a straightforward manner that \( \partial_s \tau_n^m(s) = -\tau_n^m(s)\partial_s \mathcal{L}_n^m(s)\tau_n^m(s) \) for \( 0 \leq s \leq k \), and the smoothness of \( \tau_n^m(s) \) follows inductively with Lemma 2.4. Next, after differentiating the first part of (2.7):

\[
\mathcal{L}_n^m(t)\partial_s \tau_n^m(s)\mathcal{L}_n^m(s) = -\sum_{i=0}^{l-1} \left( \begin{array}{l} l \\ i \end{array} \right) [\mathcal{L}_n^m(t)(\tau_n^m)^{\frac{1}{2}}][\tau_n^m(t)\partial_s^{l-i} \mathcal{L}_n^m(s)\tau_n^m(t)][\mathcal{L}_n^m(t)\partial_s^{l-i} \tau_n^m(s)\mathcal{L}_n^m(t)]
\]

so (2.19) follows inductively using (2.14). Finally, by setting \( \theta_1 = \frac{1}{2}, \theta_2 = 0 \) and \( X = \rho_0 f \) in (2.19), (2.18) follows with (1.11) since \( \tau_n^m(s) = \tau_n^m(s)\mathcal{L}_n^m(s)\tau_n^m(s) = \tau_n^m(s)\rho_0 \).

Next, certain inequalities related to (2.9) are needed.

**Lemma 2.5** For \( k > 0 \) small enough, the following hold:

\[
(2.20) \quad |\partial_s^i \mathcal{L}_n^m(s)(v, w) - (\partial_s^i \mathcal{L}_n^m(s)v, w)| \leq c(l)h^{m-1}||v||_m||w - u||_E
\]

\[
(2.21) \quad |\partial_s^i \mathcal{L}_n^m(s)(v, w) - (w, \partial_s^i \mathcal{L}_n^m(s)v)| \leq c(l)h^{m-1}||v||_m||w - u||_E
\]

\[
(2.22) \quad \sum_{i=0}^{l} \left( \begin{array}{l} l \\ i \end{array} \right) |\partial_s^{l-i} \mathcal{L}_n^m(s)(\partial_s^{i-1} \tau_n^m(s) - \partial_s^{i-1} \tau_n^m(s))f, X)| \leq c(l)h^{m-1}||f||_{m-2}||X - u||_E
\]

\[ \forall v \in H^m \cap H_0^m, \forall w \in H^2 \cap H_0^2 + S_h, \forall u \in H^2 \cap H_0^2, \forall f \in H^m, \forall X \in S_h \quad 2 \leq m \leq r, \quad l \geq 0, \quad 0 \leq s \leq k, \quad 0 \leq n \leq n^* - 1. \]

**Proof:** First, note that:

\[
\partial_s^i \mathcal{L}_n^m(s)(v, w) - (\partial_s^i \mathcal{L}_n^m(s)v, w) = \sum_{i=0}^{l-1} (\partial_s^i \mathcal{L}_n^m(s)(\mathcal{L}_n^m(t^n + \delta_t^n s)(\tau_n^m(v, w) - (\mathcal{L}_n^m(t^n + \delta_t^n s)\tau_n^m(v, w))
\]

so (2.20) follows with (2.9). Also, (2.21) follows similarly. For the remaining inequality, the key observation is that by (2.17), the left side of (2.22) is equal to:

\[
|\partial_s^i [\mathcal{L}_n^m(s)(\tau_n^m(s)f, X) - (f, X)]| = |\partial_s^i [\mathcal{L}_n^m(s)(\tau_n^m(s)f, X) - (\mathcal{L}_n^m(s)\tau_n^m(s)f, X)]|
\]

and (2.22) follows using (2.20) and (2.4).

The groundwork for a generalization of (1.9) is now complete.
Theorem 2.3 For \( k > 0 \) small enough, the following holds for \( 0 \leq n \leq n^* - 1, 0 \leq s \leq k, l \geq 0, \) and \( 2 \leq m \leq r \):

\[
\| \partial_s^l [\tilde{T}^n(s) - \tilde{T}_h^n(s)]v \| + h \| \partial_s^l [\tilde{T}^n(s) - \tilde{T}_h^n(s)]v \|_E \leq c(l) h^m \| v \|_{m-2} \quad \forall v \in H^{m-2}.
\]

Proof: With \( 2 \leq m \leq r \), let \( v \in H^{m-2} \) and define \( X_i \in S_h \) to be the closest to \( \partial_s^l \tilde{T}^n(s)v \) in the norm \( \| \cdot \|_E \). Then, define:

\[
E^l \equiv \partial_s^l [\tilde{T}^n(s) - \tilde{T}_h^n(s)]v = [\partial_s^l \tilde{T}^n(s)v - X_i] - [\partial_s^l \tilde{T}_h^n(s)v - X_i] \equiv E_0^l - E_h^l.
\]

By (1.8) and (2.4):

\[
\| E_0^l \| \leq c(l) h^{m-1} \| v \|_{m-2}.
\]

Next, by (2.12) and (2.13):

\[
c\| E_h^l \|_E^2 \leq \tilde{D}_h^n(s)(E_0^l, E_h^l) = \tilde{D}_h^n(s)(E_0^l, E_h^l) - \tilde{D}_h^n(s)(E^l, E_h^l) \leq c \| E_0^l \|_E \| E_h^l \|_E + \| \tilde{D}_h^n(s)(E^l, E_h^l) \|
\]

By (2.22), with ill-defined sums understood to be zero:

\[
\| \tilde{D}_h^n(s)(E^l, E_h^l) \| = \left| \sum_{i=0}^l \left( \begin{array}{c} l \\ i \end{array} \right) \partial_s^{l-i} \tilde{D}_h^n(s)(E^l, E_h^l) - \sum_{i=0}^{l-1} \left( \begin{array}{c} l \\ i \end{array} \right) \partial_s^{l-i} \tilde{D}_h^n(s)(E^l, E_h^l) \right| 
\]

\[
\leq c(l) h^{m-1} \| v \|_{m-2} \| E_0^l \|_E + c \| E_h^l \|_E \sum_{i=0}^{l-1} \| E^i \|_E.
\]

So, the indicated estimate for \( \| E^l \|_E \) follows inductively from the last three inequalities. Now, a duality argument is used to complete the proof. Define \( X_i^* \in S_h \) to be the closest to \( \tilde{T}^n(s)^* E^l \) in the norm \( \| \cdot \|_E \). Then, with ill-defined sums understood to be zero:

\[
\| E^l \|^2 = \sum_{i=0}^l \left( \begin{array}{c} l \\ i \end{array} \right) [(E^l, \partial_s^{l-i} \tilde{L}^n(s)^* \tilde{T}^n(s)^* E^l) - \partial_s^{l-i} \tilde{D}_h^n(s)(E^l, \tilde{T}^n(s)^* E^l)]
\]

\[ + \sum_{i=0}^l \left( \begin{array}{c} l \\ i \end{array} \right) \partial_s^{l-i} \tilde{D}_h^n(s)(E^l, \tilde{T}^n(s)^* E^l - X_i^*) + \sum_{i=0}^{l-1} \left( \begin{array}{c} l \\ i \end{array} \right) \partial_s^{l-i} \tilde{D}_h^n(s)(E^l, X_i^*)
\]

\[ - \sum_{i=0}^l \left( \begin{array}{c} l \\ i \end{array} \right) (E^l, \partial_s^{l-i} \tilde{L}^n(s)^* \tilde{T}^n(s)^* E^l) \equiv \sum_{j=1}^l F_j.
\]

By (2.21) and (2.6), \( F_1 \) satisfies:

\[
|F_1| + |F_2| \leq c(l) h \| E^l \| \sum_{i=0}^l \| E^i \|_E
\]

while the case for \( F_2 \) follows with (2.12), (1.8), and (2.6). Then, by (2.22), (1.8), and (2.6):

\[
|F_3| \leq c(l) h^{m-1} \| v \|_{m-2} \| X_i^* - \tilde{T}^n(s)^* E^l \|_E \leq c(l) h^m \| v \|_{m-2} \| E^l \|.
\]

Finally, by (2.5) and (2.6):

\[
|F_4| \leq c(l) \| E^l \| \sum_{i=0}^{l-1} \| E^i \|.
\]

Now (2.23) follows inductively.
3 The Base Scheme.

In this section, the base scheme (1.38) is analyzed for the approximation of the solution to (1.1) and (1.5) is established. That the stages are well-defined depends on the next lemma.

Lemma 3.1 Provided (1.81) is satisfied, \([I + kA\mathcal{L}_h^n]\) is invertible, and for \(k\) small enough, \([I + kA\mathcal{L}_h^n]\) is as well. Also the following hold:

\[
\|(k\mathcal{L}_h^n)\theta [I + kA\mathcal{L}_h^n]^{-1}X\| \leq c\|X\|, \tag{3.1}
\]
\[
\|(k\mathcal{L}_h^n)\theta_1 [I + kA\mathcal{L}_h^n]^{-1}(k\mathcal{L}_h^n)\theta_2 X\| \leq c\|X\|, \tag{3.2}
\]
\[
\|(k\mathcal{L}_h^n)\theta_1 [I + kA\mathcal{L}_h^n]^{-1}(k\mathcal{L}_h^n)\theta_2 X\| \leq c\|X\|, \tag{3.3}
\]

\(\forall X \in S_h, \ 0 \leq \theta \leq 1, \ \theta_1, \theta_2 = 0, \frac{1}{2}; \ \theta_1 = -\theta_2 = \pm \frac{1}{2}, \ 0 \leq m \leq n^*, \ 0 \leq n \leq n^* - 1.\)

Proof: The invertibility of \([I + kA\mathcal{L}_h^n]\) and the estimate (3.1) involve a spectral argument after \(A\) is transformed to Jordan form, and the details are provided by Karakashian [13]. Now set:

\[E_1 = [I + kA\mathcal{L}_h^n]^{-1}kA(\mathcal{L}_h^n - \mathcal{L}_h^n)\]
and \[E_2 = kA(\mathcal{L}_h^n - \mathcal{L}_h^n)[I + kA\mathcal{L}_h^n]^{-1}\]
so that:

\[(\mathcal{L}_h^n)^{\frac{1}{2}}[I + kA\mathcal{L}_h^n](\mathcal{T}_h^n)^{\frac{1}{2}} = [I + kA\mathcal{L}_h^n][I - (\mathcal{L}_h^n)^{\frac{1}{2}}E_1(\mathcal{T}_h^n)^{\frac{1}{2}}], \]

\[(\mathcal{T}_h^n)^{\frac{1}{2}}[I + kA\mathcal{L}_h^n](\mathcal{L}_h^n)^{\frac{1}{2}} = [I - (\mathcal{T}_h^n)^{\frac{1}{2}}E_2(\mathcal{L}_h^n)^{\frac{1}{2}}][I + kA\mathcal{L}_h^n].\]

By (3.1) and (2.16):

\[
\|((\mathcal{L}_h^n)^{\frac{1}{2}}E_1(\mathcal{T}_h^n)^{\frac{1}{2}}X)\| + \|((\mathcal{T}_h^n)^{\frac{1}{2}}E_2(\mathcal{L}_h^n)^{\frac{1}{2}}X)\| \leq c\|X\| \quad \forall X \in S_h.
\]

Hence, for \(k\) small enough, \([I + kA\mathcal{L}_h^n]\) is invertible. Next, for \(\theta_2 = 0, \pm \frac{1}{2}:\)

\[(k\mathcal{L}_h^n)^{\frac{1}{2}}[I + kA\mathcal{L}_h^n]^{-1}(k\mathcal{L}_h^n)^{\theta_2} = [I - (k\mathcal{L}_h^n)^{\frac{1}{2}}E_1(\mathcal{T}_h^n)^{\frac{1}{2}}]^{-1}(k\mathcal{L}_h^n)^{\theta_2 + \frac{1}{2}}[I + kA\mathcal{L}_h^n]^{-1}\]
and (3.2) follows for \(\theta_1 = \frac{1}{2}.\) For \(\theta_1 = 0, \pm \frac{1}{2}:\)

\[(k\mathcal{L}_h^n)^{\theta_1}[I + kA\mathcal{L}_h^n]^{-1}(k\mathcal{L}_h^n)^{\frac{1}{2}} = (k\mathcal{L}_h^n)^{\theta_1 + \frac{1}{2}}[I + kA\mathcal{L}_h^n]^{-1}[I - (\mathcal{T}_h^n)^{\frac{1}{2}}E_2(\mathcal{L}_h^n)^{\frac{1}{2}}]^{-1}\]
and (3.2) follows for \(\theta_2 = \frac{1}{2}.\) Now, for the case \(\theta_1 = \theta_2 = 0,\) with \(X \in S_h\) chosen arbitrarily:

\[
\|X\|^2 \leq \frac{1}{2}\|I + kA\mathcal{L}_h^n|X|^2 + \frac{1}{2}\|X\|^2 + k|(A\mathcal{L}_h^nX, X)|.
\]

Then with \(\Psi = (\mathcal{L}_h^n)^{\frac{1}{2}}X,\) by (2.16):

\[
|(A\mathcal{L}_h^nX, X)| \leq |(A\Psi, \Psi)| + |((\mathcal{T}_h^n)^{\frac{1}{2}}[\mathcal{L}_h^n - \mathcal{L}_h^n](\mathcal{T}_h^n)^{\frac{1}{2}}\Psi, A^T\Psi)| \leq c(1 + k)(\mathcal{L}_h^nX, X).
\]

Also by (3.2) with \(\theta_1 = \frac{1}{2}, \theta_2 = 0:\)

\[
\|(k\mathcal{L}_h^n)^{\frac{1}{2}}X\| \leq c\|I + kA\mathcal{L}_h^n|X|.
\]
and the remaining case for (3.2) follows after combining the last three inequalities. Finally, using:

$$(kL_h^m)^{\delta_1}[I + kAL_h^m]^{-1}(kL_h^m)^{\delta_2} = [(L_h^m)^{\delta_1}(T_h^m)^{\delta_1}](I + kAL_h^m)^{-1}(kL_h^m)^{\delta_2} \left[ (T_h^m)^{\delta_2}(L_h^m)^{\delta_2} \right]$$

(3.3) follows with (1.14), (1.15), and (3.1).

Now, for the sequel, let the following be defined:

$$\xi^n \equiv U^n_h - \omega^n,$$

$$r^n_h \equiv I - kb^T L_h^n[I + kAL_h^n]^{-1}e,$$

$$\xi^n \equiv u^n - \omega^n,$$

$$\eta^n \equiv r^n_h[I + kAL_h^n]^{-1}e,$$

$$\bar{u}^n(s) \equiv \sum_{m=0}^{\mu-1} D^l e \delta^l u^n \frac{s^l}{l!}, \quad (0 \leq s \leq k)$$

$$\bar{u}^n \equiv \bar{u}^n(k),$$

$$\bar{\omega}^n(s) \equiv \bar{r}^n_h(s) \bar{u}^n(s), \quad (0 \leq s \leq k)$$

$$\bar{\omega}^n \equiv \bar{\omega}^n(k).$$

After some straightforward calculations, the following error equation is established:

$$\xi^{n+1} = \eta^n + kb^T L_h^n[I + kAL_h^n]^{-1}\{\bar{\omega}^n - \epsilon \omega^n - kA \sum_{m=0}^{\mu-1} \Gamma^n_{m} \epsilon \partial_t \omega(r^n_m)\}$$

$$- kb^T A^{-1}[I + kAL_h^n]^{-1}A \sum_{m=0}^{\mu-1} \Gamma^n_{m} L(r^n_m)[\bar{u}^n - \epsilon u(r^n_m)]$$

$$- kb^T A^{-1}[I + kAL_h^n]^{-1}A \sum_{m=0}^{\mu-1} \Gamma^n_{m} \epsilon \partial_t \{[P^t(r^n_m) - P_0] u(r^n_m)\}$$

$$- \{\omega^{n+1} - \omega^n - kb^T \sum_{m=0}^{\mu-1} \Gamma^n_{m} \epsilon \partial_t \omega(r^n_m)\}$$

$$\equiv \eta^n + \sum_{i=1}^{4} \psi^n_i \equiv \eta^n + \psi^n \quad 0 \leq n \leq n^* - 1. \tag{3.4}$$

Now, stability is to be established in the following norms, which according to (1.11) are well-defined for $0 \leq n \leq n^*$:

$$\|x\|_n \equiv \{(x, x) + k(L_h^n x, x))^{\frac{1}{2}} x \in S_h. \tag{3.5}$$

Also, from (1.16) with $l = 0$, it follows that these norms are equivalent:

$$c_1 \|x\|_m \leq \|x\|_n \leq c_2 \|x\|_m \quad \forall x \in S_h, \quad 0 \leq m, n \leq n^*. \tag{3.6}$$

As in section 2, let the following be defined in the natural way for the product spaces:

$$(\Phi, \Psi) \equiv \sum_{i=1}^{q} (\phi_i, \psi_i), \quad \|\Phi\| \equiv (\Phi, \Phi)^{\frac{1}{2}} \quad \Phi, \Psi \in L_2,$$

$$\|X\|_n \equiv \left\{\sum_{i=1}^{q} \|\phi_i\|^2_n \right\}^{\frac{1}{2}} \quad X \in S_h.$$
Finally, (3.17) follows after using (3.7) and (1.26) in:
\[ \| (kL_h^n)^{1/2} R_h^n \xi^n \| \leq \| (kL_h^n)^{1/2} (R_h^n - r_h^n) (kL_h^n)^{-1/2} \| (kL_h^n)^{1/2} \xi^n \| + \| r_h^n (kL_h^n)^{1/2} \xi^n \|. \]

Next, (3.15)-(3.17) are used to obtain (3.13). Suppose that \( \epsilon_2 \) is small enough that \( c_2 < 1 \). Then, assume that \( k_0 > 0 \) is small enough that if \( \theta \equiv (1 - c_1)/(1 + c_6 k_0) > 0 \), then \( c_2 + \theta > 1 \). Next, multiply (3.17) by \( \theta \) and add the result to (3.16). With \( c_6 \equiv c_2 + \theta - 1 > 0 \), and \( 0 < k \leq k_0 \):
\[ \| R_h^n \xi^n \|^2 + (1 + c_6) \| (kL_h^n)^{1/2} R_h^n \xi^n \|^2 \leq \| \xi^n \|^2. \]

By (1.11), there is a \( c_6 > 0 \) such that:
\[ c_6 k \| R_h^n \xi^n \|^2 \leq \frac{1}{2} c_6 \| (kL_h^n)^{1/2} R_h^n \xi^n \|^2. \]

Also, by (2.15), with \( \chi^n \equiv (kL_h^n)^{1/2} R_h^n \xi^n \):
\[ \| (kL_h^{n+1})^{1/2} R_h^{n+1} \xi^n \|^2 = \| \chi^n \|^2 + (\| T_h^n \|^{1/2} L_h^{n+1} - L_h^n \| T_h^{n+1/2} (\chi^n, \chi^n) \right) \leq (1 + c_7 k) \| (kL_h^n)^{1/2} R_h^n \xi^n \|^2. \]

From the last three inequalities, it follows that:
\[ (1 + c_6 k) \| R_h^n \xi^n \|^2 + (1 + \frac{1}{2} c_6 k) (1 + c_7 k)^{-1} \| (kL_h^{n+1})^{1/2} R_h^{n+1} \xi^n \|^2 \leq \| \xi^n \|^2. \]

So assume that \( k_0 \) above, is also small enough that \( (1 + \frac{1}{2} c_6 k)(1 + c_6 k_0)^{-1} (1 + c_7 k_0)^{-1} \geq 1 + \epsilon_1 \), for some \( \epsilon_1 > 0 \). Then (3.13) follows for some \( \hat{c} \in (-c_6, 0) \).

The next two lemmas are useful in subsequent consistency estimates.

**Lemma 3.3** Let \( t_0, t_1, t_2 \in [0, t^*] \) and \( |t_2 - t_1| \leq ct \). Then, for integers \( m, l \geq 0 \):

(3.18) \[ \sup_{0 \leq t \leq t^*} \| L_h^l (t_0) \partial_t^i \omega(t) \| \leq c(l) \| u^0 \|_{2(l+i)} \quad \theta = 0, \frac{1}{2} \]

(3.19) \[ \| E \| \leq c(l)(k^{m+1} + h^2 k^m) \| u^0 \|_{2l}, \quad E \equiv \int_{t_1}^{t_2} (t - t)^{m} \partial_t^i \omega(t) dt. \]

Also, there exist \( E_1 \) and \( E_2 \) such that \( E = E_1 + E_2 \) while:

(3.20) \[ \| [kL_h(t_0)]^{1/2} E_1 \| \leq c(l) h k^{m+1/2} \| u^0 \|_{2(l+i)} \quad i = 0, 1 \]

(3.21) \[ \| kL_h(t_0) E_2 \| \leq c(l) k^{m+1+i} \| u^0 \|_{2(l+i)} \quad i = 0, 1. \]

Furthermore, for \( 0 \leq n \leq n^* \):

(3.22) \[ \| E \|_n \leq c(l)(k^{m+1} + h k^{m+1} + h^2 k^m) \| u^0 \|_{2l}. \]

**Proof.** By (1.6) or (1.17), (1.7), (1.19) and (1.4), for \( 0 \leq t \leq t^* \), and \( \theta = 0, \frac{1}{2} \):
\[ \| L_h^l (t_0) \partial_t^i \omega(t) \| \leq c(l) \| \partial_t^i \omega(t) \|_E \leq c(l) \| \partial_t^i \omega(t) \|_E + c(l) \| \partial_t^i u(t) \|_2 \leq c(l)(h + 1) \| u^0 \|_{2(l+i)} \]

which gives (3.18). Next:
\[ E = (t - t_1)^{m} \partial_t^{i-1} \eta(t) - m \int_{t_1}^{t_2} (t - t)^{m-1} \partial_t^{i-1} \eta(t) dt + \int_{t_1}^{t_2} (t - t)^{m} \partial_t^i u(t) dt \]

18
and (3.19) follows with (1.19) and (1.4). Now, define:

$$E_1 \equiv \int_{t_1}^{t_2} (t_2 - t)^m \partial_t^i [\omega(t) - P_E(t_0)u(t)] dt$$

$$= - (t_2 - t_1)^m \partial_t^i \left[ \omega(t_1) - P_E(t_0)u(t_1) \right] + m \int_{t_1}^{t_2} (t_2 - t)^{m-1} \partial_t^i [\omega(t) - P_E(t_0)u(t)] dt,$$

$$E_2 \equiv \int_{t_1}^{t_2} (t_2 - t)^m P_E(t_0) \partial_t^i u(t) dt$$

$$= - (t_2 - t_1)^m P_E(t_0) \partial_t^i u(t_1) + m \int_{t_1}^{t_2} (t_2 - t)^{m-1} P_E(t_0) \partial_t^i u(t) dt.$$

By (1.17), (1.19), (1.18), and (1.4), for $i = 0, 1$:

$$\| [k L_h(t_0)^{\frac{1}{2}}] E_1 \| \leq ck^{m+\frac{1}{2}+i} \sup_{0 \leq t \leq t^*} \{ \| \partial_t^{i-1+\eta(t)} \|_E + \| [I - P_E(t_0)] \partial_t^{i-1+i} u(t) \|_E \}$$

By (1.2) and (1.4), for $i = 0, 1$:

$$\| k L_h(t_0) E_2 \| \leq ck^{m+1+i} \sup_{0 \leq t \leq t^*} \| L(t_0) \partial_t^{i-1+i} u(t) \| \leq c(l)k^{m+1+i} \| u_0 \|_2(t+i).$$

Now, since $E = E_1 + E_2$, (3.20) and (3.21) are established. Finally:

$$(k L_h E, E) \leq \frac{1}{2} \| (k L_h^{\frac{1}{2}}) E_1 \|^2 + \frac{1}{2} \| (k L_h^{\frac{1}{2}}) E_2 \|^2 + \frac{1}{2} \| k L_h E \|^2$$

and (3.22) follows after combining this with (3.19)-(3.21).

**Lemma 3.4** The following hold for $0 \leq s \leq k$, and $0 \leq t \leq t^*$:

(3.23) $\| \mathcal{L}_h^\theta(t) \partial_\sigma^l \tilde{\omega}^n(s) \| \leq c \| u_0 \|_{2\mu} \quad 0 \leq l \leq \mu - 1, \quad \theta = 0, \frac{1}{2}$

(3.24) $\| \partial_\sigma^l \tilde{\omega}^n(s) \| + h \| \mathcal{L}_h^\theta(t) \partial_\sigma^l \tilde{\omega}^n(s) \| \leq ch^2 \| u_0 \|_{2\mu}.$

**Proof:** From (1.17) or (1.6), (2.18), (2.2), and (1.4), it follows that for $0 \leq l \leq \mu - 1$ and $\theta = 0, \frac{1}{2}$:

$$\| \mathcal{L}_h^\theta(t) \partial_\sigma^l \tilde{\omega}^n(s) \| \leq c(l) \sum_{i=0}^{l} \| \partial_\sigma^{-i} \tilde{T}_h^n(s) \partial_\sigma^i \tilde{\omega}^n(s) \| \leq c(l) \sum_{i=0}^{l} \mu - 1 \| \partial_\sigma^{-i} \tilde{T}_h^n(s) \partial_\sigma^i \tilde{\omega}^n(s) \|$$

which gives (3.23). Now, since $\partial_\sigma^l \tilde{\omega}^n(s) \equiv 0$, from (2.23), (2.2), and (1.4), it follows that:

$$\| \partial_\sigma^l \tilde{\omega}^n(s) \| = \| \partial_\sigma^l [\omega^n(s) - \tilde{\omega}^n(s)] \| \leq c \sum_{i=0}^{\mu} \| \partial_\sigma^{i-1} [\tilde{T}_h^n(s) - \tilde{T}_h^n(s)] \partial_\sigma^i \tilde{\omega}^n(s) \|$$

which gives (3.24). The remaining component of (3.24) follows similarly, after using (1.17) first.

The order of consistency is established in the next four lemmas.
Lemma 3.5 $\psi_1^n$ of (3.4) satisfies:

\[(3.25) \quad ||\psi_1^n||_n \leq c(k^2 + h^2 + h^2k^{-\frac{1}{2}} + h^2k^{-1})||u_0||_{2(\mu+1)}.
\]

**Proof:** First, it is proved that:

\[(3.26) \quad \partial_\star^l \omega^n(0) = D^l e \partial_\star^l \omega^n \quad 0 \leq l \leq \mu - 1.
\]

Now, the result of differentiating $L_h^n(s)\omega^n(s) = P_0 L_n(s)\omega^n(s)$ is:

\[
\sum_{i=0}^{l} \left( \sum_{m=0}^{\mu-1} \Gamma_m^l(\delta_m^n)^{-i} \binom{l}{i} L_h^{(l-i)}(t^n + \delta_m^n) \partial_\star^i \omega^n(s) \right) =
\]

\[
P_0 \sum_{i=0}^{l} \left( \sum_{m=0}^{\mu-1} \Gamma_m^l(\delta_m^n)^{-i} \binom{l}{i} L_h^{(l-i)}(t^n + \delta_m^n) \right) \sum_{j=i}^{\mu-1} D^i e \partial_\star^j u^n \frac{s^{j-i}}{(j-i)!}.
\]

Letting $s \to 0$, with (1.35), it follows that for $0 \leq l \leq \mu - 1$:

\[L_h^n \partial_\star^l \omega^n(0) = P_0 \sum_{i=0}^{l} \left( \binom{l}{i} L_h^{(l-i)}(t^n) D^i e \partial_\star^i u^n - \sum_{i=0}^{l-1} \binom{l}{i} L_h^{(l-i)}(t^n) \partial_\star^i \omega^n(0) \right).
\]

Then (3.26) follows inductively with:

\[L_h^n \partial_\star^l \omega^n = P_0 \sum_{i=0}^{l} \left( \binom{l}{i} L_h^{(l-i)}(t^n) D^i e \partial_\star^i u^n - \sum_{i=0}^{l-1} \binom{l}{i} L_h^{(l-i)}(t^n) \partial_\star^i \omega^n \right)
\]

which results after differentiating $L_h(t)\omega(t) = P_0 L(t)u(t)$. Therefore:

\[\omega^n - \omega^n = \sum_{i=0}^{\mu-1} D^i e \partial_\star^i \omega^n \frac{k^l}{l!} + E, \quad E \equiv \frac{1}{(\mu - 1)!}\int_0^k (k - s)^{\mu-1} \partial_\star^l \omega^n(s)ds.
\]

Next, by (1.35) and (1.33):

\[kA \sum_{m=0}^{\mu-1} \Gamma_m^l e \partial_\star^l (r_m^n) = kA \sum_{m=0}^{\mu-1} \Gamma_m^l e \partial_\star^{l+1} \omega^n \frac{k^l}{l!} + F = \sum_{l=0}^{\mu-2} \sum_{m=0}^{\mu-1} A\Gamma_m^l e \int_{r_m^n} (r_m^n - t)^{\mu-2} \partial_\star^l \omega^n(t)dt.
\]

Now define:

\[\tilde{E} \equiv k^{\frac{1}{2}} b T A^{-1} [I + kA L_h^n]^{-1} (kL_h^n)^{\frac{1}{2}} A(T_h^n)^{\frac{1}{2}} \tilde{E} \equiv (L_h^n)^{\frac{1}{2}} \tilde{E}.
\]

so that by (3.2), (2.14), and (2.24):

\[||\tilde{E}||_n \leq c k^{\frac{1}{2}} ||(L_h^n)^{\frac{1}{2}} E|| \leq c k^{\mu + \frac{1}{2}} \sup_{0 \leq s \leq k} ||(L_h^n)^{\frac{1}{2}} \partial_\star^l \omega^n(s)|| \leq c k^{\mu + \frac{1}{2}} ||u_0||_{2(\mu+1)}.
\]

Next, by Lemma 3.3, let $F = F_1 + F_2$ where with (1.36):

\[\|(kL_h^n)^{\frac{1}{2}} F_1\| \leq c k^{\mu + \frac{1}{2}} ||u_0||_{2(\mu+1)}, \quad ||kL_h^n F_2\|| \leq c k^{\mu+1} ||u_0||_{2(\mu+1)},
\]
and:

$$\|F\|_n \leq c(k^{\mu} + h^k + h^2k^{\mu-1})\|u^0\|_{2\mu}.$$ 

Then, define:

$$\tilde{F} = b^T A^{-1}[I + kA\tilde{L}_h^n]^{-1}(kL_h^n)^{\frac{1}{2}} A(\tau_h^n)^{\frac{1}{2}} [(\tau_h^n)^{\frac{1}{2}} F]$$

$$+ b^T A^{-1}[I + kA\tilde{L}_h^n]^{-1}(kL_h^n)^{\frac{1}{2}} A[(kL_h^n)^{\frac{1}{2}} F_1] + b^T A^{-1}[I + kA\tilde{L}_h^n]^{-1} A[kL_h^n F_2]$$

so that by (3.2), (2.16), and the last three inequalities:

$$\|\tilde{F}\|_n \leq c\|F\|_n + c\|(kL_h^n)^{\frac{1}{2}} F_1\| + c\|kL_h^n F_2\| \leq c(k^{\mu} + h^k + h^2k^{\mu-1})\|u^0\|_{2(\mu+1)}.$$ 

Now since \(\psi^* = E - \tilde{F}\), (3.25) follows.

Lemma 3.6 \(\psi^*_2\) of (3.4) satisfies:

(3.27) \[\|\psi^*_2\|_n \leq c k^{\mu+1} \|u^0\|_{2(\mu+1)}.\]

Proof: Define \(\tilde{v}(s) \equiv \tilde{L}^n(s)\tilde{u}^n(s)\) so that with ill-defined terms understood to be zero:

$$\partial_s^i \tilde{v}(s) = \sum_{i=0}^{\mu-1} \left( \begin{array}{c} i \\ i \end{array} \right) \sum_{m=0}^{\mu-1} \Gamma_m^i [(\delta^n_m)^{-i} L^{(l-i)}(t^n + \delta^n_m s)][\sum_{j=i}^{\mu-1} D^j e\partial_s^j u^n \left( \frac{s^{j-i}}{(j-i)!} \right)].$$ 

Letting \(s \to 0\), with (1.35) and (1.1), it follows that for \(0 \leq l \leq \mu - 1:\)

$$\partial_s^i \tilde{v}(0) = \sum_{i=0}^{\mu-1} \left( \begin{array}{c} i \\ i \end{array} \right) \sum_{m=0}^{\mu-1} \Gamma_m^i [(\delta^n_m)^{-i} L^{(l-i)}(t^n + \delta^n_m s)] D^j e\partial_s^j u^n = -D^j e\partial_s^j u^n.$$ 

Hence:

$$\tilde{L}^n u^n = -\sum_{l=0}^{\mu-1} D^j e\partial_s^j u^n \frac{k^l}{l!} + E, \quad E = \frac{1}{(\mu-1)!} \int_0^k (k-s)^{\mu-1} \partial_s^\mu \tilde{v}(s) ds.$$ 

Next, by (1.1) and (1.35):

$$\sum_{m=0}^{\mu-1} \Gamma_m^n \mathcal{L}(r_m^n)\mathcal{E}(r_m^n) = -\sum_{m=0}^{\mu-1} \Gamma_m^n \partial_s^i u(r_m^n) = -\sum_{l=0}^{\mu-1} \Gamma_m^n [(\delta^n_m)^l] \partial_s^{l+1} u^n \frac{k^l}{l!} - F$$

$$= -\sum_{l=0}^{\mu-1} D^j e\partial_s^{l+1} u^n \frac{k^l}{l!} - F, \quad F = \frac{1}{(\mu-1)!} \sum_{m=0}^{\mu-1} \Gamma_m^n \int_{t^n}^{r_m^n} (r_m^n - t)^{\mu-1} \partial_s^{\mu} \tilde{v}(t) dt.$$ 

Hence by (3.2):

$$\|\psi^*_2\|_n \leq ck(\|E\| + \|F\|).$$

Now, by (2.2) and (1.4):

$$\|E\| \leq c k^\mu \sum_{l=0}^{\mu} \sup_{0 \leq s \leq k} \|\partial_s^l \tilde{L}^n(s)\partial_s^j u^n(s)\| \leq c k^\mu \sum_{l=0}^{\mu-1} \|\partial_s^j u^n\|_2 \leq c k^\mu \|u^0\|_{2\mu}.$$
Also, by (1.36) and (1.4):
\[ ||F|| \leq c k^\mu \sup_{0 \leq t \leq t^*} ||\partial_t^{\mu+1} u(t)|| \leq c k ||u^0||_{z(\mu+1)} \]
and (3.27) follows from the last three inequalities.

**Lemma 3.7** \( \psi_n^g \) of (3.4) satisfies:

(3.28) \[ ||\psi_n^g||_n \leq c k h^n ||u^0||_{r+2} \]

**Proof.** By (3.2) and (1.36):
\[ ||\psi_n^g||_n \leq \sum_{m=0}^{\mu-1} ||\partial_t^m ((P E(r_m^n) - P_0) u(r_m^n))|| \leq \sum_{m=0}^{\mu-1} (||\partial_t^m u(r_m^n)|| + ||(I - P_0)\partial_t u(r_m^n)||) \]
and (3.28) follows with (1.19), (1.20), and (1.4).

**Lemma 3.8** \( \psi_n^h \) of (3.4) satisfies:

(3.29) \[ ||\psi_n^h||_n \leq c (k^{\mu} + k^{\mu-\frac{1}{2}} + k^{\mu-1}) ||u^0||_{2(\mu+1)} \]

**Proof.** First:
\[ \omega^{n+1} - \omega^n = \sum_{l=1}^{\mu} \partial_t^l \omega^n \frac{k^l}{l!} + E, \quad E = \frac{1}{\mu!} \int_{t^n}^{t^{n+1}} (t^{n+1} - t)^\mu \partial_t^{\mu+1} \omega(t) dt. \]

By (1.35) and (1.34):
\[ kb^T \sum_{m=0}^{\mu-1} \Gamma_m^n e \partial_t (r_m^n) = \sum_{l=0}^{\mu-1} b^T \sum_{m=0}^{\mu-1} \Gamma_m^n (n_m^l) e \partial_t^{l+1} \omega^n \frac{k^{l+1}}{l!} + F = \sum_{l=0}^{\mu-1} b^T D e \partial_t^{l+1} \omega^n \frac{k^{l+1}}{l!} + F = \sum_{l=1}^{\mu-1} \partial_t^l \omega^n \frac{k^l}{l!} + F, \quad F = \frac{k}{(\mu - 1)!} \sum_{m=0}^{\mu-1} b^T \Gamma_m^n e \int_{t^n}^{t_m^n} (r_m^n - t)^{\mu-1} \partial_t^{\mu+1} \omega(t) dt. \]
Hence \( \psi_n^h = -E + F \) and (3.29) follows after applying Lemma 3.3 to \( E \) and \( F \), and using (1.36) to obtain inequalities of the form (3.22).

With the consistency complete, it is now appropriate to discuss the development of the techniques used. First, it is possible to construct an error equation alternative to (3.4) which circumvents the constructions of section 2. However, this requires inverse properties. For example, one option involves the following replacements:
\[ \tilde{\omega} \rightarrow \sum_{l=0}^{\mu-1} D e \partial_t^l \omega^n \frac{k^l}{l!}, \quad \psi_2 \rightarrow kb^T A^{-1} [I + kA \tilde{L}_h^n]^{-1} A \sum_{m=0}^{\mu-1} \Gamma_m^n \mathcal{L}_h (r_m^n) [\tilde{\omega} - e\omega(r_m^n)]. \]
Then in the proof of Lemma 3.6, \( \tilde{v}(s) \) is changed to \( \tilde{L}_h^n(s) \tilde{\omega}(s) \), and bounding derivatives of the latter involves bounding products of the form \( L_h^{(i)}(s) T_h^{(j)}(t) \). This can be accomplished using inverse assumptions as demonstrated by Bales [2].
Also, the original idea for overcoming the suboptimal convergence rates mentioned in connection with (1.39), was to find \( q \times q \) matrices \( \{D_l\}_{l=0}^{\nu-1} \) with which the following would lead to optimal convergence estimates:

\[
\sum_{m=0}^{\nu-1} \Gamma_m^n(\delta_m^n)^l \equiv D_l, \quad 0 \leq l \leq \nu - 1; \quad D_h^n \equiv \sum_{m=0}^{\nu-1} \Gamma_m^n L_h(t^n + \delta_m^n k) \approx \sum_{l=0}^{\nu-1} D_l e^{(0)}(t^n) k^l.
\]

However, attempts to prove an optimal order of consistency have repeatedly led to the following conditions for the matrices \( \{D_l\}_{l=0}^{\nu-1} \):

\[
D_0 e = e; \quad D_i D_j e = D_{i+j} e, \quad 0 \leq i, j, i + j \leq \nu - 1; \quad lAD_{l-1} e = D_l e, \quad 1 \leq l \leq \nu - 1.
\]

Consider for example, adapting the proof of Lemma 3.5. Unfortunately, even though the number of unknowns matches the number of constraints in the equations above, it is shown in [14] that they can be solved only if \( \nu \leq q + 1 \).

Now, (1.5) is established in the following for (1.38).

**Theorem 3.1** Under the conditions of Lemma 3.1 and either Proposition 3.1 or 3.2, \( \{U_h^n\}_{n=0}^{n^*} \) are well-defined by (1.37) and (1.38), and the following holds:

\[
(3.30) \quad \max_{0 \leq n \leq n^*} \|U_h^n - u^n\| \leq c^* (h^r + k\mu + h^\mu k^{\mu-\frac{1}{2}} + h^2 k^{\mu-1}) \|u_0\|_\alpha.
\]

Also, unless \( \tilde{c} < 0 \) in (3.9), \( c^* \) depends exponentially on \( t^* \).

**Proof:** Set \( E \equiv [(h^r + k\mu + h^\mu k^{\mu-\frac{1}{2}} + h^2 k^{\mu-1}) \|u_0\|_\alpha]^2 \). Then, combining (3.9), (3.25), (3.27), (3.28) and (3.29) for (3.4):

\[
\|\xi^{n+1}\|_{n+1} \leq (1 + \tilde{c}k)\|\xi^n\|^2 + c_1 kE \quad 0 \leq n \leq n^* - 1.
\]

After dividing this by \( (1 + \tilde{c}k)^{n+1} \) and summing, the result is:

\[
\|\xi^n\|^2 \leq (1 + \tilde{c}k)^n\|\xi^0\|^2 + c_1 |\tilde{c}|^{-1}|1 - (1 + \tilde{c}k)^n|E \quad 0 \leq n \leq n^*.
\]

Now, according to (1.37), \( [I + k L_h] \xi^0 = [P_0 - P_E^0] u_0 \). So with (1.20), (1.18) and a spectral argument, it follows that:

\[
(3.31) \quad \|\xi^0\|^2_0 \leq c \|[P_0 - P_E^0] u_0\| \|[I + k L_h]^{-1}[P_0 - P_E^0] u_0\| \leq c h^r \|u_0\|_r.
\]

Then, (3.30) follows with (1.19) and the last two inequalities.

**4 Iterative Approximations.**

In this section, the iterative scheme (1.46) is analyzed for the approximation of the solution to (1.1), and (1.5) is established. First, a brief discussion of Preconditioned Iterative Methods (PIM's) is given. See Hageman and Young [11] for more information.

Let \( H \) be any finite-dimensional Hilbert space equipped with an inner product \( \langle \cdot, \cdot \rangle_H \) and an associated norm \( \| \cdot \|_H \). Also, let \( Q: H \to H \) be \( H \)-selfadjoint and positive definite, and suppose that an approximation is required for the solution \( x^* \) to:

\[
(4.1) \quad Qx^* = b.
\]
Then, suppose that $Q_0: H \to H$ is $H$-selfadjoint and positive definite, and that solving:

\[ Q_0 \tilde{x} = b \]  

is relatively inexpensive. Furthermore, assume that $Q$ and $Q_0$ are equivalent:

\[ \rho_1(Q_0x, x)_H \leq (Qx, x)_H \leq \rho_2(Q_0x, x)_H \quad \forall x \in H. \]  

The operator $Q_0$ is called the preconditioner and the PIM’s of interest in this work are those with the following properties:

i. If $\{x_j\}_{j=0}^I$ are given approximations to $x^*$ of (4.1), then calculating $x_{j+1}$ only involves computing $Qx, Q_0x, (Qx, x)_H,$ and $(Q_0x, x)_H$ for certain $x \in H,$ and solving equations of the form (4.2).

ii. There is a smooth decreasing function $\sigma: (0,1) \to (0,1)$ such that $\sigma(1) = 0$ and if (4.3) holds, then:

\[ \|Q_0^{\frac{1}{2}}[x^* - x_j]\|_H \leq c[\sigma(\rho_1/\rho_2)]^I\|Q_0^{\frac{1}{2}}[x^* - x_0]\|_H. \]

For example, the Preconditioned Conjugate Gradient Method satisfies the above properties, and it is popular for having $\sigma(s) = (1 - \sqrt{s})/(1 + \sqrt{s})$ as opposed to say $(1 - s)/(1 + s),$ which is offered by various other PIM’s.

Now, the rough discussion prior to (1.46) is expanded with more details. First, suppose that for $0 \leq n \leq n^* - 1,$ the approximations $\{U^n_k\}_{m=0}^m$ have been computed using methods described below, and recall that an efficient procedure is needed for computing $\bar{U}^n_k$ defined by (1.40). Next, let $\bar{V}_0^n$ denote an initial approximation to $\bar{U}^n_k$ given as indicated in (1.42). Now, instead of actually computing $\{V^n_k\}_{0 \leq i \leq l_n}$ as suggested by (1.41), proceed as follows. Let a sequence of positive integers $\{j_n\}_{n=0}^{n^*-1}$ be specified. Then, suppose in an inductive fashion, that for $l \geq 1,$ $\bar{V}^n_{l-1,j_n}$ has been computed from $j_n$ PIM iterations as prescribed below, and let $\bar{V}^n_i$ be defined by the outer iteration:

\[ [I + k\Lambda L^n_k](S\bar{V}^n_i) = \{ScU^n_k + k\lambda S(L^n_k - L^n_k)\bar{V}^n_{l-1,j_n}\} \quad 1 \leq l \leq l_n \]

with the understanding that $\bar{V}_{0,j_n}^n \equiv \bar{V}^n_i.$ Letting $n$ and $l$ be fixed, (4.5) can be written in the form:

\[ [I + k\lambda_i L^n_k]\psi_i = \phi_i - k\theta_i L^n_k\psi_{i-1} \quad 1 \leq i \leq q \]

where $\psi_0 \equiv 0, \psi_i \equiv (S\bar{V}^n_i)i, 1 \leq i \leq q,$ and according to (1.35) with $l = 0$:

\[ \phi_i \equiv [ScU^n_k + k\lambda S \sum_{m=1}^{n^*-1} \Gamma^m_m(L^n_k - L^n_k)\bar{V}^n_{l-1,j_n}]i. \]

The natural preconditioning for (4.6) involves $[I + kL^n_k]$ which, according to (1.16) and (1.31), is equivalent to the operators of (4.6), i. e., for $1 \leq i \leq q$ and $0 \leq n \leq n^*:

\[ \rho_1([I + kL^n_k]X, X) \leq ([I + \lambda_i L^n_k]X, X) \leq \rho_2([I + kL^n_k]X, X) \quad \forall X \in S^n_k. \]
Now, to cover the case that $A$ is not diagonalizable, define $\tilde{\psi}_i$ with:

\begin{equation}
[I + k\lambda_iL_h^n]^{n} \tilde{\psi}_i = \phi_i - k\theta_iL_h^n\tilde{\psi}_{i-1} \quad 1 \leq i \leq q
\end{equation}

where $\tilde{\psi}_0 \equiv 0$. Also, to obtain $\tilde{\psi}^n_i$ for $1 \leq i \leq q$, set $\tilde{\psi}^0_i \equiv (S\tilde{V}^{-1}_{i-1,j_n})_i$ and let iterates $\{\tilde{\psi}^j_i\}_{0 \leq j \leq j}$ be given by a PIM with preconditioner $[I + kL_h^0]$. Then as (4.4) follows from (4.3), from (4.8) it follows that:

\begin{equation}
||\tilde{\psi}_i - \tilde{\psi}^j_i||_0 \leq c[\sigma(\rho_1/\rho_2)]^j||\tilde{\psi}_i - \tilde{\psi}^0_i||_0.
\end{equation}

Finally, take $\Psi \equiv (\psi_1, \psi_2, \ldots, \psi_q)^T$ and $\tilde{\psi}^j = (\tilde{\psi}_1^j, \tilde{\psi}_2^j, \ldots, \tilde{\psi}_q^j)^T$ so that $\tilde{V}^n = S^{-1}\Psi$ and inner iterates for (4.5) are defined by:

\begin{equation}
\tilde{V}_{i,0}^n = \tilde{V}^n_{i-1,j_n} \quad \tilde{V}_{i,j}^n = S^{-1}\tilde{\psi}^j, \quad 1 \leq j \leq j_n.
\end{equation}

Now the next objective is to show that:

\begin{equation}
||\tilde{U}_{i,j}^n - \tilde{V}_{i,j}^n||_0 \leq (ck + c[\sigma(\rho_1/\rho_2)]^n)||\tilde{U}_f^n - \tilde{V}^n_{i-1,j_n}||_0 \quad l \geq 1.
\end{equation}

Then, given some $\varepsilon_0 > 0$, $j_n$ is chosen so that:

\begin{equation}
||\tilde{U}_f^n - \tilde{V}_{i,j}^n||_0 \leq \beta_n ||\tilde{U}^n - \tilde{V}_{i-1,j_n}||_0 \quad 1 \leq l \leq l_n
\end{equation}

where:

\begin{equation}
\beta_n^2 \leq \begin{cases} ck^2, & 0 \leq n \leq \mu \\ \varepsilon_0^r, & 0 \leq n \leq n^* - 1. \end{cases}
\end{equation}

From the last three inequalities, it follows that the integers $\{j_n\}_{n=0}^{n^*}$ may be chosen to satisfy (1.45) as claimed in the Introduction. First, the outer iterations (1.41) and (4.5) are shown to be well-conceived.

**Lemma 4.1** With $\tilde{U}_f^n$ given by (1.40), the following holds:

\begin{equation}
||\tilde{U}_f^n - \tilde{V}_1||_0 \leq ck ||\tilde{U}_f^n - \tilde{V}_1||_0
\end{equation}

for every $\tilde{V}_1, \tilde{V}_2 \in S_h$ satisfying:

\begin{equation}
[I + kAL_h^n]\tilde{V}_2 = e\tilde{U}_f^n + kA(\tilde{L}_h^n - \tilde{P}_h^n)\tilde{V}_1.
\end{equation}

**Proof:** Since:

\begin{equation}
\tilde{U}_f^n - \tilde{V}_2 = [I + kAL_h^n]\tilde{V}_2 = e\tilde{U}_f^n + kA(\tilde{L}_h^n - \tilde{P}_h^n)(\tilde{T}_h^n)(\tilde{L}_h^n)\frac{1}{2}(\tilde{U}_f^n - \tilde{V}_1).
\end{equation}

(4.15) follows with (3.2), (2.16), and (3.6).

The next lemma shows that $\{\tilde{V}_{i,j}^n\}_{j \geq 0}$ converges to $\tilde{V}_f^n$ at a rate which reflects (4.10) whether or not the right sides of (4.6) and (4.9) are the same.

**Lemma 4.2** With $\tilde{V}_f^n$, $\tilde{V}_{i,j}^n$, and $\tilde{V}_{i,0}^n$ given by (4.5) and (4.11):

\begin{equation}
||\tilde{V}_f^n - \tilde{V}_{i,j}^n||_0 \leq c[\sigma(\rho_1/\rho_2)]^n ||\tilde{V}_f^n - \tilde{V}_{i,0}^n||_0.
\end{equation}
Proof: Letting \( \sigma \equiv \sigma(\rho_1/\rho_2) \), with (4.10), it follows that:

\[
\|\psi_i - \tilde{\psi}_i\|_0 \leq \|\psi_i - \check{\psi}_i\|_0 + \|\tilde{\psi}_i\|_0 \leq \|\psi_i - \check{\psi}_i\|_0 + c\sigma^j \|\psi_i - \tilde{\psi}_i\|_0
\]

\[
\leq (1 + c\sigma^j) \|\psi_i - \check{\psi}_i\|_0 + c\sigma^j \|\psi_i - \tilde{\psi}_i\|_0.
\]

Subtracting (4.9) from (4.6), with (3.6), (1.31), and a spectral argument, it follows that:

\[
\|\psi_i - \tilde{\psi}_i\|_0 \leq c\|\{I + k\lambda_i L_n\}^{-1}k\theta_i L_n^2(\psi_{i-1} - \tilde{\psi}_{i-1})\|^2_n
\]

\[
\leq c\{(\{I + kL_n^2\}(I + k\lambda_i L_n^{-2})\}(kL_n^3)\}(\psi_{i-1} - \tilde{\psi}_{i-1})\)
\]

\[
\leq c\|\psi_{i-1} - \tilde{\psi}_{i-1}\|^2_0 \quad 1 \leq i \leq q
\]

Now, the last two inequalities give:

\[
\|\psi_i - \tilde{\psi}_i\|_0 \leq c\|\psi_{i-1} - \tilde{\psi}_{i-1}\|_0 + c\sigma^j \|\psi_i - \tilde{\psi}_i\|_0
\]

from which it follows recursively that:

\[
\|\psi_i - \tilde{\psi}_i\|_0 \leq c\sigma^j \sum_{m=1}^i \|\psi_m - \tilde{\psi}_m\|_0.
\]

Then (4.16) follows after recalling (4.11) and that \( \tilde{\psi}_i \) = \( S^{-1}\Phi \).

Finally, (4.12) is established in the following.

Lemma 4.3 With \( U_n^p \) defined by (1.40), the sequence \( \{\tilde{V}_n\}_{i=0}^\infty \) satisfies (4.18).

Proof: Applying Lemma 4.1 to (4.5):

\[
\|\tilde{V}_n - \tilde{V}_i\|_0 \leq c\|\tilde{V}_n - \tilde{V}_{i-1,n}\|_0
\]

Using this with (4.16) and (4.11):

\[
\|\tilde{V}_n - \tilde{V}_{i,n}\|_0 \leq c\sigma^j \|\tilde{V}_n - \tilde{V}_{i-1,n}\|_0 = c\sigma^j \|\tilde{V}_n - \tilde{V}_{i-1,n}\|_0
\]

\[
\leq c\sigma^j \{\|\tilde{V}_n - \tilde{V}_{i,n}\|_0 + \|\tilde{V}_n - \tilde{V}_{i-1,n}\|_0\} \leq c\sigma^j (c + 1) \|\tilde{V}_n - \tilde{V}_{i-1,n}\|_0.
\]

Now, (4.12) follows after triangulating with \( \tilde{V}_n \).

The next objective is to show that the convergence rate (1.5) can be preserved even when \( \{j_n\}_{n=0}^{n-1} \) are chosen so that (4.13) and (4.14) hold. So additional stability and consistency arguments follow. First, define:

\[
\zeta^n \equiv U_n - \omega_n \quad \text{and} \quad \psi^n \equiv R_n^p \omega^n - \omega^{n+1}
\]

where \( \psi^n \) is as in (3.4). Now, according to (1.46) and (1.38):

\[
U_{n+1}^n - R_n^p U_n^p = b^T A^{-1}(U_n^p - \tilde{U}_n^p),
\]

26
so it follows that:

\[
(4.17) \quad s^{n+1} = R_h^n s^n + \phi^n - b^T A^{-1}(\bar{U}_h^n - \bar{U}_h^n).
\]

By (4.13) and (1.46), \((\bar{U}_h^n - \bar{V}_h^n)\) can be estimated in terms of \((\bar{U}_h^n - \bar{V}_h^n)\). So, the error equation (4.17) is supplemented with the following one, which is obtained from (1.40) and (1.42) after some straightforward calculations:

\[
\bar{U}_h^n - \bar{V}_h^n = \sum_{m=n-1}^{n-1} (-1)^{n-m} \left( \frac{\mu_n + 1}{n-m} \right) [I + kA \bar{U}_h^n]^{-1} kA (\bar{L}_h^n - \bar{L}_h^n)[I + kA \bar{L}_h^n]^{-1} \varepsilon^n m
\]

\[
+ [I + kA \bar{L}_h^n]^{-1} \sum_{m=n-1}^{n-1} (-1)^{n-m} \left( \frac{\mu_n}{n-m} \right) [s^{m+1} - s^m]
\]

\[
- \sum_{m=n-1}^{n-1} (-1)^{n-m} \left( \frac{\mu_n + 1}{n-m} \right) (\bar{U}_h^m - \bar{U}_h^m)
\]

\[
- \sum_{m=n-1}^{n-1} (-1)^{n-m} \left( \frac{\mu_n + 1}{n-m} \right) [I + kA \bar{L}_h^n]^{-1} kA (\bar{L}_h^n - \bar{L}_h^n)[I + kA \bar{L}_h^n]^{-1}
\]

\[
x\{\bar{\omega}^m - c\omega^m - kA \sum_{i=0}^{\mu-1} \Gamma_i^m e\partial_i \omega(r_i^m)\}
\]

\[
(4.18)
\]

\[
- k \sum_{m=n-1}^{n-1} (-1)^{n-m} \left( \frac{\mu_n + 1}{n-m} \right) [I + kA \bar{L}_h^n]^{-1} A P_0 \sum_{i=0}^{\mu-1} \Gamma_i^m \partial_i \{[P_E(r_i^m) - P_0]u(r_i^m)\}
\]

\[
- k \sum_{m=n-1}^{n-1} (-1)^{n-m} \left( \frac{\mu_n + 1}{n-m} \right) [I + kA \bar{L}_h^n]^{-1} A P_0 \sum_{i=0}^{\mu-1} \Gamma_i^m \partial_i \{[P_E(r_i^m) - P_0]u(r_i^m)\}
\]

\[
+ \sum_{m=n-1}^{n-1} (-1)^{n-m} \left( \frac{\mu_n + 1}{n-m} \right) \bar{\omega}^m
\]

\[
- [I + kA \bar{L}_h^n]^{-1} \sum_{m=n-1}^{n-1} (-1)^{n-m} \left( \frac{\mu_n + 1}{n-m} \right) \{\bar{\omega}^m - c\omega^m - kA \sum_{i=0}^{\mu-1} \Gamma_i^m e\partial_i \omega(r_i^m)\}
\]

\[
\equiv \sum_{l=1}^{8} \Theta_l^n \quad 1 \leq n \leq n^* - 1.
\]

Before analyzing these error equations, a few adjustments must be made in Propositions 3.1 and
3.2 for the following stronger stability inequality:

\[
\|s^{n+1}\|_{n+1}^2 \leq (1 + \epsilon k)\|s^n\|_n^2 - c_0\|(I - r_h^n)\|_n^2 + c k^{-1}\|\tilde{U}_h^n - \tilde{U}_h^n\|_n^2 \\
+ c k (h^\mu + h k^{\mu - \frac{1}{2}} + h^2 k^{\mu - 1})\|u_0\|_\alpha^2 \quad 0 \leq n \leq n^* - 1.
\]  

(4.19)

**Proposition 4.1** Let (1.29) be satisfied. Then there are constants \( c_0 > 0 \) and \( \tilde{c} \), such that (4.19) holds. In fact, \( \tilde{c} < 0 \) if (1.27) holds and \( c(1) \) of (1.19) is small enough.

**Proof.** By the same manipulations leading (3.10)) for (4.17) it follows that:

\[
(1 - c_3 k)\|s^{n+1}\|_{n+1}^2 \leq \|r_h^n s^n\|_n^2 + \epsilon^{-1} c_1 k\|s^n\|_n^2 + c k^{-1}\|\tilde{U}_h^n - \tilde{U}_h^n\|_n^2 + c k^{-1}\|\psi^n\|_n^2.
\]

By (1.26), \( I - r_h^n \) has a square root. Hence, taking \( \chi^n \equiv [I + k L_h^n]^{-\frac{1}{2}} s^n \), with (1.29) it follows that:

\[
\|r_h^n s^n\|_n^2 = \chi^n \|\chi^n\|_n^2 - (\chi^n, [I - r_h^n] \chi^n) \leq \|s^n\|_n^2 - \delta ([I - r_h^n] \chi^n, \chi^n).
\]

Using (3.12), there is a \( \bar{c} \leq 0 \) such that:

\[-([I - r_h^n] \chi^n, \chi^n) \leq \frac{1}{2} (r_h^n \chi^n, \chi^n) + \frac{1}{2} (1 + \bar{c} k) \|\chi^n\|_n^2 - \|\chi^n\|_n^2 = \frac{1}{2} \bar{c} k \|s^n\|_n^2 - \frac{1}{2} ([I - r_h^n] \chi^n, \chi^n),
\]

where \( \bar{c} < 0 \) if (1.27) holds. Now with \( \bar{c} > \frac{1}{2} \delta \bar{c} + c_3 + \epsilon^{-1} c_1 \), and \( c_0 = \frac{1}{2} \delta \), (4.19) follows after combining (3.25), (3.27), (3.28), (3.29) and the last three inequalities.

As with Proposition 3.2, \( \bar{c} < 0 \) is guaranteed for (4.19) by the following.

**Proposition 4.2** Let (1.27) and (1.28) be satisfied. Then, there are constants \( c_0 > 0 \) and \( \bar{c} < 0 \) such that (4.19) holds.

**Proof.** In the proof of Proposition 3.2, replace \( \xi^n \) with \( s^n \), and \( \psi^n \) with \( \psi^n - b^T \lambda^{-1}(\tilde{U}_h^n - \tilde{U}_h^n) \). Then with \( \epsilon \equiv \frac{1}{2} (c_2 - c_1) \), redefine \( \theta \equiv (1 - c_1 - 2 \epsilon)/(1 + c_3 k_0) \) so that the last part of the proof is readily changed to give the following instead of (3.13):

\[
\|R_h^n s^n\|_n^2 + (1 + \epsilon_1)\|(k L_h^n + 1)^{\frac{1}{2}} R_h^n s^n\|_n^2 \leq (1 + \bar{c} k)\|s^n\|_n^2 - \epsilon\|(k L_h^n)^{\frac{1}{2}} s^n\|_n^2.
\]

As with (3.14), it follows that:

\[
\|s^{n+1}\|_{n+1}^2 \leq (1 + \bar{c} k)\|s^n\|_n^2 - \epsilon(k L_h^n s^n, s^n) + c k^{-1}\|\tilde{U}_h^n - \tilde{U}_h^n\|_n^2 + c k^{-1}\|\psi^n\|_n^2.
\]

Next, since \( \nu \geq 1, r(0) = 1 = -r'(0) \). So, there is a \( c_0 > 0 \) such that for all \( z \geq 0 \), \( r(z) \) is greater than the linear function \( 1 - \frac{\epsilon}{2 c_0} z \), i.e., \( -\epsilon z \leq -2 c_0 [1 - r(z)] \), \( \forall z \geq 0 \). Also, using (1.26), \( c_0 \) can be assumed small enough that \( -\epsilon \leq -2 c_0 [1 - r(z)] \), \( \forall z \geq 0 \). After multiplying the latter by \( z \) and adding the result to former, it follows that:

\[-\epsilon(k L_h^n \chi, \chi) \leq -c_0([I + k L_h^n] [I - r_h^n] \chi, \chi) \quad \forall \chi \in S_h.
\]

Hence, (4.19) follows with (3.25), (3.27), (3.28) and (3.29) and the last two inequalities.

Now, estimation of the terms of (4.18) begins.
Lemma 4.4 \( \{ \Theta_{\alpha}^{n} \}_{\alpha=1}^{3} \) of (4.18) satisfy:

\[
(4.20) \quad \sum_{\alpha=1}^{3} \| \Theta_{\alpha}^{n} \|_{n} \leq c \sum_{m=n-1-\mu_{n}}^{n-1} \{ \| s^{m+1} - s^{m} \|_{m} + \| \tilde{U}_{n}^{m} - \tilde{U}_{n}^{m} \|_{m} \} + ck \sum_{m=n-1-\mu_{n}}^{n-1} \| s^{m} \|_{m}.
\]

**Proof:** First, note that:

\[
\Theta_{\alpha}^{n} = \sum_{m=n-1-\mu_{n}}^{n-1} (-1)^{n-m} \left( \binom{\mu_{n} + 1}{n-m} \right) (I + kA\tilde{L}_{n}^{m})^{-1} (k\tilde{L}_{n}^{m})^{1/2} A
\]

\[
\times (\tilde{T}_{n}^{m})^{1/2} \{ (\tilde{L}_{n}^{m} - L_{n}^{m}) + (L_{n}^{m} - \tilde{L}_{n}^{m}) \} (\tilde{T}_{n}^{m})^{1/2} [ (L_{n}^{m})^{1/2} (L_{n}^{m})^{1/2} ] (k\tilde{L}_{n}^{m})^{1/2} \| I + kA\tilde{L}_{n}^{m} \|^{-1} e_{n}^{m}.
\]

So, \( \Theta_{\alpha}^{n} \) is estimated using (3.2), (2.16), (2.15), and (1.15). Also, estimates for \( \Theta_{\beta}^{n} \) and \( \Theta_{\delta}^{n} \) follow with (3.2) and (3.6).

Lemma 4.5 \( \{ \Theta_{\alpha}^{n} \}_{\alpha=4}^{6} \) of (4.18) satisfy:

\[
(4.21) \quad \sum_{\alpha=4}^{6} \| \Theta_{\alpha}^{n} \|_{n} \leq ck(h^{\alpha} + k^{\alpha}) \| u^{0} \|_{\alpha}.
\]

**Proof:** Recall \( E \) and \( F \) defined in the proof of Lemma 3.5. By (3.18), and (3.23):

\[
\| E \| + \| F \| \leq ck^{\alpha} \| u^{0} \|_{2(\mu+1)}.
\]

So \( \Theta_{\alpha}^{n} \) can be estimated using the techniques applied for the estimation of \( \Theta_{\alpha}^{n} \). Also, the same manipulations used to prove Lemmas 3.6 and 3.7 give corresponding estimates for \( \Theta_{\beta}^{n} \) and \( \Theta_{\delta}^{n} \).

Lemma 4.6 \( \Theta_{\gamma}^{n} \) of (4.18) satisfies:

\[
(4.22) \quad \| \Theta_{\gamma}^{n} \|_{n} \leq ck(k^{\mu n} + h^{k^{\mu n}-\frac{1}{2}} + k^{2} k^{\mu n-1}) \| u^{0} \|_{2(\mu+1)}.
\]

**Proof:** By (3.26), for \( n-1-\mu_{n} \leq m \leq n-1 \):

\[
\tilde{\omega}^{m} \equiv E^{m} + F^{m}, \quad F^{m} \equiv \frac{1}{(\mu-1)!} \int_{0}^{k} (k-s)^{\mu-1} \partial_{s}^{\mu} \tilde{\omega}^{m}(s) ds
\]

and taking \((m-n)\lambda|_{m=n-1-i=0} = 1\):

\[
E^{m} \equiv \sum_{\lambda=0}^{\mu-1} D^{\lambda} k^{\frac{k^{\lambda}}{\lambda!}} \{ \sum_{i=0}^{\mu-1} (m-n)^{i} \partial_{i}^{\mu} \omega_{\mu}^{n} \lambda + G_{\gamma}^{m} \}, \quad G_{\gamma}^{m} \equiv \frac{1}{(\mu-1)!} \int_{0}^{m} (t^{\mu} - t)^{\mu-1} \partial_{t}^{\mu} \omega(t) dt.
\]

Next, since:

\[
\gamma_{n}^{n} \equiv \sum_{m=n-1-\mu_{n}}^{n-1} (-1)^{n-m} \left( \binom{\mu_{n} + 1}{n-m} \right) (m-n)^{i} = 0 \quad 0 \leq i \leq \mu_{n}
\]

29
it follows after some re-indexing that:

\[
\sum_{m=n-1-\mu_n}^{n} (-1)^{n-m} \binom{\mu_n + 1}{n - m} E^m = \\
\sum_{l=0}^{\mu_n - 1} \frac{D^l}{l!} \left\{ \sum_{j=l+\mu_n + 1}^{\mu} \frac{\gamma_{j-l}^n}{(j-l)!} \beta_j^l \omega^n k^j \right\} \sum_{m=n-1-\mu_n}^{n} (-1)^{n-m} \binom{\mu_n + 1}{n - m} k^l G^m_l
\]

where ill-defined sums are understood to be zero. Now, by Lemma 3.3:

\[
k^l \| \beta_j^l \omega^n \|_n \leq c k^{\mu_n + 1} \| u^0 \|_{2(\mu + 1)} \quad \mu_n + 1 \leq j \leq \mu
\]

\[
k^l \| G^m_l \|_n \leq c k(\mu^2 + h k^{\mu-\frac{1}{2}} + h^2 k^{\mu-1}) \| u^0 \|_{2(\mu + 1)} \quad 0 \leq l \leq \mu - 1.
\]

Hence:

\[
\| \sum_{m=n-1-\mu_n}^{n} (-1)^{n-m} \binom{\mu_n + 1}{n - m} E^m \|_n \leq c k(\mu^2 + h k^{\mu-\frac{1}{2}} + h^2 k^{\mu-1}) \| u^0 \|_{2(\mu + 1)}.
\]

Also, by (3.24):

\[
\| F^m \|_n \leq c(k^{\mu-\frac{1}{2}} + h^2 k^{\mu-1}) \| u^0 \|_{2(\mu + 1)} \quad n - 1 - \mu_n \leq m \leq n.
\]

Then (4.22) follows from the last two inequalities.

**Lemma 4.7** $\Theta^m_\delta$ of (4.18) satisfies:

(4.23) \[ ||\Theta^m_\delta||_n \leq c k(\mu + h^2 k^{\mu-1}) \| u^0 \|_{2(\mu + 1)}. \]

**Proof:** As in the proof of Lemma 3.5:

\[
\tilde{\omega}^m - \epsilon \omega^m - k A \sum_{i=0}^{\mu-1} \Gamma_i^m e \partial_t \omega(r_i^m) = E^m - F^m, \quad E^m = \frac{1}{(\mu - 1)!} \int_0^k (k - s)^{\mu-1} \partial_s^\mu \omega^m(s) ds
\]

and by (1.35):

\[
F^m = \frac{k^\mu}{(\mu - 1)!} A D^{\mu-1} e \partial_t^{\mu} \omega^m + \frac{k}{(\mu - 1)!} \sum_{i=0}^{\mu-1} A \Gamma_i^m e \int_{r_i^m}^{r_i^m} (r_i^m - t)^{\mu-1} \partial_t^{\mu+1} \omega(t) dt = F_1^m + F_2^m.
\]

First, using (3.2):

\[
||\Theta^m_\delta||_n \leq c \left( \sum_{m=n-1-\mu_n}^{n} (||E^m|| + ||F_1^m||) \right) + c \left( \sum_{m=n-1-\mu_n}^{n} (-1)^{n-m} \binom{\mu_n + 1}{n - m} F_1^m. \right)
\]

Then, with (3.24):

\[
||E^m|| \leq c h^2 k^{\mu} \| u^0 \|_{2\mu} \quad n - 1 - \mu_n \leq m \leq n.
\]

Also, by Lemma 3.3:

\[
||F_2^m|| \leq c(k^{\mu} + h^2 k^{-1}) \| u^0 \|_{2(\mu + 1)} \quad n - 1 - \mu_n \leq m \leq n.
\]
Finally, note that:

\[
\sum_{m=n-1-\mu_n}^{n} (-1)^{n-m} \binom{\mu_n + 1}{n-m} \nabla^m = \frac{k^\mu}{(\mu - 1)!} A D^{\mu - 1} e
\]

\[
\times \{ \sum_{m=n-1-\mu_n}^{n} (-1)^{n-m} \binom{\mu_n}{n-m} \int_{t_{m-1}}^{t_m} \partial^\mu_{u(t)} dt - \sum_{m=n-1-\mu_n}^{n} (-1)^{n-m} \binom{\mu_n + 1}{n-m} \partial^\mu_{\eta^m} \}. 
\]

So, by (1.4) and (1.19):

\[
\| \sum_{m=n-1-\mu_n}^{n} (-1)^{n-m} \binom{\mu_n + 1}{n-m} \| F_1^m \| \leq c k (h^2 k^{\mu - 1} + k^\mu)\| u^0 \|_2 (\mu + 1).
\]

Now, (4.23) follows after combining the last four inequalities.

Next, the above lemmas are combined with (4.13) for the estimation of the term \( k^{-1}\| \tilde{\Omega}^n_h - \tilde{\Omega}^n_h \|_n^2 \) in (4.19).

**Proposition 4.3** With \( \tilde{\Omega}^n_h \) defined by (1.40) and \( \tilde{\Omega}^n_h \) by (1.46), the following hold:

\[
k^{-1}\| \tilde{\Omega}^n_h - \tilde{\Omega}^n_h \|_n^2 \leq c k^{-1} \beta_n^2 \sum_{m=n-1-\mu_n}^{n-1} \{\| \tilde{\Omega}^m_h - \tilde{\Omega}^m_h \|_m^2 + \| s^{m+1} - s^m \|_m^2 \} + c k (h^r + k^\mu + h k^{\mu - 1} + h^2 k^{\mu - 1})\| u^0 \|_\alpha^2 
\]

\[
1 \leq n \leq n^* - 1,
\]

(4.24)

\[
\| \tilde{\Omega}^0_h - \tilde{\omega}^0 \|_0 \leq c k^\mu \| u^0 \|_\alpha.
\]

(4.25)

**Proof:** By (1.46), (4.13) and (3.6):

\[
\| \tilde{\Omega}^n_h - \tilde{\Omega}^n_h \|_n \leq c \beta_n^2 \| \tilde{\Omega}^n_h - \tilde{\omega}^n \|_n \quad 0 \leq n \leq n^* - 1.
\]

Then, combining (4.20), (4.21), (4.22), and (4.23) for (4.18) leads to:

\[
\| \tilde{\Omega}^n_h - \tilde{\omega}^n \|_n \leq \sum_{m=n-1-\mu_n}^{n-1} \{\| \tilde{\Omega}^m_h - \tilde{\Omega}^m_h \|_m + \| s^{m+1} - s^m \|_m \} + c k \sum_{m=n-1-\mu_n}^{n-1} \| s^m \|_m
\]

\[
+ c k (h^r + k^\mu + h k^{\mu - 1} + h^2 k^{\mu - 1})\| u^0 \|_\alpha \quad 1 \leq n \leq n^* - 1.
\]

From (4.14) and (1.43), it follows that:

\[
\beta_n^2 k^\mu \leq c k^\mu \quad 0 \leq n \leq n^* - 1.
\]

Finally, (4.24) follows after combining the last three inequalities. Also, by (3.2), (3.31), and (3.18):

\[
\| \tilde{\Omega}^0_h - \tilde{\omega}^0 \|_0 \leq c \| U^0_h \|_0 \leq c \| s^0 \|_0 + c \| \omega^0 \|_0 \leq c \| u^0 \|_\alpha
\]

and (4.25) follows after combining this with the two estimates above including the case \( n = 0 \).

Now, (4.24) demands an estimation of the differences \( \| s^{n+1} - s^n \|_n \) and this is the content of the following.
Proposition 4.4 If (1.29) and (1.30) are satisfied, then the following holds:

\[ c_1\|s^{n+1} - s^n\|^2 + \|([I - r_h^{n+1}]^\frac{1}{2}s^{n+1} - s^n)\|^2 + c_2\|\tilde{U}_h - \tilde{U}_h^n\|^2 \]

(4.26)

\[ + (1 + c_3k)\|\|I - r_h^n\|^\frac{1}{2}s^n\|^2 + c_4k^2((h^r + k^\mu + h^k\mu - \frac{1}{2} + h^2k\mu - 1)^2\|u^0\|_\alpha^2 \leq n \leq n^* - 1. \]

Proof: The following is established after some straightforward calculations:

\[ ([I + kL_h^{n+1}][I - r_h^{n+1}][s^{n+1} - s^n], [s^n + 1 - s^n]) + ([I + kL_h^{n+1}][I - r_h^{n+1}][s^{n+1} - s^n]) \]

(4.27)

\[ = 2\|([I + kL_h^{n+1}][s^{n+1} - r_h^{n+1}s^n], [s^n + 1 - s^n]) + ([I + kL_h^{n+1}][I - r_h^{n+1}][s^n, s^n]). \]

By (1.29) and (3.6), there is a \( c_1 > 0 \) such that:

\[ ([I + r_h^{n+1}][I + kL_h^{n+1}]^\frac{1}{2}[s^{n+1} - s^n], [I + kL_h^{n+1}]^\frac{1}{2}[s^{n+1} - s^n]) \geq 2c_1\|s^{n+1} - s^n\|^2. \]

(4.28)

Next, using (3.6):

\[ 2\|([I + kL_h^{n+1}][s^{n+1} - r_h^{n+1}s^n], [s^n + 1 - s^n]) \leq c\|s^{n+1} - r_h^{n+1}s^n\|^2 + c_2\|\|I + kL_h^{n+1}][s^{n+1} - s^n]\|^2 + c\|\|I + kL_h^{n+1}][I - r_h^{n+1}][s^n, s^n]. \]

Combining (3.25), (3.27), (3.28) and (3.29) for (4.17), it follows that:

\[ \|s^{n+1} - r_h^{n}s^n\|_h \leq c(h^r + k^\mu + h\mu - \frac{1}{2} + h^2\mu - 1)^2\|u^0\|_\alpha + c\|\tilde{U}_h^n - \tilde{U}_h^n\|^2. \]

Combining the last two inequalities with (3.7) and (3.8), the result is:

\[ 2\|([I + kL_h^{n+1}][s^{n+1} - r_h^{n+1}s^n], [s^n + 1 - s^n]) \leq c_2\|s^n\|^2 + c\|\tilde{U}_h^n - \tilde{U}_h^n\|^2 \]

(4.29)

\[ + c_2((h^r + k^\mu + h\mu - \frac{1}{2} + h^2\mu - 1)^2\|u^0\|_\alpha^2 + c_1\|s^{n+1} - s^n\|^2. \]

For the last term in (4.27), suppose first that (1.27) holds. After some calculations:

\[ ([I + kL_h^{n+1}][I - r_h^{n+1}] - [I + kL_h^n][I - r_h^n][s^n, s^n]) = (E(kL_h^n)\frac{1}{2}s^n, (kL_h^n)\frac{1}{2}s^n) \]

where:

\[ E = (kL_h^n)^{-\frac{1}{2}}[r_h^n - r_h^{n+1}](kL_h^n)^{-\frac{1}{2}} + ([T_{n+1}^\frac{1}{2}L_h^{n+1}[T_{n+1}^\frac{1}{2}[(kL_h^n)^\frac{1}{2}[r_h^n - r_h^{n+1}]])^{-\frac{1}{2}} \]

\[ + (T_{n+1}^\frac{1}{2}[L_h^{n+1} - L_h^n][T_{n+1}^\frac{1}{2}[I - r_h^n]. \]

By (3.8), (2.15), (1.13), and (1.26):

\[ \|E\chi\| \leq ck\|\chi\| \quad \forall \chi \in \mathcal{S}_h. \]

(4.31)

Next, define \( r_\varepsilon(z) \equiv [1 + z]/[1 + (1 - \varepsilon)z] \) with \( \varepsilon > 0 \) small enough that with (3.11) and (1.27):

\[ |r_\varepsilon(z)r(z)| \leq \begin{cases} (1 + \varepsilon z)(1 - \theta z) & 0 < z \leq z_1 \\ (1 - \varepsilon)^{-1}\sup_{z \geq z_1} |r(z)| & z_1 \leq z \end{cases} \leq 1. \]
Hence:

\[ \varepsilon(kL_h^n, \chi, \chi) \leq ([I + kL_h^n][I - r_h^n]X, \chi) \quad \forall \chi \in S_h. \]

Combining this with (4.30) and (4.31):

\[ \left| \left\{ [I + kL_h^{n+1}][I - r_h^{n+1}] - [I + kL_h^n][I - r_h^n] \right\} \xi^n, \xi^n \right| \leq c e^{-1} k([I + kL_h^n][I - r_h^n]s^n, s^n). \]

Finally, for the case that (1.27) holds, (4.26) follows after combining (4.28), (4.29), and (4.32) for (4.27). Now, assume that (1.27) fails, so that \( r(\infty) \equiv 1 - b^T A^{-1} e = 1 \). Nevertheless, by (1.30) and (1.11), \([I - r_h^n]\) is positive and invertible, so define:

\[ \tilde{r}_n \equiv [I + kL_h^n][I - r_h^n] \quad \text{and} \quad F^2 \equiv (kL_h^n)[I + kL_h^n]^{-2} r_n^{-1}. \]

Then, instead of (4.30), the following is used:

\[ \left\{ [I + kL_h^{n+1}][I - r_h^{n+1}] - [I + kL_h^n][I - r_h^n] \right\} s^n, s^n = \]

\[ (F^2((kL_h^n)^{-1} + (kL_h^n)^{1/2})[r_{n+1} - \tilde{r}_n][(kL_h^n)^{-1/2} + (kL_h^n)^{1/2}]F^{1/2}_n s^n, \tilde{r}_n^{1/2} s^n) \]

From (1.30), it follows that:

\[ ||FX|| \leq c||x|| \quad \forall \chi \in S_h. \]

Next, since \( b^T A^{-1} e = 1 - r(\infty) = 0 \):

\[ r^n_h = I - b^T A^{-1} \{(kA\mathcal{L}_h^n)[I + kA\mathcal{L}_h^n]^{-1}\} e = I + b^T A^{-1} [I + kA\mathcal{L}_h^n]^{-1} e \]

and hence:

\[ \tilde{r}_n = -b^T A^{-2} e + b^T A^{-1}(A^{-1} - I)[I + kA\mathcal{L}_h^n]^{-1} e. \]

Therefore:

\[ \tilde{r}_{n+1} - \tilde{r}_n = b^T (I - A^{-1})[I + kA\mathcal{L}_h^{n+1}][I + kA\mathcal{L}_h^{-1}](T_h^n)^{1/2}[(T_h^n)^{1/2} - (L_h^n)^{1/2}](L_h^n)^{1/2}[I + kA\mathcal{L}_h^n]^{-1} e. \]

So by (3.3) and (2.15), for \( \theta_1, \theta_2 = \pm 1/2 \):

\[ ||(kL_h^n)^{\theta_1} [\tilde{r}_{n+1} - \tilde{r}_n](kL_h^n)^{\theta_2} x|| \leq c k||x|| \quad \forall \chi \in S_h. \]

Combining this with (4.34) for (4.33) gives (4.32) and hence (4.26).

Finally, the convergence result (1.5) is established for (1.46) as follows.

**Theorem 4.1** Let the conditions of either Proposition 4.1 or 4.2, in addition to those of Lemma 3.1 and Proposition 4.4 be satisfied. Then, \{j_n\}_{n=0}^{n-1} can be chosen so that (4.19) and (4.14) hold and provided \( \varepsilon_0 > 0 \) is small enough, the approximations \{U_h^n\}_{n=0}^{n-1} obtained by (1.37) and (1.46) satisfy:

\[ \max_{0 \leq n \leq n^*} ||U_h^n - u^n|| \leq c^* (h^* + k^* + h^* k^* - h^* k^*) ||u^0||_\alpha. \]

Also, unless \( \tilde{c} < 0 \) in (4.19), \( c^* \) depends exponentially on \( t^* \).
Proof. Add $c_1 \| \tilde{U}_n^t - \tilde{U}_n^t \|_n^2$ to both sides of (4.26) and multiply the resulting inequality by $e^{k-1}t^{n+1}$. When this is added to (4.19), the result is:

$$\|s^{n+1}\|_{n+1}^2 + c_1 e^{k-1}t^{n+1}(\|s^{n+1} - \zeta_n\|_n^2 + \|\tilde{U}_n - \tilde{U}_n\|_n^2) + e^{k-1}t^{n+1}\|I - r_n^{n+1}\|\frac{1}{2} s^{n+1}\|_{n+1}^2$$

$$\leq (1 + \tilde{c}k + c_2 e^{kt^{n+1}})\|s^*_n\|_n^2 + ck^{-1}\|\tilde{U}_n - \tilde{U}_n\|_n^2 + ck[(h^r + \mu + h\mu - \frac{1}{2} + h^2 k\mu^{-1})\|u^0\|\alpha]^2$$

$$+ [e^{k-1}t^{n+1}(1 + c_3k) - c_0]\|I - r_n\|\frac{1}{2} s^*_n\|_n^2 \quad 1 \leq n \leq n^* - 1.$$

Now, for the compression of this inequality and others below, let the following be defined:

$$Z^n \equiv \|s^n\|_n^2, \quad D^{n+1} \equiv \|s^{n+1} - \zeta_n\|_n^2 + \|\tilde{U}_n - \tilde{U}_n\|_n^2,$$

$$S^n \equiv \|I - r_n\|\frac{1}{2} s^*_n\|_n^2, \quad E \equiv [(h^r + \mu + h\mu - \frac{1}{2} + h^2 k\mu^{-1})\|u^0\|\alpha]^2.$$

With this notation, the following results after estimating $c_1 e^{k-1}t^{n+1}D^{n+1}$ with (4.24):

$$Z^{l+1} + c_4 k^{1}t^{l+1}D^{l+1} + e^{k-1}t^{l+1}S^{l+1} \leq (1 + \tilde{c}k + c_2 e^{kt^l})Z^l$$

$$+ c_4 \beta_l^2 \sum_{m=l-1-\mu}^{l-1} [k^{1-1}D^m + kZ^m] + ckE + [e^{k-1}t^l + \varepsilon(1 + c_3t^*) - c_0]S^l \quad 1 \leq l \leq n^* - 1.$$

Now, assume that $\varepsilon > 0$ is chosen small enough that $\varepsilon(1 + c_3t^*) \leq c_0$. In fact, if $\tilde{c} < 0$, suppose that for some $\tilde{c} < 0, 1 + \tilde{c}k + c_2 e^{kt^*} \leq 1 + \tilde{c}k$. Otherwise, if $\tilde{c} > 0$, take $\tilde{c} > 0$ in the following. Now, after summing the last inequality over $1 \leq l \leq n \leq n^* - 1$, the result is:

$$(Z^{n+1} - Z^1) + \varepsilon k^{-1}(t^{n+1}S^{n+1} - t^1S^1) + c_1 e^{k-1} \sum_{l=1}^{n} t^{l+1}D^{l+1} \leq \tilde{c}k \sum_{l=1}^{n} Z^l$$

$$+ c_4 \sum_{l=1}^{n} \beta_l^2 \sum_{m=l-1-\mu}^{l-1} \sum_{l=1}^{n} [kZ^m + k^{1-1}D^m] + ct^*E \quad 1 \leq n \leq n^* - 1.$$

By (4.14) and (3.31), for $1 \leq n \leq n^* - 1$:

$$\tilde{c}k \sum_{l=1}^{n} Z^l + c_4 k \sum_{l=1}^{n} \beta_l^2 \sum_{m=l-1-\mu}^{l-1} \sum_{l=1}^{n} Z^l \leq (\tilde{c} + c_4 \varepsilon_0(\mu + 1)t^*)k \sum_{l=1}^{n} Z^l + c_4 k \varepsilon_0 \sum_{l=1}^{n} Z^l + ckE \quad 1 \leq n \leq n^* - 1.$$

where $\tilde{c} \leq 0$ if $\tilde{c} < 0$ and $\varepsilon_0 > 0$ is small enough. Otherwise, take $\tilde{c} > 0$ in the following. Next, since $(l+1)/(m+1) \leq \mu + 2$ if $0 \leq l - 1 - \mu \leq m \leq l - 1$, it follows using (4.14) that for $1 \leq n \leq n^* - 1$:

$$c_4 k \sum_{l=1}^{n} \beta_l^2 \sum_{m=l-1-\mu}^{l-1} D^{m+1} \leq c_4 k \varepsilon_0 \sum_{l=1}^{n} \sum_{l=1}^{n} \frac{l+1}{m+1} t^{m+1}D^{m+1} \leq c_4 \varepsilon_0 k \sum_{l=1}^{n} t^{l+1}D^{l+1} + cD^1.$$

Combining the last three inequalities, for $1 \leq n \leq n^* - 1$:

$$Z^{n+1} + \varepsilon k^{1}t^{n+1}S^{n+1} + (c_4 k - c_5 \varepsilon_0)k^{1} \sum_{l=1}^{n} t^{l+1}D^{l+1} \leq (Z^1 + \varepsilon S^1 + cD^1) + ct^*E + \tilde{c}k \sum_{l=1}^{n} Z^l.$$
By (3.6), (4.26), (4.25), (1.26) and (3.31):

\[ Z^1 + [S^1 + D^1] \leq [cD^1 + cZ^0] + [S^1 + D^1] \leq c(1 + k^2)[Z^0 + E] + (1 + ck)S^0 \leq c(Z^0 + E) \leq cE. \]

Now, assume that \( \varepsilon_0 > 0 \) is chosen small enough so that:

\[ \|s^{n+1}\|_{n+1}^2 \leq ct^*(h^{r + \kappa} + hh^{\kappa - \frac{1}{3}} + h^2k^{\kappa - 1} + \|u^0\|_a)^2 + \bar{c}k \sum_{i=0}^{n} ||s_i^0||_i^2 \quad 0 \leq n \leq n^* - 1. \]

If \( c \leq 0 \), ignore the last sum and (4.35) follows after (1.19). If \( c > 0 \), then (4.35) follows with the discrete Gronwall Lemma and (3.31), but with \( \epsilon^* \) depending exponentially on \( t^* \).

\[ \square \]

5 Examples.

The principal aim of this section is to present some computational results showing the strength of methods analyzed in this work. However, it is appropriate to first indicate that the set of IRKM's which satisfy the many conditions imposed in foregoing proofs, is by no means vacuous. For example, in [15], it is explained that there exist \( q \)-stage methods of order \( q + 1 \) and satisfying (1.26)-(1.32) and (1.44), provided \( q = 1, 2, 3, \) or \( 5 \). Furthermore, [15] gives explicit constructions of families of such methods for \( q = 2 \) and \( 3 \). On the other hand, it is shown in [15], that for every positive integer \( q \), there exists a collocation type IRKM satisfying (1.27), (1.29)-(1.32), and (1.44).

As mentioned in the Introduction and more carefully in [15], the preferred methods in a parallel environment are those for which the eigenvalues of \( A \) are distinct. These have been referred to as multiply implicit (MIRK) methods. Further, they are called real if \( \sigma(A) \subset \mathbb{R} \), and otherwise complex. While the latter case has not been studied here, it is discussed in [15]. By considering that discussion together with the results of Bramble and Sammon [3], it can be seen that complex MIRK's can be analyzed using quadratic preconditioning and hence inverse assumptions.

In contrast to MIRK's, there are the well-known methods for which the eigenvalues of \( A \) are identical and real. [12] As seen in (4.9), these so-called singly implicit (SIRK) methods offer a computational advantage on serial machines since at each time step, they require the formation of only a single new matrix with the dimension of \( S_h \). A selection from this set of methods was made for the example considered below.

The following problem is of the class defined in the Introduction:

\[
\begin{cases}
\partial_t u = -L(t)u & \text{in } (-1,1) \times [0,1] \\
u = 0 & \text{on } \{-1,1\} \times [0,1] \\
u(x,0) = 1 - x^2 & \text{in } (-1,1)
\end{cases}
\]

where:

\[ L(t)u \equiv -\partial_x(\ell_1(x,t)\partial_x u) + \ell_0(x,t)u, \]

\[ \ell_1(x,t) \equiv \frac{1}{18} \log(2)(3 - x^2)(2 + x^2)^{t+1}, \quad \ell_0(x,t) \equiv \log(2 + x^2) - \frac{1}{3} \log(2)(2 + x^2)^t. \]

The solution is given by:

\[ u(x,t) = \frac{1 - x^2}{(2 + x^2)^t}. \]

For the spatial discretization, the Ordinary Galerkin Method was used and $S_h$ was constructed of smooth cubic splines defined on a uniform mesh. For the temporal discretization, the well-known three-stage diagonally implicit (DIRK) method was used as it satisfies (1.26)-(1.32). [8]

Now let (1.46) be identified as the modified method, and an analogue based on (1.39) as the classical method. In addition, let a hybrid method be given by (1.46), but with $D^t$ replaced by $T^t$ in (1.35). These three methods were tested on the ICASE SUN 3/180. Defining $E(h, k) = \| U_h^n - u^n \|$, the $L_2$ errors $E(k) \equiv E(k, k)$ are reported in Tables 1 - 3, together with estimates of the convergence order obtained according to the formula: $\log(E(k_2)/E(k_1))/ \log(k_2/k_1)$.

With regard to time consumption, recall that the computational burden for the classical method

is in forming $q$ new stiffness matrices at each time step. On the other hand, with the constants \( c_n \) chosen in the natural way as indicated in the Introduction, the burden for the modified method is in forming the terms $\phi_i$ of (4.7), for the right side of (4.9). Also, the initial steps are relatively expensive, but the effect of this diminishes as the number of time steps increases. Note that among the three methods tested, numbers for the modified method were obtained with greater speed and accuracy, as well as with fourth order convergence. On the other hand, the others suffer from suboptimal convergence as explained in the Introduction. However, no rigorous explanation can be offered for the identical accuracy obtained by the classical and hybrid methods. Further, this author is unaware of any proof of the better than second order convergence seen in Tables 2 and 3. In this connection, note that the above solution has no time derivatives which are even in the domain of $L(t)^2$, a condition considered necessary to escape order reduction in a general way. Nevertheless, only second order convergence is demonstrated for example, in Experiment 7.5.1 of Dekker and Verwer [8], where a stiff ordinary differential equation is considered. Further, the modified method has been applied to this problem to give not only fourth order convergence, but accuracy exceeding that reported for any method discussed in the Experiment.

A new class of fully discrete Galerkin/Runge-Kutta methods is constructed and analyzed for linear parabolic initial boundary value problems with time dependent coefficients. Unlike any classical counterpart, this class offers arbitrarily high order convergence while significantly avoiding what has been called order reduction. In support of this claim, error estimates are proved, and computational results are presented. Additionally, since the time stepping equations involve coefficient matrices changing at each time step, a preconditioned iterative technique is used to solve the linear systems only approximately. Nevertheless, the resulting algorithm is shown to preserve the original convergence rate while using only the order of work required by the base scheme applied to a linear parabolic problem with time independent coefficients. Furthermore, it is noted that special Runge-Kutta methods allow computations to be performed in parallel so that the final execution time can be reduced to that
