Pat Adamson  
Turbulence Prediction Systems  
Boulder, Colorado  

This presentation contains results of field experiments for detection of Clear Air Turbulence and Low Level Wind Shear utilizing an infrared airborne system. The hits, misses and nuisance alarms score and presented for the encounters. The infrared spatial resolution technique is explained and graphs are presented.  
The popular index of aircraft hazard \( F = \frac{W_X}{S} - \frac{V_N}{A_S} \) is developed for a remote temperature sensor.
THE PROBLEM

- WIND SHEAR
  - 1 accident per 5,000,000 T + L @A
  - 1 strong shear per 65,000 T + L @B

- SOURCES OF WIND SHEAR
  - downbursts
  - microbursts

- DURATION @C
  - severe winds - 2 to 4 minutes
  - life span - 5 to 15 minutes

- SIZE COLUMN @D
  - 4km or 2.5 miles

- EFFECTIVE DIAMETER OF OUTFLOW @C,D
  - > 2 x column diameter

- DIFFERENTIAL VELOCITY ACROSS BURST @C
  - > 56 knots average

- MICROBURSTS OFTEN HAS LATERAL MOTION

TURBULENCE PREDICTION SYSTEMS
THE ELEMENTS THAT CAN IMPROVE THE FLIGHT CREW'S ABILITY TO RELIABLY DETECT AND AVOID HAZARDOUS WIND SHEAR INCLUDE:

THE DEVELOPMENT OF FORWARD-LOOKING WIND SHEAR SENSORS FOR AIRCRAFT.

THE IMPROVED UTILIZATION AND INTEGRATION OF PRESENT-POSITION SENSORS.

REFERENCE: "INTEGRATED FAA WIND SHEAR PROGRAM PLAN"; U.S. DEPARTMENT OF TRANSPORTATION; FEDERAL AVIATION ADMINISTRATION; APRIL 1987; DOT/FAA/DL-87/1; DOT/FAA/VS-87/1; DOT/FAA/AT-87/1.
REMOTE SENSING TECHNIQUES FOR WIND VELOCITY ARE NO PANACEA

ALL REMOTE SENSORS INFIER

TABLE 4 LISTS SOME ADVANTAGES AND DISADVANTAGES OF THE REMOTE-SENSING TECHNIQUES FOR WIND. IN GENERAL, LONG-RANGE MEASUREMENTS REQUIRE RADAR, AND SHORT-RANGE APPLICATIONS USE LIDAR OR SODAR DEPENDING ON WHETHER SPATIAL RESOLUTION OR LOW COST IS A PRIMARY CRITERION FOR SELECTION. FOR SOME REQUIREMENTS, SUCH AS A LOW-COST SENSOR FOR AIRCRAFT USE, THERE MAY NOT BE AT PRESENT A SUITABLE REMOTE-SENSING TECHNIQUE. (Emphasis added)

UNIFORM DISTRIBUTED GASES

INFRARED IS ABSORBED BY THE UNIFORM DISTRIBUTED GASES AS A FUNCTION OF WAVE LENGTH

NOTE: TRANSMITTANCE/KILOMETER
FOR EXAMPLE:
@ 13.5 MICRONS
TRANSMITTANCE = .60/KM
@ 5 KM
TRANSMITTANCE = (.60)^-5 = 7.8%

REFERENCE: HANDBOOK OF OPTICS; WALTER G. DRISCOLL, EDITOR;
McGRAW-HILL BOOK COMPANY; 1978; FIGURE 17, PAGE 14-43.
Radiative transfer theory via the transfer equation (RTE) demonstrates that a "horizontally looking" infrared (IR) radiometer can easily detect temperature changes as small as 0.3C at a distance of 10 km. The IR pass band for such observations is the carbon dioxide (CO2) band. In this instance we refer to transfer calculations in the 695 to 725 cm\(^{-1}\) pass band.

The RTE expresses the radiant emission received through a horizontal path in the atmosphere at an IR detector through a filter, \(\Phi(x)\), as

\[
N = -\int \int B(v,T)\frac{\partial \tau(v(CO_2))}{\partial z} dz dz, \quad (2)
\]

where \(N\) and \(B\) are radiance \((\text{cm}^2 \cdot \text{sr}^{-1})\); \(v\) is wave number \((\text{cm}^{-1})\); \(T\) is temperature \((^\circ \text{K})\); \(\tau\) is the optical mass \((\text{g cm}^{-2})\); \(z\) is distance \((\text{cm})\).

The filter function, \(\Phi(x)\), in equation (2) determines the IR pass band to which the CO2 band low altitude wind shear radiometer responds. Since the CO2 portion of the spectrum is broad, ranging from nominally 630 to 710 cm\(^{-1}\), it is necessary to choose a passband of a width of 20 to 30 cm\(^{-1}\), within the broad band which will provide a suitable range capability. The absorption (and emission) across the CO2 band varies considerably thus allowing a greater or lesser horizontal atmospheric penetration. For example the CO2 Q-branch centered near 667 cm\(^{-1}\) would permit a range of only a few meters.

Weighting functions are defined by

\[
\frac{\partial \tau}{\partial z} = \frac{-\bar{K}_{A \nu} p q z}{RT} \exp \left( -\frac{\bar{K}_{A \nu} p q z}{RT} \right) \int \frac{\bar{K}_{A \nu} p q z}{RT} dz \quad (3)
\]

where \(\tau\) is the atmospheric transmission \((\text{dimensionless})\); \(\Delta \nu\) is the wave number interval \((\text{cm}^{-1})\); \(\bar{K}_{A \nu}\) is the CO2 absorption coefficient \((\text{cm} \cdot \text{g}^{-1})\); \(p\) is pressure \((\text{cm} \cdot \text{g}^{-1})\); \(q\) is mass mixing ratio of CO2 \((\text{dimensionless})\); \(R\) is the universal gas constant \((\text{cm} \cdot \text{g}^{-1})\).

The weighting function describes the range characteristics of the filter, and thus the range of the radiometer. Figure 3 illustrates weighting or ranging functions for various center frequency passbands either 20 cm\(^{-1}\) wide for CO2. The position of the peak of the weighting function defines the "look" distance or range of the instrument. As an example we employed the weighting function of Fig. 3 at a center frequency for the CO2 filter of 685 cm\(^{-1}\) (20 cm\(^{-1}\) wide). We assumed a horizontal temperature constant at 288K in one instance and 286K from 1.0 to 1.6 km distance in the other calculation. The CO2 mixing ratio (mass) was assumed 5.28 x 10\(^{-6}\) \(\text{cm}^{-2} \text{sr}^{-1}\). This corresponds to a temperature difference of 2K.

VALIDATION OF INFRARED WEIGHTING FUNCTION

IN 1979, RESEARCHER DR. PETER KUHN AND NASA TEST PILOT MR. GLEN STINNET FLEW THE NASA LEAR JET #705 OVER THE SANTA BARBARA CHANNEL ALTERNATING BETWEEN LAND (40°C) AND THE CHANNEL (15°C) TO VALIDATE THE WEIGHTING FUNCTION.

THIS VALIDATION INVOLVED USING A BARNES PRT5 RADIOMETER AND INTERCHANGING 6 CO2 FILTERS UNTIL THE WEIGHTING FUNCTION WAS VALIDATED.

REFERENCE: PERSONAL CORRESPONDENCE DR. PETER KUHN; AUGUST 1987
WET CASE 10/13/87

RECEIVED AT NASA
LANGLEY FROM
F. PROCTOR
THE END PRODUCT OF AIRBORNE IR SENSOR IS:

\[ \frac{\Delta \Phi_e}{\Delta t} \] (change in radiant flux)

\[ \frac{\Delta T}{\Delta t} \] (temperature)

FROM WHICH WE GET:

\[ \frac{\Delta T}{\Delta t} \] (temperature)

FROM THIS WE WILL CALCULATE A HAZARD INDEX WHICH APPLIES TO THE AIRCRAFT'S FLIGHT PATH.

TURBULENCE PREDICTION SYSTEMS
WIND SHEAR "HIT"

\[ F = \frac{\dot{W}_x}{g} - \frac{W_h}{V} \]

- Hazard index

Alert and warning threshold determined by max. permissible F in relation to aircraft performance capability.

- F is a sensed quantity

- Hazard index applicable to both insitu-sensed information and remote-sensed wind shear

Industry review of forward looking sensor technology for detection of wind shear
NASA Langley Research Center 24-25 Feb. 1987, Rowland L. Bowles
F FACTOR

WE NEED TO ASSESS THE THREAT TO THE AIRCRAFT IN BOTH THE HORIZONTAL AND VERTICAL WIND COMPONENTS.

-HORIZONTAL CASE

THERE IS A GOOD EMPIRICAL RELATIONSHIP BETWEEN TEMPERATURE DROP AND HORIZONTAL WIND VELOCITY.

TURBULENCE PREDICTION SYSTEMS

305
U WINDS VERSUS TEMPERATURE DROP
HORIZONTAL WINDS

KNOTS (MAXIMUM)

FAW  +  191  FLO  Δ  TAS  ×  HAL  ▼  KUH

MAXIMUM TEMPERATURE DROP (DEGREES C)
FROM THE NASA TASS MODEL THE RELATIONSHIP IS:

\[ \Delta u_{m/s} = 2.5 \Delta T^\circ C \]

SO TO GET HORIZONTAL PORTION OF \( F \) FACTOR WE GET:

\[ F_h = -\Delta T \cdot 2.5 \]

\( F_h \) IN \( m/s \)

\( g \)

WHICH THEN IS THE TEMPERATURE EQUIVALENT OF:

\[ F_h \cdot \frac{\Delta T \cdot 2.5}{g} \]

NEGATIVE BUOYANCY HAS LONG BEEN RECOGNIZED AS THE MAJOR FORCING FACTOR IN DOWNBURSTS.

THE BUOYANT FORCE IS:

\[ F_B = g \frac{\Delta T}{T_m} \]

WHERE

\[ \Delta T = T - T_m \]

\[ T = \text{TEMPERATURE OF AIR PARCEL} \]

\[ T_m = \text{AMBIENT TEMPERATURE} \]
FOSTER'S WORK ALLOWS US TO CALCULATE THE VERTICAL VELOCITY FROM THE TEMPERATURE DROP

\[ w \int_{w_0}^{0} dw = \frac{g \Delta T^o}{T_m} \int_{0}^{Z} (1 - z/z) \, dz \]

WHICH REDUCES TO

\[ w_c = \frac{g \Delta T^o}{T_m} \]

AND

\[ w_c = \sqrt{-\frac{g \Delta T^o}{T_m}} \]

SEE PLOT OF FOSTER VS 191 TEMPERATURE DROP RELATED TO VERTICAL WINDS

REFERENCE: "THUNDERSTORM GUSTS COMPARED WITH COMPUTED DOWNDRAFT SPEEDS"; BY DONALD FOSTER; MONTHLY WEATHER REVIEW, MARCH 1958, PP. 91-94.

REFERENCE: "A SHORT COURSE IN CLOUD PHYSICS"; BY R.R. ROGERS; 2ND EDITION; INTERNATIONAL SERIES IN NATURAL PHILOSOPHY VOLUME 96; 1979.

TURBULENCE PREDICTION SYSTEMS
WE CAN THEN ASSUME SOME $Z$ (ALTITUDE) AND

\[
F_v = \sqrt{\frac{-g \cdot Z \cdot \Delta T}{T_m}} \div \text{Airspeed}
\]

WHICH IS THE TEMPERATURE EQUIVALENT OF

\[
F_v = \frac{V_w}{A_s}
\]

SO COMBINED HAZARD FACTOR AS A FUNCTION OF TEMPERATURE IS:

\[
F = \frac{2.5 \cdot -\Delta T}{g} + \sqrt{\frac{-g \cdot Z \cdot \Delta T}{T_m}} \div \text{Airspeed}
\]

TURBULENCE PREDICTION SYSTEMS
CONCLUSIONS:

NOW WE HAVE COVERED BOTH ASPECTS OF CONCERN TO THE AIRCRAFT FROM THE

HORIZONTAL WIND RATE OF CHANGE AS A FUNCTION OF EMPIRICAL AND MODELLED WORK RELATED TO TEMPERATURE DROP.

VERTICAL WIND VELOCITY FROM A WELL ACCEPTED FORCING FACTOR RELATED TO TEMPERATURE DROP

THIS CALCULATED HAZARD INDEX HAS RELEVANCE TO THE IN SITU SYSTEMS PRESENTLY IN USE

TURBULENCE PREDICTION SYSTEMS
JIM EVANS (MIT Lincoln Labs) - Your program sounds like a good way to start trying to address some of the false alarms. On the other hand, one hopes they don't penetrate microburst very often. How are you working at trying to establish what the detection probability is for this combined system?

PAT ADAMSON (TPS) - One of the things we are going to do--and that was part of my last slide--Since the hazard index is applicable to both systems assuming that everybody did their math correctly, we will time tag the data. Part of our data gathering technique will be to look for shears or hazard index such that they may not be terribly hazardous to the aircraft. And it will look for a similar event to occur at some time after that in the reactive system. That is what we are hoping to do. If we get shears over the year that is bad or good, I don't know which.

JIM EVANS (MIT Lincoln Labs) - Again, I understand how you can do that comparison, what I meant was how will you? This plane could fly all summer and never see a microburst. How will you establish whether it detects microbursts or not, in this situation? Wouldn't you really have to have the same system and get a plane out and try to fly it around and try to fly it through microburst?

PAT ADAMSON (TPS) - Well, I don't think so. I mean, I think that has already been proven. I think for example, the report I just showed from Quinn and Sinclair was a completely equipped plane that the B57B was a completely equipped plane--I think they worked properly, it showed they worked in the optimum research section. I don't think we are every going to get proof that they work in the operational setting--nobody is going to take that chance.
