Abstract

A new parabolized Navier-Stokes (PNS) code has been developed to compute the hypersonic, viscous, chemically reacting flow fields around three-dimensional bodies. The flow medium is assumed to be a multicomponent mixture of thermally perfect but calorically imperfect gases. The new PNS code solves the gas dynamic and species conservation equations in a coupled manner using a noniterative, implicit, approximately-factored, finite-difference algorithm. The space-marching method is made well-posed by special treatment of the streamwise pressure gradient term. The code has been used to compute hypersonic laminar flow of chemically reacting air over cones at angles of attack. The results of the computations are compared with the results of reacting boundary-layer computations and show excellent agreement.

Nomenclature

A* : reference area, (m²)
α_f : frozen speed of sound
C_d : total drag coefficient
C_f : skin-friction coefficient
C_p : pressure coefficient
C_s : frozen specific heat of the mixture
c : kinematic binary diffusion coefficient
h : static enthalpy
H : total enthalpy of the mixture
h_f : enthalpy of formation of species s
K_r : backward reaction rate constant for the mth reaction
K_f : forward reaction rate constant for the mth reaction
L* : reference length, (m)
L_e : binary Lewis number
m : diffusion mass flux vector
n : number of reactions
M_f : frozen Mach number
M : molecular mass
n : number of species

N_A : Avogadro number, 6.022169 x 10²³ (kmol⁻¹)
N_e : electron number density, (m⁻³)
N_r : number of reactants (including catalytic third bodies)
p : static pressure of the mixture
q : heat flux vector
R* : universal gas constant, 8314.34 J/(kmol-K)
Re : Reynolds number based on L*
S_t : Stanton number
t : time
T : static temperature of the mixture
u, v, w : Cartesian components of the mass-averaged velocity
V : magnitude of the mass-averaged velocity
w_s : mass production rate of species s
X_s : mole fraction of species s
Z_r,s : Cartesian coordinates (physical space)
ζ, η, ζ : third body efficiency (relative to argon) of the rth catalytic body
α : angle of attack
θ_s : mole-mass ratio of species s
δ : cone half angle
κ : thermal conductivity
μ : molecular viscosity
ξ, η, ξ : generalised coordinates
ρ : mass density
σ : safety factor
τ : shear stress

Subscripts
i, j, k : finite-difference indices
r, a : indices denoting species
w : wall
x, y, z : partial derivative w.r.t. x, y, z
ξ, η, ζ : partial derivative w.r.t. ξ, η, ζ
∞ : freestream

Superscripts
* : dimensional quantity
s : chemical quantity
i : inviscid quantity
T : transpose
v : viscous quantity
x, y, z : Cartesian components
ξ, η, ξ : transformed components

Introduction

Accurate numerical simulations of the aerothermodynamic environments around the recently proposed hypersonic vehicles¹,² must account for the various complex relaxation phenomena such as vibrational excitation, chemical reactions, ionization, etc., which occur in the shock
layers. The numerical simulation of complete thermochemical nonequilibrium has been successfully accomplished by Park* for one-dimensional flows. The extension of this analysis to higher dimensional flows is quite complicated and requires further research. However, as a first step, the problem can be simplified by assuming the flow field to be in thermal equilibrium but not in chemical equilibrium. The numerical simulation of viscous, chemically reacting, external flows around three-dimensional configurations is the focus of attention of several investigations today.

The numerical methods currently employed fall into two main categories, (i) time-marching methods and (ii) space-marching methods. In the time-marching methods, the time-asymptotic solutions to the Navier-Stokes equations are computed. These methods are accurate but require a substantial amount of computer time. Space-marching methods, on the other hand, require much less computer time and provide accurate solutions in cases where they are applicable. In the latter category, the viscous shock-layer (VSL) equations have been widely used to compute three-dimensional, viscous, chemically reacting flows. These equations are uniformly valid in the shock layer but fail in the presence of crossflow separation. This deficiency is overcome through the use of the parabolized Navier-Stokes (PNS) equations. Bhutta and Lewis were the first to use the PNS equations to compute chemical nonequilibrium flow fields. They solved the chemistry and gas dynamics separately and used an iterative approach to couple the two. In contrast to their approach, Prabhu et al. developed a chemical nonequilibrium PNS code in which the gas dynamics and chemistry were solved simultaneously in a noniterative manner. This two-dimensional/axisymmetric code was successfully applied to reacting flows over wedges and cones and was found to be very competitive in terms of both efficiency as well as computing time. Having established the feasibility of computing reacting flows with a coupled approach, a new PNS code for three-dimensional bodies has been developed in the present study.

The present paper describes in detail the development of this new PNS code which can compute chemically reacting flow fields around three-dimensional bodies. As in the previous study, the gas dynamic and species conservation equations are solved in a coupled manner. A noniterative, implicit, approximately-factored, finite-difference method is used to solve the PNS equations. The flow medium considered in the present computations is air consisting of six species and electrons. The electrons are eliminated from the species set using the principle of conservation of charge. The source terms are treated in a partially implicit manner in the present formulation. The code has been used to compute a number of chemically reacting flow fields around cones at angles of attack. The results of the computations are compared with those of a reacting boundary-layer code.

Governing Equations

The equations governing the steady, three-dimensional laminar flow of a multicomponent gas have been obtained from the equations in Ref. 14 by (i) neglecting the time-derivative terms, (ii) assuming the flow to be in thermal equilibrium, (iii) neglecting radiation, and by (iv) assuming mass diffusion to be binary and due to concentration gradients only. These equations can be written in nondimensional, strong conservation-law form in Cartesian coordinates for an n-component system as:

\[ \frac{E'_x + F'_y + G'_z}{Re} = \frac{1}{Re} \left( E''_x + F''_y + G''_z \right) + W' \]  (1)

The \((n + 4)\)-component vector of conservation variables \(Q\) is chosen as

\[ Q = \{ \rho, \rho u, \rho v, \rho w, pH, \rho e_1, \rho e_2, \ldots, \rho e_{n-1} \}^T \]  (2)

\(E', F',\) and \(G'\) are the \((n + 4)\)-component inviscid flux vectors. \(E'', F'',\) and \(G''\) are \((n - 4)\)-component viscous flux vectors. \(W'\) is the vector of chemical source terms. All these vectors are functions of the elements of the vector \(Q\) and their spatial derivatives. Explicit expressions for elements of the flow and source vectors are given in Appendix A. Note that the vector of dependent variables contains both the fluid dynamic and chemistry variables and that only \((n - 1)\) of the \(n\) species continuity equations are required because the mass fractions sum to unity. Thus, the \(n\)th species continuity equation is replaced by the following algebraic equation

\[ c_n = 1 - \sum_{r=1}^{n-1} c_r \]  (3)

In addition to the above equations, the following equations are also used

\[ p = \frac{\beta_l p^l}{\rho c_\infty V_{\infty}} \]  (4)

\[ H = \frac{1}{2} \left( s^2 + u^2 + w^2 \right) \]  (5)

\[ M = \left( \sum_{r=1}^{n} \frac{c_r}{M_r} \right)^{-1} \]  (6)

where Eq. 4 is the equation of state for perfect gases, Eq. 5 is the definition of the mixture total enthalpy and Eq. 6 is the definition of the mixture molecular mass.

The following nondimensionalisation has been employed in the present formulation

\[ x, y, z = \frac{x', y', z'}{L^*} \]

\[ u, v, w = \frac{u', v', w'}{V_{\infty}} \]

\[ \rho = \frac{\rho^*}{\rho c_\infty} \]

\[ \beta = \frac{\beta^*}{\beta c_\infty} \]

\[ T = \frac{T^*}{T_{\infty}} \]

\[ D = \frac{D^*}{D_{\infty}} \]

The other nondimensional quantities appearing in the equations are

\[ Re = \frac{\rho c_\infty V_{\infty} L^*}{\mu c_\infty} \]

\[ \beta_1 = \frac{K_1 V_{\infty}^2}{M_{\infty} c_\infty^2} \]

\[ \beta_2 = \frac{K_2 V_{\infty}^2}{\mu c_\infty} \]

\[ \beta_3 = \frac{\rho c_\infty D_{\infty}}{\mu c_\infty} \]  (8)
In order to close the system of governing equations, the thermodynamic and transport properties of the constituent gases and the mixture are required. This is discussed in the next subsection.

Gas Model, Thermodynamic and Transport Properties

(a) Gas Model

The chemical mode used in the present calculation is air consisting of molecular oxygen (O₂), atomic oxygen (O), molecular nitrogen (N₂), nitric oxide (NO), nitric oxide ion (NO⁺), atomic nitrogen (N), and electrons (e⁻). These species are indexed \( s = 1 \) to \( 6 \) in the order shown with the electrons being treated as a special case. The following reactions are considered between the constituent species:

\[
\begin{align*}
(1) & \quad O_2 + M_1 = 2O + M_1 \\
(2) & \quad N_2 + M_2 = 2N + M_2 \\
(3) & \quad N_2 + N = 2N + N \\
(4) & \quad NO + M_3 = N + O + M_3 \\
(5) & \quad NO + O = O_2 + N \\
(6) & \quad N_2 + O = NO + N \\
(7) & \quad N + O = NO^+ + e^-
\end{align*}
\]

where \( M_1, M_2, \) and \( M_3 \) are catalytic third bodies. The above model has six species \( (n = 6) \), seven reactions \( (m = 7) \) and ten reactants \( (n_t = 10) \) including electrons. The reaction rate has been obtained from Blottner.

(b) Specific Heat and Enthalpy

The enthalpies (J/kg) and specific heats (J/kg-K) of the species are obtained from the following relations:

\[
\begin{align*}
h_s' &= T' \cdot C_{1,s}(T') + h_{0,s}' \\
C_{p,s} &= C_{2,s}(T')
\end{align*}
\]

Tables of \( C_{1,s} \) and \( C_{2,s} \) as functions of \( T' \) (K) are obtained from Ref. 13. Cubic spline interpolation is used in these tables. The enthalpy and frozen specific heat of the mixture are given by the following expressions:

\[
h' = \sum_{s=1}^{n} \varepsilon_s h_s' \\
C_{p,m} = \sum_{s=1}^{n} \varepsilon_s C_{p,s}
\]

where the subscripts on the differentiation indicate that the composition of the mixture is frozen locally.

(c) Viscosity and Thermal Conductivity

The viscosity \( (N-s/m^2) \) of species \( s \) is calculated from curve fits developed in Ref. 13. These curve fits are of the form:

\[
\mu_s = 0.1 \exp [(A_s \log T' + B_s) \log T' + C_s']
\]

where \( A_s, B_s, \) and \( C_s \) are constants. The thermal conductivity \( (W/m-K) \) of species \( s \) is computed using Eucken's semiempirical formula:

\[
\kappa_s = \rho_s \cdot \frac{\mu_s}{\gamma_s} \cdot \left( \frac{\gamma_s \cdot M_s^2}{R_s} + \frac{5}{4} \right)
\]

The viscosity and thermal conductivity of the mixture are calculated using Wilke's semiempirical mixing rule:

\[
\mu' = \sum_{s=1}^{n} \frac{X_s \mu_s'}{\phi_s} \quad \kappa' = \sum_{s=1}^{n} \frac{X_s \kappa_s}{\phi_s}
\]

\[
\phi_s = \sum_{r=1}^{n} X_r \left[ 1 + \left( \frac{\mu_s}{\mu_r} \cdot \frac{M_r}{M_s} \right)^{1/4} \right] \left[ \sqrt{\frac{1 + M_s}{M_r}} \right]^{-1}
\]

Wilke's mixing rule is considered adequate for weakly ionising flows.

(d) Diffusion Coefficient

The binary Lewis numbers for all the species are assumed to be the same constant \( L_e \). The kinematic binary diffusion coefficient \( D^* \) \( (m^2/s) \) is then computed from the definition:

\[
D^* = \frac{\kappa \cdot L_e}{\rho \cdot C_{p,f}}
\]

The dimensional thermodynamic and transport properties are nondimensionalised using Eq. 7 prior to their use in the code.

Coordinate Transformation

Consider a gerneralised transformation of the spatial coordinates as shown below:

\[
\xi = \xi(x, y, z), \quad \eta = \eta(x, y, z), \quad \zeta = \zeta(x, y, z)
\]

where \( \xi \) is the “streamwise” coordinate, \( \eta \) is the “normal” coordinate and \( \zeta \) is the “circumferential” coordinate. Using this transformation, the governing equations can be recast into the strong conservation form given by:

\[
\begin{align*}
\mathbf{E}_\xi + \mathbf{F}_\eta + \mathbf{G}_\zeta &= \frac{1}{Re} \left( \mathbf{E}_\zeta - \mathbf{F}_\xi - \mathbf{G}_\eta \right) - \mathbf{W} \\
\end{align*}
\]

where \( \mathbf{E}, \mathbf{F}, \mathbf{G}, \mathbf{E}^*, \mathbf{F}^*, \mathbf{G}^*, \) and \( \mathbf{W}^* \) are the transformed inviscid and viscous fluxes and chemical source terms, respectively. Their forms are given in Appendix A.

The equation set, Eq. 19, is simplified by making the thin-layer approximation, i.e., the viscous and diffusion effects in the streamwise and meridional directions are assumed to be negligibly small compared to those in the normal direction. Therefore, the set of equations is simplified to:

\[
\mathbf{E}_\xi + \mathbf{F}_\eta + \mathbf{G}_\zeta = \frac{1}{Re} \mathbf{E}_\zeta + \mathbf{W}^*
\]

where \( \mathbf{E}^*, \mathbf{F}^*, \mathbf{G}^* \) contain derivatives with respect to the \( \eta \) coordinate only.

Streamwise Pressure Gradient

In its present form, Eq. 20, is hyperbolic-elliptic in the streamwise or marching direction \( \xi \) and consequently the
space-marching method of solution is ill-posed. The technique used to overcome this problem was originally proposed by Vigneron et al.\textsuperscript{10} for ideal gases and later extended to chemically reacting flows by Prabhu et al.\textsuperscript{13} Using this technique it was found that the governing equations are hyperbolic-parabolic if and only if (i) there is no axial flow separation in the solution domain, (ii) the local frozen Mach number is greater than unity in the inviscid part of the flow field, and (iii) only a fraction \( \omega \) of the streamwise pressure gradient \( \partial p/\partial \xi \) is retained in the subsonic part of the flow field. The magnitude of \( \omega \) depends on the local frozen Mach number and is determined from the expression

\[
\omega = \min \left\{ 1, \sigma M_f^2 \left[ 1 + \chi (M_f^2 - 1) \right]^{-1} \right\}
\]

where \( \sigma \) (0.8 \( \leq \sigma \leq 0.9 \)) is a factor of safety and

\[
X = \frac{\beta_i}{M_C p_f}
\]

\[
M_f^2 = \left[ \left( \frac{\xi}{J} \right)^2 + \left( \frac{\eta}{J} \right)^2 \right] / \left[ \frac{\partial \chi}{\partial J} \right]
\]

\[
\alpha_f = \frac{1}{1 - \lambda} C_f p_f T
\]

Introducing \( \omega \) into Eq. 20, the streamwise inviscid flux can be split as follows

\[
\mathbf{E}' = \mathbf{E}'' + \mathbf{E}''' (26)
\]

Using Eq. 26, Eq. 20 can be rewritten as

\[
\mathbf{E}'_i + \mathbf{F}'_i + \mathbf{G}'_i = \frac{1}{Re} \mathbf{P}'_i + \mathbf{W}' - \mathbf{E}'' (27)
\]

Further, the last term of Eq. 27 is normally neglected in the subsonic region. Hence the final set of equations that is solved is

\[
\mathbf{E}'_i + \mathbf{F}'_i + \mathbf{G}'_i = \frac{1}{Re} \mathbf{P}'_i + \mathbf{W}' (28)
\]

Numerical Solution of PNS Equations

The numerical algorithm used to solve the system of equations, Eq. 28, is an adaptation of the one developed by Tannehill et al.\textsuperscript{17} The factored algorithm is implemented as the following sequence of steps

(a) Normal Sweep: \( k = 2, 3, \ldots, N K \)

\[
\left\{ \dot{A}_{i,k,j} - \Delta \xi \dot{A}_{i,k,j} + \Delta \xi \frac{\partial}{\partial \xi} \left( \dot{C}_{i,k,j} \right) \right\} \Delta \dot{Q}_{i,k,j} = \]

\[
- \Delta \xi \frac{\partial \dot{E}'_i}{\partial \xi} |_\zeta - \Delta \xi \left[ \frac{\partial}{\partial \eta} \left( \dot{F}'_{i,k,j} - \frac{1}{Re} \dot{P}'_{i,k,j} \right) \right] + \]

\[
\frac{\partial}{\partial \xi} \left( \dot{C}_{i,k,j} \right) \right\} - \Delta \xi \dot{W}'_{i,k,j} (29)
\]

(b) Circumferential Sweep: \( j = 1, 2, \ldots, NJ \)

\[
\left\{ \dot{A}_{i,k,j} - \Delta \xi \dot{A}_{i,k,j} + \Delta \xi \frac{\partial}{\partial \eta} \left( \dot{B}_{i,k,j} \right) \right\} \Delta \dot{Q}_{i,k,j} = \]

\[
\frac{1}{Re} \dot{M}_{i,k,j} \}
\]

\[
\Delta \dot{Q}_{i,k,j} = \left( \dot{A}_{i,k,j} - \Delta \xi \dot{A}_{i,k,j} \right) \Delta \dot{Q}_{i,k,j} (30)
\]

(c) Update:

\[
Q_{i+1,k,j} = Q_{i,k,j} + \Delta Q_{i,k,j} (31)
\]

where the Jacobian matrices are

\[
\dot{A} = \frac{\partial \dot{E}'_i}{\partial \dot{Q}}, \quad \dot{B} = \frac{\partial \dot{F}'_i}{\partial \dot{Q}}, \quad \dot{C} = \frac{\partial \dot{G}_i}{\partial \dot{Q}}
\]

The subscripts \( i, k, j \) are indices associated with the directions \( \xi, \eta, \zeta \), respectively. \( NJ \) and \( NK \) are the total number of grid points in the \( \eta \) and \( \zeta \) directions, respectively. \( \Delta \xi \) is the marching stepsize. The derivatives \( \partial / \partial \eta \) and \( \partial / \partial \zeta \) are replaced by conventional three-point central-difference operators. The algorithm is first-order accurate in the \( \xi \) direction and second-order accurate in the \( \eta \) and \( \zeta \) directions. Freestream fluxes are subtracted from the inviscid fluxes in order to preserve freestream. Fourth-difference explicit and second-difference implicit smoothing operators are also added to the factored operators. These have not been shown above but their forms can be found in Ref. 12.

The Jacobian matrices \( \dot{A}, \dot{B}, \dot{C}, \dot{M}, \) and \( \dot{A}^c \) represent the linearisation of the fluxes and source terms and the elements of these matrices are given in Appendices B, C, and D. In the linearisation of the viscous flux, the transport properties are assumed to be locally constant. The caret above the symbols for the fluxes, Jacobians, and source terms signifies that the geometry is not linearized along with the flow variables.

The left hand sides of Eqs. 29 and 30 correspond to a block-tridiagonal system of equations. The blocks are square matrices of order \( (n + 4) \). For the six-species air model considered in the present calculations, the blocks are square matrices of order 10. The block-tridiagonal solver for the 10 x 10 blocks is developed along the same lines as the one by Steger\textsuperscript{18} for 5 x 5 blocks.

Boundary Conditions

In the present work, only flows without yaw are considered. Therefore, at every streamwise station the computational domain is bounded by (i) the outer boundary which is taken to be the freestream, (ii) the inner boundary which is taken to be the wall, and (iii) the pitch plane of symmetry. Any discontinuities in the flowfield are "captured" as a part of the solution.

At the pitch plane of symmetry reflection boundary conditions are imposed and thus, flow symmetry is maintained.

The following nondimensional boundary conditions are imposed implicitly at the wall

**ORIGINAL PAGE IS OF POOR QUALITY**
(a) \( u = 0, \quad v = 0, \quad w = 0, \quad \delta_n = 0 \)
(b) \( T = T_v \) (isothermal wall) or \( \delta_n(T) = 0 \) (adiabatic wall)
(c) \( \epsilon_s = \epsilon_{sw} \) (catalytic wall) or \( \delta_n(\epsilon_s) = 0 \) (noncatalytic wall), \( s = 1, 2, \ldots, n - 1 \)

The nondimensional boundary conditions at the outer boundary are
(a) \( u = \cos \alpha, \quad v = 0, \quad w = \sin \alpha \)
(b) \( T = 1, \quad \rho = 1, \quad e_{<1} = e_{<1}, \quad e_{<1} = 1, 2, \ldots, n - 1 \)

Initial Conditions

The PNS equations require initial conditions in addition to the boundary conditions. The usual procedure is to use an initial data surface generated by a full Navier-Stokes code. For conical or pointed bodies, however, the code generates its own starting solution. This starting solution is generated iteratively using a "stepback" procedure.\textsuperscript{12,10}

Decoding

The primitive variables \( \rho, u, v, w, H, c_1, c_2, \ldots, c_{n-1} \) at station \( i + 1 \) are easily obtained from the elements of \( Q \). The mass fraction of the \( n \)th species is computed using Eq. 3 and the static enthalpy of the mixture is computed using Eq. 5. For a given species distribution \( c_1, c_2, \ldots, c_n \) and mixture enthalpy \( H \), the temperature is iteratively determined using the following algorithm\textsuperscript{12}

\[
T^{k+1} = T^k - \frac{\sum_{n=1}^{n} \frac{c_n}{c_{n1}} (T^k - \hat{T})}{\sum_{n=1}^{n} \frac{c_n}{c_{n1}} (T^k - \hat{T})}
\]

where \( k \) is the index of iteration. The iterations are continued until

\[
|T^{k+1} - T^k| < \epsilon
\]

where \( \epsilon \) is a small positive quantity. Once the temperature is determined, the thermodynamic and transport properties are easily computed using the expressions given in the previous sections.

Grid Generation

An algebraic grid generation procedure is used in the present calculations. In this procedure, the point on the body surface and the point on the outer boundary are connected by a straight line and the grid points are distributed on this line using the following stretching function

\[
s(\eta) = 1 - \beta \left\{ \frac{(\beta + 1)^{n-1} - (\beta - 1)^{n-1}}{(\beta + 1)^{n-1} + (\beta - 1)^{n-1}} \right\}
\]

\[
\eta = \frac{k - 1}{NK - 1} \quad k = 1, 2, \ldots, NK
\]

where \( \beta (\beta > 1) \) is the stretching parameter and \( NK \) is the total number of points on the grid line. Note that \( s(0) = 0 \) and \( s(1) = 1 \) and the points are clustered close to the wall for values of \( \beta \) close to 1. Such clustering is necessary for good resolution of the subsonic viscous layer.

The coordinates of the grid points are then obtained from

\[
z = z_w + n_1 s(\eta) \delta(\xi)
\]
\[
y = y_w + n_2 s(\eta) \delta(\xi)
\]
\[
z = z_w + n_3 s(\eta) \delta(\xi)
\]

where \( n_1, n_2, \) and \( n_3 \) are the direction cosines of the unit vector along the grid line and \( \delta \) is the linear distance of the outer boundary from the body surface.

The metrics are then computed using first-order accurate one-sided differences in the \( \xi \) direction and second-order accurate central differences in the \( \eta \) and \( \zeta \) directions.

Results

In order to validate the present nonequilibrium PNS code, two test cases were computed. The coordinate system employed in the present calculations is shown in Fig. 1.

Test Case 1

The first test case computed was that of hypersonic laminar flow of dissociating air over a 10 degree cone at 0 degree angle of attack. The altitude chosen was 60.96 km where the ambient pressure and temperature are 20.35 atm and 252.6 K, respectively. The remaining flow conditions are

\[
V_w = 8100 \text{ m/s}
\]
\[
T_w = 1200 \text{ K} \text{ and noncatalytic wall}
\]
\[
e_{<1} = 0.2629 \quad \text{and} \quad e_{<1} = 0.7371
\]
\[
\zeta_e = 1.4
\]

The computation was started at \( x = 1.5 \times 10^{-2} \) using the initial solution generated by the "stepback" procedure. The solution was then marched to \( x = 3.5 \). The marching step size was chosen to be \( \Delta \xi = f b \) where \( f > 1 \) and \( b \) is the maximum thickness of the subsonic layer (in the present calculations, a value of 2 was assigned to \( f \)). The grid used in the calculations consisted of 67 points in the normal direction and 21 points in the meridional direction. The distance of the first point away from the body surface was varied linearly from \( 3 \times 10^{-4} \) to \( 2.3 \times 10^{-4} \) which determined the appropriate stretching parameter \( \beta \). The grid lines were placed normal to the body and the height of the outer boundary was kept fixed at 0.5. The edge of the boundary layer was located approximately using total enthalpy as the criterion. The edge values of pressure, temperature and velocity at the last station were then used as the uniform edge conditions for the reacting boundary-layer (RBL) code of Ref. 13.

Fig. 1 Coordinate system.
The surface pressure coefficient is defined as

\[ C_p = \frac{P_w - P_{oo}}{\frac{1}{2} \rho o V^2} \]  

(38)

In Fig. 2, the axial variation of the surface pressure coefficient is compared against the edge pressure of the boundary-layer code. The pressure predicted by the PNS code is initially higher than the edge pressure of the RBL code but eventually asymptotes to the latter value. The higher pressure is believed due to the leading edge effect. It must be recalled here that the PNS equations contain a normal momentum equation. This permits the interaction of the outer inviscid region with the inner viscous region. At the altitude considered, this interaction is fairly strong because the Reynolds number is low. Consequently, the pressure is higher. As the solution proceeds downstream, the interaction is reduced and one obtains near boundary-layer behavior. The increase in pressure leads to some differences between the PNS and boundary-layer results as will be discussed later.

The PNS equations are uniformly valid in the shock layer and as mentioned earlier the solution domain includes both the viscous and inviscid regions. In Figs. 3-8 only 20 percent of the solution domain is shown in order to emphasize the details of the viscous boundary layer. Pitch plane profiles of tangential velocity and temperature at \( x = 3.5 \) are compared in Figs. 3 and 4, respectively. The agreement between the two codes is excellent. Mass fraction profiles of \( O \) and \( NO \) at \( x = 3.5 \) are compared in Figs. 5 and 6, respectively. The mass fractions have been normalized using the corresponding wall values. The agreement between the two codes is again excellent. The wall values of the mass fractions were also found to be in very good agreement. The electron density (number of electrons per m\(^3\)) is obtained from the mass fraction of the \( NO^+ \) ion. This follows from charge conservation and is defined as

\[ N_e = \frac{\rho c_{NO^+} N_{NO^+}}{M_{NO^+}} \]  

(39)

In Figs. 7 and 8, profiles of the mass fraction of \( NO^- \) and electron density obtained are compared. Again, the mass fractions and densities have been normalized using the corresponding wall values. The curve corresponding to the PNS calculations passes below the symbols representing the boundary-layer calculations. This is due to the fact that the PNS code predicts a higher amount of \( NO^+ \) near the wall. The onset of chemical reactions occurs earlier in the PNS code than in the RBL code because of the initial high pressures. This effect persists downstream and hence the disparity. The electron densities have been obtained from the mass fractions of \( NO^+ \) and consequently these densities will exhibit an identical behavior.
The skin-friction coefficient and the Stanton number are defined as:

\[ C_f = \frac{r_w}{\frac{1}{2} \rho_w V_w^2} \]
\[ St = \frac{r_w}{\rho_w V_w (H_w - H_\infty)} \]

where the wall shear stress \((N/m^2)\) is computed from

\[ r_w = -\mu_w \frac{\partial V}{\partial n} \]

and the total heat transfer \((W/m^2)\) is computed from

\[ q_w = -\kappa_w \frac{\partial T}{\partial n} - \rho_w C_w \sum_{s=1}^{n} h_s \frac{\partial T_s}{\partial n} \]  

The first term in Eq. 43 is the conductive heating rate and the second the diffusive heating rate. The partial derivative, \(\partial T/\partial n\), is taken in the direction normal to the surface of the body. In Figs. 9 and 10, the skin-friction coefficient and Stanton number are plotted as functions of the distance along the cone axis. The coefficients predicted by the two codes are in very good agreement.
The total drag coefficient is defined as

\[ C_d = \frac{D^*}{\frac{1}{2} \rho \infty V_\infty^2 A^*} \]  

(44)

where \( D^* \) (N) is the total drag, i.e., the sum of the pressure drag and the skin-friction drag. The base pressure drag has been neglected. In the present study, trapezoidal integration was used to compute the total drag. The cross-sectional area at \( x = 3.5 \) was chosen as the reference area.

The value of the drag coefficient predicted by the PNS code was 0.1037 which is in very good agreement (less than 1 percent) with the value of 0.1043 predicted by the RBL code.

The ideal gas and equilibrium air models represent two physical extremes. In the former case, there are no reactions (infinitely slow reactions) and in the latter case, the reactions proceed at an infinite rate. In the gas model considered in the present calculations, the reactions proceed at finite-rate and hence is between these two extremes. In order to demonstrate this, the PNS code of Ref. 20 was modified and specialized to two-dimensional and axisymmetric bodies. New curve fits\(^1\) for the thermodynamic properties of equilibrium air were used in the code. For the ideal gas calculations the ratio of specific heats was set to 1.4. The code was then used to compute the flow around the 10 deg. cone for the same freestream conditions. In Fig. 11, the temperature profiles at \( x = 3.5 \) obtained for the three gas models are compared. It is evident from the figure that the peak temperature for the finite-rate chemistry case lies between the peak for the ideal gas and equilibrium air models. In the ideal gas case there are no internal degrees of freedom for the energy to be stored. For the finite-rate reaction case, some of the energy goes into exciting the internal degrees of freedom and some into chemical reactions. This effectively lowers the peak temperature. For the equilibrium air gas, thermochemical equilibrium is achieved instantaneously at every point of the flow field and hence a much lower peak temperature. In Fig. 12, the effect of the three gas models on the Stanton number is shown. The Stanton number has been plotted as a function of the axial distance. The equilibrium Stanton number is slightly greater than the finite-rate chemistry model which in turn is greater than the ideal gas Stanton number.

**Test Case II**

In order to validate the angle of attack capability of the code, a simple test case was chosen. In this test case, hypersonic laminar flow of reacting air over a 10 degree cone...
In Figs. 14a-14d, the effect of angle of attack on the mass fraction atomic oxygen in the pitch plane is shown. The amount of atomic oxygen at the wall decreases with increasing angle of attack. However, due to diffusional effects, atomic oxygen is present over a larger distance from the body. On the windside, the amount of atomic oxygen increases at the wall but is present over a smaller distance.

For different angles of attack, the axial variation of the surface pressure and Stanton number on the windward and leeward meridians is shown in Figs. 15a-15d and Figs. 16a-16d, respectively. The increase in surface pressure and heat transfer on the windside and the decrease on the leeside with increasing angle of attack is evident from these figures.

The computations were performed on either the CRAY-XMP/48 or the CRAY-2 (NAS) computers at NASA Ames Research Center. Each test case involved 10 x 10 block matrices and required 4.3 milliseconds per grid point per step on the CRAY-XMP computer. The first test case required 2000 steps and the second test case required 1800 steps for the lowest angle of attack calculation to 600 steps for the highest angle of attack calculation.

Concluding Remarks

A new PNS code was developed to compute hypersonic laminar flow of chemically reacting air consisting of six species and electrons. The species were treated as calorically imperfect but thermally perfect gases. A noniterative, implicit, approximately-factored, space-marching method was used to solve the coupled set of gas dynamic and species conservation equations. In order to validate the code, two test cases were computed. The first test case was that of hypersonic flow over a 10 deg. cone at 0 deg. angle of attack. The results of this calculation were compared against those of a reacting boundary-layer code. The agreement was found to be very good. These results were further shown to lie between two extremes (ideal gas and equilibrium air). The second test computed was that of hypersonic laminar flow of reacting air over a 10 deg. cone at several angles of attack. Due to the unavailability of experimental data for this case, the numerical results were simply compared against the results of the 0 deg. calculation. These calculations were performed not only to demonstrate the three-dimensional capabilities of the code but also to provide "benchmark" calculations for future code developers. Work is currently being done in the area of shock fitting. A simple turbulence model (Cebeci-Smith) has also been incorporated into the present code and this option remains to be validated. The present study indicates that there is a need for a comprehensive experimental database for validation of nonequilibrium codes.

Appendix A: Fluxes and Source Terms

(a) Fluxes

The (n + 4)-component inviscid flux vectors \( E' \), \( F' \), and \( G' \) are

\[
E' = \left\{ p, p u, pu^2 + p, puw, puw, puh, pwc_1, pwc_2, \ldots, pwc_{n-1} \right\}^T
\]

\[
F' = \left\{ pu, puv, pu^2 + p, puw, puh, pwc_1, pwc_2, \ldots, pwc_{n-1} \right\}^T
\]

\[
G' = \left\{ pw, pwu, pwu, pw^2 + p, pwH, pwc_1, pwc_2, \ldots, pwc_{n-1} \right\}^T
\]

\[ (A1) \]
and the \((n + 4)\)-component viscous flux vectors \(E^v\), \(F^v\), and \(G^v\) are

\[
E^v = \{0, r^{v, x}, r^{v, y}, r^{v, z}, u r^{v, x} + v r^{v, y} + w r^{v, z} - q^v, m_{1}^{v}, m_{2}^{v}, \ldots, m_{n-1}^{v}\}^T
\]

\[
F^v = \{0, r^{v, x}, r^{v, y}, r^{v, z}, u r^{v, x} + v r^{v, y} + w r^{v, z} - q^v, m_{1}^{v}, m_{2}^{v}, \ldots, m_{n-1}^{v}\}^T
\]

\[
G^v = \{0, r^{v, x}, r^{v, y}, r^{v, z}, u r^{v, x} + v r^{v, y} + w r^{v, z} - q^v, m_{1}^{v}, m_{2}^{v}, \ldots, m_{n-1}^{v}\}^T
\]

(A2)

The expressions for the components of the shear stress tensor, the heat flux vector and the diffusion mass flux vector are given below

\[
r^{x} = \frac{2}{3} \mu (u_x - u_y - u_z) \quad q^v = -\beta_2 \kappa T_v - \sum_s [h_s - h_a] m_s^v
\]

\[
r^{y} = \frac{2}{3} \mu (-u_x + 2u_y - u_z) \quad q^v = -\beta_2 \kappa T_v - \sum_s [h_s - h_a] m_s^v
\]

\[
r^{z} = \frac{2}{3} \mu (-u_x - u_y + 2u_z) \quad q^v = -\beta_2 \kappa T_v - \sum_s [h_s - h_a] m_s^v
\]

(A3)

The chemical source vector \(W^c\) is

\[
W^c = \{0, 0, 0, 0, 0, 0, \ldots, 0\}^T
\]

(A4)

where \(\dot{\omega}\) is the mass production or depletion rate of species \(s\).

(b) Chemical Source Terms

Consider a multicomponent system of \(n\) species undergoing \(m\) simultaneous elementary reactions. Let \(n_r\) be the total number of reactants. These reactions can be represented symbolically as

\[
\sum_{i=1}^{m} \nu_{i\cdot}^{r} A_i = \sum_{i=1}^{m} \nu_{i\cdot}^{p} A_i \quad k = 1, 2, \ldots, m
\]

where \(\nu_{i\cdot}^{r}, \nu_{i\cdot}^{p}\) are the stoichiometric coefficients and \(A_i\) is the chemical symbol of the \(i\)th species. Using the law of mass action, the nondimensional mass production rate of species \(s\) is

\[
\dot{\omega}_s = M_s \sum_{k=1}^{m} (\nu_{s\cdot}^{r} - \nu_{s\cdot}^{p}) \left\{ K_{f,k}(T) \prod_{r=1}^{n_r} [p_{r\cdot}^{s}]^{\nu_{r\cdot}^{r}} - K_{b,k}(T) \prod_{r=1}^{n_r} [p_{r\cdot}^{s}]^{\nu_{r\cdot}^{p}} \right\}
\]

(A5)

The nondimensional mole-mass ratios of the reactants are defined as

\[
\gamma_r = \left\{ \begin{array}{ll} c_r/M_r & \text{if } r = 1, 2, \ldots, n_r \hfill \\ \sum_{r=n+1}^{n} \gamma_{r'} & \text{if } r = n + 1, n + 2, \ldots, n \hfill \end{array} \right. \quad (A6)
\]

The reaction rates are functions of temperature and are expressed in the modified Arrhenius form, where the nondimensional forward and backward rates are written as

\[
K_{f,k}(T) = \exp(\log_e(C_{1,k}) + \frac{C_{2,k}}{T} + C_{3,k} \log_e T)
\]

\[
K_{b,k}(T) = \exp(\log_e(D_{1,k}) + \frac{D_{2,k}}{T} + D_{3,k} \log_e T)
\]

(A7)

(A8)

where

\[
C_{1,k} = \frac{L}{V_{\infty}} \left( \frac{\rho_{\infty}}{M_{\infty}} \right)^{\alpha_2 - 1} 10^{3-800 T_{\infty}} C_{2,k} C_{1,k}, \quad C_{2,k} = \frac{C_{3,k}}{T_{\infty}}
\]

\[
D_{1,k} = \frac{L}{V_{\infty}} \left( \frac{\rho_{\infty}}{M_{\infty}} \right)^{\alpha_2 - 1} 10^{3-800 T_{\infty}} D_{2,k} D_{1,k}, \quad D_{2,k} = \frac{D_{3,k}}{T_{\infty}}
\]

(A9)

(A10)
\[ a_k = \sum_{r=1}^{n_k} \nu_{k,r}, \quad \beta_k = \sum_{r=1}^{n_k} \nu_{k,r}^2 \]  
\[ \text{and } C_{1,k}, C_{2,k}, C_{3,k}, D_{1,k}, D_{2,k}, \text{and } D_{3,k} \text{ are constants for a particular reaction } k. \]

(c) Transformed Fluxes

Under the coordinate transformation, Eq. 18, the transformed fluxes and source vectors are given by

\[ \mathbf{E'} = \left( \frac{\ell_x}{J} \right) \mathbf{E} + \left( \frac{\ell_y}{J} \right) \mathbf{F} + \left( \frac{\ell_z}{J} \right) \mathbf{G} \]
\[ \mathbf{F'} = \left( \frac{\ell_x}{J} \right) \mathbf{E} + \left( \frac{\ell_y}{J} \right) \mathbf{F} + \left( \frac{\ell_z}{J} \right) \mathbf{G} \]
\[ \mathbf{G'} = \left( \frac{\ell_x}{J} \right) \mathbf{E} + \left( \frac{\ell_y}{J} \right) \mathbf{F} + \left( \frac{\ell_z}{J} \right) \mathbf{G} \]
\[ \mathbf{W'} = \left( \frac{1}{J} \right) \mathbf{W} \]

where \( J \) is the Jacobian of the coordinate transformation.

The \((n+4)\)-component transformed viscous flux vector, \( \mathbf{F'} \), for the thin-layer approximations is

\[ \mathbf{F'} = J \begin{pmatrix} 0 \\ \ell_1 u_n + \ell_2 v_n + \ell_3 w_n \\ \ell_4 u_n + \ell_5 v_n + \ell_6 w_n \\ \ell_7 u_n + \ell_8 v_n + \ell_9 w_n \\ \frac{1}{2} (\ell_1 - \ell_2) (u^2)_n + \frac{1}{2} (\ell_2 - \ell_3) (v^2)_n + \frac{1}{2} (\ell_3 - \ell_4) (w^2)_n \end{pmatrix} \]

where the coefficients \( \ell_1, \ell_2, \ldots, \ell_9 \) are

\[ \ell_1 = \mu \left[ \frac{4}{3} \left( \frac{n_x}{J} \right)^2 + \left( \frac{n_y}{J} \right)^2 + \left( \frac{n_z}{J} \right)^2 \right] \]
\[ \ell_2 = \mu \left[ \frac{n_x}{J} + \frac{4}{3} \left( \frac{n_y}{J} \right)^2 + \left( \frac{n_z}{J} \right)^2 \right] \]
\[ \ell_3 = \mu \left[ \frac{n_x}{J} + \left( \frac{n_y}{J} \right)^2 + \frac{4}{3} \left( \frac{n_z}{J} \right)^2 \right] \]
\[ \ell_4 = \frac{\mu}{3} \left( \frac{n_x}{J} \right) \left( \frac{n_y}{J} \right) \]
\[ \ell_5 = \frac{\mu}{3} \left( \frac{n_x}{J} \right) \left( \frac{n_z}{J} \right) \]
\[ \ell_6 = \frac{\beta}{\rho \nu} \left[ \frac{n_x}{J} + \left( \frac{n_y}{J} \right)^2 + \left( \frac{n_z}{J} \right)^2 \right] \]
\[ \ell_7 = \frac{\beta}{\rho \nu} \left[ \frac{n_x}{J} + \left( \frac{n_y}{J} \right)^2 + \left( \frac{n_z}{J} \right)^2 \right] \]
\[ \ell_8 = \beta \nu \left[ \frac{n_x}{J} + \left( \frac{n_y}{J} \right)^2 + \left( \frac{n_z}{J} \right)^2 \right] \]
\[ \ell_9 = \beta \nu \left[ \frac{n_x}{J} + \left( \frac{n_y}{J} \right)^2 + \left( \frac{n_z}{J} \right)^2 \right] \]

(d) Geometrical Parameters

The Jacobian and the metrics of the coordinate transformation are

\[ J = \left[ x_t (y_n x_t - y_t x_n) + x_n (y_n x_t - y_t x_n) + x_t (y_t x_n - x_n y_t) \right]^{-1} \]

\[ \frac{\ell_x}{J} = (y_n x_t - y_t x_n) \quad \frac{\ell_y}{J} = (x_n x_t - x_t x_n) \quad \frac{\ell_z}{J} = (x_t y_n - y_n x_t) \]
\[ \frac{n_x}{J} = (y_t x_t - y_t x_n) \quad \frac{n_y}{J} = (x_n x_t - x_t x_n) \quad \frac{n_z}{J} = (x_t y_n - y_n x_t) \]
\[ \frac{\nu_x}{J} = (x_n x_n - x_n x_n) \quad \frac{\nu_y}{J} = (x_n x_t - x_t x_n) \quad \frac{\nu_z}{J} = (x_t y_n - y_n x_t) \]

Appendix B: Inviscid Jacobians

The inviscid Jacobian is an \((n+4)\) x \((n+4)\) matrix. The expressions for the elements of this matrix are given below.

Define the following quantities

\[ \phi_s = \begin{cases} \frac{\mu}{\rho} T (1/M_s - 1/M_n) - (h_s - h_n) & \text{if } s < n; \\
\frac{\mu}{\rho} T (1/M_n) - h_n & \text{if } s = n. \end{cases} \]
\[
\begin{align*}
\dot{S}_x &= \frac{S_x}{f}, \quad \dot{S}_y = \frac{S_y}{f}, \quad \dot{S}_z = \frac{S_z}{f} \\
\dot{U} &= \dot{S}_x u + \dot{S}_y v + \dot{S}_z w
\end{align*}
\] (B2)

(a) Global Continuity

\[
\begin{align*}
\dot{\lambda}_{1,3} &= \dot{S}_x \\
\dot{\lambda}_{1,2} &= \dot{S}_y \\
\dot{\lambda}_{1,4} &= \dot{S}_z
\end{align*}
\] (B4)

(b) $\xi$-Momentum

\[
\begin{align*}
\dot{\lambda}_{2,1} &= -u\dot{U} + \omega_x \dot{S}_z \left(\frac{V^2}{2} + \phi_n\right) \\
\dot{\lambda}_{2,2} &= \dot{S}_x - \omega_x \dot{S}_y u \\
\dot{\lambda}_{2,3} &= (1 - \omega_x) \dot{S}_x u + \dot{U} \\
\dot{\lambda}_{2,4} &= \dot{S}_y u - \omega_x \dot{S}_x v \\
\dot{\lambda}_{2,5} &= \omega_x \dot{S}_x w
\end{align*}
\] (B5)

(c) $\eta$-Momentum

\[
\begin{align*}
\dot{\lambda}_{3,1} &= -v\dot{U} + \omega_x \dot{S}_y \left(\frac{V^2}{2} + \phi_n\right) \\
\dot{\lambda}_{3,2} &= \dot{S}_y - \omega_x \dot{S}_y u \\
\dot{\lambda}_{3,3} &= (1 - \omega_x) \dot{S}_y v + \dot{U} \\
\dot{\lambda}_{3,4} &= \dot{S}_y v - \omega_x \dot{S}_y w \\
\dot{\lambda}_{3,5} &= \omega_x \dot{S}_y w
\end{align*}
\] (B6)

(d) $\zeta$-Momentum

\[
\begin{align*}
\dot{\lambda}_{4,1} &= -w\dot{U} + \omega_x \dot{S}_z \left(\frac{V^2}{2} + \phi_n\right) \\
\dot{\lambda}_{4,2} &= \dot{S}_z - \omega_x \dot{S}_z u \\
\dot{\lambda}_{4,3} &= \dot{S}_z - \omega_x \dot{S}_z v \\
\dot{\lambda}_{4,4} &= (1 - \omega_x) \dot{S}_z w + \dot{U} \\
\dot{\lambda}_{4,5} &= \omega_x \dot{S}_z w
\end{align*}
\] (B7)

(e) Energy

\[
\begin{align*}
\dot{\lambda}_{5,1} &= -\dot{U} H \\
\dot{\lambda}_{5,2} &= \dot{S}_x H \\
\dot{\lambda}_{5,3} &= \dot{S}_y H \\
\dot{\lambda}_{5,4} &= \dot{S}_z H \\
\dot{\lambda}_{5,5} &= \dot{U}
\end{align*}
\] (B8)

(f) Species Continuity ($s = 1, 2, \ldots, n - 1$)

\[
\begin{align*}
\dot{\lambda}_{s+1,1} &= -\dot{U} c_s \\
\dot{\lambda}_{s+1,2} &= \dot{S}_x c_s \\
\dot{\lambda}_{s+1,3} &= \dot{S}_y c_s \\
\dot{\lambda}_{s+1,4} &= \dot{S}_z c_s \\
\dot{\lambda}_{s+1,5} &= \dot{U}
\end{align*}
\] (B9)
Notes
(1) The elements not listed above are identically zero.
(2) The elements of the inviscid Jacobian $\partial E^i/\partial Q$ are obtained by setting $S_x = \xi_x$, $S_y = \xi_y$ and $S_z = \xi_z$.
(3) The elements of the inviscid Jacobian $\partial P^i/\partial Q$ are obtained by setting $S_x = \eta_x$, $S_y = \eta_y$, $S_z = \eta_z$, and $\omega = 1$.
(4) The elements of the inviscid Jacobian $\partial C^i/\partial Q$ are obtained by setting $S_x = \xi_x$, $S_y = \xi_y$, $S_z = \xi_z$, and $\omega = 1$.

Appendix C: Viscous Jacobian
The viscous Jacobian is also an $(n + 4) \times (n + 4)$ matrix. The expressions for the elements of this matrix are given below. The following notation is used:

$\psi_s = J\xi_s \quad s = 1, 2, \ldots, 8$

where $\xi_1, \xi_2, \ldots, \xi_8$ are defined in Eq. A14.

(a) $\xi$-Momentum

$\tilde{M}_{3,1} = -[\psi_1(\frac{u}{\rho})_\rho + \psi_4(\frac{v}{\rho})_\rho + \psi_6(\frac{w}{\rho})_\rho]$

$\tilde{M}_{3,2} = \psi_1(\frac{\rho}{\rho})_\rho$

$\tilde{M}_{3,3} = \psi_4(\frac{\rho}{\rho})_\rho$

$\tilde{M}_{3,4} = \psi_6(\frac{\rho}{\rho})_\rho$

(b) $\eta$-Momentum

$\tilde{M}_{4,1} = -[\psi_4(\frac{u}{\rho})_\rho + \psi_2(\frac{v}{\rho})_\rho + \psi_6(\frac{w}{\rho})_\rho]$

$\tilde{M}_{4,2} = \psi_4(\frac{\rho}{\rho})_\rho$

$\tilde{M}_{4,3} = \psi_2(\frac{\rho}{\rho})_\rho$

$\tilde{M}_{4,4} = \psi_6(\frac{\rho}{\rho})_\rho$

(c) $\xi$-Momentum

$\tilde{M}_{5,1} = -[\psi_6(\frac{u}{\rho})_\rho + \psi_3(\frac{v}{\rho})_\rho + \psi_7(\frac{w}{\rho})_\rho]$

$\tilde{M}_{5,2} = \psi_6(\frac{\rho}{\rho})_\rho$

$\tilde{M}_{5,3} = \psi_3(\frac{\rho}{\rho})_\rho$

$\tilde{M}_{5,4} = \psi_7(\frac{\rho}{\rho})_\rho$

(d) Energy

$\tilde{M}_{6,1} = -[(\psi_1 - \psi_7)(\frac{u^2}{\rho})_\rho + (\psi_2 - \psi_7)(\frac{u^2}{\rho})_\rho + (\psi_3 - \psi_7)(\frac{v^2}{\rho})_\rho + 2\psi_4(\frac{uv}{\rho})_\rho + 2\psi_5(\frac{uw}{\rho})_\rho + 2\psi_6(\frac{uw}{\rho})_\rho + 2\psi_7(\frac{uw}{\rho})_\rho + (\psi_8 - \psi_7)(\frac{h_2 - h_1}{\rho})_\rho + (\psi_9 - \psi_7)(\frac{c^2_{21}}{\rho})_\rho + \cdots + (\psi_n - \psi_7)(h_{n-1} - h_n)(\frac{c_{n-1}}{\rho})_\rho]$

$\tilde{M}_{6,2} = (\psi_1 - \psi_7)(\frac{u}{\rho})_\rho + \psi_4(\frac{v}{\rho})_\rho + \psi_5(\frac{w}{\rho})_\rho$

$\tilde{M}_{6,3} = \psi_4(\frac{\rho}{\rho})_\rho + (\psi_2 - \psi_7)(\frac{v}{\rho})_\rho + \psi_6(\frac{w}{\rho})_\rho$

$\tilde{M}_{6,4} = \psi_5(\frac{u}{\rho})_\rho + \psi_7(\frac{w}{\rho})_\rho + (\psi_3 - \psi_7)(\frac{w}{\rho})_\rho$

18
\[ \dot{m}_{s,0} = \psi_1 \left( \frac{1}{\rho} \right)_{n} \]
\[ \dot{m}_{s,0} = (\psi_s - \psi_1) (h_{1} - h_{n}) \left( \frac{1}{\rho} \right)_{n} \]
\[ \dot{m}_{s,n+1} = (\psi_s - \psi_1) (h_{n-1} - h_{n}) \left( \frac{1}{\rho} \right)_{n} \]

(c) Species Continuity \((s = 1, 2, \ldots, n - 1)\)

\[ \dot{m}_{s+n,1} = -\psi_s \left( \frac{1}{\rho} \right)_{n} \quad s = 1, 2, \ldots, n - 1 \]
\[ \dot{m}_{s+n+1} = \psi_s \left( \frac{1}{\rho} \right)_{n} \quad s = 1, 2, \ldots, n - 1 \]

Notes

(1) The elements not listed above are identically zero.

(2) \(( \cdot )_{n} = \delta_{n} ( \cdot )\).

Appendix D: Source Term Jacobian

The chemical source vector, \(\dot{W}^c\), is a function of the mixture temperature, density, and mass concentrations. This is mathematically expressed as

\[ \dot{W}^c = \frac{1}{j} \dot{W}^c (T, \rho, \gamma_1, \gamma_2, \ldots, \gamma_n) \]

\((D1)\)

The Jacobian of the source term is

\[ \dot{\lambda} = \frac{\partial \dot{W}^c}{\partial Q} = \frac{1}{j} \frac{\partial \dot{W}^c}{\partial Q} \]

\((D2)\)

Using Eq. \(D1\) and the chain rule, the partial derivative in Eq. \(D2\) can be written as

\[ \frac{\partial \dot{W}^c}{\partial Q} = \frac{\partial \dot{W}^c}{\partial T} \frac{\partial T}{\partial Q} + \frac{\partial \dot{W}^c}{\partial \Gamma} \frac{\partial \Gamma}{\partial Q} \]

\((D3)\)

where \(\Gamma\) is the vector containing the mass concentrations of the reactants. The derivative \(\partial \dot{W}^c/\partial T\) is easily evaluated since the reaction rate constants are the only quantities that depend explicitly on the temperature. The derivative \(\partial T/\partial Q\) is a \(1 \times (n + 4)\) row vector whose elements are

\[ \left( \frac{\partial T}{\partial Q} \right) = \frac{1}{\rho C_T} \left\{ \frac{V^2}{2} - h_n, -u, \ldots, -w, j, -(h_1 - h_n), -(h_2 - h_n), \ldots, -(h_{n-1} - h_n) \right\} \]

\((D4)\)

Evaluation of the second term of Eq. \(D3\) is little more involved. The derivative \(\partial \dot{W}^c/\partial \Gamma\) is obtained by differentiating Eq. \(A5\) with respect to the elements of \(\Gamma\) and the derivative \(\partial \Gamma/\partial Q\) is easily evaluated using Eq. \(A6\).
The research performed during NASA Grant NAG 2-245 is described by the 7 documents listed below:
