ABSTRACT

This paper examines the question of sharing of rights and information in the Take-Grant Protection Model by concentrating on the similarities between the two; in order to do this, we state and prove new theorems for each that specifically show the similarities. The proof for one of the original theorems is also provided. These statements of necessary and sufficient conditions are contrasted to illustrate the proposition that transferring rights and transferring information are fundamentally the same, as one would expect in a capability-based system. We then discuss directions for future research in light of these results.

1. Introduction

Capability-based protection systems control access to objects by means of a ticket or capability. This piece of information, typically an ordered pair consisting of an address and a set of rights, grants to the holder unconditional access to the object at the given address in the manner indicated by the set of rights. If the ticket is copied to another process, that process has access to the object commensurate with the associated ticket. For this reason, capabilities are normally made inaccessible to ordinary processes.

In addition to being a grant of rights, a capability is also information. When an

This work was supported by grant NAG 2-480 from the National Aeronautics and Space Administration (NASA) to Dartmouth College, and a Burke Award from Dartmouth College.
object possesses a capability, it knows the location (address) of some other object and how it may access that other object (set of rights). No action of any kind is necessary to implement the use of a capability; the possessor need not be checked against an access control list, or provide a special key; just knowing what the ticket contains means the object has those rights to that object. In essence, then, a capability is permissions encoded as information.

In this paper we explore how the transfer of rights and the transfer of information are reflected in a capability-based protection model. We shall use the Take-Grant Protection Model, introduced in [5] and expanded upon in [1,2,6-8], because both sharing of rights and sharing of information in that model has been analyzed at some length. This model also has some interesting theoretical properties: specifically, whether or not a right (or information) can be transferred may be determined in time linearly proportional to the size of the graph even if the number of objects which can be created is unbounded. This is a direct consequence of the graph rewriting rules, which will be explained in the second and fourth sections. These rules make the model mono-operational; indeed, for any such system, there is an algorithm that decides whether that system and a given initial state is safe for a generic right. (With the more general system, of course, the question is undecidable [4].)

The next section discusses the sharing of rights; we present a framework for stating the standard theorem, and do so. We then state and prove a slightly different (albeit equivalent) theorem; this theorem parallels a result presented in a later section, after we have discussed the sharing of information in the model; in that section, another theorem presents necessary and sufficient conditions for information transfer to
occur. Following this, we state and prove a version of this theorem which parallels the standard theorem for sharing rights. We conclude by looking at the idea of "meta-theorems" and how the dual nature of rights in a capability system demonstrates their utility.

2. Transfers of Authority

Let a finite, directed graph called a protection graph represent a system to be modeled. A protection graph has two distinct kinds of vertices, called subjects and objects. Subjects are the active vertices, and (for example) can represent users; they can pass information and authority by invoking graph rewriting rules. Objects, on the other hand, are completely passive; they can (for example) represent files, and do nothing.

In protection graphs, the subjects are represented by ● and objects by O. Vertices which may be either subjects or objects are represented by ⊙. Pictures are very often used to show the effects of applying a graph rewriting rule on the graph; the symbol \( \rightarrow \) is used to mean that the graph following it is produced by the action of the graph rewriting rule on the graph preceding it. The rewriting rule itself is often written after the derived graph. The symbol \( \rightarrow^* \) represents several rule applications. The term witness means a sequence of graph rewriting rules which produce the predicate or condition being witnessed, and a witness is often demonstrated by listing the graph rewriting rules that make up the witness (usually with pictures.)

The edges of a protection graph are labelled with subsets of a finite set \( R \) of rights. Suppose that \( \{r, w, t, g\} \subseteq R \), where \( r \), \( w \), \( t \), and \( g \) represent read, write, take, and grant rights, respectively. When written as labels on a graph, the set braces are
normally omitted.

The Take–Grant Model permits users with certain rights to transfer rights from one vertex to another. The rules governing the transfer of rights are called *de jure* rules and are as follows:

**take**: Let \( x, y, \) and \( z \) be three distinct vertices in a protection graph \( G_0 \), and let \( x \) be a subject. Let there be an edge from \( x \) to \( y \) labelled \( \gamma \) with \( t \in \gamma \), an edge from \( y \) to \( z \) labelled \( \beta \), and \( \alpha \subseteq \beta \). Then the *take* rule defines a new graph \( G_1 \) by adding an edge to the protection graph from \( x \) to \( z \) labelled \( \alpha \). Graphically,

\[
\begin{array}{c}
\bullet \quad t \\
\bullet \quad \beta \\
\bullet \quad \gamma \\
\end{array}
\quad \rightarrow \quad
\begin{array}{c}
\bullet \quad \alpha \\
\bullet \quad \beta \\
\bullet \quad \gamma \\
\end{array}
\]

The rule is written: "\( x \) takes \((\alpha \text{ to } z)\) from \( y \)."

**grant**: Let \( x, y, \) and \( z \) be three distinct vertices in a protection graph \( G_0 \), and let \( x \) be a subject. Let there be an edge from \( x \) to \( y \) labelled \( \gamma \) with \( g \in \gamma \), an edge from \( x \) to \( z \) labelled \( \beta \), and \( \alpha \subseteq \beta \). Then the *grant* rule defines a new graph \( G_1 \) by adding an edge to the protection graph from \( y \) to \( z \) labelled \( \alpha \). Graphically,

\[
\begin{array}{c}
\bullet \quad g \\
\bullet \quad \beta \\
\bullet \quad \gamma \\
\end{array}
\quad \rightarrow \quad
\begin{array}{c}
\bullet \quad g \\
\bullet \quad \beta \\
\bullet \quad \alpha \\
\end{array}
\]

The rule is written: "\( x \) grants \((\alpha \text{ to } z)\) to \( y \)."

**create**: Let \( x \) be any subject in a protection graph \( G_0 \) and let \( \alpha \) be a subset of \( R \).

Create defines a new graph \( G_1 \) by adding a new vertex \( y \) to the graph and an edge from \( x \) to \( y \) labelled \( \alpha \). Graphically,
The rule is written: "x creates (α to new vertex) y."

`remove`: Let x and y be any distinct vertices in a protection graph $G_1$ such that x is a subject. Let there be an explicit edge from x to y labelled β, and let α be any subset of $R$. Then `remove` defines a new graph $G_1$ by deleting the α labels from β. If β becomes empty as a result, the edge itself is deleted. Graphically,

```
\begin{tikzpicture}

\node (x) at (0,0) [shape=circle,fill=black]{};
\node (y) at (1,0) [shape=circle,fill=black]{};
\node (z) at (1.5,0) [shape=circle,fill=black]{};
\node (a) at (2,0) [shape=circle,fill=black]{};
\node (b) at (3,0) [shape=circle,fill=black]{};
\node (c) at (4,0) [shape=circle,fill=black]{};

\draw[->] (x) to node [above] {\alpha} (y);
\draw[->] (y) to node [right] {\beta} (z);
\draw[->] (z) to node [left] {\alpha} (c);
\draw[->] (c) to node [below] {\beta} (b);
\draw[->] (b) to node [left] {\alpha} (a);
\draw[->] (a) to node [below] {\beta} (x);
\end{tikzpicture}
```

The rule is written: "x removes (α to) y."

The edges which appear in the above graphs are called `explicit` because they represent authority known to the protection system.

Note that there is a duality between the take and grant rules when the edge labelled $t$ or $g$ is between two subjects. Specifically, with the cooperation of both subjects, rights can be transmitted backwards along the edges. The following two lemmas (from [5]) demonstrate this:

**Lemma 1:**

```
\begin{tikzpicture}

\node (x) at (0,0) [shape=circle,fill=black]{};
\node (y) at (1,0) [shape=circle,fill=black]{};
\node (z) at (1.5,0) [shape=circle,fill=black]{};
\node (a) at (2,0) [shape=circle,fill=black]{};
\node (b) at (3,0) [shape=circle,fill=black]{};
\node (c) at (4,0) [shape=circle,fill=black]{};

\draw[->] (x) to node [above] {t} (y);
\draw[->] (y) to node [right] {\alpha} (z);
\draw[->] (z) to node [left] {\alpha} (c);
\draw[->] (c) to node [below] {\alpha} (b);
\draw[->] (b) to node [left] {t} (a);
\draw[->] (a) to node [below] {\alpha} (x);
\end{tikzpicture}
```

**Lemma 2:**

```
\begin{tikzpicture}

\node (x) at (0,0) [shape=circle,fill=black]{};
\node (y) at (1,0) [shape=circle,fill=black]{};
\node (z) at (1.5,0) [shape=circle,fill=black]{};
\node (a) at (2,0) [shape=circle,fill=black]{};
\node (b) at (3,0) [shape=circle,fill=black]{};
\node (c) at (4,0) [shape=circle,fill=black]{};

\draw[->] (x) to node [above] {g} (y);
\draw[->] (y) to node [right] {\alpha} (z);
\draw[->] (z) to node [left] {\alpha} (c);
\draw[->] (c) to node [below] {\alpha} (b);
\draw[->] (b) to node [left] {g} (a);
\draw[->] (a) to node [below] {\alpha} (x);
\end{tikzpicture}
```
As a result, when considering the transfer of authority between subjects, neither direction nor label of the edge is important, so long as the label is in the set \( \{t,g\} \).

The first question that comes to mind is under what conditions can rights be shared? To answer this question, we first need to examine some characteristics of take-grant graphs.

**Definition:** A \( tg\)-path is a nonempty sequence \( v_0, \ldots, v_k \) of distinct vertices such that for all \( i, 0 \leq i < k \), \( v_i \) is connected to \( v_{i+1} \) by an edge (in either direction) with a label containing \( t \) or \( g \).

Note that the vertices in a \( tg\)-path may be either subjects or objects.

**Definition:** Vertices are \( tg\)-connected if there is a \( tg\)-path between them.

**Definition:** An island is a maximal \( tg\)-connected subject-only subgraph.

Any right that one vertex in an island has can be obtained by any other vertex in that island. In other words, an island is a maximal set of subject-only vertices which possess common rights.

With each \( tg\)-path, associate one or more words over the alphabet \( \{\overleftarrow{t}, \overrightarrow{t}, \overleftarrow{g}, \overrightarrow{g}\} \) in the obvious way. If the path has length 0, then the associated word is the null word \( \varepsilon \).

**Definition:** A vertex \( v_0 \) initially spans to \( v_k \) if \( v_0 \) is a subject and there is a \( tg\)-path between \( v_0 \) and \( v_k \) with associated word in \( \{\overleftarrow{t}, \overrightarrow{g}\} \cup \{\varepsilon\} \).

**Definition:** A vertex \( v_0 \) terminally spans to \( v_k \) if \( v_0 \) is a subject and there is a \( tg\)-path between \( v_0 \) and \( v_k \) with associated word in \( \{\overrightarrow{g}\} \).

**Definition:** A bridge is a \( tg\)-path with \( v_0 \) and \( v_k \) both subjects and the path’s associ-
An initial span is a tg-path along which the first vertex in the path can transmit authority; a terminal span is a tg-path along which the first vertex in the path can acquire authority. A bridge is an edge along which a right can be passed, possibly by using lemma 1 and 2 as well as the de jure rules. As a note, a bridge is said to be *directed away from* \(v_0\). The following diagram illustrates these terms:

![Diagram](image)

- islands: \(I_1=\{p,u\}, I_2=\{w\}, I_3=\{y, s'\}\)
- bridges: \(u, v, w\) and \(w, x, y\)
- initial span: \(p\) with associated word: \(v\)
- terminal span: \(s', s\) with associated word: \(t\)

The following predicate formally defines the notion of *transferring authority*:

**Definition:** The predicate \(\text{can share}(\alpha, x, y, G_0)\) is true for a right \(\alpha\) and two vertices \(x\) and \(y\) if and only if there exist protection graphs \(G_1, \ldots, G_n\) such that \(G_0 G_1 \cdots G_n\) using only de jure rules, and in \(G_n\) there is an edge from \(x\) to \(y\) labelled \(\alpha\).

In short, if \(x\) can acquire \(\alpha\) rights to \(y\), then \(\text{can share}(\alpha, x, y, G_0)\) is true. The theorem which establishes necessary and sufficient conditions for this predicate to hold is [5]:

**Theorem 3:** The predicate \(\text{can share}(\alpha, x, y, G_0)\) is true if and only if there is an edge from \(x\) to \(y\) in \(G_0\) labelled \(\alpha\), or if the following hold simultaneously:

(i) there is a vertex \(s \in G_0\) with an \(s\)-to-\(y\) edge labelled \(\alpha\);
(ii) there exists a subject vertex $p'$ such that $p'=p$ or $p'$ initially spans to $x$;

(iii) there exists a subject vertex $s'$ such that $s'=s$ or $s'$ terminally spans to $s$; and

(iv) there exist islands $I_1, \ldots, I_v$ such that $p'$ is in $I_1$, $s'$ is in $I_v$, and there is a bridge from $I_j$ to $I_{j+1}$ ($1 \leq j < v$).

This statement of the necessary and sufficient conditions can be much simpler, and that is the topic of the next section.

3. Alternate Necessary and Sufficient Conditions for *can-share*

For reasons that will become clear in the next section, we can state conditions necessary and sufficient for *can-share* to be true as follows:

**Theorem 4:** The predicate $can\text{-}share(\alpha, x, y, G_0)$ is true if and only if there is a vertex $s$ with an edge to $y$ labelled $\alpha$, and a sequence of subjects $u_1, \ldots, u_m$ such that all of the following conditions hold simultaneously:

(i) $u_1=x$ or $u_1$ initially spans to $x$;

(ii) $u_m=s$ or $u_m$ terminally spans to $s$; and

(iii) for all $i$ ($1 \leq i < m$), there is a $tg$-path between $u_i$ and $u_{i+1}$ with an associated word in $B$.

**Proof:** ($\iff$) We prove this by induction on $m$.

**Basis:** $m=1$. First, note that if $u_1=s$, $u_1$ has $\alpha$ rights to $y$; but if if $u_1 \neq s$, then by applying the *take* rule (repeatedly if necessary), $u_1$ can acquire $\alpha$ rights to $y$. If $u_1=x$, we are done. If not, by using the take rule (possibly repeatedly), $u_1$ can acquire *grant* rights to $x$, and can then use the grant rule to give $x$ $\alpha$ rights over $y$. Since only the
take and grant (de jure) rules were used, $can\cdot share(\alpha, x, y, G_0)$ is true by definition.

**INDUCTION HYPOTHESIS:** For all $m \leq k$, if the three conditions in the theorem are true, then $can\cdot share(\alpha, x, y, G_n)$ is true.

**INDUCTION STEP:** Let $m = k+1$. By the induction hypothesis, clearly $can\cdot share(\alpha, u_2, y, G_n)$ is true. It suffices to consider whether $u_1$ can get $\alpha$ rights to $y$. For if $u_1 = x$, we are done, and if not, then $u_1$ initially spans to $x$; so $u_1$ may use a (possibly null) series of take rules to acquire $grant$ rights over $x$, and then use the grant rule to pass its $\alpha$ rights to $x$.

Consider now whether or not $u_1$ may acquire $\alpha$ rights to $y$. Note that $u_1$ and $u_2$ are distinct, else $m = k$, not $k+1$. By condition (iii), the word associated with the $tg$-path between $u_1$ and $u_2$ is in $B$. So let us consider those one at a time. In these cases, by the take rule and the definition of $bridge$, it is necessary to consider only those cases where bridges are of length 2 or less.

Case 1. The associated word is $\vec{r}$.

In this case $u_1$ simply applies the take rule to acquire $\alpha$ rights to $y$.

Case 2. The associated word is $\vec{g}$.

The result is true by lemma 2; take $x = u_1$, $y = u_2$, and $z = y$ in that lemma.

Case 3. The associated word is $\vec{r}$.

The result is true by lemma 1; take $x = u_2$, $y = u_1$, and $z = y$ in that lemma.

Case 4. The associated word is $\vec{g}$.

In this case $u_2$ simply applies the grant rule to give $\alpha$ rights to $y$. 
Case 5. The associated word is $tg$.

Let $z$ be the intermediate vertex; note that it must be an object. Then $u_2$ simply applies the grant rule to give $\alpha$ rights to $z$, and $u_1$ simply uses the take rule to acquire them.

Case 6. The associated word is $gt$.

The following construction suffices. First, $u_1$ creates ($tg$ to new) $v$:

Then, $u_1$ grants ($g$ to $v$) to $z$:

Next, $u_2$ takes ($g$ to $v$) from $z$:

After that, $u_2$ grants ($\alpha$ to $y$) to $v$:

Finally, $u_2$ grants ($\alpha$ to $y$) to $v$: 
In all cases, $u_1$ can acquire $\alpha$ rights to $y$ using only the *de jure* rules; so by the definition of $\text{can\-share}$, $\text{can\-share}(\alpha, x, y, G_n)$ is true. This proves the induction step and hence the claim.

($\Rightarrow$) Assume now $\text{can\-share}(\alpha, x, y, G_n)$ is true. By inspection of the *de jure* rules, none adds an incoming edge with right $\alpha$ to a vertex $y$ unless there is already an edge with that right and with $y$ as target; hence, there must exist a vertex $s$ with an $\alpha$ edge to $y$ in $G_0$.

Now consider the *de jure* rule applications $\rho_1, \ldots, \rho_n$ needed to produce a witness to the predicate in $G_n$. Without loss of generality, we may eliminate all instances of the remove rule, since that rule never adds edges, and without loss of generality we may reorder the rule applications so all create rules come at the beginning. We induct on the number $n$ to prove the claim.

**Basis:** If $n = 1$, then either the take or grant rule was used, since the create rule would not add a new edge to an existing vertex. The initiator must have been a subject by the nature of the rules.

If the take rule was used, then, $x$ initiated it and took from $s$ $\alpha$ rights to $y$; in this case, if $s$ is not a subject, choose $m = 1$ and $u_1 = x$ in the theorem. Conditions (i) and (ii) clearly hold, and condition (iii) trivially holds. On the other hand, if $s$ is a subject, choose $m = 2$, $u_1 = x$, and $u_2 = y$. Then all three conditions hold.
Now suppose the grant rule was used. Then s initiated it and granted to x α rights to y. In this case, if x is not a subject, choose \( m = 1 \) and \( u_1 = s \) in the theorem. Conditions (i) and (ii) clearly hold, and condition (iii) trivially holds. On the other hand, if x is a subject, choose \( m = 2 \), \( u_1 = x \), and \( u_2 = y \). Then all three conditions hold.

In either case, \( can\_share(\alpha, x, y, G_0) \)'s being true implies that all three conditions hold, as claimed.

**INDUCTION HYPOTHESIS:** For \( n = 1, \ldots, k \), if \( can\_share(\alpha, x, y, G_0) \) is true, then all three conditions hold.

**INDUCTION STEP:** Let \( n = k + 1 \) and consider the rule \( \rho_n \). If it is a create rule, then there is an edge from x to y labelled \( \alpha \) in \( G_{n-1} \), since the create rule cannot add a new incoming edge to an existing vertex; in this case the induction hypothesis assures us that the three conditions hold.

The proof that the claim holds for the take and the grant rules are very similar, so we present the one for take here. Suppose the rule \( \rho_{k+1} \) is a take rule. For this rule to be applied to \( G_k \), x must be a subject, there must be an x-to-z edge labelled \( t \), and a z-to-y edge labelled \( \alpha \) for some vertex z in \( G_k \). So \( can\_share(t, x, z, G_k) \) and \( can\_share(\alpha, z, y, G_k) \) both hold.

If z exists in \( G_0 \), it is clear that the predicates \( can\_share(t, x, z, G_0) \) and \( can\_share(\alpha, z, y, G_0) \) both hold. Condition (i) follows immediately from the first of these and the induction hypothesis, and condition (ii) from the second and the induction hypothesis. So, consider the first of those two predicates. By the induction hypothesis, there is a subject vertex \( z' \) such that either \( z' = z \) or \( z' \) terminally spans to
z (condition (ii).) By the second, there is a subject vertex \( z'' \) such that either \( z'' = z \) or \( z'' \) initially spans to \( z \) (condition (i).) Note that by the definition of bridge, the path between \( z' \) to \( z'' \) is a bridge unless \( z' = z'' \). In either case, the union of the sets of \( u_i s \) of the two predicates provides the \( u_i s \) for \( can\_share(\alpha, x, z, G_0) \) between each is a tg-path with associated word in \( B \). This proves condition (iii).

If, on the other hand, \( z \) does not exist in \( G_0 \) (and therefore was created by one of the create rules), consider the graph \( G_c \) that exists after all create rules have been applied but before any other de jure rules have been used. The vertex \( z \) must lie in a subgraph connected to the original graph \( G_0 \) by one edge. Call the vertex lying on this edge and existing in \( G_0, z_0 \). Thus, there is a path between \( z_0 \) and \( z \); moreover, by the nature of the create rule, this path is directed out of \( z_0 \) and towards \( z \). Let \( z_0, \ldots, z_m = z \) be the vertices on the path. All but the last of them must be subjects (because each invokes the create rule to create the next one.) Further, the edge between \( z_{m-1} \) and \( z \) must contain a \( t \) in its label, since no de jure rule adds an incoming edge with a right unless there is already an incoming edge with that right; so, if the edge in question did not have a \( t \) in its label, \( can\_share(t, x, z, G_c) \) would be false. Also, since rights may only be transferred using the take and grant rules, the label of each edge in the path from \( z_0 \) to \( z \) must contain either a \( t \) or a \( g \). By the induction hypothesis, then, \( can\_share(t, z_0, z, G_c) \) is true. This means that either \( can\_share(g, z_0, x, G_c) \) is true or \( can\_share(t, x, z_0, G_c) \) is true.

To show that \( can\_share(\alpha, z_0, y, G_0) \) is true consider a witness to \( can\_share(\alpha, z, y, G_0) \). Append to that witness a take rule of the form “\( z_0 \) takes (\( \alpha \) to \( y \)) from \( z \).” These rules produce a series of protection graphs generated by a sequence of de jure
rule applications, and in the final one there is an edge labelled $\alpha$ from $z_0$ to $y$. But by definition, this means $\text{can-share}(\alpha, z_0, y, G_0)$ is true.

Now, if $\text{can-share}(t, x, z_0, G_c)$ is true, as $z_0$ exists in $G_0$ and $\text{can-share}(\alpha, z_0, y, G_0)$ is true, we have already shown that all three conditions hold. A similar argument when $\text{can-share}(g, z_0, x, G_c)$ is true also shows that all three conditions hold. This proves the induction hypothesis for $n = k + 1$.

Since the induction step is successful, the claim is proven. $\square$

Return now to the picture discussed in the earlier section:

In this picture, we can easily see that $\text{can-share}(\alpha, p, q, G_0)$ is true; take $u_1 = p$, $u_2 = u$, $u_3 = w$, $u_4 = y$, and $u_5 = s'$. Condition (i) holds as $u_1 = p$; condition (ii) holds as $u_5$ terminally spans to $s$; and condition (iii) holds as all words associated with the paths between the subjects are bridges.

It should be clear why this theorem holds. Since an island is a set of subjects connected by edges labelled $\text{take}$ and $\text{grant}$, the vertices of the island involved in the sharing of the right are all connected by elements of $B$. Between each island is a bridge, and of course the associated words are in $B$. So the theorem in this section merely focuses attention on these vertices and ignores the others in the island. Similarly, the conditions in theorem 3 simply merge all subsequences of the $u_i$'s that have no objects as part of the $tg$-path between them into an island. This reasoning can be made more formal to show:
Corollary 5: The conditions in theorem 3 hold if and only if the conditions in theorem 4 hold.

Of course, this theorem also preserves the following property:

Corollary 6: Truth or falsity of the predicate *can-share* may be determined in linear time in the size of the initial graph.

Let us now consider the transfer of information, and re-examine the proof of the predicate governing that type of transfer or connection.

4. Transfers of Information

The *de jure* rules control the transfer of authority only; they say nothing about the transfer of information. The two are clearly different; for example, if a user is shown a document containing information which he does not have authority to read, the information has been transferred to the user. The *de jure* rules do not model cases like this. Instead, we use a different set of rules, called *de facto* rules, to derive paths along which information may flow.

In order to describe transfers of information, we cannot use explicit edges, because no change in authority occurs. Still, some indication of the paths along which information can be passed is necessary. Hence, we use a dashed line, labelled by $r$, to represent the path of a potential *de facto* transfer. Such an edge is called an implicit edge. Notice that implicit edges cannot be manipulated by the *de jure* rules, since the *de jure* rules can affect only authorities recorded in the protection system, and implicit edges do not represent such authority.

A protection graph records all authorities as explicit edges, so when a *de jure* rule
is used to add a new edge, an actual transfer of authority has taken place. But when a *de facto* rule is used, a path along which information can be transferred is exhibited; the actual transfer may, or may not, have occurred. It is impossible to tell this from the graph, because the graph records authorities and *not* information. For the purposes of this model, however, we shall assume that if it is possible for information to be transferred from one vertex to another, such a transfer has in fact occurred.

One set of proposed *de facto* rules was introduced in [1] to model the transfer of information. Although these are not the only rules possible, their effects have been explored, and so we shall use them.

*post*: Let $x$, $y$, and $z$ be three distinct vertices in a protection graph $G_0$ and let $x$ and $z$ be subjects. Let there be an edge from $x$ to $y$ labelled $\alpha$, where $r \in \alpha$, and an edge from $z$ to $y$ labelled $\beta$, where $w \in \beta$. Then the *post* rule defines a new graph $G_1$ with an implicit edge from $x$ to $z$ labelled $(r)$. Graphically,

![post rule diagram]

*pass*: Let $x$, $y$, and $z$ be three distinct vertices in a protection graph $G_0$, and let $y$ be a subject. Let there be an edge from $y$ to $x$ labelled $\alpha$, where $w \in \alpha$, and an edge from $y$ to $z$ labelled $\beta$, where $r \in \beta$. Then the *pass* rule defines a new graph $G_1$ with an implicit edge from $x$ to $z$ labelled $(r)$. Graphically,

![pass rule diagram]
spy: Let \( x, y, \) and \( z \) be three distinct vertices in a protection graph \( G_0 \), and let \( x \) and \( y \) be subjects. Let there be an edge from \( x \) to \( y \) labelled \( \alpha \), where \( r \in \alpha \), and an edge from \( y \) to \( z \) labelled \( \beta \), where \( r \in \beta \). Then the spy rule defines a new graph \( G_1 \) with an implicit edge from \( x \) to \( z \) labelled \( \{r\} \). Graphically,

\[
\begin{array}{c}
\bullet \ x \quad r \\
\bigcirc \ y \\
\bullet \ z
\end{array}
\quad \quad \quad
\begin{array}{c}
\bullet \ x \quad r \\
\bigcirc \ y \\
\bullet \ z
\end{array}
\]

find: Let \( x, y, \) and \( z \) be three distinct vertices in a protection graph \( G_0 \), and let \( y \) and \( z \) be subjects. Let there be an edge from \( y \) to \( x \) labelled \( \alpha \), where \( w \in \alpha \), and an edge from \( z \) to \( y \) labelled \( \beta \), where \( w \in \beta \). Then the find rule defines a new graph \( G_1 \) with an implicit edge from \( x \) to \( z \) labelled \( \{r\} \). Graphically,

\[
\begin{array}{c}
\bigcirc \ x \quad w \\
\bullet \ y \\
\bullet \ z
\end{array}
\quad \quad \quad
\begin{array}{c}
\bigcirc \ x \quad w \\
\bullet \ y \\
\bullet \ z
\end{array}
\]

Note that these rules add implicit and not explicit edges. Further, as these rules model information flow, they \textit{can} be used when either (or both) of the edges between \( x \) and \( y \), or \( y \) and \( z \), are implicit.

4.1. Information Flow in a Graph with Static Rights

Now, consider the conditions necessary for a potential \textit{de facto} transfer to exist in a graph.

Definition: The predicate \( \text{canKnow}(x, y, G_0) \) is true if and only if there exists a sequence of graphs \( G_1, \ldots, G_n \) \((0 \leq n)\), such that \( G_i \xrightarrow{} G_{i+1} \) \((0 \leq i < n)\) by one of the \textit{de facto} rules and in \( G_n \) either an \( x \)-to-\( y \) edge labelled \( r \) exists or a \( y \)-to-\( x \) edge labelled
w exists and if the edge is explicit, its source is a subject.

Intuitively, canknowf(x, y, G0) is true if and only if x has the authority to read y, y has the authority to write to x, or an implicit edge from x to y can be added by means of the de facto rules. Note the duality of read and write. If x can write to y, then y effectively can read x. All x has to do is write to y any information that y wants to see. This duality will play an important role in later results.

Definition: An rw-path is a nonempty sequence v0, . . . ,vk of distinct vertices such that for all i, 0≤i<k, vi is connected to vi+1 by an edge (in either direction) with a label containing an r or a w.

With each rw-path, associate one or more words over the alphabet {r, w, r, w} in the obvious way; for instance, the protection graph

\[ \text{\bullet} \rightarrow \text{\bigcirc} \rightarrow \text{\bullet} \]

has associated \( r^wF \) and \( w^rW \). If the path has length 0, then the associated word is the null word \( v \).

Definition: An rw-path \( v_0, \ldots, v_k \), \( k \geq 1 \), is an admissible rw-path if and only if it has an associated word \( a_1a_2 \cdots a_k \) in the regular language \( (r \cup w)^* \), and if \( a_i=r \) then \( v_{i-1} \) is a subject and if \( a_i=w \) then \( v_i \) is a subject.

Note that there cannot be two consecutive objects on an rw-admissible path. Given these definitions,

Theorem 7: Let x and y be vertices in a protection graph G0. Then canknowf(x, y, G0) is true if and only if there is an admissible rw-path between x and y.
4.2. Information Flow in a Graph with Changing Rights

These results can be extended to include both *de jure* and *de facto* rules. To do so, we must define terms combining characteristics of those used in both the *de jure* and *de facto* developments.

**Definition:** The predicate \( \text{can know}(x, y, G_0) \) is true if and only if there is a sequence of protection graphs \( G_1, \ldots, G_n \) such that \( G_0 \sqsubset^* G_n \) and in \( G_n \) either a \( x \)-to-\( y \) edge labelled \( r \) exists, or a \( y \)-to-\( x \) edge labelled \( w \) exists and, if the edge is explicit, its source is a subject.

This is merely \( \text{can know}(x, y, G_0) \) without the restriction on the types of rules used.

**Definition:** An \( \text{rwtg-path} \) is a nonempty sequence \( v_0, \ldots, v_k \) of distinct vertices such that for all \( i, 0 \leq i < k \), \( v_i \) is connected to \( v_{i+1} \) by an edge (in either direction) with a label containing a \( t \), \( g \), \( r \), or a \( w \).

With each \( \text{rwtg-path} \), associate one or more words over the alphabet \( \{ t, t, g, g, p, p, w, w \} \) in the obvious way.

**Definition:** The vertex \( v_0 \) \( \text{rw-initially spans} \) to \( v_k \) if \( v_0 \) is a subject and there is an \( \text{rwtg-path} \) between \( v_0 \) and \( v_k \) with associated word in \( \{ t^* w \} \).

**Definition:** A vertex \( v_0 \) \( \text{rw-terminally spans} \) to \( v_k \) if \( v_0 \) is a subject and there is an \( \text{rwtg-path} \) between \( v_0 \) and \( v_k \) with associated word in \( \{ t^* p \} \).

**Definition:** A bridge is an \( \text{rwtg-path} \) with associated word in the regular language

\[
B = \{ \overline{t}^* \cup t^* \cup \overline{t}^* g \overline{t}^* \cup \overline{t}^* g \overline{t}^* \}
\]

(Note that this is the same as the definition given earlier in this section.) A connection
is an rwtg-path with associated word in the regular language

\[ C = \{ \epsilon^* \mathcal{P} \cup \epsilon^* \mathcal{W} \cup \epsilon^* \mathcal{P} \mathcal{W} \} \]

We can characterize the set of graphs for which can·know is true:

In order to appreciate these results, let us now look at some examples of the uses of the rules; these will be useful in deriving our later results. These two results are quite basic, and state that there is a bridge or connection between two subjects, either can (with the co-operation of the other) read information from the other. More formally:

**Lemma 8:** If there is a bridge from \( x \) to \( y \), then \( x \) can obtain an implicit read edge to \( y \).

**Proof:** By the take rule and the definition of bridge, it suffices to prove the lemma for bridges of length 2 or less. Six cases arise.

Case 1: First, \( y \) creates (\( rw \) to new vertex) \( z \):

Then, \( x \) takes (\( rw \) to \( z \)) from \( y \):

Finally, \( x \) and \( y \) use the post rule:
Case 2: First, \( x \) creates (\( rw \) to new vertex) \( z \):

\[
\begin{array}{c}
\text{x} \\
\text{g} \\
\text{y}
\end{array}
\quad \Rightarrow
\begin{array}{c}
\text{z} \\
\text{g} \\
\text{x} \\
\text{y}
\end{array}
\]

Then, \( x \) grants (\( rw \) to \( z \)) to \( y \):

\[
\begin{array}{c}
\text{z} \\
\text{g} \\
\text{x} \\
\text{y}
\end{array}
\quad \Rightarrow
\begin{array}{c}
\text{z} \\
\text{g} \\
\text{x} \\
\text{y}
\end{array}
\]

Finally, \( x \) and \( y \) use the post rule:

\[
\begin{array}{c}
\text{z} \\
\text{g} \\
\text{x} \\
\text{y}
\end{array}
\quad \Rightarrow
\begin{array}{c}
\text{z} \\
\text{g} \\
\text{x} \\
\text{y}
\end{array}
\]

Case 3: First, \( x \) creates (\( rw \) to new vertex) \( v \):

\[
\begin{array}{c}
\text{x} \\
\text{g} \\
\text{y}
\end{array}
\quad \Rightarrow
\begin{array}{c}
\text{z} \\
\text{g} \\
\text{x} \\
\text{y}
\end{array}
\]

Next, \( x \) grants (\( rw \) to \( v \)) to \( z \):

\[
\begin{array}{c}
\text{z} \\
\text{g} \\
\text{x} \\
\text{y}
\end{array}
\quad \Rightarrow
\begin{array}{c}
\text{z} \\
\text{g} \\
\text{x} \\
\text{y}
\end{array}
\]

Then \( y \) takes (\( rw \) to \( v \)) from \( z \):

\[
\begin{array}{c}
\text{z} \\
\text{g} \\
\text{x} \\
\text{y}
\end{array}
\quad \Rightarrow
\begin{array}{c}
\text{z} \\
\text{g} \\
\text{x} \\
\text{y}
\end{array}
\]
Then $y$ takes ($rw$ to $v$) from $z$:

Case 4:

\[
\begin{align*}
\text{t} & \quad \text{see case 1} \\
x & \quad y
\end{align*}
\]

Case 5:

\[
\begin{align*}
g & \quad \text{see case 2} \\
x & \quad y
\end{align*}
\]

Case 6:

\[
\begin{align*}
t & \quad g & \quad \text{see case 3} \\
x & \quad y & \quad z
\end{align*}
\]

In all cases, $x$ gets implicit read rights over $y$, proving the claim. \qed

**Lemma 9**: Let $x$ and $y$ be subjects with a bridge or connection between them. Then at least one of the following is true:

(i) an explicit read edge from $x$ to $y$ exists or may be added;

(ii) an implicit read edge from $x$ to $y$ may be added; or

(iii) an explicit write edge from $y$ to $x$ exists or may be added.

**Proof**: If there is a bridge between $x$ and $y$, case (i) holds by lemma 8. So, suppose there is a connection from $x$ to $y$. If the associated word is in $\bar{r}^x \bar{r}^y$, by using the take rule, $x$ can obtain an explicit read edge to $y$, establishing case (i). If the associated
word is in $W^{\dagger}$, by using the take rule, $y$ can obtain an explicit write edge to $x$, establishing case (iii). If the associated word is in $i^*W^{\dagger}$, $x$ and $y$ can each apply the take rule until $x$ obtains a read edge to a vertex to which $y$ has a write edge (or vice versa); then $x$ and $y$ can use the post rule to add an implicit read edge from $x$ to $y$ (case (ii).) □

5. Statement and Proof of can*know

The following theorem was presented in [1]; the proof has been expanded upon here.

**Theorem 10:** The predicate can*know($x, y, G_0$) is true if and only if there is a sequence of subjects $u_1, \ldots, u_m$ such that all of the following conditions hold simultaneously:

(i) $u_1 = x$ or $u_1$ rw-initially spans to $x$;

(ii) $u_m = y$ or $u_m$ rw-terminally spans to $y$; and

(iii) for all $i$ ($1 \leq i < m$), there is an $rwtg$-path between $u_i$ and $u_{i+1}$ with an associated word in $B \cup C$.

**Proof:** ($\Leftarrow$) Assume the three conditions hold. By lemma 9, if $p$ and $q$ are subjects joined by an $rwtg$-path with associated word in $B \cup C$, then one can add an implicit read edge between them. Once this is done, there is an $rw$-admissible path from $x$ to $y$; by theorem 7, this is a necessary and sufficient condition for can*know($x, y, G_0$) to be true.

($\Rightarrow$) Assume can*know($x, y, G_n$) is true. If a witness can be found by applying de jure rules only, then can*share($r, x, y, G_0$) is true. Let $v_1, \ldots, v_n$ be the sequence
of subjects in theorem 4 instantiating that predicate, and let \( s \) be the vertex with an \( r \) edge to \( q \). Taking \( m = n + 1 \), \( u_i = v_i \) for \( 1 \leq i \leq n \), and \( u_{n+1} = s \) (if \( s \) is a subject) or \( m = n \) and \( u_i = v_i \) for \( 1 \leq i \leq n \) (if \( s \) is an object), conditions (i), (ii), and (iii) follow immediately.

So suppose at least one de facto rule application had to be used. Since de jure rules do not manipulate implicit edges, we may without loss of generality reorder the rule applications so that all de jure rules precede all de facto rules. It follows by theorem 7 that there exists an \( rw \)-admissible path in the graph resulting from the application of the de jure rules but before any de facto rules are applied. Let \( x = v_0, \ldots, v_l = y \) be the vertices on that path. We now show by induction on the length \( l \) of the path that the desired conditions hold.

**Basis:** Let \( l = 1 \). Then by the definition of an \( rw \)-admissible path, either \( x \) is a subject and \( rw \)-terminally spans to \( y \), or \( y \) is a subject and \( rw \)-initially spans to \( x \). In the first case, take \( n = 1 \) and \( x = u_1 \) in the claim to see that conditions (i) and (ii) are true and condition (iii) is trivially true; in the other case, take \( n = 1 \) and \( y = u_1 \) in the claim to see once again that conditions (i) and (ii) are true and condition (iii) is trivially true.

**Induction Hypothesis:** For \( l = 1, \ldots, k \), if \( can\_know(x, y, G_0) \), then the three conditions hold.

**Induction Step:** Let \( l = k + 1 \) and consider which de facto rule was applied to produce the witness. What follows assumes that the rule application \( \rho_1 \) was a spy rule; the proofs for the other rules are similar.

If \( z \) exists in \( G_0 \), that the spy rule was used means there is an (implicit or explicit) edge from \( x \) to \( z \), and an (implicit or explicit) edge from \( z \) to \( y \). If the edge from \( x \)
to $z$ is explicit, theorem 4 gives us condition (i) (take $u_1 = x$ in that theorem.) If it is implicit, since $z$ and $y$ are distinct (by definition of the spy rule), we may apply the induction hypothesis to obtain condition (i). Similarly, regardless of whether the edge is implicit or explicit, either theorem 4 or the induction hypothesis gives us condition (ii). Finally, condition (iii) follows from either the induction hypothesis or theorem 4 (remember, condition (iii) requires the edge labels to be in a subset of what condition (iii) requires) or both.

Now suppose $z$ does not exist in $G_0$. Then by the nature of the create rule, $z$ must be in a subgraph connected to the vertices in $G_0$ by a single edge; moreover, there is a path $z_0, \ldots, z_m = z$ with edges from $z_i$ to $z_{i+1}$, and for $0 \leq i < m$, $z_i$ is a subject. If the edge from $x$ to $z$ is explicit, this means that by theorem 4, as $z_0$ lies on all possible paths from $x$ to $z$, one of $can\cdot share(g, z_0, x, G_0)$ and $can\cdot share(t, x, z_0, G_0)$ is true. In either case, as $x$ and $z_0$ are subjects, by lemma 8, $can\cdot know(x, z_0, G_0)$ is true. On the other hand, if the edge from $x$ to $z$ is implicit, since $z$ and $y$ are distinct (by definition of the spy rule), we may apply the induction hypothesis to show $can\cdot know(x, z_0, G_0)$ is true. The three conditions follow immediately.

An example will perhaps clarify what the theorem says. Consider the graph:

![Diagram](attachment:image.png)

Take $u_1 = p$, $u_2 = x$, $u_3 = z$, and $u_4 = s$. $s$ indeed $rw$-terminally spans to $q$, and between each pair of $u_i$s there is a bridge (between $x$ and $q$, and between $s$ and $z$) or connection (between $x$ and $z$). In this case, therefore, $can\cdot know(p, q, G_0)$ is true. In
fact, the following witnesses the predicate:

(1) \( z \) takes (\( r \) to \( q \)) from \( s \);

(2) \( x \) grants (\( r \) to \( y \)) to \( p \);

(3) \( p \) and \( z \) use the post rule to add an implicit edge labelled \( r \) from \( p \) to \( z \);

(4) \( p \) and \( z \) use the spy rule to add an implicit edge labelled \( r \) from \( p \) to \( q \).

However, note that \( \text{canShare}(r, p, q, G_0) \) is false because there is no bridge between \( x \) and \( z \).

6. An Alternate Statement of \( \text{canKnow} \)

Earlier, we gave a statement of the necessary and sufficient conditions for \( \text{canShare} \) to be true that is quite similar to the conditions for \( \text{canKnow} \) to be true. In this section, we prove a symmetric result, namely that the conditions for \( \text{canKnow} \) to be true may be stated in a form quite similar to the original statement of the theorem for \( \text{canKnow} \). The theorem relies upon lemma 9, which states a set of conditions that must be met before \( \text{canKnow} \) is true. Hence, the theorem given next really only tries to establish when there will be a series of bridges or connections from a vertex \( q \) to another vertex \( p \) along which information can be sent.

**Theorem 11:** Let \( p \) and \( q \) be vertices in a protection graph \( G_0 \). Then \( \text{canKnow}(p, q, G_0) \) is true if, and only if, \( \text{canShare}(r, p, q, G_0) \) is true or all of the following conditions hold:

(i) There is a subject \( p' \) such that \( p' = p \) or \( p' \) is \( rw \)-initially connected to \( p \);

(ii) There is a subject \( q' \) such that \( q' = q \) or \( q' \) is \( rw \)-terminally connected to \( q \);
(iii) There is a sequence of islands \( \{I_j \mid 1 \leq j \leq m\} \) such that there is a bridge or connection from \( I_j \) to \( I_{j+1} \), \( 1 \leq j \leq m \), and \( p' \in I_1 \), and \( q' \in I_m \).

**Informal argument:** To prove the "if" part, note that if \( \text{can\-share}(r, p, q, G_0) \) is true then by definition \( \text{can\-know} \) is true. If not, condition (i) says that \( p' \) can send any information it gets to \( p \), and part (ii) says that \( q' \) can obtain any information it needs from \( q \). Condition (iii) simply says that \( q' \) can send the information to a vertex \( z_1 \) in \( I_{m-1} \), which can in turn send it to a vertex \( z_2 \) in \( I_{m-2} \), and so on, until a vertex \( z_{m-1} \) in \( I_1 \) gets the information. By the properties of an island, this means that \( p' \) can get the information. Putting all this together, \( \text{can\-know} \) is true.

Going the other way involves considering the rule applications needed to produce a witness. We can require all \( \text{de facto} \) rules to be applied last, and examine the conditions needed for them to be applied. For example, in the pass rule, there is a vertex \( y \) for which \( \text{can\-share}(w, y, p, G_n) \) and \( \text{can\-share}(r, y, p, G_n) \) are true. From the conditions required for both \( \text{can\-share} \) rules to hold, the three condition of the theorem must be true. (In the formal proof, we will show this for the post and spy rules; the formal proof for the pass and find rules are left as an exercise for the reader.) And if no \( \text{de facto} \) rules are used to generate a witness to \( \text{can\-know} \), obviously \( \text{can\-share}(r, p, q, G_0) \) is true.

**Proof:** \( (\Leftarrow) \) Consider condition (i). As \( p' \) is \( \text{rw}\)-initially connected to \( p \), it either has or can obtain (through the take rule) a write edge to \( p \). Similarly, by condition (i), if \( q' \) is \( \text{rw}\)-terminally connected to \( q \), it either has or can obtain (using the take rule) a read edge to \( q \). Thus, it suffices to show \( \text{can\-know}(p', q', G_0) \) is true by condition (iii); merely apply the spy rule (if \( q' \neq q \)), and then the post rule (if \( p' \neq p \)), to obtain
cun\text{\textbackslash know}(p, q, G_0).

We show condition (iii) implies \textit{cun\textbackslash know}(p', q', G_0) by inducting on \(m\), the number of islands in that condition.

**Basis:** Let \(m = 1\). Then \(p'\) and \(q'\) are in the same island, whence by cases 1, 2, 4, and 5 of lemma 8, \textit{cun\textbackslash know}(p', q', G_0) is true.

**Induction Hypothesis:** For \(m = 1, \ldots, k\), if condition (iii) holds, \textit{cun\textbackslash know}(p', q', G_0) also holds.

**Induction Step:** Let \(m = k + 1\). Let \(z_k\) be the subject in \(I_k\) that bounds the bridge or connection between \(I_k\) and \(I_{k+1}\); let \(z_{k+1}\) be \(z_k\)'s counterpart in \(I_{k+1}\). By lemma 9, \textit{cun\textbackslash know}(z_{k+1}, q', G_0) holds; by lemma 8, this means \textit{cun\textbackslash know}(z_k, q', G_0) holds; and by the induction hypothesis, \textit{cun\textbackslash know}(p', z_k, G_0) holds; whence by the spy rule, \textit{cun\textbackslash know}(p', q', G_0) is true. This proves the induction hypothesis, and hence the "if" part of the theorem.

(\Rightarrow) Now assume \textit{cun\textbackslash know}(p, q, G_0) is true, and consider a minimal set of rule applications \(p_i\) needed to produce a witness. Without loss of generality, we may reorder the \(p_i\)'s so that all \textit{de jure} rule applications precede any \textit{de facto} rule applications, since \textit{de facto} rule applications do not change the state of the protection graph. If no \textit{de facto} rules are applied, the witness will end with an explicit read edge from \(p\) to \(q\), in which case \textit{cun\textbackslash share}(r, p, q, G_0) holds; the three conditions then follow from theorem 3. So suppose that at least one \textit{de facto} rule application is needed.

Induct on the number \(m\) of such \textit{de facto} rule applications.

**Basis:** Let \(m = 1\). Each of the \textit{de facto} rules must be considered. We will give the proof for the post rule; the other rules are treated similarly.
Consider the post rule. In order to apply this rule, there must be a vertex \( x \) such that \( \text{can} \text{share}(r, p, x, G_0) \) and \( \text{can} \text{share}(w, q, y, G_0) \) are true. By theorem 3, this means that there is a sequence of islands \( I_1, \ldots, I_j \) with \( p \in I_1 \), and a vertex \( a \in I_j \) which terminally spans to another vertex \( a' \), which has a read edge to \( x \):

![Diagram](attachment:image)

Similarly, there is a sequence of islands \( J_1, \ldots, J_k \), with \( q \in J_k \), and a vertex \( b \in J_1 \) which terminally spans to another vertex \( b' \), which has a write edge to \( x \):

![Diagram](attachment:image)

Now, combining these two facts, relabel the islands \( J_1, \ldots, J_k \) as \( I_{j+1}, \ldots, I_{j+k} \). Note that, as a terminal span has associated word in \( \vec{r}^k \), we have a connection \( \vec{r}^k \vec{w} \vec{r}^k \) from \( a \) to \( b \):
This is condition (iii). Taking \( p' = p \) and \( q' = q \), conditions (i) and (ii) hold.

**INDUCTION HYPOTHESIS:** Let \( m = 1, \ldots, k \). Then after \( n \) de facto rule applications, if \( \text{can*know}(p, q, G_0) \) is true, conditions (i), (ii), and (iii) hold.

**INDUCTION STEP:** Let \( n = k + 1 \), and assume the \( k+1 \)st rule applied is a spy rule (proofs for the other three rules are similar.)

As the spy rule is used, \( p \) is a subject, and there is a subject vertex \( x \) such that \( \text{can*know}(p, x, G_0) \) and \( \text{can*know}(x, q, G_0) \) are true. By the induction hypothesis, the first \( \text{can*know} \) ensures that there is a subject \( p' \) such that \( p' = p \) or \( p' \) \( \text{rw-initially} \) spans to \( p \), giving condition (i); the second \( \text{can*know} \) ensures that there is a subject \( q' \) such that \( q' = q \) or \( q' \) \( \text{rw-terminally} \) spans to \( q \), giving condition (ii). By the induction hypothesis, condition (iii) is assumed to hold for both \( \text{can*know}(p, x, G_0) \) and \( \text{can*know}(x, q, G_0) \). So, let \( I_1, \ldots, I_j \) and \( J_1, \ldots, J_k \) be the sets of islands for \( \text{can*know}(p, x, G_0) \) and \( \text{can*know}(x, q, G_0) \), respectively. Thus, the configuration is:
Again, relabel $J_1, \ldots, J_k$ to be $I_{j+1}, \ldots, I_{j+k}$; also, recall that an $rw$-terminal span between subjects is a connection. This establishes condition (iii), proving the induction hypothesis and the claim.

Hence, theorem 11 has been proven. □

Let us return to the example of the previous section.

![Diagram](image)

Take $p'=p$, $q'=s$, $I_1=\{p, x\}$, and $I_2=\{s, a\}$. As $s$ indeed $rw$-terminally spans to $q$, and there is a connection between $I_1$ and $I_2$, $can\cdot know(p, q, G_0)$ is true, agreeing with our previous result.

It should be clear that this theorem and the one presented in the previous section are equivalent. As cases 1, 2, 4, and 5 of lemma 8 show, if there is an edge between two subjects labelled $t$ or $g$ an implicit edge labelled $r$ can be added between those vertices. Hence in addition to being a subgraph in which rights may be freely transferred, an island is also a subgraph in which information may be freely transferred assuming all subjects co-operate. (If not, other conditions apply; see [2].) Hence, the islands connected by bridges and connections ensures that provides a sequence of subjects connected by bridges and connections along which information can flow, as condition (v) requires. Hence the conditions in theorem 11 being true implies the conditions in theorem 10 are true. Similarly, the sequence of subjects in theorem 10 may be grouped into islands (if need be, the islands may contain only one vertex) to obtain the conditions for theorem 11. This reasoning can be made more formal to show:
Corollary 12: The conditions in theorem 10 hold if and only if the conditions in theorem 11 hold.

Of course, this theorem also preserves the following property:

Corollary 13: Truth or falsity of the predicate can\textemdash know may be determined in linear time in the size of the initial graph. or connection.

7. Discussion and Future Directions

One of the more striking features of these theorems is the similarity between theorems 3 and 11, and between theorems 4 and 10. Let us look at the first two in some detail.

Take the capability represented by the s-to-\(x\) edge in theorem 3 to be a piece of information. Then the only difference between the two theorems lies in the nature of the paths along which the information is transmitted; if the information is a capability, the class of paths is much smaller than if it were ordinary information. This makes sense, because one of the characteristics of capabilities is that "... no ordinary program can manufacture or modify the bit pattern with which a capability is represented" [3]. Capabilities are very special pieces of information, and cannot be handed around like the contents of a file. So, in the Take-Grant Protection Model, the \textit{de jure} rules manipulate the flow of capability information, and the \textit{de facto} rules implement the flow of all other types of information.

This suggests two things. In [6], the notion of classifying subjects into \textit{groups} was explored in the context of "groups of users." One could extend the classification to quantities to be controlled, and provide several different sets of rules, each set
describing the flow of that quantity throughout the graph. One would then have to discuss the interactions of the different rules and the quantities as the rules were applied. Interestingly enough, only the flow of capabilities would change the explicit edges in the graph, since the graph is designed to abstract only the capabilities; in some instances, a new graph might have to be defined. (This has been done with the de facto rules and the implicit edges; when one deals with implicit edges, one uses a "pseudo-graph" with dashed arrows representing edges that "really aren't there.")

Continuing on in our speculations, since the characterization of the transfer of capabilities and information is so similar, the idea of a "meta-theorem" that captures the generalized notion of "sharing" immediately suggests itself. This theorem, and a corresponding one for the predicates describing the theft of information and rights, would be broad enough to incorporate the extensions to the model that deal with information flow of all kinds, classes of information and subjects, and so forth. Such theorems would be a step forward in making Take-Grant type protection models practical and useful.
