ABSTRACT

The rapid two-dimensional slewing and vibrational control of the unsymmetrical flexible SCOLE (Spacecraft Control Laboratory Experiment) with multi-bounded controls has been considered. Pontryagin's Maximum Principle has been applied to the nonlinear equations of the system to derive the necessary conditions for the optimal control. The resulting two-point boundary-value problem is then solved by using the quasilinearization technique, and the near-minimum time is obtained by sequentially shortening the slewing time until the controls are near the bang-bang type. The trade-off between the minimum time and the minimum flexible amplitude requirements has been discussed. The numerical results show that the responses of the nonlinear system are significantly different from those of the linearized system for rapid slewing. The SCOLE station-keeping closed-loop dynamics are re-examined by employing a slightly different method for developing the equations of motion in which higher order terms in the expressions for the modal shape functions are now included. If no force actuators are mounted on the beam, the modal amplitude responses are more easily excited than when these actuators are included. System responses are dependent on both the force actuator locations as well as the state and control weighting matrix elements. A preliminary study on the effect of actuator mass on the closed-loop dynamics of large
space systems is conducted. A numerical example based on a
coupled two-mass two-spring system illustrates the effect of
changes caused in the mass and stiffness matrices on the
closed-loop system eigenvalues. In certain cases the need
for redesigning control laws previously synthesized, but not
accounting for actuator masses, is indicated.

CHAPTER V
CONCLUSIONS AND RECOMMENDATIONS
I. INTRODUCTION

The present grant, NSG-1414, Supplement II, continues the research effort initiated in May 1977 and accomplished in the previous grant years (May 1977 - May 1988) as reported in Refs. 1-15*. This research has concentrated on the control of the orientation and the shape of very large, inherently flexible proposed future spacecraft systems. Possible future applications of such large spacecraft systems (LSS) include: large scale multi-beam antenna communication systems; Earth observation and resource sensing systems; orbitally based electronic mail transmission; as platforms for orbital based telescope systems; and as in-orbit test models designed to compare the performance of flexible LSS systems with that predicted based on computer simulations and/or scale model Earth-based laboratory experiments. In recent years the grant research has focused on the orbital model of the Spacecraft Control Laboratory Experiment (SCOLE) first proposed by Taylor and Balakrishnan*6 in 1983.

The present report is divided into five chapters. Chapter II is based on a paper presented at the 1989 AAS/AIAA Astrodynamics Conference and describes rapid two-

*References cited in this report are listed separately at the end of each chapter.
dimensional slewing and vibration control of the asymmetrical SCOLE configuration where the beam flexibility is included in the model. Pontryagin's maximum principle has been applied to the nonlinear equations of the system to derive the necessary conditions for the optimal control where the Shuttle mast, and reflector (multiple-bounded) controls are considered. The resulting two-point boundary value problem is then solved by using the quasilinearization technique, and the near minimum time is obtained by sequentially shortening the slewing time until the controls are nearly of the bang-bang type. The trade-off between the minimum flexible amplitude and minimum slewing time are discussed.

In the next chapter (Chapter III) a slightly different method for developing the equations of motion for the SCOLE system during stationkeeping is presented involving a more direct approach in matrix manipulation, and including higher order terms in the expressions for the mast modal shape functions. Closed-loop responses for the system modeled by this approach are compared with similar responses as presented in Ref. 14 (based on the Ph.D. thesis of C.M. Diarra) for the same ranges of the state and control penalty matrices. Further emphasis is placed on evaluating how the flexible modes of the SCOLE mast are excited during representative stationkeeping operations.
A preliminary study of the effect of actuator mass on the design of control laws for large space systems is the subject of Chapter IV. A numerical example based on a coupled two-mass two-spring system is selected to illustrate the effects of varying the masses and stiffnesses (one at a time) on the closed-loop eigenvalues, and to determine what changes should be incorporated into the control laws previously designed, but not accounting for actuator masses.

Finally, Chapter V describes the main general conclusions together with general recommendations. At the end of the grant year reported here and after submission of our proposal for the 1989-90 grant year\textsuperscript{17}, the thrust of this research has been redirected to provide more direct support to the new NASA Controls/Structures Interaction (CSI) program.

II. RAPID IN-PLANE MANEUVERING OF THE FLEXIBLE ORBITING SCOLE

The rapid two-dimensional slewing and vibrational control of the unsymmetrical flexible SCOLE (Spacecraft Control Laboratory Experiment) with multi-bounded controls has been considered. Pontryagin's Maximum Principle has been applied to the nonlinear equations of the system to derive the necessary conditions for the optimal control. The resulting two-point boundary-value problem is then solved by using the quasilinearization technique, and the near-minimum time is obtained by sequentially shortening the slewing time until the controls are near the bang-bang type. The trade-off between the minimum time and the minimum flexible amplitude requirements has been discussed. The numerical results show that the responses of the nonlinear system are significantly different from those of the linearized system for rapid slewing.

INTRODUCTION

The large-angle maneuvering and vibrational control problem of a flexible spacecraft has been the subject of considerable research by many authors through different approaches to various structural models. Among them, many authors placed their efforts on different control strategies
while using rather simplified spacecraft dynamic models. A few investigators have considered different and yet complicated structural models. Among all the control strategies used, Pontryagin’s Maximum Principle is an important and a basic method to such a coupled nonlinear dynamics and control problem. Although this method usually produces open-loop control strategies, it has the advantage of being able to handle control problems of more complicated structures (nonlinear dynamics and control), and it may prove to be useful in control-structure interaction problems. Unfortunately, most of the applications of this method to the slewing problem have been restricted to some simplified model, for example, a central hub with two or four symmetrically connected beams. Numerical problems appear to have limited the extension of the techniques based on the Maximum Principle to more complex system models.

However, by considering such extensions, we may encounter many interesting phenomena and produce many useful results. In this paper, we aim at using the Maximum Principle for a slightly more complicated structural model, namely, the 2-dimensional orbiting SCOLE. The complexity of the present problem stems from three considerations: (1) more nonlinear terms than before included in the dynamical equations; (2) more control variables used in this system; and (3) the rapid slewing or near-minimum time slewing which may produce large flexible modal amplitudes. We hope, through the present analysis, to reveal, to some extent, how the nonlinear system is different from the linearized system, and how some parameters, such as the slewing time, and the weighting elements on the controls, affect the responses of the system.

This paper consists of three parts: formulation of the system equations by using Lagrange’s formula; derivation of the optimal control problem which results in the two-point boundary-value problem (TPBVP); and simulation of slews for different boundary conditions and control variables.
FORMULATION OF THE STATE EQUATIONS

System Configuration

The Shuttle-beam-reflector system discussed in this paper is shown in Fig. 1. The Shuttle and the reflector are considered to be rigid bodies. The beam is assumed connected to the Shuttle at its mass center, $o_s$. In addition, the reflector is attached to the beam at an offset point, $a_r$, which is $x_r$ away from the mass center of the reflector, $o_r$. Both beam ends are considered to be fixed.

Fig. 1 shows the structure in the pitch plane, since our present purpose is to analyze the planar motion of the system. The equations of motion in this plane are also valid for the motion in the roll plane, except for that case the inertia parameters are different.

Three coordinate systems are used in Fig. 1: $(k_o,i_o)$, the orbit's axes; $(k_s,i_s)$, the Shuttle fixed coordinates;
and \((k_i, i_i)\), the reflector fixed coordinates. \(s\) is the rotation angle of the Shuttle with respect to the orbit coordinates. The transverse displacement of the beam from its undeformed position is \(w(z, t)\), where \(z\) is the coordinate along the \(k_z\) axis, and \(t\) is time. If the displacement is assumed to be small, then, an approximate expression for the rotation angle of the cross section of the beam is, 
\[
\phi(z, t) = s \frac{\partial w(z, t)}{\partial z}. 
\]

The free vibration of this structure can be considered as a free-free beam (Bernoulli-Euler type) vibration problem with boundary conditions including the masses and moments of inertia of the Shuttle and the reflector. The partial differential equation for this problem can be solved by using the separation of variable method, in which \(w(z, t)\) is assumed as
\[
\psi(z, t) = \sum_{i=1}^{\infty} \psi_i(z) \eta_i(t) \quad (1)
\]
where \(\psi_i(z)\) is the \(i\)th mode function (shape) and \(\eta_i(t)\) is the associated amplitude of the \(i\)th mode. The natural frequencies and mode shapes for the pitch and roll motions are listed in Ref. 5, and will be used in this paper.

If the first \(n\) modes of the flexible system are used in the formulation of the dynamical equations of the system, the expression in Eq. (1) can be rewritten as
\[
\psi(z, t) = \sum_{i=1}^{n} \psi_i(z) \eta_i(t) = \psi^T(z) \eta(t) \quad (2)
\]
where \(\psi^T = [\psi_1 \ldots \psi_n]\), \(\eta = [\eta_1 \ldots \eta_n]^T\). Then, we have,
\[
\dot{\psi} = \frac{\partial \psi}{\partial t} = \psi^T \dot{\eta} \quad (3)
\]
\[
\psi' = \psi(z, t) = (d \psi^T / dz) \eta = \psi^T \eta \quad (4)
\]
\[
\ddot{\psi} = \frac{\partial \psi}{\partial z} = (d \psi^T / dz) \eta = \psi^T \eta \quad (5)
\]
\[
\delta \psi_j = \psi^T(z_j) \delta \eta \quad (6)
\]
\(\theta\) and \(\eta\) are the generalized coordinates of the system.
Kinetic Energy

The kinetic energy of the system, \( T \), consists of three parts, \( T_s \), \( T_b \), \( T_r \), representing the kinetic energy of the Shuttle, the beam, and the reflector, respectively,

\[
T = T_s + T_b + T_r
\]  

where

\[
T_s = \frac{1}{2} I_s \dot{\theta}_s^2
\]

\[
T_b = \frac{1}{2} \int_0^L \rho \left[ (\phi_s^2 + z^2) \dot{\phi}_s^2 + \dot{\phi}_s^2 + 2z \omega \dot{\omega} \right] dz
\]

\[
T_r = \frac{1}{2} I_r \left( \dot{\theta}_r + \dot{\phi}_r \right)^2 + \frac{1}{2} m_r \left\{ \left( \dot{\phi}_r^2 + \omega^2 \right) \dot{\theta}_r^2 + 2L \dot{\omega} \dot{\omega} + \dot{\phi}_r^2 \right. \\
\left. - 2x_r \left( \dot{\theta}_r + \dot{\phi}_r \right) \left[ (\dot{\phi}_r + \omega) \sin \phi_r - \dot{\phi}_r \cos \phi_r \right] \right\}
\]

Potential Energy

The elastic potential energy of the beam is

\[
V = \frac{EI}{2} \int_0^L \left( \frac{\partial^2 u}{\partial z^2} \right)^2 dz
\]

where \( EI \) is the constant flexural rigidity of the cross section of the beam.

Generalized Forces

The virtual work done by the controls is

\[
\delta W = u_1 \delta \theta + \sum_{j=2}^4 u_j \cdot \delta r_j
\]

where \( u_1 \) is the control torque on the Shuttle, and \( u_2 \) and \( u_3 \) are the actuator force vectors on the beam, and \( u_4 \) is the control force vector on the center of the reflector. The \( \delta \theta \), and \( \delta r_j \) are the associated virtual displacements.

From Fig. 1, we have,

\[
u_j = u_1 \left[ \cos(\theta + \phi_j) i_0 - \sin(\theta + \phi_j) k_0 \right]
\]

\[
r_j = (z_j \cos \theta - \omega_j \sin \theta) k_0 + (z_j \sin \theta + \omega_j \cos \theta) i_0, \quad j = 2, 3, 4.
\]
where $u_j$ is the magnitude of $u_j$ along the $k_j$ axis; $w_j = w(z_j, t)$; and $\phi_j = \phi(z_j, t)$. In this paper, $z_1 = L/3$, $z_2 = 2L/3$, and $z_3 = L$. After substituting these expressions into Eq. (12), and noting the expression for $\delta w$ in Eq. (6), we can get,

$$\delta W = \sum_{j=1}^{4} u_j (z_j \cos \phi_j + w_j \sin \phi_j) | \delta \theta + \sum_{j=2}^{4} \psi^T (z_j) u_j \cos \phi_j \delta \eta$$

$$= Q_\theta \delta \theta + Q_\eta \delta \eta \quad (13)$$

where $Q_\theta$ and $Q_\eta$ are the generalized forces associated with $\theta$ and $\eta$, respectively.

**Dynamical Equations**

After substituting the expressions (2-5) into the kinetic energy in Eqs. (7-10) and the potential energy in Eq. (11), and using the following matrix/vector notations,

$$\int_0^L \rho \dot{\psi}^T \dot{z} + m \dot{w}^T = \eta^T [ \int_0^L \rho \psi \dot{w}^T \dot{z} + m \dot{\psi} (L) \psi^T (L) ] \eta = \eta^T M_\theta \eta$$

$$\int_0^L \rho \dot{\psi}^T \dot{z} + m \dot{w}^T + I \dot{\phi} = \dot{\eta}^T [ M_\phi + I \psi^T (L) \psi^T (L) ] \dot{\eta} = \dot{\eta}^T M_\phi \dot{\eta}$$

$$\int_0^L \frac{\partial^2 \psi}{\partial z^2} dz = \eta^T ( \int_0^L \psi \psi \dot{z} \dot{z} ) \dot{\eta} = \eta^T K_\eta$$

$$\int_0^L \rho \dot{z} \dot{\psi} \dot{z} + I \dot{\phi} + m L \dot{w} = \eta^T [ \int_0^L \rho \psi \dot{z} \dot{z} + L \psi^T (L) + m \dot{L} \psi^T (L) ] \dot{\eta} = \dot{\eta}^T M_\psi \dot{\eta}$$

we can obtain the Lagrangian of the system,

$$L = \frac{1}{2} \dot{\eta}^T \left[ I + \eta^T M_\theta \eta + 2m \dot{\psi} \dot{z} \dot{z} + L \psi \dot{z} \dot{z} \right]$$

$$+ \dot{\eta}^T \left[ \eta^T M_\phi + m \dot{\phi} + m \dot{\psi} \dot{\psi} \dot{z} \dot{z} + L \dot{\phi} \dot{\psi} \dot{z} \dot{z} \right]$$

$$+ \frac{1}{2} \dot{\eta}^T M_\phi \eta$$

$$(14)$$

where $I = I_\theta + I_\phi + \int_0^L \rho \dot{z} \dot{z} + m \dot{L} \dot{L}$ is the total moment of inertia of the undeformed system. The Lagrange equations,

$$\frac{d}{dt} \left( \frac{\partial L}{\partial \dot{\eta}} \right) - \frac{\partial L}{\partial \eta} = Q_\eta$$

of the system can be obtained in the following matrix form,
\[
M(\eta) \begin{bmatrix} \dot{\theta} \\ \dot{\eta} \end{bmatrix} = F(\theta, \eta, \dot{\eta}) + B(\eta)u \quad (15)
\]

with

\[
M(\eta) = \begin{bmatrix}
I + \eta^T M_1 \eta + 2m_r x_r (\omega_r \cos \phi_r - L \sin \phi_r) & \text{symmetry} \\
M_1 + M_2 \eta \cos \phi_r + m_s \sin \phi_r & M_3 - M_3 \sin \phi_r
\end{bmatrix} 
\]

\[
F = \begin{bmatrix}
-2\dot{\theta} (M_2 \eta + m_c \cos \phi_r - M_1 \eta \sin \phi_r) + m_r \dot{\phi}_r (L \cos \phi_r + \omega_r \sin \phi_r) \\
\dot{\phi}_r (M_2 \eta + m_c \cos \phi_r - M_1 \eta \sin \phi_r) + (\phi_r M_1 - 2\dot{\theta} M_3) \eta \cos \phi_r - K\eta
\end{bmatrix} 
\]

\[
B = \begin{bmatrix}
z_1 \cos \phi_2 - \omega_2 \sin \phi_2 & z_3 \cos \phi_3 - \omega_3 \sin \phi_3 & z_4 \cos \phi_4 - \omega_4 \sin \phi_4 \\
\psi(z_1) \cos \phi_2 & \psi(z_3) \cos \phi_3 & \psi(z_4) \cos \phi_4
\end{bmatrix} 
\]

where \( u = [u_1, u_2, u_3, u_4]^T \) is the control vector. Other notations used in these equations are

\[
M_1 = m_r x_r \psi'(L) \psi(L), \quad M_2 = M_1 + M_1^T, \quad M_3 = M_1 - M_1^T; \\
M_4 = m_r x_r \psi'(L) \psi^T(L); \\
m_s = m_r x_r [\psi(L) + L \psi'(L)], \quad m_2 = m_r x_r [\psi(L) - L \psi'(L)].
\]

We need the following linearized version of Eqs. (15) to compare the responses of the two systems.

\[
\begin{bmatrix}
I & -m_1 I \\
m_1 & M_3
\end{bmatrix} \begin{bmatrix} \dot{\theta} \\ \dot{\eta} \end{bmatrix} = \begin{bmatrix}
0 & 0 \\
0 & K
\end{bmatrix} \begin{bmatrix} \theta \\ \eta \end{bmatrix} + \begin{bmatrix}
1 & -z_1 \\
\psi(z_1) & \psi(L)
\end{bmatrix} u \quad (19)
\]

For convenience, by introducing the notations

\[
y_i^T = [\theta, \eta^T] = [y_{i,1}, \ldots, y_{i,k}], \quad k = n+1, \quad y_i = \dot{y}_i, \quad y^T = [y_1^T, y_k^T]
\]

Eqs. (15) can be rewritten in the state form

\[
\dot{\hat{y}}_i = \hat{y}_i \\
\dot{\hat{y}}_i = M^{-1}(\eta)[F(\eta, \hat{y}_i) + B(\eta)u]
\]

\[
2.7
\]
DERIVATION OF THE OPTIMAL CONTROL PROBLEM

Objective
The purpose of this paper is to find the optimal controls which rapidly drive the system from an initial state, \( y(t=0) \), to a final required state, \( y(t=t_f) \). Since the magnitudes of these controls are, in practice, bounded, the optimal controls for the minimum time slewing problem are usually of the bang-bang type. However, this kind of control will generally introduce large flexible amplitudes. Therefore, a near-minimum-time slew is of primary interest to us.

Necessary Conditions
Instead of starting from the minimum time control problem, we set out to deal with the optimal control problem with a quadratic cost function,

\[
J = \frac{1}{2} \int_0^{t_f} (y_1^T Q_1 y_1 + y_2^T Q_2 y_2 + u^T R u) dt \tag{21}
\]

where \( Q_1, Q_2 \), and \( R \) are weighting matrices, \( t_f \) is the given slewing time. This kind of problem has been considered by a list of authors. However, in their analysis, \( t_f \) is fixed and there is no limitation on the magnitude of the controls. On the contrary, in the present problem, the slewing time \( t_f \) is no longer fixed, because we want to find a rapid slew or a near-minimum-time slew. The magnitudes of the controls, \( u \), are also bounded,

\[
|u_i| \leq u_{ib}, \quad i=1,2,3,4. \tag{22}
\]

Our strategies to solve this problem are described in the following. First, the necessary conditions based on Eqs. (20-21) are derived. Then, the constraints, Eq. (22), are imposed on these necessary conditions to modify the controls. Finally, in the solution process of the resulting TBPVP, the slewing time is shortened sequentially, in order to find the near-minimum-time slewing. As we have discussed in Ref. 6, when the slewing time is shortened, the optimal control, will approach the optimal control of the minimum time slewing problem, that is, becoming the bang-bang type. It is clear that, when the controls approach the bang-bang type, the value of the index \( J \) in Eq. (21) will increase and approach its maximum value.
The Hamiltonian of the system is,

\[
H = \frac{1}{2}(y_i^T Q_i y_i + y_i^T Q_u y_i + u^T Ru) + \lambda_i^T y_i + \lambda_i^T M^{-1}(F + Bu)
\]  

(23)

where \( \lambda_i \) and \( \lambda_i^2 \) are the costate vectors associated with \( y_i \) and \( y_i^2 \), respectively. By using the Maximum Principle, the necessary conditions for the unrestricted optimal control problem are the dynamical equations (20) plus the following differential equations for the costates,

\[
\dot{\lambda}_i = -\frac{\partial H}{\partial y_i} = -Q_i y_i - \frac{\partial F^T M^{-1} \lambda_i}{\partial y_i} - (F + Bu)^T (F + Bu) + \lambda_i^T \frac{\partial M^{-1}}{\partial y_i} \lambda_i
\]

(24)

\[
\dot{\lambda}_i^2 = -\frac{\partial H}{\partial y_i^2} = -Q_i y_i - \frac{\partial F^T M^{-1} \lambda_i^2}{\partial y_i^2}
\]

(25)

where \( \lambda_i \) represents a special matrix (similar for \( \lambda_i^2 \)). As well as the expressions for the optimal control,

\[
\frac{\partial H}{\partial u} = 0, \quad u = -R^{-1} B^T M^{-1} \lambda_i
\]

(26)

The control rules in Eq. (26) are then modified by the following expressions:

\[
\begin{cases}
-u_i^b, & \text{if } u_i < -u_i^b \\
u_i, & \text{if } |u_i| < u_i^b \\
-u_i^b, & \text{if } u_i > u_i^b
\end{cases}
\]

where

\[
u_i = -(R^{-1} B^T M^{-1} \lambda_i), \quad i = 1, 2, 3, 4.
\]

(27)

By substituting the control expressions into the dynamical equations (20) and the costate equations (24), we can obtain a set of \( 4(n+1) \) differential equations for the states and the costates. To obtain the control, \( u \), we need to solve this set of differential equations with the \( 4(n+1) \) given boundary conditions: \( y(t=0) \) and \( y(t=t_f) \). This problem is called TPBVP because the B.C.'s are specified at the two ends of the slewing period.

Solution of the TPBVP

The quasilinearization algorithm and the method of particular solutions are used to solve this nonlinear TPBVP.
NUMERICAL RESULTS

Some common parameters of the SCOLE used in this paper are,

\[ EI = 4 \times 10^7 \text{ lb-ft}^2, \rho = 0.09554 \text{ slug/ft}, L = 130 \text{ ft}, \]
\[ m_s = 6366.46 \text{ slug}, m_r = 12.42 \text{ slug}, \]
\[ u_{1b} = 10,000 \text{ ft-lb}, u_{1b} = u_{2b} = 10 \text{ lb}, u_{3b} = 800 \text{ lb}. \]

Other different structural parameters are listed in Table 1.

All the numerical tests done in this paper are rest-to-rest slews, that is, they use the same boundary conditions for the states: \( \eta(t=0) = 0, \eta(t=t_r) = 0; \theta(t=0) = 0, \) and \( \theta(t=t_r) = \theta^*, \) where \( \theta^* \) is the required slewing angle, ranging from 20 deg to 180 deg. All these slewings can be divided into the following 3 groups.

Group 1

In this group, only the Shuttle control torque has been used, i.e., \( u = u_{1b}. \) The weighting matrices \( Q_1 = Q_2 = 0 \) and the weighting on \( u_{1b}, r_1 = 10^{-5}. \) Figs. 2 show the near-minimum-time slewing about the roll axis, through 90 deg (Fig. 2A). The near-minimum-time, \( t_r, \) has been calculated to be 27.8 sec. The control torque is near the bang-bang type (Fig. 2F). The maximum amplitude of the first mode of the linearized system is 9.2 ft (Fig. 2B), which is less than 10% of the total length of the beam. The first modal amplitude response of the nonlinear system has a shape similar to that for the linearized system, but with a shifting of the amplitude. The second mode and the third mode of the nonlinear system have quite different time histories from their linearized
counterparts (Figs. 2C-D). The rotation angle, $\phi_r$, and the displacement, $\psi_r$, at the reflector end of the beam are also plotted in Figs. 2A and 2E. They have shapes similar to the amplitude of mode 1, because the first mode dominates the deformation of the beam for this slew.

The slewing about the pitch axis has responses similar to those about the roll axis. To make a comparison, the results of many other slewings in this group are listed in Table 2. $\eta_{1\text{max}}$ is the maximum value of the first modal amplitude of the linearized system. Note that the number of vibrational cycles of the first mode increases as the slew angle, $\theta^*$, increases.

$^a$One cycle. $^b$Two cycles with one big peak and one small peak. $^c$Two cycles with two equal peaks. $^d$Three cycles with two big equal peaks and one small peak.

### Group 2

In this group, the force on the reflector, $u^*_r$, is added to the system. The weighting on the states, $Q_1$ and $Q_2$, are still chosen to be zero, and $r_i = 10^{-5}$. The effect on the slewing responses of adding the control force $u^*_r$ may be analyzed by changing the values of $t_f$ and/or $r_i$, the weighting on $u^*_r$. Since the first modal amplitude dominates the deflection of the beam, our main concern will concentrate on the variation of the first modal amplitude.

To illustrate the effect of the parameters, $t_f$ and $r_i$, on the time response of the first modal amplitude, let's
consider a special case without lose of generality, i.e., the 90 deg slew ing about the roll axis, the same case plotted in Figs. 2 but with the control \( u_4 \) added. In Fig. 2B, the time response of the first modal amplitude can be approximately expressed as \(-\eta_1_{\text{max}} \sin(2\pi t/t_f)\). This response is 180° out-of phase with the control \( u_1 \) (Fig. 2F), because of the inertia effect of the flexible beam. However, when \( u_4 \) is added to the system, the torque produced by \( u_4 \) will accelerate the slew and balance the deflection of the beam produced by \( u_1 \).

It is not hard to imagine, from the physical point of view, that when \( u_4 \) increases to a large value, the response of the first modal amplitude may be in-phase with \( u_1 \) (or \( u_4 \)), i.e., \( \eta_1(t) \approx \eta_1_{\text{max}} \sin(2\pi t/t_f) \). Therefore, between the small values and the large values of \( u_4 \), there must exist a critical value at which the phase of the first modal response changes from out-of-phase to in-phase. It is also expected that during the "phase-change" period, the maximum value of the first amplitude becomes a minimum. This conjecture, fortunately, has been proved to be true in our calculations.

One way to change the value of \( u_4 \) is to change the value of \( r_4 \), for fixed slew ing time \( t_f \). Another is to change \( t_f \) while maintaining \( r_4 \) fixed. These results are plotted in Figs. 3A-3B. We should point out that for large values of \( r_4 \) (Fig. 3A) or large values of \( t_f \) (Fig. 3B), \( u_4 \) is small and the response of the first modal amplitude is out-of-phase. On the contrary, small \( r_4 \) or \( t_f \) results in large \( u_4 \) and, therefore, in-phase response. In each of these cases, a minimum value of \( \eta_1_{\text{max}} \) exists. It is also interesting to know that, at these critical values of \( r_4 \) or \( t_f \), \( \eta(t) \) experiences two oscillation cycles with two equal peak values (or valley values) of the linearized system, i.e., \( \eta(t) \approx \eta_1_{\text{max}} \sin(4\pi t/t_f) \). The dotted lines in Figs. 3A-B represent the nonlinear system responses. The nonlinear response has a shift from the linear response, especially when \( t_f \) or \( r_4 \) is reduced. Also, we have observed that, at the critical points, although the amplitudes are small in value, the linear and the nonlinear systems have quite different time response histories.
A complete relationship between the three parameters, \( \eta_{\text{max}} \), \( t_r \), and \( r_s \) can be investigated through the 3-dimensional surface in Fig. 4. The lower ditch on this surface represents the minimum value area of \( \eta_{\text{max}} \). Although the global minimum value of \( \eta_{\text{max}} \) occurs when \( t_r \) is quite large, there exists a local minimum value, \( \eta_{\text{max}} = 0.41 \) ft, around the middle of the ditch, where \( t_r = 23.881 \) sec and \( r_s = 0.86 \). This important point can be chosen as the trade-off point between rapid slew and small amplitude requirements, at which neither \( t_r \) nor \( \eta_{\text{max}} \) is too large. The response shapes of the first modal amplitude for the different values of \( t_r \) and \( r_s \) are different. In the hilltop areas, only one vibrational cycle of \( \eta_1(t) \) exists, but along the deep valleys of the ditch, \( \eta_1(t) \) has two vibrational cycles with two equal peaks. More surprisingly, at the local minimum point mentioned above, \( \eta_1(t) \) experiences three vibrational cycles with three equal peaks. The responses for this case are shown in Figs. 5, where the linear and nonlinear systems are quite different in spite of the small modal amplitudes.

**Group 3**

Based on the example shown in Figs. 5, the controls, \( u_1 \) and \( u_3 \) are added to the control system in this group. The associated weightings on these controls are \( r_1 = 10.0 \) and \( r_3 = 20.0 \). Also, the weightings on \( \eta_1 \) and \( \eta_2 \) are selected as \( 200.0 \) and \( 1000.0 \), respectively, to show the further reduction of the modal amplitudes. These results are plotted in Figs. 6. Compared with the results in Figs. 5, the modal amplitudes have been slightly reduced and the maximum value of \( u_4 \) has been reduced due to the addition of \( u_1 \) and \( u_3 \). Note that \( u_4 \) is not shown in Figs. 6 because of its similarity to that in Figs. 5.

**CONCLUSION**

The Maximum Principle has been applied to the rapid slewing problem of the planar flexible orbiting SCOLE. The dynamical equations used contain more nonlinear terms than those used by other authors, and the responses indicate the large differences between the nonlinear and the linearized systems, not only in the rapid slews where large modal amplitudes are involved, but also in the small-amplitude slews. The analysis between the relationship of the
parameters, $\eta_{1, \max}, t_r,$ and $r_a$, indicates that the conflict between the rapid slew and the small flexible amplitude requirements may be compromised for multi-input control systems. The effects of these parameters on the 3-dimensional SCOLE model slewing responses need to be investigated.

III. CONTROL OF THE ORBITING SCOLE WITH THE FIRST FOUR MODES

A. Formulation

In order to complete the calculation of the elements of the state and control influence matrices for the orbiting SCOLE system linearized about the nominal station keeping motion, we list all equations of the system which are based on the formulation of Ref[1] as follows:

1. Generic Modal Equations of the Beam

\[ \ddot{A}_n + \omega_n^2 A_n - \frac{1}{L} \ G_1(\beta_n) \ \dot{\eta}_2 + \frac{1}{L} \ G_2(\beta_n) \ \dot{\eta}_1 + \frac{2}{L} \ \omega_0 \ G_3(\beta_n) \eta_2 \\
- \frac{2}{L} \ G_2(\beta_n) \eta_3 + \frac{4}{L} \ \omega_0 \ G_2(\beta_n) \eta_1 - \frac{3}{L} \ \omega_0 \ G_1(\beta_n) \eta_2 = F \]  

where

\( A_n \ (n=1,2,3,4) \) is a time dependent amplitude of the nth mode.
\( \eta_i \ (i=1,2,3) \) are angular displacements about roll, pitch and yaw axes.

\( G_1(\beta_n) = f_3(\beta_n) A_1n + f_4(\beta_n) B_{1n} + f_5(\beta_n) C_{1n} + f_6(\beta_n) D_{1n} \)

\( G_2(\beta_n) = f_3(\beta_n) A_{2n} + f_4(\beta_n) B_{2n} + f_5(\beta_n) C_{2n} + f_6(\beta_n) D_{2n} \)

\( G_3(\beta_n) = f_3(\beta_n) A_{3n} + f_4(\beta_n) B_{3n} \)

\( f_3(\beta_n) = - \frac{\sin(\beta_n L)}{\beta_n^2} + \frac{L \cos(\beta_n L)}{\beta_n} \)

\( f_4(\beta_n) = \frac{\cos(\beta_n L)}{\beta_n^2} + \frac{L \sin(\beta_n L)}{\beta_n} - \frac{1}{\beta_n^2} \)

\( f_5(\beta_n) = - \frac{L \cosh(\beta_n L)}{\beta_n} + \frac{\sinh(\beta_n L)}{\beta_n^2} \)

\( f_6(\beta_n) = \frac{L \sinh(\beta_n L)}{\beta_n} - \frac{\cosh(\beta_n L)}{\beta_n^2} + \frac{1}{\beta_n^2} \)

\( F = F_x \ [ V_{3x} S_{xn}(-L) + V_{2x} S_{xn}(-2L/3) + V_{1x} S_{xn}(-L/3) ] \\
+ F_y \ [ V_{3y} S_{yn}(-L) + V_{2y} S_{yn}(-2L/3) + V_{1y} S_{yn}(-L/3) ] \)
\[ S_{xn}(Z) = A_{1n} \sin(\beta_n Z) + B_{1n} \cos(\beta_n Z) + C_{1n} \sinh(\beta_n Z) + D_{1n} \cosh(\beta_n Z) \]

\[ S_{yn}(Z) = A_{2n} \sin(\beta_n Z) + B_{2n} \cos(\beta_n Z) + C_{2n} \sinh(\beta_n Z) + D_{2n} \cosh(\beta_n Z) \]

\[ \theta_n(Z) = A_{3n} \sin(\beta_n Z) + B_{3n} \cos(\beta_n Z) \]

\[ \beta_n = \beta_n^2 \sqrt{\frac{E I}{G A}} \]

2. System Equations without Flexibility and External Forces

\[ \ddot{\eta}_1 I_{xx} - \ddot{\eta}_2 I_{xy} - \ddot{\eta}_3 I_{xz} - \omega_0^2 \eta_3 (I_{xx} - I_{yy} + I_{zz}) - \omega_0 \dot{\eta}_2 I_{y} - \omega_0^2 \eta_2 I_{xy} = 0 \] (2)

\[ \ddot{\eta}_2 I_{yy} + \ddot{\eta}_1 I_{xy} + \ddot{\eta}_3 I_{yz} - \omega_0^2 \eta_1 (I_{xx} - I_{yy} + I_{zz}) - \omega_0 \dot{\eta}_2 I_{xy} - \omega_0^2 \eta_2 I_{y} = 0 \] (3)

\[ \ddot{\eta}_3 I_{zz} - \ddot{\eta}_1 I_{xz} - \ddot{\eta}_3 I_{yz} - \omega_0^2 \eta_1 (I_{xx} - I_{yy} + I_{zz}) - \omega_0 \dot{\eta}_2 I_{xy} - \omega_0^2 \eta_2 I_{y} = 0 \] (4)

where

\[ I_{xx} = I_{s1} + I_{R1} + \frac{ML^2}{3} + M_R(L^2 + Y^2) \]

\[ I_{yy} = I_{s2} + I_{R2} + \frac{ML^2}{3} + M_R(L^2 + X^2) \]

\[ I_{zz} = I_{s3} + I_{R3} + M_R(X^2 + Y^2) \]

\[ I_{xy} = M_R XY \]

\[ I_{xz} = I_{s4} + M_R XL \]

\[ I_{yz} = M_R YL \]
3. System Equations with the First Four Flexible Modes

\[ \begin{align*}
\ddot{\eta}_1 I_{xx} - \ddot{\eta}_2 I_{xy} - \ddot{\eta}_3 I_{xz} &- \omega_0^2 \eta_1 (I_{xx} - I_{yy} - I_{zz}) - \omega_0^2 \eta_2 (I_{xy} - I_{yx}) - 4 \omega_0^2 \eta_3 (I_{xz} - I_{zx}) - 3 \omega_0^2 \eta_4 (I_{xy} - I_{yx}) \\
&+ \sum_{n=1}^{4} A_n \dot{q}_n d_{1n} - \sum_{n=1}^{4} A_n \dot{q}_n d_{2n} + \sum_{n=1}^{4} A_n \dot{q}_n d_{3n} = T_x
\end{align*} \]

(5)

\[ \begin{align*}
\ddot{\eta}_2 I_{yy} + \ddot{\eta}_1 I_{xy} + \ddot{\eta}_3 I_{yz} - \ddot{\eta}_1 \omega_0 I_{yx} + \ddot{\eta}_3 \omega_0 I_{xy} - 3 \omega_0^2 \eta_2 (I_{xz} - I_{zx}) + \sum_{n=1}^{4} A_n \dot{q}_n d_{4n} - \sum_{n=1}^{4} A_n \dot{q}_n d_{5n} = T_y
\end{align*} \]

(6)

\[ \begin{align*}
\ddot{\eta}_3 I_{zz} - \ddot{\eta}_1 I_{xz} - \ddot{\eta}_2 I_{yz} + \ddot{\eta}_1 \omega_0 (I_{xx} - I_{yy} - I_{zz}) - \omega_0^2 \eta_2 (I_{xy} - I_{yx}) + 4 \omega_0^2 \eta_2 (I_{yz} - I_{zy}) - 3 \omega_0^2 \eta_3 (I_{xz} - I_{zx}) \\
&+ \sum_{n=1}^{4} A_n \dot{q}_n d_{6n} + \sum_{n=1}^{4} A_n \dot{q}_n d_{7n} - \sum_{n=1}^{4} A_n \dot{q}_n d_{8n} = T_z
\end{align*} \]

(7)

where

\[ I_{xx}, I_{yy}, I_{zz}, I_{xy}, I_{yz}, I_{xz} \text{ are same as in 2.} \]

\[ T_x = M_x U_x + F_y U_y + F_y U_y + F_y U_y + F_y U_y ] \]

\[ T_y = M_y U_y + F_x U_x + F_x U_x + F_x U_x + F_x U_x ] \]

\[ T_z = M_z U_z + X F_y U_y + Y F_x U_x - Y F_x U_x ] \]

B. System State Equations

In this section we recast all system equations (1-7) into matrix form.

Let

\[ X = [ \eta_1 \eta_2 \eta_3 \dot{\eta}_1 \dot{\eta}_2 \dot{\eta}_3 ]^T \]

as a state vector and
as a control input. We then set up the system state equations by two different methods and get the state matrix and influence matrix, respectively.

1. Method of Ref[1]

Generic modal equations of the beam:

\[
\begin{bmatrix}
\ddot{A}_1 \\
\ddot{A}_2 \\
\ddots \\
\ddot{A}_n
\end{bmatrix} + [D_1] \begin{bmatrix}
\dot{A}_1 \\
\dot{A}_2 \\
\ddots \\
\dot{A}_n
\end{bmatrix} + [D_2] \begin{bmatrix}
\dot{\eta}_1 \\
\dot{\eta}_2 \\
\ddots \\
\dot{\eta}_n
\end{bmatrix} + [D_3] \begin{bmatrix}
\eta_1 \\
\eta_2 \\
\ddots \\
\eta_n
\end{bmatrix} = [F] \begin{bmatrix}
V_{1x} \\
V_{1y} \\
V_{2x} \\
V_{2y}
\end{bmatrix}
\] (8)

System equations without flexibility and external forces:

\[
\begin{bmatrix}
\ddot{\eta}_1 \\
\ddot{\eta}_2 \\
\ddots \\
\ddot{\eta}_n
\end{bmatrix} + [E_1] \begin{bmatrix}
\dot{\eta}_1 \\
\dot{\eta}_2 \\
\ddots \\
\dot{\eta}_n
\end{bmatrix} + [E_3] \begin{bmatrix}
\eta_1 \\
\eta_2 \\
\ddots \\
\eta_n
\end{bmatrix} = 0
\] (9)

System equations with the first four flexible modes:

\[
\begin{bmatrix}
\ddot{\eta}_1 \\
\ddot{\eta}_2 \\
\ddots \\
\ddot{\eta}_n
\end{bmatrix} + [E_1] \begin{bmatrix}
\dot{\eta}_1 \\
\dot{\eta}_2 \\
\ddots \\
\dot{\eta}_n
\end{bmatrix} + [E_3] \begin{bmatrix}
\eta_1 \\
\eta_2 \\
\ddots \\
\eta_n
\end{bmatrix} = [F] \begin{bmatrix}
V_{1x} \\
V_{1y} \\
V_{2x} \\
V_{2y}
\end{bmatrix} + [E_6] \begin{bmatrix}
U_x \\
U_y \\
U_z
\end{bmatrix}
\] (10)

We then recast eq(9) by inverting the matrix 
\[
[E_1]^{-1}
\].
After substituting eq(11) into eq(8), the result is,

\[
\begin{bmatrix}
\ddot{\eta}_1 \\
\ddot{\eta}_2 \\
\ddot{\eta}_3 \\
\ddot{\eta}_4
\end{bmatrix}
= -\begin{bmatrix}
E_1^{-1}E_3 & 0 & 0 & 0 \\
0 & E_1^{-1}E_5 & 0 & 0 \\
0 & 0 & E_1^{-1}E_5 & 0 \\
0 & 0 & 0 & E_1^{-1}E_5
\end{bmatrix}
\begin{bmatrix}
\dot{\eta}_1 \\
\dot{\eta}_2 \\
\dot{\eta}_3 \\
\dot{\eta}_4
\end{bmatrix}
- \begin{bmatrix}
-D_1 & 0 & 0 & 0 \\
0 & -D_2 E_1^{-1}E_3 & 0 & 0 \\
0 & 0 & -D_2 E_1^{-1}E_3 & 0 \\
0 & 0 & 0 & -D_2 E_1^{-1}E_5
\end{bmatrix}
\begin{bmatrix}
\eta_1 \\
\eta_2 \\
\eta_3 \\
\eta_4
\end{bmatrix}
+ \begin{bmatrix}
F_1 \\
F_2 \\
F_3 \\
F_4
\end{bmatrix}
\tag{11}
\]

or briefly

\[
\ddot{\eta} = [C_1] \dot{\eta} + [C_2] \dot{\eta} + [C_3] \eta + [F] V
\tag{13}
\]

where

\[
A = \begin{bmatrix}
A_1 & A_2 & A_3 & A_4
\end{bmatrix}^T
\]

\[
\ddot{\eta} = \begin{bmatrix}
\ddot{\eta}_1 & \ddot{\eta}_2 & \ddot{\eta}_3 & \ddot{\eta}_4
\end{bmatrix}^T
\]

\[
\eta = \begin{bmatrix}
\eta_1 & \eta_2 & \eta_3
\end{bmatrix}^T
\]

\[
\dot{\eta} = \begin{bmatrix}
\dot{\eta}_1 & \dot{\eta}_2 & \dot{\eta}_3
\end{bmatrix}^T
\]

\[
V = \begin{bmatrix}
V_{1x} & V_{1y} & V_{2x} & V_{2y} & V_{3x} & V_{3y}
\end{bmatrix}^T
\]

\[
[C_1] = -[D_1]
\]

\[
[C_2] = -[D_3 - D_2 E_1^{-1} E_3]
\]

\[
[C_3] = -[D_4 - D_2 E_1^{-1} E_5]
\]

Then eq(13) without the external forces is substituted into eq(10) with the result

\[
\ddot{\eta} = [C_5] \dot{\eta} + [C_4] \ddot{\eta} + [C_6] \eta + [C_7] A + [M_1]\dot{\lambda} + [M_4]U
\tag{14}
\]

where

3.5
\[ \begin{align*}
\ddot{\eta} &= \begin{bmatrix} \ddot{\eta}_1 & \ddot{\eta}_2 & \ddot{\eta}_3 \end{bmatrix}^T \\
\dot{A} &= \begin{bmatrix} \dot{A}_1 & \dot{A}_2 & \dot{A}_3 & \dot{A}_4 \end{bmatrix}^T \\
U' &= \begin{bmatrix} U_x & U_y & U_z \end{bmatrix}^T \\
[C_4] &= -\left[E_1^{-1}(E_3 + E_2 C_2)\right] \\
[C_5] &= -\left[E_1^{-1} E_4\right] \\
[C_6] &= -\left[E_1^{-1}(E_5 + E_2 C_3)\right] \\
[C_7] &= -\left[E_1^{-1}(E_6 + E_2 C_4)\right] \\
[M_3] &= [E_1^{-1} M_1] \\
[M_4] &= [E_1^{-1} M_2]
\end{align*} \]

Eqs (14) and (13) may be combined as follows:

\[\begin{bmatrix} \ddot{\eta} \\ \dot{A} \end{bmatrix} = \begin{bmatrix} C_4 & C_5 \\ C_4 & 0 \end{bmatrix} \begin{bmatrix} \ddot{\eta} \\ \dot{A} \end{bmatrix} + \begin{bmatrix} C_6 & C_7 \\ C_3 & C_1 \end{bmatrix} \begin{bmatrix} \eta \\ A \end{bmatrix} + \begin{bmatrix} M_3 & M_4 \\ F & 0 \end{bmatrix} \begin{bmatrix} V \\ U' \end{bmatrix} \tag{15}\]

The system state equation becomes

\[\dot{X} = [A] X + [B] U\]

where

\[\begin{bmatrix} A \end{bmatrix} = \begin{bmatrix}
0 & 0 & 1 & 0 \\
0 & 0 & 0 & 1 \\
C_6 & C_7 & C_4 & C_5 \\
C_3 & C_1 & C_2 & 0
\end{bmatrix}\quad \text{and}\quad \begin{bmatrix} B \end{bmatrix} = \begin{bmatrix}
0 & 0 \\
0 & 0 \\
M_3 & M_4 \\
\Phi & 0
\end{bmatrix}\]

2. Direct Method

The generic modal equation (eq(8)) and system equation (eq(10)) may be directly combined to yield:
Eq (16) may be rewritten, following the inversion of the acceleration coefficient matrix, as

\[
\begin{bmatrix}
E_1 & E_2 \\
D_2 & I
\end{bmatrix}
\begin{bmatrix}
\ddot{\eta} \\
\ddot{A}
\end{bmatrix} = \begin{bmatrix}
-E_3 & -E_4 \\
-D_3 & 0
\end{bmatrix}
\begin{bmatrix}
\dot{\eta} \\
\dot{A}
\end{bmatrix} + \begin{bmatrix}
-E_5 & -E_6 \\
-D_4 & D_1
\end{bmatrix}
\begin{bmatrix}
\eta \\
A
\end{bmatrix} + \begin{bmatrix}
M_1 & M_2 \\
F & 0
\end{bmatrix}
\begin{bmatrix}
V \\
U'
\end{bmatrix}
\] (16)

or briefly

\[
\begin{bmatrix}
\ddot{\eta} \\
\ddot{A}
\end{bmatrix} = \begin{bmatrix}
E_1 & E_2 \\
D_2 & I
\end{bmatrix}^{-1}
\begin{bmatrix}
-E_3 & -E_4 \\
-D_3 & 0
\end{bmatrix}
\begin{bmatrix}
\dot{\eta} \\
\dot{A}
\end{bmatrix} + \begin{bmatrix}
E_1 & E_2 \\
D_2 & I
\end{bmatrix}^{-1}
\begin{bmatrix}
-E_5 & -E_6 \\
-D_4 & D_1
\end{bmatrix}
\begin{bmatrix}
\eta \\
A
\end{bmatrix} + \begin{bmatrix}
M_1 & M_2 \\
F & 0
\end{bmatrix}
\begin{bmatrix}
V \\
U'
\end{bmatrix}
\] (17)

We can get the system state equation from eq (18), that is

\[
\dot{x} = [A]x + [B]u
\] (19)

where

\[
[A'] = \begin{bmatrix}
E_1 & E_2 \\
D_2 & I
\end{bmatrix}^{-1}
\begin{bmatrix}
-E_3 & -E_4 \\
-D_3 & 0
\end{bmatrix}
\]

\[
[A''] = \begin{bmatrix}
E_1 & E_2 \\
D_2 & I
\end{bmatrix}^{-1}
\begin{bmatrix}
-E_5 & -E_6 \\
-D_4 & D_1
\end{bmatrix}
\]

\[
[B'] = \begin{bmatrix}
E_1 & E_2 \\
D_2 & I
\end{bmatrix}^{-1}
\begin{bmatrix}
M_1 & M_2 \\
F & 0
\end{bmatrix}
\]

We can get the system state equation from eq (18), that is

\[
\dot{x} = [A]x + [B]u
\] (19)

where

\[
[A] = \begin{bmatrix}
0 & I \\
A'' & A'
\end{bmatrix}
\]

and

\[
[B] = \begin{bmatrix}
0 \\
B
\end{bmatrix}
\]
C. Control Synthesis - LQR

The system state equation can be represented as

$$\dot{X} = [A] X + [B] U$$  \hspace{1cm} (20)

An LQR cost function is selected as follows:

$$J = \int_{0}^{\infty} (X^T Q X + U^T R U) \, dt$$  \hspace{1cm} (21)

The optimal control, $U$, based on the LQR theory is given by

$$U = - [R^{-1} B^T P] X$$  \hspace{1cm} (22)

where $P$ is the positive definite solution of the steady state Ricatti matrix equation:

$$PA + A^T P - PBR^{-1} B^T P + Q = 0$$  \hspace{1cm} (23)

The closed loop system equation becomes

$$\dot{X} = [A - BK] X$$  \hspace{1cm} (24)

Let $X(0)$ be an initial state vector. Based on some assumed $Q$ and $R$ penalty matrices, the closed loop dynamic responses can be simulated as

$$X(t) = e^{[A - BK] t} X(0)$$  \hspace{1cm} (25)

which is based on the feedback control given by

$$U(t) = - K X(t)$$  \hspace{1cm} (26)

The total torque impulse about the three axes are

$$T_x = \int_{0}^{\infty} |T_x(t)| \, dt$$  \hspace{1cm} (27)

$$T_y = \int_{0}^{\infty} |T_y(t)| \, dt$$  \hspace{1cm} (28)

$$T_z = \int_{0}^{\infty} |T_z(t)| \, dt$$  \hspace{1cm} (29)

where

$$\begin{bmatrix}
T_x(t) \\
T_y(t) \\
T_z(t)
\end{bmatrix} = \begin{bmatrix} M_1 & M_2 \end{bmatrix} \begin{bmatrix} Y(t) \\
U(t)
\end{bmatrix}$$
D. Numerical Results

The ORACL3 control software in the IBM computer system was used to calculate the state matrix \([A]\) and influence matrix \([B]\) and to simulate the closed loop system responses as well as the total torque of the system for given sets of initial conditions.

We select the force factors, \(F_x = F_y = 1\) and torque factors \(M_x = M_y = M_z = 1\), which means that the components of \(V\) and \(U\) reflect the actual actuator force and shuttle torque values. According to the SCOLE configuration and parameter values (listed in the Appendix), the \([A]\) and \([B]\) matrix values of the method of Ref. [1] and the direct method are listed in Tables 1, 2, 3, and 4.

We select the initial states
\[
X_1(0) = 6 \text{ degrees} \\
X_2(0) = X_3(0) = X_4(0) = X_5(0) = X_6(0) = X_7(0) = 0
\]
and the diagonal weighting matrices as:
\[
\text{trace } Q = \begin{bmatrix}
10^7, 10^7, 10^8, 5 \times 10^5, 10^6, 3 \times 10^5, 5 \times 10^7 \\
10, 10, 10, 10, 10, 10, 10, 10
\end{bmatrix}
\]
\[
\text{trace } R = \begin{bmatrix}
100, 100, 100, 100, 100, 0.001, 0.001, 0.001
\end{bmatrix}
\]
The simulation of the optimal closed-loop system responses, using both the method of Ref. [1] and the direct method, are plotted in Figs. 1, 2, 3 and 4.

The total control torque-moments of the system required about the roll axis are 30,529 ft-lbs for the method of Ref. [1] and 31,250 ft-lbs for the direct method.
method. The torques needed about the other two axes are much less than the components about the roll axis. Also, the maximum torques of the system are 6,525 ft-lb for the method of Ref. [1] and 5,802 ft-lb in the direct method.

E. Conclusions
1. By comparing the results of the method of Ref. [1] and the direct method, it is seen that the results are similar to each other.
2. In the responses resulting from the direct method for the same initial displacement about the roll axis, it is seen that the first four flexible modes are generally excited more than for the results of the method of Ref. [1].
3. If no force actuators are added to the beam and reflector complete damping of the modal responses requires a much longer time (Fig. 6) than when the force actuators are utilized together with the Shuttle torquers (Figs. 2 and 4). However, the use of force actuators results in initially larger overshoots as compared with the case depicted in Fig. 6.
4. The system responses are dependent on the force actuator locations and the weighting matrices (Q,R) values. Suitable values of the penalty matrices and actuator locations should be selected so that the system control becomes optimal.
5. From the system analysis, we find the flexibility of the SAGE system is not greatly excited during transversal station
keeping operations. System responses and the total torque impulses needed are similar to the rigidized SCOLE system (see Ref. [1]).

IV. Control Structure Interaction - Preliminary Study of the Effect of Actuator Mass on the Design of Control Laws

The dynamics of large space structures are described using the finite element method as:

\[ M \ddot{X} + C \dot{X} + KX = BU \quad (1) \]

where

- \( X \) = nx1 vector representing degrees of freedom
- \( M \) = nxn mass matrix
- \( C \) = nxn damping matrix
- \( K \) = nxn stiffness matrix
- \( B \) = nxm control influence matrix
- \( U \) = mx1 control vector

Using modal analysis\(^2\) and modern control theory\(^3\), state variable feedback control laws of the form

\[ U = -F_r \dot{X} - F_p X \quad (2) \]

where

- \( F_r \) and \( F_p \) are rate and position control gain matrices of appropriate dimensions are designed. To implement the control law given by equation (2) physical actuators are needed. These physical actuators have finite mass and, thus, change the mass and stiffness of the structure to be controlled. This mass can be as much as fifteen percent of the uncontrolled structure.\(^4\) Thus the control laws designed without taking this mass into consideration have to be reevaluated for their stability and performance degradation.

Assuming \( \Delta M \) and \( \Delta K \) are the changes in the mass and stiffness...
matrices due to actuators the dynamics of the controlled system can be written as:

\[(M+\Delta M)\ddot{X} + (C+BF_p)\dot{X} + (K + \Delta K+BF_p)X = 0 \quad (3)\]

Since the control law is designed for the stability of the controlled system, the matrices M, C+BF_p, and K are positive definite matrices. If the changes in the mass matrix and stiffness matrix, \(\Delta M\) and \(\Delta K\), are also assumed to be positive definite then the matrices \((M+\Delta M)\), \((C+BF_p)\), and \((K + \Delta K+BF_p)\) are also positive definite. Thus, equation (3) is stable, though performance degradation cannot be commented on. The assumption that \(\Delta M\) and \(\Delta K\) are positive is a valid assumption, as the dynamics of the oscillatory motion of the structure with the added actuator masses can be described based on the finite element method or energy conservation techniques, and thus, \((M+\Delta M)\) and \((K+\Delta K)\) must be positive definite. As \((M +\Delta M)\), \((K+\Delta K)\) are positive definite and \((M+\Delta M)\), \((K+BF_p)\) are positive definite, the matrices \((M+\Delta M)\), \((K+\Delta K+BF_p)\) are also positive definite. Thus, as M and K are positive definite and \((M+\Delta M)\) and \((K+\Delta K)\) are positive definite, \(\Delta M\) and \(\Delta K\) are positive definite. The effect of the actuator mass on the structural damping is not considered here.

In this analysis the modal truncation is not taken into account and thus, the control spill-over problem will not arise. The performance degradation is analysed using a two mass, two spring, two actuator system.
Numerical Example:

The two-mass two-spring system is shown in Figure 1 and its equations of motion are written as:

\[
\begin{pmatrix}
  m_1 & 0 \\
  0 & m_2
\end{pmatrix}
\begin{bmatrix}
  \ddot{x}_1 \\
  \ddot{x}_2
\end{bmatrix}
+ \begin{pmatrix}
  k_1 + k_2 & -k_2 \\
  -k_2 & k_2
\end{pmatrix}
\begin{bmatrix}
  x_1 \\
  x_2
\end{bmatrix}
= \begin{pmatrix}
  1 & 0 \\
  0 & 1
\end{pmatrix}
\begin{bmatrix}
  u_1 \\
  u_2
\end{bmatrix}
\]  

The control law of the form
Numerical Example:

The two-mass two-spring system is shown in Figure 1 and its equations of motion are written as:

\[
\begin{bmatrix}
    m_1 & 0 \\
    0 & m_2
\end{bmatrix}
\begin{bmatrix}
    \dddot{x}_1 \\
    \dddot{x}_2
\end{bmatrix}
+ \begin{bmatrix}
    k_1 + k_2 & -k_2 \\
    -k_2 & k_2
\end{bmatrix}
\begin{bmatrix}
    \ddot{x}_1 \\
    \ddot{x}_2
\end{bmatrix}
= \begin{bmatrix}
    1 & 0 \\
    0 & 1
\end{bmatrix}
\begin{bmatrix}
    u_1 \\
    u_2
\end{bmatrix}
\]

(4)

The control law of the form

\[
\begin{bmatrix}
    u_1 \\
    u_2
\end{bmatrix}
= -\begin{bmatrix}
    f_{11} & f_{12} \\
    f_{21} & f_{22}
\end{bmatrix}
\begin{bmatrix}
    \ddot{x}_1 \\
    \ddot{x}_2
\end{bmatrix}
\]

(5)

is designed with the following numerical values for the mass, stiffness and control gain matrices.

\[
m_1 = 2, \quad m_2 = 1, \quad k_1 = 4, \quad k_2 = 1
\]
\[
f_{11} = 1, \quad f_{12} = f_{21} = 0, \quad f_{22} = 1
\]

The numerical simulation is conducted varying the masses and stiffnesses, one at a time, and the closed-loop eigenvalues are tabulated in Table 1. From Table 1, it can be observed that the change in mass, \(m_2\), has a maximum effect on the degradation of the closed-loop eigenvalues. A 15% change in \(m_2\) pushed the leftmost eigenvalue to the right by around 11% while the second eigenvalue moved to the right by around 5%. A 15% change in \(m_1\) moved the eigenvalue closest to the imaginary axis to the right by 5%. Thus, this simple example and numerical simulation demonstrates that the
actuator masses affect the performance of the control law that is designed without taking these masses into consideration. It is also worthwhile to observe that a change in the stiffness moves the eigenvalues to the right as well as to the left and can be explained as the effect of the increase in the stiffness on one mass or the other.

To understand the performance degradation due to actuators an exhaustive simulation of the closed-loop controlled system has to be done with the following considerations:

1. The masses needed to implement specific control forces have to be evaluated.
2. The change in stiffness due to change in mass has to be determined.
3. Simulation has to be conducted with changes in the total mass and stiffness matrices rather than individual masses as is done in this study.

A control system design to accommodate the effect of the actuator masses has to be done in iterative fashion incorporating the change in mass and stiffness into the dynamic model until a satisfactory control law is arrived at.

V. CONCLUSIONS AND RECOMMENDATIONS

The maximum principle of Pontryagin has been applied to the rapid maneuvering problem of the planar, flexible orbiting SCOLE. The resulting two-point boundary value problem is solved by applying the quasilinearization technique, and the near-minimum time is obtained by shortening the maneuvering time in a sequential manner until the controls are near the bang-bang type. The results indicate that responses of the nonlinear system for the flexible modal amplitudes may be significantly different from those of the corresponding linearized system for rapid slewing maneuvers. This research is currently being extended to the three dimensional slewing of the flexible SCOLE system.

From an analysis and simulation of the SCOLE station-keeping dynamics it is found that the flexible vibrations of the mast are not greatly excited during typical station-keeping operations. System responses are highly dependent on the force actuator locations and the numerical values of the state and control penalty matrices included in the LQR control law design. Force actuators mounted at 1/3 and 2/3 of the mast length along the mast are effective in suppressing the flexible mast vibrations.

A preliminary examination of the effect of actuator mass on the design of control laws for large flexible space systems demonstrates that actuator masses can influence the
performance of the closed-loop system where the control law has been designed without taking these masses into consideration. To understand better the possible degradation in performance due to the presence of actuator masses, additional studies are required to accurately evaluate the changes in the stiffness matrix due to specific actuator masses, and simulations must be performed incorporating changes in the total mass and stiffness matrices, rather than individual masses as was done here.

Finally, the current (1989-90) grant work has been redirected so as to lend greater support to the new Controls/Structures Interaction (CSI) program and focusing on specific CSI evolutionary configurations, in addition to the treatment of the SCOLE 3-D slewing problem.
