Abstract
Above incident energies of about 2 eV, the contribution to the total cross section in e+H2 scattering from the $\Sigma_u^+$ symmetry is insufficient to account for the experimental value. We describe calculations we have carried out of the lowest partial waves of $\Sigma_u^+$ symmetry and $\Pi_u$ symmetry using the Kohn variational method. The contributions to the total cross section from the two equivalent partial waves of $\Pi_u$ symmetry significantly reduce the discrepancy with experiment up to incident energies of 4-5 eV. Comparisons are made with recent R-matrix calculations performed by Danby and Tennyson.

Introduction
For incident energies up to about 2 eV, the contribution to the total cross section in e+H2 scattering from the lowest partial wave of $\Sigma_u^+$ symmetry is sufficient to account for the experimental value provided Hylleraas-type lowest partial wave of $\Sigma_u^+$ symmetry includes the positron-electron distance as a linear factor, are included in the Kohn trial function. The lowest partial wave of $\Sigma_u^+$ symmetry is the analogue of the s-wave in positron-electron scattering. The next symmetries from which significant contributions may be expected as the energy increases above 2 eV are the $\Sigma_u^+$ and $\Pi_u$ symmetries. The lowest partial waves of these symmetries are the analogue of the p-wave in positron-electron scattering. The decrease in symmetry in changing from an atomic target such as H or He to H2 splits the p-wave between the two symmetries: the $m = 0$ component is included in the $\Sigma_u^+$ symmetry, whereas the $m = \pm 1$ component is included in the $\Pi_u$ symmetry.

The asymptotic effective potential between the target hydrogen molecule and an incident positron is of the form

$$V(r) \sim \frac{Q P_2(\cos \theta)}{r^3} - \frac{\alpha_0 P_2(\cos \theta)}{2r^4} - \frac{\alpha_2 P_2(\cos \theta)}{2r^4}$$

(1)

where $r$ and $\theta$ are spherical coordinates of the positron measured from the nuclear centre of mass, with the z-axis along the nuclear axis. $Q$ is the quadrupole moment of the hydrogen molecule. The first term in (1) is the asymptotic form of the static potential, first order in the interaction between the positron and the target. The other terms are of second order. $\alpha_0$ and $\alpha_2$ are respectively the spherical and non-spherical dipole polarisabilities of the hydrogen molecule, and are linear combinations of $\alpha_||$ and $\alpha_\perp$, the dipole polarisabilities parallel and perpendicular to the nuclear axis. In second order perturbation theory, the expressions for $\alpha_||$ and $\alpha_\perp$ are made up of contributions from virtual excitations to states of $\Sigma_u^+$ and $\Pi_u$ electronic symmetry respectively.

The $\Sigma_u^+$ partial wave trial function used in reference 2 did not include functions with the correct asymptotic form to deal with the long-range polarisation of the molecule. However, there is evidence from Kohn calculations of e+H and e+He scattering that short-range exponentially decaying trial functions are adequate in the case of the s-wave except in the vicinity of zero energy. It is reasonable to expect that this will be the case for Kohn calculations of the lowest partial wave of $\Sigma_u^+$ symmetry in e+H2 scattering. There is no centrifugal barrier and the phase shift is determined by the positron-molecule interaction at all separations and not just when the positron is far from the molecule.

This is not the case for higher partial waves which experience centrifugal barriers. For sufficiently low incident energies long-range behaviour dominates and the phase shifts for these partial waves may be obtained from the first Born approximation using the asymptotic potential (1). Armour and Plummer show for e+H2 scattering that the correct behaviour of the phase shifts at very low energies follows naturally from the Kohn equations if the trial function includes long-range polarisation functions of the correct form.

Several authors have reported poor convergence of p-wave phase shifts at low incident energies (incident wave number $k = 0.1 a_0^{-1}, 0.2 a_0^{-1}$) in Kohn calculations of e+H and e+He scattering that did not include long-range polarisation functions in the trial function. Armour found similar behaviour at low energies in a Kohn
calculation of the lowest partial wave of \( \Sigma^+_u \) symmetry in \( e^+H_2 \) scattering that took no account of long-range polarisation. The trial functions for the present calculations of the lowest partial waves of \( \Sigma^+_u \) and \( \Pi_u \) symmetries include long-range polarisation functions, separable correlation functions of \( \Sigma^+_g, \Sigma^+_u, \Pi_u \), and \( \Pi_g \) electronic symmetries, and Hylleraas-type functions, important at higher energies \( (k > 0.1 \text{ a}_0^{-1}) \) for taking into account short-range interactions between the positron and the target electrons.

The Calculations

The calculations are extensions of the earlier calculations\(^2\). Prolate spheroidal coordinates are employed in the fixed nuclei model and the open channel functions are made up of solutions to the free-particle equation in this coordinate system appropriate to the lowest partial waves of \( \Sigma^+_u \) symmetry and \( \Pi_u \) symmetry, respectively. With \( \mathcal{Y}_G \) the model \( H_2 \) ground-state wave function, the correlation functions are of the form

\[
N(\lambda^a_1, \lambda^b_1, \nu^c_1; \mu^d_1) \left[ M_1 \cos(\phi_1 - \phi_3) \right] \rho^e_1 \left[ M_2 \cos(\phi_2 - \phi_3) \right] \rho^f_1 \left[ M_3 \cos(\phi_3) \right] e^{-\beta(\lambda^a_1, \lambda^b_1)} \mathcal{Y}_G. \tag{2}
\]

Coordinates 1 and 2 represent the electrons and coordinates 3 represent the positron, and

\[
f_i(3) = \begin{cases} 
\sin \lambda^a_3 & \text{or} \\
\cos \lambda^a_3 & \left(1 - e^{-\gamma(\lambda^a_3 - 1)}\right) \nu^c_3 \mu^d_3 \rho^e_3 \left[ M_3 \cos(\phi_3) \right] \lambda^a_3 \}
\end{cases} \tag{3}
\]

The \( \Sigma^+_u \) wave calculation is described elsewhere\(^1\). We find that the low-energy \( (k \leq 0.1 \text{ a}_0^{-1}) \) behaviour is dominated by the polarisation functions: the Born approximation is approximately obeyed in this region although the phase shifts fall off slightly as \( k \) approaches \( 0.1 \text{ a}_0^{-1} \). For higher incident energies up to \( k = 1.0 \text{ a}_0^{-1} \) the Hylleraas functions contribute most to the phase shifts, although the polarisation functions remain important. There is good agreement with eigenphase sums for the \( \Sigma^+_u \) symmetry obtained by Danby and Tennyson\(^1\) using the \( R \)-matrix method with a systematic treatment of intermediate and long-range polarisation using polarised pseudostates. Towards the top of the energy range the \( R \)-matrix eigenphase sums become increasingly larger than the Kohn phase shifts; this may be due to the fact that the Kohn calculation does not allow for mixing of partial waves. Both calculations predict that the contribution to the total scattering cross section from this symmetry is much too small to reduce significantly the discrepancy with experiment above 2 eV.

For the \( \Pi_u \) wave, the polarisation functions again dominate low energy behaviour and the Born approximation is followed for \( k < 0.1 \text{ a}_0^{-1} \). Above \( k = 0.1 \text{ a}_0^{-1} \) the polarisation functions have less influence. The phase shifts using separable and separable plus polarisation functions are slightly larger than the corresponding \( R \)-matrix eigenphase sums for the \( \Pi_u \) symmetry\(^1\). As in the case of the \( \Sigma^+_g \) wave\(^2\), the inclusion of the Hylleraas functions substantially boosts the calculated phase shifts. The discrepancy with the experimental total cross section is significantly reduced; adding together the contributions from the \( \Sigma^+_g, \Sigma^+_u \) and the two equivalent \( \Pi_u \) partial waves gives totals that are comparable with the results of Hoffman et al\(^1\) up to 4–5 eV.
We are currently adapting our calculations to allow for mixing of partial waves in each symmetry. This may improve results at the upper end of the energy range under consideration. The R-matrix results suggest that higher symmetries give contributions to the total cross section comparable to that of the $\Sigma^+_g$ symmetry above $k = 0.4 a_0^{-1}$. We are currently adapting our work to include the $\Pi^+_g$ symmetry.
