1.0 INTRODUCTION

A computer program has been written which utilizes the algebraic grid generation techniques described in Part 1 of this technical memorandum. This FORTRAN 77 program is known as GRID2D/3D and can be used to generate grid systems within both two- and three-dimensional (2-D and 3-D) spatial domains. The program was developed for use on an IBM PC, XT, or AT compatible computer but can be easily modified for use on a workstation or mainframe computer. This part of the technical memorandum (Part 2) is a user's manual for GRID2D/3D. A complete listing of the program is also provided.
1.1 Methods Used in GRID2D/3D

For a complete description of the grid generation techniques used in GRID2D/3D, the reader is encouraged to read Part 1 of this technical memorandum. Here, we mention only a few brief facts concerning the inner workings of the program. GRID2D/3D uses either the Two- or Four-Boundary Method to generate grid systems. The Six-Boundary Method is not yet a part of GRID2D/3D but may be included in future versions. Boundary curves are described parametrically by using tension spline interpolation, while boundary surfaces are described by using three-dimensional bidirectional Hermite interpolation.

1.2 Programs in GRID2D/3D

GRID2D/3D is actually made up of two programs — GRID2D and GRID3D. As the names imply, GRID2D generates grid systems for 2-D spatial domains, while GRID3D does the same for 3-D ones. The programs are quite similar, but each has its own distinctive features which will be described in Section 2.0. Two related programs, 3DSURF and PRGRID, deal with the viewing of grids once they have been generated. These programs will be discussed in Section 3.0.

2.0 USING GRID2D/3D TO GENERATE GRID SYSTEMS

In this section, a description of how to generate grid systems for 2-D and 3-D spatial domains is presented. Instructions are given in the context of using GRID2D/3D on an IBM PC compatible computer; however, use of the program on a
workstation or mainframe computer follows the same general procedure with only minor changes in file handling.

2.1 How to Generate Grid Systems in Two-Dimensional Spatial Domains

GRID2D/3D can be used to generate grids for 2-D spatial domains which meet the following criteria:

1. The domain of interest is a 2-D region with two or four specified boundary curves.
2. Each boundary curve is described by a set of discrete points which lie along the curve.

If these criteria have been met, the user must then answer the following questions:

1. Should the Two-Boundary Method or the Four-Boundary Method be used?
2. How many grid points are desired in the \( \xi \) and \( \eta \) directions?
3. Is any clustering of grid points needed?
4. What "K factors" (mentioned in Part 1 of this technical memorandum) should be used?

Once these questions have been answered, an input file should be constructed according to the format shown in figures 2-1 and 2-2. A guide to the grid control parameters mentioned in these figures is given in table 2-1.

The numbering of boundary curves is an important part of the input file, and the user should consult figure 2-3 to see how the numbered curves are mapped to the "transformed" domain. Figures 2-4 and 2-5 present sample 2-D grid input files for GRID2D/3D.
When running GRID2D/3D on a PC using MS-DOS, the user should first specify the input and output files using the DOS SET command. This is accomplished by typing

```
set 7=input.dat
set 8=output.dat
```

at the DOS prompt. The user should substitute the appropriate names for the input and output files. After this, the program can be run by typing

```
grid2d
```
at the DOS prompt.

The 2-D grid output files created by GRID2D/3D are printed out using the following algorithm (listed in pseudocode):

```plaintext
PrintOnOneLine (IL) (# of grid points in the \( \xi \) "direction")
PrintOnOneLine (JL) (# of grid points in the \( \eta \) "direction")
for i=1 to IL
  for j=1 to JL
    PrintOnOneLine (x(i, j) y(i, j) 1.0)
  end for j
end for i
```

The user should notice that a 1.0 has been tacked onto the end of each \((x, y)\) grid point ordered pair. This was done to facilitate the use of the 3DSURF graphics program which is described in Section 3.0.

### 2.2 How to Generate Grid Systems in Three-Dimensional Spatial Domains

GRID2D/3D can be used to generate grids for 3-D spatial domains which meet the following criteria:

1. The domain of interest is a 3-D region with two or four specified boundary surfaces.
2. All boundary surfaces are four-sided with each side having four edge curves. Each of these edge curves is described by a set of discrete points which lie along the curve.

If these criteria have been met, the user must then answer the following questions:

1. Should the Two-Surface Method or the Four-Surface Method be used?
2. How many grid points are desired in the $\xi$, $\eta$, and $\zeta$ directions?
3. Is any clustering of grid points needed?
4. What "K factors" (mentioned in Part 1 of this technical memorandum) should be used?

Once these questions have been answered, an input file should be constructed according to the format shown in figure 2-6. Note that a 3-D grid input file for GRID2D/3D contains information about only one grid. This is different from a 2-D grid input file in which more than one grid can be specified. A guide to the grid control parameters in figure 2-6 was given previously in table 2-1.

The numbering of boundary curves is an important part of the input file, and the user should consult figure 2-7 to see how the numbered curves are mapped to the "transformed" domain. It should be noted that the boundary surfaces are formed from their edge curves as follows:

- surface 1 - formed from curves 1 - 4
- surface 2 - formed from curves 5 - 8
- surface 3 - formed from curves 9 - 12
- surface 4 - formed from curves 13 - 16

It should be further noted that some of the curves are identical. Thus, curves 1 and 9 are the same, as are curves 2 and 13, curves 5 and 10, and curves 6 and 14. The reason for this is that the authors felt that it was simpler to have the user repeat the necessary curves in the input file to preserve a logical structure (i.e., surface 1 possesses edge curves 1 through 4, surface 2 possesses edge curves 5 through 8, and so on).

Figure 2-8 presents a sample 3-D grid input file for GRID2D/3D.
When running the program on a PC using MS-DOS, the user should first specify the input and output files using the DOS SET command. This is accomplished by typing

```
set 7=input.dat
set 8=output.dat
```

at the DOS prompt. The user should substitute the appropriate names for the input and output files. After this, the program can be run by typing

```
grid3d
```

at the DOS prompt.

The 3-D grid output files created by GRID2D/3D are printed out using the following algorithm (listed in pseudocode):

```
PrintOnOneLine (IL) (# of grid points in the \( \xi \) "direction")
PrintOnOneLine (JL) (# of grid points in the \( \eta \) "direction")
PrintOnOneLine (KL) (# of grid points in the \( \zeta \) "direction")
for i=1 to IL
  for j=1 to JL
    for k=1 to KL
      PrintOnOneLine (x(i, j) y(i, j) z(i, j, k))
    end for k
  end for j
end for i.
```

### 3.0 HOW TO VIEW THE TWO- AND THREE-DIMENSIONAL GRID SYSTEMS GENERATED

Two additional programs have been written to accompany GRID2D/3D. These two programs allow the user to see the grid which GRID2D/3D has produced as a graphics image on the computer screen and as hardcopy output from a Hewlett Packard HP-7470A pen plotter. The program which yields the graphics image/plotter output is called 3DSURF and is written in Turbo Pascal.
3DSURF is intended for use on an IBM PC, XT, or AT compatible computer and supports both CGA and EGA graphics. This program takes a 2-D grid file created by GRID2D/3D and draws the resulting grid on the CRT and the pen plotter (if desired); however, 3-D grid files created by GRID2D/3D are not suitable as input for 3DSURF. For this reason, another program, PRGRID, has been written. PRGRID uses a 3-D grid file created by GRID2D/3D to generate an output file suitable for use as input to 3DSURF. This section is intended to show how 3DSURF and PRGRID can be used.

3.1 How to Use 3DSURF

3DSURF allows the user to plot surface grids on the computer screen. Two-dimensional grid output files from GRID2D/3D are already in the proper format for use with 3DSURF. Three-dimensional grid output files from GRID2D/3D must be used as input for PRGRID as detailed in the next subsection to create files suitable for use with 3DSURF.

An input file for 3DSURF consists of a list of the grid point locations for one or more grid surfaces together with the number of grid points for each surface. The 2-D grid output files from GRID2D/3D have been “padded” in the sense that a z-coordinate of 1.0 has been assigned to all grid points generated by GRID2D/3D. Output files from PRGRID naturally have z-coordinates since they represent 3-D grids. The user should look at a 2-D grid output file from GRID2D/3D or an output file from PRGRID using an editor to see what these files actually look like.

Assuming the user has a suitable input file for 3DSURF (i.e., a 2-D grid output file from GRID2D/3D or an output file from PRGRID), 3DSURF can be invoked by typing

3dsurf
at the DOS prompt. The program will begin by asking the user for the input file name which the user should type in (including the appropriate drive information). The program will then inform the user how many surface grids are in the specified input file and ask how many of these surfaces the user actually wants to see. After the user responds, the program will ask for a list of the numbers of each surface to be displayed. The user should enter these numbers as a list on one line, each number separated from the next by a space. As an example, suppose that the user has just indicated that he or she wishes to view three surfaces out of a possible twelve in some file. If the surfaces that he or she wants to see are the third, fifth, and ninth in the file, then he or she should type

3 5 9

when asked for the surface numbers. Having been informed which surfaces are to be displayed, the program will prompt the user for what is referred to as the View Reference Point (VRP). This point represents the location of the user's eye as he or she views the surface or surfaces. For 2-D grids, an appropriate VRP is

0.0 0.0 1.0.

The VRP coordinates should be entered exactly as just described (i.e., as an ordered triple of real numbers separated by spaces, representing the x, y, and z locations of the VRP). A scale factor will also be requested. Numbers between 0.0 and 1.0 will reduce the image, while a value of 1.0 allows the program to automatically scale the image to fill the screen. Finally, the program will ask the user whether he or she wishes to generate pen plotter output. This is possible only if the PC is connected to a Hewlett Packard HP-7470A pen plotter (baud rate = 4800). The appropriate responses are “y” for yes and “n” for no. Having received a response, the program will generate a view of the grid as if the user were looking at it from the VRP. Parallel projection is used (i.e., no perspective), and no effort is made to hide lines or surfaces which should be
hidden from view. Once a grid has been displayed, the user only needs to hit <RETURN> to produce a menu asking whether he or she wishes to continue.

3.2 How to Use PRGRID

Once a 3-D grid output file has been generated with GRID2D/3D, the user is often interested in evaluating the resulting grid visually using 3DSURF. As mentioned previously, 3-D grid output files from GRID2D/3D are not suitable as input files for 3DSURF. For this reason, the FORTRAN 77 program PRGRID has been written. PRGRID reads 3-D grid files created by GRID2D/3D and produces output files which can be used as input files for 3DSURF.

When running PRGRID, the user should first specify the input and output files using the DOS SET command. This is accomplished by typing

set 7=input.dat
set 8=output.dat

at the DOS prompt. The user should substitute the appropriate names for the input and output files. After this, the program can be run by typing

prgrid

at the DOS prompt. The user will be informed of the number of grid points in the $\xi$, $\eta$ and $\zeta$ “directions” (IL, JL, and KL, respectively) and will be asked for three new numbers. These numbers are referred to as IL1, JL1, and KL1, and they represent the grid point numbers where an internal “chunk” will be removed from the grid to allow the user to see the “inside” of the 3-D grid (fig. 3-1). The output files created by PRGRID contain information about the 12 surfaces shown in figure 3-1. Since plotting the entire 3-D grid without hiding appropriate lines and surfaces would be confusing, PRGRID basically filters out all of the other grid points not contained in surfaces 1
through 12. As a consequence, its output files provide 3DSURF with information about only the outside “shell” of the 3-D grid with a “chunk” taken out to show the grid’s interior features. Usually, the first nine surfaces are sufficient, but sometimes the other three (10–12) prove visually helpful. Here, we note that if the user specifies that IL1=IL, JL1=JL, and KL1=KL, then the output file from PGRGRID will contain only the six surfaces which correspond to the six faces of the cube-shaped “transformed” domain.

4.0 EXAMPLES

In this section, we provide two sample input files for GRID2D/3D, together with the grids that were generated using these files. By examining these input files and the resulting grids, it is hoped that the user may become more familiar with the use of GRID2D/3D. The first file will be referred to as INLET.DAT and is a GRID2D/3D input file for generating a two-zone grid for a 2-D supersonic inlet. INLET.DAT is listed in figure 4-1, and the corresponding grid is shown in figure 4-2. The geometry of the inlet dictates the use of a zonal approach due to the separation of the interior and exterior flows. Clustering in the η “direction” was used to place more grid points near the solid surfaces in anticipation of complex boundary layer flow there. Other zonal configurations could be used to better resolve the physics of the flow (e.g., to facilitate shock capturing during the solution if the flow is supersonic).

The second example input file for GRID2D/3D will be referred to as STATOR.DAT and is actually four separate files—ZONE1.DAT, ZONE2.DAT, ZONE3.DAT, and ZONE4.DAT, listed in figures 4-3 through 4-6, respectively. These files create a four-zone grid between the blades of a 3-D axial turbine stator. The resulting grid is shown in figure 4-7. A single-zone grid was found to be unsatisfactory, so four zones were chosen to minimize grid skewness while maintaining (to as high a
degree as possible) grid line orthogonality at the boundaries. Even with a judicious choice of zones, it was still necessary to smooth the \( \zeta \) grid lines along the zonal interfaces. Such smoothing is often necessary in cases where the geometry contains sharp corners in the boundaries. A method for smoothing was given previously in Section 4.1 of Part 1 of this technical memorandum.

### 5.0 SUMMARY

Part 2 of this technical memorandum has presented a user's manual for \textsc{GRID2D/3D} — a versatile and efficient computer program for generating grid systems inside complex-shaped 2-D and 3-D spatial domains. The structures of the input and output files for \textsc{GRID2D/3D} have been discussed, and the details necessary to use \textsc{GRID2D/3D} for generating grid systems have been given. Two related programs, \textsc{3DSURF} and \textsc{PRGRID}, have also been described. These programs are used to view the grid systems generated by \textsc{GRID2D/3D} on the CRT and may also be used to generate a hardcopy output of a grid on a Hewlett Packard HP-7470A pen plotter. Two example grids were presented showing both the input files and the resulting grids. Finally, a complete listing of \textsc{GRID2D/3D} is given in the Appendixes.
A.1 Listing of GRID2D

PROGRAM Grid2D

C This program generates a two-dimensional algebraic grid system using
transfinite Hermite interpolation. The geometric configuration of the
grid is determined by information provided by the user at run-time via
an input file. The user selects either the "two-boundary technique" or
the "four-boundary technique" depending on whether two or four
boundaries of the spatial domain need to be mapped correctly. Boundary
curves are formed from sets of discrete data points using tension splines.

**FIGURE 4-6.** CONCLUDED.
FIGURE 4-7. - GRID GENERATED BY GRID2D/3D USING 3-D GRID INPUT FILE STATOR.DAT (A COMBINATION OF FILES ZONE1.DAT, ZONE2.DAT, ZONE3.DAT, AND ZONE4.DAT).
An efficient computer program, called GRID2D/3D, has been developed to generate single and composite grid systems within geometrically complex two- and three-dimensional (2- and 3-D) spatial domains that can deform with time. GRID2D/3D generates single grid systems by using algebraic grid generation methods based on transfinite interpolation in which the distribution of grid points within the spatial domain is controlled by stretching functions. All single grid systems generated by GRID2D/3D can have grid lines that are continuous and differentiable everywhere up to the second-order. Also, grid lines can intersect boundaries of the spatial domain orthogonally. GRID2D/3D generates composite grid systems by patching together two or more single grid systems. The patching can be discontinuous or continuous. For continuous composite grid systems, the grid lines are continuous and differentiable everywhere up to the second-order except at interfaces where different single grid systems meet. At interfaces where different single grid systems meet, the grid lines are only differentiable up to the first-order. For 2-D spatial domains, the boundary curves are described by using either cubic or tension spline interpolation. For 3-D spatial domains, the boundary surfaces are described by using either linear Coon's interpolation, bi-hyperbolic spline interpolation, or a new technique referred to as 3-D bi-directional Hermite interpolation. Since grid systems generated by algebraic methods can have grid lines that overlap one another, GRID2D/3D contains a graphics package for evaluating the grid systems generated. With the graphics package, the user can generate grid systems in an interactive manner with the grid generation part of the program; no modifications are needed in the grid generation part of the program. This technical memorandum describes the theory and method used in GRID2D/3D. Part 1 of this technical memorandum, under a separate cover, contains the computer program, GRID2D/3D, and a user's manual.
