Subject: Delivery of Final Report and MOTIF Comp Builder, NASA Grant 9-339, Specification Driven Language; SwRI Project 05-2768

Dear Ms. Rice:

Attached is the final report for the Specification Driven Language research grant, NASA Grant 9-339. The final report consists of three separate papers and two appendices. The final report papers describe the research performed during the grant. The first paper describes the Specification Driven Language research. The second paper describes the state of the image processing field and how image processing techniques could be applied toward automating the generation of Comps. The third paper describes the development of a flight certified compiler for Comps.

The first appendix contains source code listings of the original NASA Computation Development Environment (CODE) prototype. The second appendix contains the source code listings of the X Windows MOTIF version of the Comp Builder. A Masscomp 1/4" tape is also included which contains the MOTIF Comp Builder source code in "tar" format.

If you have any questions or comments, please feel free to contact Timothy J. Barton at (512) 522-3540, or Dr. Steven W. Dellenback at (512) 522-3914.

Sincerely,

Melvin A. Schrader  
Director  
Data Systems Department

1.0 Introduction

Southwest Research Institute (SwRI) was awarded a grant by NASA-Johnson Space Center (JSC) to perform research in the area of Specification Driven Languages (NASA Grant NAG 9-339). The purpose of the research was to investigate alternative programming techniques/concepts which could be utilized in the software development environments.

This final report is a summary of the work performed under the previously cited grant. In summary, the grant focused on the following areas of research:

- Investigated what techniques NASA and other organizations are using as an alternative form of program development. Primary research included a thorough investigation of three NASA developed languages:
  - COmputation Development Environment (CODE),
  - Space Station User Interface Language (UIL), and
  - Ground Operations Aerospace Language (GOAL).

- Performed an in depth analysis and a proof-of-concept prototype implementation of a NASA-JSC defined language (COmputation Development Environment - CODE or Comp Builder) in a UNIX/X Windows environment. The effort involved enhancing the language specification as well as extensive research into alternative user interfaces.

- Performed preliminary investigation into what type of alternative user interfaces could be developed for future software development environments. In the future, the ability to directly generate software programs from engineering drawings will play a major role in NASA's success in rapidly developing and controlling complex systems. A white paper detailing various alternatives was developed and is included in this report.

- Performed preliminary research into how compiler concepts could be applied to a language definition so that a compiler could be developed which would generate flight certified software. Such a tool, with an appropriate user interface, should drastically shorten the program development cycle. A white paper discussing the various attributes that a flight certified compiler should contain was developed and is included in this report.

The results of the research areas described above are contained in the remaining sections of this final report.

1.0 CODE Language and Implementation Evaluation

In order to establish a baseline for the Specification Driven Language grant, a review of existing NASA languages was performed. SwRI investigated the following languages and their constructs:

- Computational Development Environment (CODE)
- Ground Operations Aerospace Language (GOAL)
- Systems Test and Operations Language (STOL)
- TAE Command Language (TCL)
- User Interface Language (UIL) for Space Station Freedom

These languages were investigated to identify currently employed concepts acceptable to the target Specification Driven Language, referred to as the Mission Operations Application Language (MOAL). It was determined that none of the languages currently used or under development would fulfill the requirements of the MCC environment. These languages did however have various constructs that were integrated into the definition of the MOAL.

Initial investigation was focused on the CODE development environment and its language due to its relationship with MCC. CODE was developed by MCC/MOD and had already demonstrated that an "English-like" language tailored to MCC requirements could be developed. SwRI evaluated both the CODE language and its implementation. The evaluation of the CODE language and the evaluation of the CODE implementation are included as appendices to this report.

1.1 CODE Language Evaluation

The initial research of this grant was the evaluation of the CODE language and its constructs. As a means of evaluating the CODE language, SwRI developed a Backus-Naur Form (BNF) representation of the CODE language. The BNF representation permits a more scientific appraisal of the language under study. The BNF allows the implementation of the language to be isolated from the basic language itself. This was important because the work on this grant focused on both the language definition and implementation.

The BNF representation of the CODE language is contained as Appendix A of this report, an evaluation of the language is contained as Appendix B of this report, and an evaluation of the CODE implementation is contained as Appendix C of this report.
2.0 MOAL Language and Environment Research

As CODE's usage is expanded from INCO to more MCC flight controller positions and more NASA programs (Space Station and various payloads), the requirements of the language are changing. SwRI pursued the research and development of both an improved language and an improved development environment. SwRI developed a BNF representation for a language referred to as the Mission Operations Application Language (MOAL). SwRI also developed an X Windows based CODE development environment for evaluation purposes and to provide a platform for definition of the MOAL BNF.

2.1 MOAL Language Research

SwRI developed a BNF representation for the proposed MOAL language. The MOAL language was designed to be an extension to the NASA CODE language. The new language was designed to support all of the MCC flight controller positions instead of only INCO. The MOAL was also designed to support the requirements of various payloads, such as TSS. SwRI used the following sources of information to develop the MOAL BNF:

- The MOAL was based primarily on the CODE language BNF due to its proven applicability to the MCC environment.
- The MOAL was also based on the requirements of the other MCC positions and the requirements of various payload users. These requirements were compiled by NASA in the Comp Builder and Comp Manager Level B Requirements.
- Research into the UIL and GOAL also determined several aspects of the MOAL BNF.

Appendix D of this report contains the MOAL BNF.

2.2 MOAL Environment Research

SwRI performed research toward defining an improved environment for the MOAL language. This research has been conducted in primarily three areas:

- The first area of research involved the graphical interface of the CODE program. The original CODE program utilized a proprietary Masscomp graphics interface. For evaluation purposes, this interface was converted to an MIT X Windows graphics interface. The first version of the X Windows Comp Builder utilized the Hewlett-Packard (HP) widget set and served as a baseline for implementation of an improved user interface. The X Windows prototype also included several performance enhancements to the basic structure of the Comp Builder software. The X Windows prototype was well received by NASA and served as the basis for the WEX 2.5 version of the Comp Builder.
The second version of the X Windows Comp Builder utilized the Open Software Foundation (OSF) MOTIF widget set. The MOTIF version of the Comp Builder served as a test-bed platform for the development of the MOAL BNF and several enhancements to the user interface.

- A preliminary investigation into alternate input techniques for the MOAL environment was conducted. This investigation resulted in the Image Processing paper included in a later section of this document.

- A preliminary investigation into a flight certified environment was also conducted. This investigation resulted in the Flight Certified Compiler paper included in a later section of this document.
Appendix - A CODE BNF

The following is a BNF representation of CODE. A list of the BNF rules precedes the BNF.

1.0 CODE BNF Rules:
The following symbols are meta-symbols belonging to the BNF formalism:

\[
:: = | \{ \} ..
\]

The non-terminal: <group> is the start symbol.
The terminal: PI represents the arithmetic constant 3.159.
Comments can be entered before, after, or between any non-terminals or terminals. The following is the BNF for a comment:

\[
\text{comment} ::= \text{/*} \{ <\text{alphanumeric}> \} */
\]

1.1 BNF:
\[
\text{action_stmt} ::= <\text{set_statement}> | <\text{print_stmt}>
\]
\[
\text{alphanumeric} ::= <\text{letter}> | <\text{digit}> | <\text{id_char}>
\]
\[
\text{comp} ::= <\text{header}> <\text{statement_list}>
\]
\[
\text{defined_func} ::= \text{cos} | \text{acos} | \text{sin} | \text{asin} | \text{tan} | \text{atan} | \text{exp} | \text{log} | \text{sqrt} | \text{power}
\]
\[
\text{digit} ::= \text{0..9}
\]
\[
\text{factor} ::= <\text{variable}> | ( <\text{simple_expr}> ) | <\text{func_designator}> | - <\text{factor}>
\]
\[
\text{float} ::= <\text{float_no_zero}>\{ <\text{digit}> \} (1 \text{ decimal point max})
\]
\[
\text{float_no_zero} ::= \text{1..9} | .
\]
\[
\text{func_designator} ::= <\text{defined_func}> ( <\text{factor}> \{, <\text{factor}> \} ) | <\text{identifier}> ( <\text{factor}> \{, <\text{factor}> \} )
\]
group ::= \texttt{\{ <comp> \}}

header ::= /* <create_str> <author_str> <gname_str> <cname_str> <purpose_str> */

hex_char ::= A..F | a..f

id_char ::= _ | -

identifier ::= \texttt{<letter> \{ <alphanumeric> \}}

if_statement ::= if \texttt{<rel_expression>} then \texttt{<statement_list>} endif |

if \texttt{<rel_expression>} then \texttt{<statement_list>}
else \texttt{<statement_else>} \{ \texttt{<statement_list>} \} endif

integer ::= \texttt{<no_lead_zero> \{ <digit> | <hex_char> \}}

letter ::= A..Z | a..z

local ::= \texttt{<identifier>}

MSID ::= \texttt{<identifier>}

no_lead_zero ::= 1..9 | \texttt{<hex_char>}

number ::= \texttt{<integer> | <float>}

operator ::= + | - | \texttt{\&} | \texttt{\&\&} | \texttt{\|} | \texttt{\|\|} | \texttt{\&\&\&} | \texttt{\|\|\|} | bitAnd | bitOr | bitXor | shiftL | shiftR

print_statement ::= \texttt{\textbf{print1} <quoted_string>} |
\texttt{\textbf{print2} <quoted_string>} |
\texttt{\textbf{print3} <quoted_string>} |
\texttt{\textbf{print4} <quoted_string>} |
\texttt{\textbf{print5} <quoted_string>}

quoted_string ::= " \{ <alphanumeric> \} "

\textbf{Specification Driven Language Research}
rel_expression ::= <simple_expr> <rel_operator> <simple_expr>
rel_operator ::= < | > | <> | = | >= | <=
set_statement ::= set <set_var> = <factor>
set_var ::= <signal> | <local>
sign ::= + | -
signal ::= <identifier>
simple_expr ::= <sign> <factor> | <factor> <operator> | <simple_expr>
statement ::= <if_statement> | <action_stmnt>
statement_else ::= <action_stmnt> | <variable> = <factor>
statement_list ::= <statement> { <statement> }
variable ::= <set_var> | <MSID> | <number> | <quoted_string> | PI

author_str ::= Author: { <alphanumerics> }
cname_str ::= Comp Name: xxxxxxxx
create_str ::= Creation Time: xxxx:xx:xx:xx
gname_str ::= Group Name: xxxxxxxx
purpose_str ::= Purpose: { <alphanumerics> }
Appendix - B CODE BNF Evaluation

The CODE grammar is more compact than a traditional High Order Language (HOL) due to the fact that CODE has no formal data typing within the language (the CODE environment maintains a table of data types), a limited number of statements and a slightly restricted relational expression capability.

The representation of CODE in a BNF form facilitated the following evaluation:

- CODE was designed to meet the needs of Mission Operations Directorate (MOD) INCO flight controllers. This required only the following three statements:
  - Conditional control statement - if
  - Assignment statement - set
  - Output statement - print

CODE users have already requested additional conditional and assignment statements.

- The IF statement allows invalid statements to be added after the ELSE. There are two sets of statements available when constructing the ELSE portion of an IF statement:

```plaintext
if rel_expr
  then
    { group1 }
  else
    group2
    { group1 }
endif
```

The first statement following the ELSE allows the user to select an MSID, SIGNAL, or LOCAL, and then assign a value to these variables. These selections should not be valid unless they are contained in a SET statement. The ELSE portion of the IF statement should allow only the same statements as the THEN portion.

- The CODE language allows a value to be assigned to an MSID. This is not a valid operation, as MSIDs are values which are read from data acquisition and are not modifiable by the CODE software.

- A user function must contain one argument. CODE forces an argument to be supplied in user function calls. It is standard programming practice in HOL's to allow function calls with no arguments. The CODE language should allow these types of function calls.
The CODE program does not allow a SET statement to be added to a Comp after a SET statement is added which contains a user function call on the Right Hand Side (RHS). Two or more SET statements can be added to a Comp as long as none of them contains a user function call. The CODE program should allow multiple SET statements to be added which contain user function calls. Example:

```
set var1 = 100
set var2 = userFunc1( userFunc2( 5 ) )
/* at this point, CODE will not allow another SET statement to be */
/* added to the Comp, but will allow a PRINT or IF statement */
```

The irregularity described above always occurs when the SET statement is the first statement in a Comp.

Traditionally, in both C and PASCAL, expressions are allowed to evaluate to a simple expression. The CODE language only allows expressions to be evaluated to two simple expressions separated by a relational operator. This restricts the type of expressions that can be constructed. The CODE language designers may have intentionally designed CODE in this manner. If a relational operator is always required, the user is not required to know that 0 evaluates to FALSE, while any other value evaluates to TRUE.

```
Traditional HOL
expression ::= <simple_expr> | <simple_expr>
               <rel_operator> <simple_expr>

CODE
rel_expression ::= <simple_expr> <rel_operator> <simple_expr>
```

This feature of the CODE language is not standard when compared with traditional HOL's, but is appropriate for the non-programmer audience served by CODE.

- CODE allows the RHS of a SET statement to be a <factor>. Traditional HOL’s allow an <expression> non-terminal on the RHS of an assignment statement. This permits greater flexibility in the assignment of data values to variables.

```
Traditional HOL
set_statement ::= set <set_var> = <expression>

CODE
set_statement ::= set <set_var> = <factor>
```
The PRINT statement should only allow WEX application level messages to be output. The current CODE will allow the running comp to generate host level messages. The WEX version of CODE should restrict the type of messages generated. This issue is environment dependent, in this case the WEX environment determines the valid set of PRINT statements. Even though the valid PRINT statements are environment dependent, the language BNF has determined that all PRINT statements are valid at any time. The CODE language should be modified to only allow those PRINT statements that are valid for WEX applications.

The CODE BNF should allow the formal definition and construction of user functions. The CODE language and environment do not allow the definition of user functions. User functions must be constructed outside the CODE environment. The CODE language should include the constructs necessary to define and reference user functions built within the CODE environment.

The CODE documentation should either define the order of precedence for expression evaluation or inform the user of the dependence on the host C compiler. CODE's order of precedence of expression evaluation is directly tied to the C compiler used to install the Comps. CODE will allow the following Comp statement to be generated:

\[
\text{if PI} * \tan{(1)} + \text{PI} > 1
\]

This statement should be valid, but the order of expression evaluation is unknown without understanding how the Comp is translated into the resulting 'C' language program.

The CODE language allows the negation of a text string. Example:

\[
\text{set Var1 = userFunc1( -"text string" + 1 )}
\]

CODE allows integers and floating point numbers to be 30 characters long. This allows the user to enter numbers which are too large to be represented using standard integer arithmetic. This is both a CODE language and CODE implementation issue.

The CODE language allows the user to build Comps which contain the assignment and evaluation of mixed type expressions. These expressions may be cast by the C compiler or may cause fatal errors during the installation process. Example:

\[
\text{set Var1 = .5 + "text string" + 10}
\]

This is another case of an issue which should be addressed by both the CODE language and CODE implementation.
Appendix - C CODE Implementation Evaluation

After the evaluation of the CODE language, the CODE program was evaluated from a software design aspect. SwRI evaluated CODE's stability, portability, and overall system design.

The following is a list of problems and/or deficiencies identified in the NASA/MOD version of CODE. Several of the following items relate to the hardware differences between the MASSCOMP systems used by the CODE developers and SwRI's MASSCOMP. These items are irrelevant in a strictly homogeneous hardware environment, but such an environment should not be assumed due to the rapid advancement of workstation hardware development. A homogeneous hardware environment also adds requirements to the various contractors which develop and support NASA software. An X Windows version of the Comp Builder was requested by several NASA contractors because Masscomp workstations were not available to them, but X Window capable Sun workstations were available.

- The CODE program needs to determine the resolution of the monitor before displaying the token strings. CODE currently uses a font which is larger than the boxes allocated for the strings. The font can be changed to a smaller font which fits nicely in the boxes, but the portions of the text which exceeded the size of the boxes are not cleaned up and remain on the screen until CODE is exited.

- The user interface should be improved such that the user is not required to continue switching back and forth between the mouse and the keyboard. A function needs to be added so the user can mouse an area to continue processing instead of hitting the RETURN key. This enhancement was made in the X Windows versions of the Comp Builder.

- In the case that the RTDS environment variable is not defined, CODE currently exits, leaving the graphics on the screen. CODE should restore the screen and remove the graphics. CODE should also allow the user to enter the RTDS path if the user so desires. This enhancement was made in the X Windows versions of the Comp Builder.

- The CODE program currently uses 5 meg of static data space for tables and arrays that it maintains internally. This amount should be reduced through the use of dynamic memory allocation. The following data structures are examples of structures that should be dynamically allocated:

  - SignalTable - 800 structures of 3081+ bytes = 2,464,800
  - MSIDTable - 4000 structures of 72 bytes = 288,000
  - GroupVars - 500 structures of 100+ bytes = 50,000
  - Comp - the Comp string 20,000

- The READ process tries to rm (delete) a file using the file pointer instead of the ASCII name of the file. This will produce undetermined and potentially disastrous results. The source file archive.c contains the incorrect code:
tmpfile = fopen( ... );
system( "rm tmpfile 2>>/tmp/code.err" );

- The READ process uses the variable "found" before it is initialized. This could produce undetermined results should the Masscomp compiler change or if the CODE program is ported to another version of the Masscomp operating system or to another hardware platform, such as a Sun.

- The CODE program contains a bug in the software that performs the DELETE function. The following steps will cause the CODE program to abort:
  1. Retrieve a Comp
  2. Delete several tokens from the end of the Comp using DELETE
  3. Save the Comp
  4. Retrieve the Comp

The next time the Comp is retrieved, the CODE program will abort due to a memory Segmentation Fault and a "core" file will be created.

- The DELETE function should be modified to let the user delete any token. The current DELETE function only allows the user to delete the last token in the Comp. If the user wanted to delete the first token in the Comp, the entire Comp would have to be deleted one token at a time or the user could use the VI editor to delete the token.

- CODE allows integers and floating point numbers to be 30 characters long. This allows the user to enter numbers which are too large to be represented using standard integer arithmetic. This issue was also identified in the language evaluation section of this report. Both the CODE language and the CODE implementation should address this issue.

- Using some Masscomp configurations, the VI window does not size itself correctly within the Work Area. VI is unusable as the CODE editor, the user must use VED to edit the Comp string.

- The date calculation performed in get_header.c does not compute the date correctly. Subsequently, the date recorded in the header of all Comps is incorrect.

- Several path specifiers should be corrected. There are currently paths which are built containing multiple forward slashes. These paths could cause portability problems should a new version of the Masscomp operating system not support this type of path specifier. The following line in init_code.c is an example:

  UserFuncsLib, "/home//rtds/..."

- In init_code.c, if the MSID Table is not found, the loop control variable MSIDTble is not initialized. During the install() routine, MSIDTble is used to access arrays in memory. This uninitialized variable could cause the CODE program to access
invalid sections of memory producing undetermined results. MSIDTble should be explicitly initialized for portability.

- In init gp.c, the call to signal() which is to trap Control-C is commented out. A Control-C entered in the prompt area will abort the program leaving the CODE graphics on the screen. The Control-C signal handler should be implemented.

- It is possible to build comps using the tokens available on the screen (it is not necessary to use VI or VED) that when compiled produce C code, which may be invalid. The produced C code makes several calls to fltmsg_issue() before the fltmsg_init() call.

- Using a Masscomp 5500, the tokens in the bottom right corner of the MATH token box were not mouseable during HELP mode. If the tokens are selected, the CODE banner is displayed, and the FONT is changed. This an example of hardware dependency that should be eliminated where possible.

- The documentation needs to be updated to include all the tokens available during HELP mode. There are currently as many undocumented tokens as there are documented tokens. A user friendly program should have all the help messages defined.

- The large font may not be used during HELP mode, as the first lines of every screen are scrolled out of the top of the Work Area window.

- The comp string display routine does not allow the user to view an entire comp if it is larger than the Work Area window. Only the last section of the comp (that portion that fits within the Work Area window) is visible. There is no means to view the top of the comp except for VI or VED.

- The openFile() routine needs to let the user see the message longer (ideally a mouseable continue box). Currently, the message disappears from the screen too fast for the user to read.

- CODE does not type check the arguments to user functions to ensure they match the required parameters. Passing the wrong parameters to a user function at best case will cause the comp to abort, in worst case will cause the comp to continue execution with side effects; possibly undetected side effects.

- The UNIX system program lint generated several pages of irregularities when it examined the CODE program C source code. The following errors are typical of the numerous anomalies discovered by lint:

  Redefinition of variable data types
  Usage of uninitialized variables
  Declaration of unused variables
  Incorrect number of arguments passed to functions
Appendix - D MOAL BNF

1.0 Notes:

The following symbols are meta-symbols belonging to the BNF formalism:

```
::= |{}.. |
```

The non-terminal: <group> is the start symbol.

See Appendix E of the Comp Builder and Comp Manager Level B Requirements (JSC-23459) for the Naming Conventions and limitations of the non-terminal: <identifier>.

See Appendix C of the Comp Builder and Comp Manager Level B Requirements (JSC-23459) for the data representation and precision limits of the referenced data types.

The statement terminator is the newline character (carriage return). An exception is <expressions>, which may require multiple source lines.

1.1 BNF

```
add_operator ::= + | - | or | xor

alphanumeric ::= <digit> | <letter> | <special_char>

char ::= 'A..F | a..f'

1.0 Introduction

NASA-JSC currently maintains engineering diagrams and schematic drawings of many of the subsystems contained within the shuttle. These diagrams and drawings are often converted into a drawing containing logic symbols and text which describe an algorithm for monitoring the status of the subsystem. Figure 1-1 contains an example of a logic drawing which describes an algorithm.

![Logic Drawing Diagram]

Figure 1-1 Example Logic Drawing

The algorithms described by the logic drawings will perform range checking of data points to determine the operational stability of the subsystem. These drawings are interpreted by a human and implemented using programming language type constructs. A more efficient method of software generation would be to provide an automatic process which could "scan" the schematic drawing, as would a human, and develop a program with minimal (or no) programmer involvement.

Implementation of such a system would require an orchestration of systems from the following technologies and topics: Image Digitization, Image Processing, Pattern/Image Recognition, and Automatic Code Generation. To gain understanding of the current capabilities of these technologies, this paper will address each area individually. The intention of this breakdown is to provide insight into the current state of the related technologies, what tools are available in each, and where the fields are headed. Special emphasis will be given to viewing the individual technologies in light of the problem at hand.
2.0 Definition of the Fields of Image Scanning

A widely held misconception is the idea that all scanners (hardware and software combined) automatically interpret the documents they digitize. This is not the case. For scanners set up to perform interpretation of text alone (Optical Character Recognition), this is true, but for a mix of text and graphics, this is not the case. Another widely held misconception is the idea that the hardware issues present more of a challenge than the supporting software. Presently, this is not the case. It is important to first understand the various components of document scanning and the terms that are used to identify them.

2.1 Image Digitization/Optical Scanning

Image Digitization identifies the conversion of a physical image to a digital image stored within a computer. Image Digitization is primarily a hardware intensive function. No attempt is made to enhance the quality of the digital representation or to interpret the content of the digital image. This paper will use the term scanner to identify the hardware that generates a digital image and the term scanning to identify the process of generating a digital image.

2.2 Image Processing

Image processing identifies the manipulation of a digital image. Edge enhancement, noise filtering, and image cut and paste operations are examples of image processing techniques.

2.3 Image Recognition/Pattern Recognition

Image recognition identifies the processing of a digital image to determine the logical contents of the image. OCR is an example of image recognition. OCR software attempts to determine the actual characters of a digital image.

2.4 The Complete Package

Image scanning often involves the integration of all three of the aforementioned disciplines. First, the image is scanned (digitized). During digitization, the image may be processed using edge enhancement and noise reduction techniques. Depending on the application, recognition of the image may then be performed. To provide a tool for the automatic generation of algorithms from logic diagrams, all three disciplines will be required.
3.0 Image Digitization

The first step in the scanning of a document, say the logic diagram in Figure 1-1, is the digitization of the image. Image Digitization can also be referred to as "scanning." Image digitization is a more cumbersome term, but it more accurately describes the process which is performed. The term "scanning" is often used as a general term for the combination of image digitization, image processing, and image recognition.

3.1 Image Digitization/Optical Scanning

The goal of optical scanning is to convert a physical image into a digitized image, whether that image be a page of text, a picture, a combination of text and graphics (like a logic diagram), or a three dimensional object. A digitized image is a binary file of ones and zeros stored within a computer that represents the physical image. Software can use this binary information to reproduce the image on a computer screen, on a printer, or on a remote fax receiver.

3.2 Origins

The development of scanners has its origins several years ago in Japan where scanners were applied to fax. Since Japanese characters are essentially graphical in nature, fax is the easiest way to transfer documents.

On the other hand, scanner related software development in the United States has evolved mainly at the shoulder of word processing and desktop publishing demands. With the large volume of paper documents that need to be processed, the ability to scan in text from a physical sheet of paper to a word processing format where it can be manipulated has received a lot of attention. This process is commonly called optical character recognition (OCR). Likewise, the ability to digitize and process pictures that could be incorporated into documents has also been a priority topic (cut and paste of document graphics). As we shall see later, however, of the two scanner software products that developed around the word processing industry, only optical character recognition requires software interpretation or recognition of symbols within the digitized image. Image scanning, as it relates to pictures within word processing documents, only manipulates the bits of the image, not the symbols contained therein.

3.3 How Scanners Work

All non-color scanner technology is based on the fact that black pigment absorbs white light, and white pigment reflects it. A similar principle is used in color scanners that involves colored lights, filters, and pigments. The scanner bounces light off the image that is to be captured. If the light reflects off the image, then it reaches photoelectric cells called Charge Coupled Devices (CCD) which measure the intensity of the reflected light within their cell boundaries. The size of the CCDs and how closely they are packed together determines the resolution of the scanner. Each CCD outputs a given voltage for a given intensity of reflected light. Zero voltage represents no reflected light detected and would indicate that portion of the image is black.

A controller in the scanner takes the voltage measurement from each of the scanner's CCDs and converts it into a whole number which is stored in the computer. Because the CCDs can output only increments of the measured voltage, the true intensity is rounded to a closely cor-
responding voltage level. This is how gray-scale information from the physical image is lost in the digitized image. The controller uses the numbers collected from the CCDs to create an image bitmap file that saves one number for each pixel in the image for later use by a graphics package or other software. The graphics package, for example, would take the values contained in the bitmap file and approximate the image by lighting pixels on the screen according to the gray-scale values.

Color scanners work using the same basic principles, but color scanners use different lighting. The CCDs in color scanners use color filters, and the bitmap files contain intensity values for each pixel for each primary color. This also means the image files are three times larger than black and white image files of the same type.

3.4 Scanner Designs

There are currently four major, different configurations of scanners:

- Flatbed
- Roller-feed
- Copyboard
- Hand-held

Flatbed scanners comprise the majority of the scanners available in the market currently. Of the 21 scanners reviewed by PC Magazine in the March 28, 1989 issue, 16 were flatbed scanners. Flatbed scanners are versatile, and they utilize a traditional design borrowed from small photocopiers. Flatbed scanners are preferred for ease of use and for their ability to scan bound documents such as books and magazines.

Roller-feed scanners employ the flatbed scanner design with an additional sheet feeder mechanism. Manufacturers often offer a sheet feeder mechanism for their flatbed scanners.

Copyboard scanners look very much like a photograph enlarger or overhead projector. Copyboard scanners consist of a flat platform with the scanning device raised approximately 12" above the copyboard. Copyboard scanners are primarily designed for scanning 3-D objects, such as circuit boards, but can be used to scan flat documents as well. Copyboard scanners often require special lighting due to the distance between the scanner sensors and the subject matter.

Hand-held scanners are a relatively new design. Hand-held scanners, such as the Logitech ScanMan, often utilize a 4" wide scanning window; however, Mitsubishi Electronics offers a full 8.5" wide hand-held scanner. They have become very popular because they are inexpensive, and they have proven very useful for importing images into desktop publishing and word processing software.

3.5 Commercially Available Scanners

Scanners are now available from a wide variety of vendors for various hardware platforms. Scanners are often available from the same vendors that produce photocopiers and laser printers due to the similarities of the technologies. The personal computer (PC) market accounts for the majority of scanners purchased currently in the United States due to its large number of users and the type of applications commonly used on PCs. NASA-JSC currently
uses UNIX based MassComp workstations to implement its algorithms, so a survey of the workstation market is also included.

3.5.1 Commercially Available Scanners for the PC

The use of scanners as an input peripheral in the personal computer arena has progressed significantly in the last five years. There are currently more than 150 different products. These products range from the $169.00 Logitech hand-held scanner to the $15,950.00 Kurzweil Imaging System. According to the market research firm Dataquest, scanner sales have increased an average of 250 percent annually from 1984 to 1987. Another 200 percent increase was projected for 1988. In just three years, scanner manufacturers have doubled resolution, added gray-scale capability, and standardized graphics file formats.

The scanners reviewed in the May 1989 issue of the DataPro Research Bulletin exemplify the diversity of image scanners available. Three different scanners from three different vendors were reviewed, each representing a different segment of the PC scanner market. The first scanner reviewed was the Hewlett-Packard ScanJet Plus, an enhanced version of the popular HP ScanJet. The ScanJet Plus is relatively inexpensive, retailing at $1,595 plus $595 for a PC interface kit. It is supplied with very powerful software including OCR software which allows generation of WordPerfect files from scanned documents. It is very easy to use, and it has an extensive range of gray scale. The Microtek Scanners were reviewed next. Ranging from $995 on their low-end model to $3,995 on their high end, they have an exceptional image quality, and they work with many microcomputer systems, including Sun workstations. Microtek also bundles advanced SuperPaint graphics software with their scanners. Finally, the Xerox Pro Imager, with its $10,000 price tag, provides superior performance with 1,200 dpi resolution. The ProImager's software also allows image enhancement which goes beyond the average capabilities of graphics packages that may be bundled with scanners.

3.5.1.1 PC Bundled Software

A discussion on image manipulation and OCR is better suited for the section in this paper that addresses image processing and image recognition, so a more thorough explanation of the state of those fields is left until then. However, it is worth mentioning that an important trend in the PC arena is the marriage of third party software, such as OCR, with OEM scanner hardware and image manipulation (graphics package) software. For example, Cannon and Chinon supply OCR System's ReadRight with their scanners. Again, it is the word processing and desktop publishing industries that have carried scanner and scanner-related software with it, thus the most common areas of software development have been in OCR and graphics manipulation. Twenty-five percent of scanners sold currently have OCR capability. The majority of existing scanners are used for graphics capture and manipulation.

3.5.2 Commercially Available Scanners for UNIX Workstations

The current process used by NASA-JSC to build its algorithms utilizes UNIX based MassComp workstations. Due to its smaller segment of the computer market and more complex and diverse hardware interfaces, fewer optical scanners are available for the UNIX workstations. MassComp ( Concurrent Computer Corp.) currently does not offer a scanner or even list a third party vendor in their Solutions catalog that produces a scanner targeted for the
workstation market. Microtek Lab Inc. is currently the only vendor that offers a scanner for the very popular Sun Microsystems workstations.

Often, a scanner whose target market is PCs, will be connected to a workstation through a similar interface. The NASA-JSC Mission Operations Support Lab (MOSL) is currently using a Howtek Scanner connected to a MassComp. The Howtek scanner is targeted toward the much larger PC market but can be connected to any computer that utilizes a GP-IB interface. The GP-IB interface is not very common on workstations, though, and the software which is typically bundled with the Howtek scanners cannot be used on the workstation. NASA-JSC has had to write their own software to allow the images from the Howtek scanner to be displayed on the workstation. Compare this with the PC market where just about every scanner includes (or has available) an interface and supporting software bundled with the scanner.

Microtek Lab Inc., as mentioned previously, does offer a scanner and software targeted for the Sun Microsystems UNIX workstations. Microtek offers two different models of scanners and bundles graphics manipulation software for use in the SunView window environment. Microtek Lab is at this writing the only vendor available even to Sun users, the largest workstation market segment. Compare this with the PC market, where more than 150 different products are available.

3.6 The Future of Optical Scanners

Scanner developers will be trying to get higher resolution, better color, etc. for a long while yet. In addition, many scanner manufacturers are converting from TIFF output formats to true PostScript image output files. See Section 4.3.3 for a discussion on the various file formats. Scanning is heading toward a future of unification with other computer input and output peripherals, as well as with other image processors that are not computer peripherals. Manufacturers and users would like to see one combination machine that acts as copier, scanner, laser printer, and fax.

In the UNIX based workstation arena, more scanners and supporting software should become available as the workstation market continues to grow. As users migrate their applications from PCs to workstations in search of more processing power, the need for scanners and related software will increase. The wide acceptance of X Windows provides a non-proprietary graphics environment for scanner software development.
4.0 Image Processing

Image processing refers to the processing of an existing digital image. In his book *Robot Vision*, Berthold Klaus Paul Horn defines image processing as "the generation of new images from existing images." The definition of image processing as used throughout this paper, with the exception of the title of this paper, is the more traditional definition of image processing. Image processing can also be thought of as the processes performed between image digitization and image recognition.

Image processing is also used as a broader term to describe the entire process of scanning an image through image recognition.

4.1 Classical Image Processing Algorithms

Classical image processing deals with the raw digital images produced by scanners and video cameras. Image processing in these arenas is typically geared toward improving the quality of the digital image to provide a better image for the subsequent image recognition or image generation (screen display or printing) processes. Many of the early classical image processing techniques were derived or evolved from linear systems theory. Most of the work in classical image processing has been done as a preprocessing step for machine vision and pattern recognition. In recent years, PC scanners and their related software have borrowed from classical image processing to improve the quality of their images for OCR and graphics packages.

4.2 Noise Reduction

Images input by scanners are naturally susceptible to many types of noise. Noise within a gray-scale image can be easily removed by a form of interpolation or by Fourier transforms when the noise is isolated and has nonnoise neighboring points. This type of noise is referred to as "salt-and-pepper" noise. Other types of noise, even if they affect only a small percentage of the total image, are very hard to correct inconspicuously. A great deal of research is being conducted currently to determine the best numerical calculations to remove noise from gray-scale images. Research is investigating simple filtering and threshold algorithms and complex Fourier transforms to remove noise from images.

4.2.1 Edge Enhancement/Detection

Edge detection and enhancement are an important step in the processing of an image. In the case of OCR, it is important that the edges of each character are detectable so the character can be identified. In the case of image recognition of a logic drawing, it is important that the
shape of the logic symbols and the lines connecting the symbols can be identified. Noise reduction is an important first step before edge enhancement/detection can be performed. It is important that the noise reduction processes reduce noise around edge boundaries, especially short length edges. Shorter length edge segments must have a higher, cleaner contrast than longer length segments to be detected. This fact is illustrated by the segment lengths imposed by the Toshiba engineering diagram reader (See discussion in Section 6.2)

Edge enhancement/detection is performed by detecting a border between two regions, each of which has approximately uniform brightness. According to Horn, most work has been done on the edge enhancement process with less work being done on actual edge detection. As image recognition progresses, edge detection becomes critical so the grouping of line segments can be performed to identify shapes.

4.2.2 Dithering

Standard black-and-white photographs may contain more than one million shades of gray. Current PC-related scanner and software technology does not provide for the processing or output of this many shades of gray. As a result, dithering and gray-scaling are two methods which are used to improve the handling of continuous-tone images.

Dithering is currently the most popular method of improving continuous-tone images in PC image processing. As the gray tones are measured by the scanner, they are converted into various bitmap patterns. A high gray tone value is represented by a very dense bitmap pattern, and low gray tone is represented by a less dense bitmap pattern. Dithered images are editable, which means the bitmap for a region of the image can be altered. Dithered images are difficult to scale and are also difficult to vary in resolution. Scaling and image resolution are often modified for printing, so this is a disadvantage of dithering. Dithered images are often stored in PCX, PIC, or IMG formats.

4.2.3 Gray-scaling

Gray-scaling is another method used in PC image processing to store continuous-tone images. Gray-scaling is relatively new to the PC arena and is not used as widely as dithering. As previously described, dithering converts the gray tone value returned from the scanner into a bitmap pattern. Gray-scaling, on the other hand, keeps the gray tone value in the image file to be used later by the display software or hardware (printer or graphics display). The quality of the displayed image is determined by the range of grays available to the output device.

The majority of existing PC hardware and software does not produce gray-scale quality output. Laser printer manufacturers and software developers are working feverishly to develop gray-scale quality products. Big name corporations such as Intel, Hewlett-Packard, and Microteck have either announced gray-scale quality products or will shortly.

4.3 Graphics Packages

Graphics packages provide the user with the ability to create and manipulate images. For example, a typical graphics package would provide the user with the ability to create pictures consisting of lines, shapes, surfaces, colors, and text, as well as the ability to bring in a scanned image stored in a standard scanner output format. With the image loaded into the graphics package, the user can trim away parts of the picture, or cut and paste portions of it
as desired into his word processing and desktop publishing documents. Some more advanced graphics packages even allow the user to enhance the image by changing color content or by similar functions.

Applications that have had less of an impact on off-the-shelf image processing software, but more of an impact on the advancement of the field of study, are applications applied to special fields such as astronomy, medicine, geology, and defense. For example, computer x-ray tomography (CT) scanner images are processed by advanced medical applications to extract information about body function and to identify unusual growths without using surgery. To do this, the graphics software enhances images, rearranges picture parts, enhances color separations, or improves shading.

4.3.1 Graphics Packages for the PC

There is an endless number of PC paint and graphics packages that have been developed during the micro-computer revolution. Many of the packages originated mostly for entertainment and drawing practice. However, the demands of word processing and desktop publishing pushed the development of more advanced and complete systems. These more advanced systems combine text, drafting capabilities, freehand modes, and image processing functions into all-purpose packages that can be used by artists, illustrators, image processors, and desktop publishers.

Without question, the leaders in the PC graphics world are Adobe Corporation's Illustrator and Aldus Corporation's Freehand. Neither could be classified as a dominant number one, but together they seem to hold that position. Both are list priced at around $695. These graphics packages are the deluxe models because they can import and export a large number of different image formats, including true PostScript. They allow freehand drawing with many different colors and brushes. The packages give drafting capability by manipulating squares, lines, arrows, and all shapes as separate entities that can be moved, resized, overlaid, etc. In addition, text of all sizes and fonts can be mixed with the graphics and freehand drawings. Both are available on the Apple Macintosh computers and on the IBM PCs.

4.3.2 Graphics Packages for the Workstation

MassComp (Concurrent Computer Corp.) workstations have a fair amount of graphics software that is intended to be used as graphics routine libraries that are used to build other application programs. In the most recent release of their Solutions Catalog, no user interactive graphics package is mentioned. In summary, there is no software on the MassComp that will allow a user to interactively build or manipulate image files, while there are a great deal of tools or libraries that might be used by programmers to build such a system.

Sun Microsystems lists in its most recent issue of the Catalyst Catalog two stand-alone graphics editors and two composite, desktop publishing and graphics editors. The stand-alone packages are:

- Artisan (Media Logic Incorporated), $1,795 gray-scale, $3,250 color.
- Graphics Builder (Xerox Corporation), price not listed.

Both of these provide standard graphics creation capabilities such as drawing in color with different brushes, diagram making, etc. Differing from most PC graphics packages, these
workstation packages offer image processing functions for scanned images such as image composition, color correction and enhancement.

Desktop publishing packages are more prevalent on the workstation. These packages almost always include some form of graphics generation and manipulation. The following are two examples of desktop publishing packages that include a graphics production system:

- FrameMaker (Frame Technology Corporation), approximately $2,500.
- Publisher (Arbor Text, Inc.), $1,995.

The graphics production systems in these composite packages allow the user full-function paint and draw capabilities like one would find in the MacPaint and MacDraw programs on the PCs.

4.3.3 Standard Graphics File Formats

It is obvious that with many different scanners, image processors, graphics packages, and desktop publishers on the market, some standard in image file formats had to evolve. There are several formats that are common, including PCX, PIC, IMG, TIFF, and PostScript. TIFF and PostScript have emerged as solid standards, the leader being PostScript. It would be useful to review both of these formats individually.

4.3.3.1 Tagged Image File Format (TIFF)

Tagged Image File Format has become a standard for scanned image formats. The standard was originally developed on the Apple Macintosh and is very popular because it provides a format for porting image files between PC and Mac graphics packages.

TIFF uses tags to identify graphic elements. The simplest component of the TIFF format is a bitmap of an image. The TIFF format also stores information about the gray-scale or color of each dot in the image. The TIFF format can still be used, however, if the software you use does not provide gray-scale or color information. In addition, TIFF allows for the simultaneous storage of multiple resolution bitmaps of the same image in the same file. Thus, software can choose between the multiple resolutions depending upon the display used.

According to the October 1987 issue of PC Magazine, the big disadvantage of bitmap files is that most software arranges pixels into halftone dots, freezing the print resolution of the image. But if the software captures gray-scale information, TIFF stores it and makes it available to the software for manipulation.

4.3.3.2 PostScript Format (PSF)

PostScript Format and its successor Encapsulated PostScript (EPS) have become the leading standards for image formats across all hardware and software platforms. PostScript became the standard for text in conjunction with the word processing and laser printing fields. Its successor EPS stores images with a kind of vector format that is based on PostScript. EPS is used in graphics as well as text and is a fundamental part of the leading graphics packages on the market today.
4.4 Computer Aided Design (CAD)

For a number of years, the biggest use of PC and mini-computer graphics has been in the area of Computer Aided Design (CAD). CAD packages allow designers to interactively design whole objects or parts of objects by specifying the objects dimensions. CAD systems allow the designer to view the object under design from different viewpoints and to incorporate modifications into the design very easily. CAD systems allow designs to be produced more quickly, and they also produce renderings that are more realistic than pencil drafts. Electronically stored CAD designs can also be more easily copied and modified than pencil designs.

4.4.1 CAD Goals

The fundamental purpose of CAD packages is to capture a schematic or design from the imagination of the designer. Most of the CAD tools have focused on interacting with the designer to provide him/her with ease of input, retrieval, and manipulation of his/her designs. Many CAD software packages have elaborate facilities which allow design and display of 3-D components or schematics with easy-to-use interfaces and plenty of on-line help.

CAD software allows part libraries to be formed which can be incorporated as a portion of a larger design or reused in other designs. Design elements can be assigned names and other information that give meaning to them. Relationships between elements can be specified as well.

CAD systems are used in a wide variety of fields:
- Electrical engineering
- Automobile and aircraft design
- Architectural and building design
- Communications network design
- Water and electricity supply systems design

CAD systems allow designers to see objects on a computer screen before they are constructed. CAD systems often work in parallel with simulation software to allow the designer to exercise objects before they are constructed. In fact, advanced IC design CAD systems allow the schematic that is produced to be tested with simulation software which allows verification of the correctness and functionality of the design. Many architectural CAD systems allow the user to take a "tour" via computer through the structure being designed.

4.4.2 CAD Packages for the PC

PC CAD systems are almost as popular as word processing systems, and as a result there are numerous CAD systems available to meet every budget and need. PC CAD packages are available for as little as $2.00 and costing as much as thousands of dollars. There are two leaders in the PC world in CAD software, namely, AutoCAD and VersaCAD. AutoCAD has the advantage of being a pioneer and a mainstay in the PC CAD world, a tool against which other systems are measured. VersaCAD, while not as widely used as AutoCAD, has earned the reputation of being a more user-friendly system. Both systems essentially have the same features or functionality. VersaCAD, however, leads in allowing new users to learn and start working quickly, while AutoCAD commands are said to be cryptic and difficult.
CAD Packages for the Workstation

to learn. Each of these packages can read and write IGES files as well as AutoCAD DXF files, and both can be purchased at most PC software retailers. See Section 4.4.4 for a discussion of the various file formats.

4.4.3 CAD Packages for the Workstation

As in the PC arena, there are numerous CAD packages for the workstations. A quick look at the Sun Microsystems Catalyst Catalog reveals many different CAD systems for just the Sun hardware platform alone. Numerous other packages exist for the other workstation hardware platforms. The workstation market differs from the PC market in the number of general purpose CAD packages available. Workstation CAD packages are usually targeted toward a very specific CAD function (IC design is a popular one). CAD packages for the workstation are typically much more expensive than their PC counterparts. The following is a list of several workstation CAD packages:

- Allegro PCB Design System (Valid Logic Systems Inc.)
- Analog Design and Analysis Environment (Daisy/Cadnetix Inc.)
- AutoPCM (Cadisys Corporation)
- CAECO Designer (Silicon Compiler Systems Corporation)
- Dash Schematic Designer (Data I/O Corporation)

4.4.4 Standard CAD File Formats

As in the word processing arena, almost every CAD system uses a proprietary file format. If there are a thousand CAD systems, there are a thousand different formats in which CAD designs are electronically stored. In order for one CAD system to share designs with another CAD system, a CAD electronic file format standard had to be built.

4.4.4.1 EDIF/IGES

An attempt at defining a standard CAD file format was made in the mid 80's. This standard was formed or supported by several large companies including, Motorola, National Semiconductor, Mentor Graphics, Tektronix, Texas Instruments, AT&T, and Hewlett-Packard. The standard was called the Electronic Design Interchange Format (EDIF), but it was such a loose specification, that it took many different evolution paths. EDIF ended up being not much more than a suggested way of describing CAD files.

A follow-on standard which has succeeded in becoming a standard is the Initial Graphics Exchange Specification (IGES) which was defined by the U.S. Department of Commerce. This standard established the information structures to be used for the digital representation and communication of product definition data (CAD designs). The file format that was decided upon treats the design definition as a file of entities, each entity being represented in an application-independent format. Each specific CAD system can then map between the IGES files and its own native representation.

To do this, the CAD designs are described in terms of geometric and non-geometric information, with non-geometric information being divided into annotation, definition, and organization. The geometric data consists of a definition of the design in terms of points, curves, and surfaces. The annotation, on the other hand, consists of those elements which are used to clarify or enhance the geometry, including dimension, drafting notation, and text. The defini-
tion category provides the ability to define specific properties or characteristics of individual or collections of data entities. The structure category identifies groupings of elements from geometric, annotation, or property data which are to be evaluated and manipulated as single items.

One of the entities that is defined as part of the IGES standard is of particular interest to a later discussion in this paper. The IGES standard contains a provision which is suitable for saving the meaning (or information that leads to meaning) of CAD images. The Property Entity allows non-geometric numeric or textual information to be related to any entity. Any entity occurrence may reference one or more property entity occurrences as required. A CAD file stored in the IGES format, then, can contain information that would lead to understanding of the entities of the design (i.e., bubbles, squares, and edges).

Another entity of interest is the Implementor Defined Entity. This specification allows implementors to include entities in their IGES files that are not defined specifically in the IGES standard. It is, in effect, a generic entity that can be used by CAD programs to define non-standard things. This type of entity could be used as a hook, for example, to hang interesting information that might be needed to interpret designs from IGES file formats.

4.4.4.2 DXF

Another standard that has come about as a result of market competition is the DXF format that is used to save designs from the PC's AutoCAD package. This file format is also used by other competing CAD packages due to AutoCAD's dominance and early presence in the PC CAD arena.
5.0 Image Recognition

This paper has discussed how images (i.e., engineering diagrams) can be scanned into an image file and how that image file can then be manipulated or enhanced through graphics packages, CAD systems, and image processing. Until now, little mention has been made of how to interpret what the scanned and processed image contains that is of meaning. The focus of image recognition is separating the crude bitmap image into its component entities and determining their identity. This may involve identification of shapes, objects, or character text.

There are several areas in which image recognition has been developed into commercially viable products. Two of the applications that have received much attention are Optical Character Recognition (OCR) and Computer Aided Design (CAD). This section will provide an overview of the capabilities in these two areas and a survey of what is currently available in the market place.

The field of image recognition is still an advancing research topic, and there are many unanswered questions and unsolved problems. This chapter will address existing technologies and commercially available applications. The following chapter will address current research in the field of image recognition.

5.1 Optical Character Recognition (OCR)

Optical character recognition is the ability of a computer (whether in hardware or software) to take a scanned image of a page of text and interpret the characters that are in the scanned image to produce an ASCII (or EBCDIC) output file that is the same as the text on the original page. The ASCII file can then be edited by word processors as a document, or the text file can be used by other programs to interpret the meaning of the characters or words.

5.1.1 Origins

Optical character recognition grew in conjunction with the demand of the word processing industry to have an automated facility to input documents from paper to a digitally stored format. With massive amounts of documents to store and process via computer, it was justifiable to find an automatic alternative to hiring typists to enter the text. Since OCR is so intricately associated with the necessary process of digitizing the text image, 25% of all scanners that are currently produced have some OCR capability. Often the bundled software is tailored to the associated hardware. There are other OCR software packages that do not require specific scanner hardware that can read from standard image file formats.

5.1.2 How it Works

Whether the recognizing of characters is done in the scanner hardware, on an expansion card in the computer, or in the software alone, OCR can be divided into three categories based on the algorithms used to recognize individual characters:

- Matrix matching
- Feature extraction
- Hybrid methods
OCR is very important in the solution of automatically "scanning" logic diagrams. Logic diagrams similar to the one in Figure 1-1 contain a relatively high percentage of text, so these methods will be investigated individually.

5.1.3 Matrix Matching

First, most of the low-end OCR software packages use matrix matching, sometimes called font recognition. The OCR software contains a fixed pixel matrix for each character which can be recognized. The OCR starts at the top of the image and isolates a group of pixels using component separation. Component separation is performed using the assumption that each character will be composed of a tightly packed pattern of black pixels with a rectangular area no larger than the template characters. The isolated patterns are often called MRAs, Minimum Regions of Analysis. The isolated pattern of pixels is then matched against each of the known character matrices until a match is found. If the character does not match any of the known characters, the OCR software may choose to ignore the character or ask the user for interpretation.

Matrix matching OCR software has proven useful when recognizing monospaced characters from a restricted number of character fonts and type sizes. Matrix matching software is often capable of "learning" a new character font. The new font may be appended to the existing character matrices or may replace existing character matrices. The time to recognize each character increases and the accuracy of correct character recognition decreases as the number of known character matrices is expanded.

Matrix matching is not robust enough to recognize a new font without having been "trained" on that font. The matrices of each character in each new font must become a member of the set of matrices with which the OCR software compares. Furthermore, if this algorithm is expected to recognize characters with tilted orientations, it must be trained on all orientations of all characters of all fonts. This is obviously prohibitive, and matrix matching OCRs usually cannot recognize tilted text.

5.1.4 Feature Extraction

The next category of recognition methods, feature extraction, is usually used by more expensive OCR software. Feature extraction, sometimes called feature recognition, is based on the principal that every character has a set of distinct features which can be used to identify it. As a document is scanned, an MRA is identified and the features of a potential character within the MRA are determined. These features are compared against the features of known characters until the character is either identified or rejected.

Feature extraction is a much more powerful recognition technology than matrix matching because it is more immune to the effects of image noise, character point size, character font, and character spacing. Complex and decorative fonts may not be recognizable by feature extraction due to the extraneous characteristics for each character. Feature extraction software is more complex to develop than matrix matching software and often is enhanced by the use of context information to improve the accuracy of the recognition process.

Feature extraction software would identify the MRA "q" by determining the region's characteristics. The MRA "q" consists of a circle attached to a vertical line with the circle being located at the top of the vertical line. The letters "q," and "d," and the number "9" consist of a circle on the left of a vertical line. Due to the fact that the vertical line is straight, the number
"9" is eliminated as a possibility. The letter "d" is eliminated as a possibility due to the fact that the circle portion of the character occurs at the bottom of the vertical line instead of at the top.

5.1.5 Hybrid Methods

Alone, both matrix matching and feature extraction OCR produce several errors per page. Finally, a hybrid method of recognition which combines parts of both matrix matching and feature extraction can be used which results in fewer undetected errors. To recognize a character, the hybrid OCR algorithm would check first with a matrix to find an obvious match, then it would look for features that are characteristic of that character to solve any dispute. As a further check, a hybrid OCR algorithm takes the words it finds and looks for them in a dictionary to make sure they exist. Misinterpreted characters are found by the misspelling of the word to which they belong. For example, "The dog sut down" would be found to be "The dog sat down." Needless to say, the hybrid algorithms, though more accurate, can be processor, storage, and time intensive. All algorithms require a human proofreader to catch all of the errors.

5.1.6 Commercially Available OCR

There are an increasing number of OCR packages available. Some are stand-alone software packages, while others come standard as part of an optical scanner.

5.1.6.1 OCR for the PC

According to a DataPro Review in December 1988, the Calera Character Recognition Systems' TrueScan ($2,495) is a good buy because of its low error rate, even on dot matrix quality documents. The software also recognizes lines, tabs and columns. The software outputs the text in a variety of popular word processing formats.

An October 1989 DataPro Review praised the Kurzweil Character Recognition System (Xerox Imaging Systems) products which range from $17,950 on the high end to $2,995 on the low end. This company has a long history of good products in this industry, and the systems run on standard microcomputers. The degree of accuracy can be adjusted to the job by the user. These systems, however, do not support UNIX-based workstations.

5.1.6.2 OCR for the Workstation

Neither the most recent MassComp (Concurrent Computer Corporation) Solutions Catalog nor the latest Sun Microsystems' Catalyst Catalog mention OCR software for the workstation. This is understandable, since it would be trivial to scan in a document on a PC and then upload the document text file to a workstation word processor. Perhaps the price of workstations still prohibits their use as extensive word processing tools.

5.2 CAD Overlaying

In addition to OCR, the need for comprehensive CAD tools has been a driving force in the application of image recognition techniques in commercial CAD software. Though the principle use of CAD software to capture schematics from designers needs no image recognition, the need to capture designs that are already existing on paper into electronic formats has driven the industry to develop some software that requires image recognition.
Many CAD systems provide the ability to bring paper printed designs in through a technique called CAD overlay. The technique is not automatic at all; in fact, it is only a tool to aid in accelerating human reentering of the design. The advantage of this method of reentry is that a less skilled person could perform the job without having to understand the design.

5.2.1 How it Works
To bring a preexisting design into VersaCAD using the overlay technique, for example, one would first scan the drawing into an image file using an optical scanner and its related software. Then one would bring the drawing onto the VersaCAD screen as a background image. Next, the user would choose system-defined (or user-defined) objects such as squares, lines, and bubbles to overlay on corresponding objects in the image. One essentially recreates the design in the VersaCAD system by piecing together (overlaying) objects on the screen. The scanned image acts only as a backdrop to guide a human in the overlay (recreation) process. The result is that the design is transferred from paper to an electronic file format much more quickly than if it were redesigned without using overlays.

5.2.2 Commercially Available CAD Overlay
Both the AutoCAD and VersaCAD systems have software available to them that allow overlay design entry. AutoCAD has a supplemental package called CADOverlay, and VersaCAD has this supplemental software included in it.

5.3 Raster-to-Vector Conversion
The demand for a more automatic way of entering old designs into CAD systems and to store them electronically has brought about the need for computers to be able to "look" at a scanned image and distinguish the entities that make up that design which might be bubbles, squares, lines, text descriptions, etc. Capturing the graphics entities which make up the drawing is done by a process called raster-to-vector conversion. It must be made clear that even though raster-to-vector conversion captures the graphics entities, it still has not captured the meaning of those entities. This means that the NASA problem will require specialized software that is not commercially available to interpret meaning, even if a logic design could be scanned into an electronic format automatically with off-the-shelf software packages.

A scanned image is in a form called raster format, meaning it is just a bunch of bits that represent pixels or dots in the picture. CAD systems, on the other hand, do not store graphics information in raster format, but they use vector information to describe graphics objects. For example, a vector stores a line as a starting point and a length. The other graphics objects, such as a square, have similar vector definitions.

For a computer, the task of interpreting the scanned image into vector format is not trivial. With the advances in image recognition, edge identification and other such algorithms have been developed to the point that software can convert from raster to vector for CAD input. Depending upon the quality of the original, the conversion will have more or less errors. Almost all conversion will have errors that need to be touched up by humans. Nevertheless, this conversion and correction is much faster than manual entry.
5.3.1 Raster-to-Vector Conversion Packages for the PC

The only raster-to-vector software available on the PC is tightly associated with CAD packages. The following are three examples of available PC packages:

- CAD/camera (Autodesk Corporation) $3,000
- CADmate (Microteck Corporation) $995
- ScanPro (American Small Business Computer Corp.) $495

CAD/camera is the pioneer in the field of commercial raster-to-vector software, but without doubt, ScanPro is the best of the three. ScanPro is faster and more reliable. CAD/camera is directly associated with AutoCAD. ScanPro can also produce the vectors in AutoCAD’s DXF format.
6.0 Image Processing/Image Recognition Research

There are currently numerous research projects involving image processing and image recognition. A quick look at the number of papers published in the IEEE Transactions on Pattern Analysis and Machine Intelligence indicates the interest in image processing and image recognition. The following papers were chosen because of their relevance to the proposed solution to the NASA problem. These papers deal with separation of text and graphics and graphics symbol recognition.

6.1 Research in Graphics/Text Separation

"A Robust Algorithm for Text String Separation from Mixed Text/Graphics Images"
IEEE Transactions on Pattern Analysis and Machine Intelligence

The discussion in this research paper is directly related to the proposed NASA solution for several reasons. The paper outlines a process for separating text strings of various font styles and sizes from graphics images which contain both graphics symbols and text strings. This is ideally suited for the NASA solution because of the diversity in the content of the logic drawings currently developed by the different groups at NASA. The paper also provides experimental results which quantify the effectiveness of the algorithm using a Microtek Image Scanner and an IBM PC-AT. The Microtek scanner provides similar functionality to the scanner which NASA has already interfaced to a MassComp workstation. Much of the research being conducted in the image processing and image recognition fields is performed on custom or very expensive hardware. For example, the diagram reader discussed in the next section utilizes four processors and custom wired-logic hardware. The hardware used in this research is very similar to the hardware which is readily available currently at NASA.

Engineering diagrams and logic drawings usually contain graphical symbols and supporting textual labels or descriptions. Fletcher and Kasturi first attack the problem of interpreting drawings and diagrams by attempting to separate the graphics symbols from the text. Two image files are generated from each graphics image of an engineering diagram or logic drawing. The first image file contains the text strings which were in the original graphics image, and the second file contains only the remaining graphics symbols. This allows OCR systems to operate on an image file containing the text strings, and graphics recognition systems to operate only on the graphics symbols. The algorithm described and evaluated in the research paper focuses on the effectiveness of the graphics/text separation.

The Fletcher and Kasturi algorithm is unique in its ability to locate text regardless of the text's orientation, font style, or font size. The algorithm places several restrictions on the text within a drawing, but these guidelines are less restrictive than previously implemented algorithms. For a comparison, note the restrictions placed on the text strings in the following research paper.

The algorithm for separating the text strings from the graphical image consists of the following steps:

- Connected component generation
- Area/ration filter
- Collinear component grouping
• Logical grouping of strings into words and phrases
• Text string separation

The method uses eight connected pixels in the image to find connected pieces of a character. It assigns a bounding rectangle to the connected pixels (the character or a small graphics item) by using the minimum and maximum x and y coordinates associated with the group of pixels. The character or graphics item is then effectively blocked off.

When all the groups that are thought to be characters on the page are bounded, a search is made to find "strings" of text by comparing the centroids of the many bounding boxes. If a given box is found to be collinear with other boxes, it is assumed to be a character, and the entire string is extracted from the mixed image and placed in a separate text image file. With a separate file containing just text, an OCR system can be used on the text image file to determine individual characters. The remaining graphics image file can be converted using the raster-to-vector conversion systems discussed in Section 5.3.

This current research only addresses the issues of separating text and graphics and interpreting each into their respective ASCII and vector codes. It does not address the subject of understanding the logic represented by the graphics symbols or the meaning of the text within the drawing. It does provide a robust algorithm for the first step in the automatic scanning and interpretation of the NASA logic drawings.

6.2 Research in Reading Engineering Designs

"An Automatic Circuit Diagram Reader with Loop-Structure-Based Symbol Recognition"
IEEE Transactions on Pattern Analysis and Machine Intelligence

At Toshiba, much of the initial Large Scale Integration (LSI) engineering design work is still done on paper by engineers. These initial designs drawn on paper are then input into CAD systems for analysis, modification, and production. The process of inputting the hand-drawn engineering diagrams into the computer based CAD system is a time consuming process. An error correction process often follows the transfer from paper to computer.

Five researchers at the Toshiba Research and Development Center in Kawasaki, Japan, have reduced the time consuming process of inputting an engineering diagram into a computer by implementing a custom logic circuit diagram reader for VLSI-CAD data input. The logic circuit diagram reader automatically scans the engineering diagram, interprets the symbols and text of the diagram, and outputs the information contained in the diagram in a format that is usable by a CAD system.

The diagram reader developed by Toshiba is a circuit diagram reader only, and traditional circuit diagrams are composed of two types of symbols: loop symbols and loop-free symbols. Loop symbols are those circuit diagram symbols which are composed of one or more closed loops. The various gate symbols, such as AND and OR gates, are examples of closed loop symbols. Loop-free symbols are those circuit diagram symbols which are not composed of closed loops. The GROUND and RESISTOR symbols are examples of loop-free symbols. Many of the closed-loop symbols used in circuit diagrams are very similar in design with only subtle differences. The circuit diagram reader developed by Toshiba was designed with great emphasis on the correct interpretation of closed-loop symbols.
Closed-loop symbols are recognized in a two stage process. The first stage involves locating and delimiting the regions which contain closed-loop symbols. The Toshiba researchers call this first stage "symbol segmentation." Minimum regions of analysis (MRA) are determined in much the same way they are determined in OCR software. This is possible because each symbol's shape and size is known, due to the fact that the Toshiba prototype requires the diagrams to be drawn using a template.

In the second stage, the delimited regions are analyzed to determine which closed-loop symbol is contained within each region. The Toshiba researchers call the second stage "symbol identification." The second stage uses template matching and feature extraction, also used in OCR software, to perform symbol identification. A decision tree performs the template matching and feature extraction in parallel on each MRA. The decision tree uses the output of both identification methods to identify the symbol. The decision tree allows the software to utilize the advantages of both identification techniques without incurring the inaccuracy of an individual technique.

Figure 6-1 displays the flow of Toshiba diagram reader.

Decision trees allow new symbols to be easily incorporated into both stages. Decision trees also allow the accuracy of the two stages to be improved as more is learned about each stage and the processes are refined.

The Toshiba prototype developers found that the greatest difficulty in introducing their LSI circuit diagram reader was deciding on the drawing rules. The LSI designers requested that the additional drawing rules imposed by the diagram reader be as few as possible. The following rules were imposed to ensure accurate reading of the diagram within reasonable time limits:

- A template of the allowable logic symbols must be used.
- Eight orientations of each symbol are allowed: symbols rotated 90 degrees and their reflections.
- The lines connecting symbols must be drawn with a ruler.
- The shortest allowable line segment length is 2 mm.
- Character labels must be written in a specific font recognized by the OCR portion of the diagram reader.
- Each character must be no larger than 4 mm x 4 mm.
- Characters may be written in two orientations: left to right horizontally and bottom to top vertically.
- Diagram symbols must be at least 1 mm apart, and line segments must be at least 2 mm apart.

The circuit diagram reader implemented by Toshiba is a combination of custom image processing hardware and software. The image input device is a drum scanner which scans 10 lines/second at a resolution of 10 lines/mm. The preprocessing, component separation, and loop-symbol detection portions of the diagram reader are implemented using custom wired-logic circuits. The other processes are performed on two microprocessors and two minicomputers utilizing pipeline and multiprocessing techniques.
The Toshiba diagram reader has been tested on 851 drawings of various sizes, and 79 gate-array LSI's have been developed from drawings read by the diagram reader. The diagram reader can read an A2-size (420mm x 594mm) diagram within 20 minutes. On average, 29 error corrections or rejection modifications are required for each A2-sized diagram. The process of reading an A2-sized diagram and interactively correcting errors or identifying rejected symbols usually takes about 30 minutes when using the diagram reader. Interactively entering a comparable A2-sized drawing without using the diagram reader usually takes about one hour.

A series of ten A1-sized (594mm x 841mm) and A2-sized diagrams were read using the diagram reader. The diagrams were prepared using the established drawing rules and a char-
acter template to improve OCR. Of 2,488 possible symbols, 96.5 percent of the symbols were read correctly, and 2.8 percent of the symbols were unrecognizable by the diagram reader. Only .7 percent of the symbols were incorrectly identified.

The Toshiba reader is an example of a successful image processing application. The Toshiba diagram reader accurately reads logic-circuit diagrams without imposing a large set of unreasonable drawing rules. The diagram reader suffers from the OCR character template, which is not required but recommended, and the amount of custom hardware used to implement the diagram reader. The NASA solution could benefit from the Toshiba concept of melting several techniques to produce a more powerful product.
7.0 Possible Directions Toward A Solution

In light of the concluded survey of commercial optical scanning, image processing, and image recognition systems, several scenarios are possible that would improve the process of converting logic drawings to software. The proposed solution should meet several general guidelines:

- The solution should support the various groups at NASA
- The solution should not require extensive custom hardware
- The solution should address the ultimate goal of automatic generation of exhaustive test algorithms

The preferred scenario would be to scan in the logic drawing using a scanner which is connected to either a NASA workstation or IBM PC. The imported image file would then be processed to improve its quality. Image recognition software would then process the enhanced image file producing a logic description file. This description file would contain all of the logic contained in the original logic drawing and any associated text. The description file would then be converted into a Comp Builder (Computation Development Environment) file which would be batch compiled. The final result would be an installed computation ("comp") and a file describing an exhaustive method for testing the "comp." Such a system does not commercially exist, and research is only now beginning to show progress toward such a solution.

Several intermediary solutions are also possible. The automation path that might be taken is to scan in the logic design using a scanner and the necessary image processing associated with it. Then, convert the raster image to a vector image that can be used in a CAD system. Hopefully, this could be done completely by a system like ScanPro without the use of any overlay package like CADOverlay or the overlay capabilities of VersaCAD. This solution would definitely require human interaction. Existing import facilities are limited in their ability to automatically interpret image files. The CAD design could then be saved as an IGES or DXF file (the DXF file contains more meaning associated with each entity, but the IGES file format is more of an industry standard). At this point, the logic design is described in electronic description files. Custom software would then interpret the description files and produce a Comp Builder file. The remaining steps in the solution would follow the first solution.

Another intermediary solution would be to use computer based software to build the original logic drawings. In this way, a description file would be produced from the user's input instead of from an image file. NASA and its various groups currently use a variety of software based on both PCs and workstations to generate the logic drawings. The solution software must operate on the various group's existing hardware and gain wide-spread acceptance. This solution has been investigated by NASA, and a prototype based on the G2 Real-time AI package has been developed.

1.0 Introduction

Development of flight software at NASA is currently a tedious and time consuming process. One of the more difficult (and nebulous) phases of the development cycle is the certification phase. During this phase, a decision is made as to whether the software can be used during flight operations (i.e., the software is deemed "flight certified").

The typical operating scenario at a console during flight operations at NASA - Johnson Space Center (JSC) involves a flight controller interpreting the real-time data screens downloaded from the vehicle. With recent advances in graphics technology, an effort is underway to provide the flight controller with software which aids in the understanding/interpretation of the data.

A major restriction in the current operations scenario at NASA-JSC is that programs must be (typically) developed by trained programmers. This approach has limitations because the flight controllers must convey to the programmer what actions the software must perform. Many times programmers do not correctly interpret the requirements given to them and develop software which is not exactly what the requestor had envisioned. This limitation is being addressed through the development of simplified programming languages/interfaces (e.g., User Interface Language (UIL), Computation Development Environment (Comp Builder or CODE), etc.) which will allow a nonprogrammer to develop application programs in a controlled environment. While these "user friendly" languages will provide a simplified programming environment, they still will have the restriction that all coding must be performed before flight operations unless some automated certification tool is developed.

This paper discusses techniques which, if implemented, could allow a programming language (if the language is carefully designed) to generate programs during flight operations. The goal of this paper is to discuss the concepts and techniques that would allow the implementation of a language which would assure that a user's program is reproducible and safe (defined as behaving as implemented). The tool described in this paper is termed "flight certified compiler," a term which implies that the tool would develop flight certified software from a noncertified software source code. Criteria for what would constitute a "flight certified compiler" are discussed in Section 2.0 of this document.

The term compiler is used throughout this paper to discuss a software tool which will convert a source language into a target language (not necessarily machine language). The word compiler and translator can be used interchangeably throughout this document.

The flight certified compiler concepts discussed within this paper can be applied to a multitude of target environments. While the original impetus for this paper was based on MCC workstations, the compiler concepts discussed are generic and are not based on a particular operating system or hardware platform. As a result, the concepts presented in this paper can apply to mini-computers as well as mainframes. A worthwhile flight certified compiler should actually operate in all computing environments at NASA so that users are not restricted to a particular operational environment.
2.0 Flight Certified Software

Any software which is run in the Missions Operations Computer (MOC) during flight operations must be "flight certified." Flight certified software, in its traditional sense, is defined as software which has been reviewed by appropriate NASA personnel and, upon execution, will generate correct results and provide reproducible results (given similar input).

2.1 NASA Flight Certified Software

The NASA Flight Control Operations Handbook does not elaborate on how a piece of software becomes flight certified; rather, the handbook leaves the process to the discretion of each Division of NASA.

As a result, for the purposes of this paper and research study, the following section will establish guidelines for what constitutes a flight certified compiler.

2.2 Flight Certified Software Guidelines

The following criteria are recommended as the necessary and sufficient qualifications to term a compiler to be flight certified:

- The target language generated must be reproducible (i.e., the same input WILL ALWAYS generate the same output).
- The target language, when executed, will cause no abnormal events to occur within the host computer or to remote computers attached via a Local Area Network (LAN).
- No combination of source data structures/statements shall cause a program to generate incorrect results (i.e., the program will ALWAYS compute as directed by the user).

In order to achieve each of the above criteria, certain operations must be performed to assure that the grammar behaves as desired. The remainder of this paper discusses techniques and implementation strategies which can be applied in order to develop the desired flight certified compiler.

2.3 Language Alternatives

Over the last five years, several universal programming languages have been defined which have potential uses within the NASA-JSC MCC environment. The most notable is the User Interface Language (UIL) which is an object oriented approach to software development. The reader is referred to the UIL Language Specification for a more detailed discussion.

Another language specification under development by NASA-JSC is the Mission Operations Applications Language (MOAL) which is a procedural oriented language to be used in the development of simple computational algorithms.

While the goal of this paper is not to establish a particular language for the flight certified compiler, the prospective language should contain the following classes of constructs:
Language Alternatives

- Named, strongly typed variables/constants
- Assignment operators
- Loop constructs (pre- and post-conditional loops)
- Conditional constructs (single, and multi-case selection)
- Modularization constructs (e.g., functions)
- Data acquisition constructs (provide a mechanism for programs to efficiently and reliably acquire LAN data)
- Input/output primitives (for retrieval and display of data)

The reader will note that most of the above constructs exist in many higher order languages currently implemented. The goal in developing the flight certified compiler is to provide a target language which would allow users (nonprogrammers) to develop their own software in a highly structured environment. As a result, the remainder of this paper will focus not on the specific constructs of the language; rather, the paper will focus on what techniques need to be utilized to implement a language and allow the resulting tool to be flight certified.
3.0 Language Definition

The following section will provide the groundwork for the establishment of a flight certified compiler. The following sections discuss various theoretical concepts associated with formal language theory. The concepts must be understood and applied to a flight certified language specification before a flight certified compiler can be developed.

The reader must understand the program generation process in order to be convinced that a flight certified compiler is an achievable goal. Simply, the compilation (or interpretive) approach to generating an executable program can be broken into the following steps:

- Scan the input string provided by the user (i.e., the program) into tokens. Tokens are the smallest recognizable element of the grammar being implemented; typically tokens are operators or identifiers which are either organizationally or white space separated.
- The tokens scanned are passed through a parser to determine if the tokens represent a sentence in the target grammar. This is the syntax checking portion of the compilation process. The parser bases its syntactic rules on the way in which the grammar is specified (i.e., all the syntax rules are inherent from the grammar definition).
- Once the string of symbols is verified to be syntactically correct, target code is generated for the provided input language.
- After target code is generated, binding of external modules and variables is performed so that a complete and "executable" module is generated. This completed module may be in the specific form of absolute machine language or could be as general as a table driven environment which requires an interpreter to assist during execution time.

The first step in implementing a flight certified compiler is having the correct definition for the language to be implemented. The language to be implemented must be unambiguous (which will assure the compiler of a single parse tree). The specification of a language syntax is not an obvious and trivial action to perform. It is possible to specify a language which does not provide unique parse trees as well as creating a syntax which never parses (i.e., the parsing process will never complete). Both of these situations are not desirable within the framework of a flight certified compiler.

The following sections discuss techniques which can be utilized to demonstrate that the target language is indeed unambiguous. The discussion begins with brief descriptions of formal notations available to represent the language to be implemented within the flight certified compiler.

3.1 Context-Free Grammars

A context-free grammar (CFG) is notation for specifying the syntax of a language. The hierarchical structure of the language is described in the CFG by a set of terminals, basic symbols from which the strings of the language are formed, and a set of non-terminals, or variables
representing sequences of terminals. Formally, a CFG is denoted with a four-tuple \((V, T, P, S)\) where:

- \(V\) is a finite set of nonterminals (variables),
- \(T\) is a finite set of terminals (\(T\) is disjoint from \(V\)),
- \(P\) is the finite set of production rules. All productions have a nonterminal on the left hand side with a combination of terminals and nonterminals on the right hand side, and
- \(S\) is the start symbol and is a member of the set of non-terminals.

CFGs are characterized by always having exactly one nonterminal on the left hand side of a production. Consider the following example of a CFG:

\[
egin{align*}
\text{<sentence> ::= <noun> <verb>} \\
\text{<noun> ::= boy | girl} \\
\text{<verb> ::= walks | talks}
\end{align*}
\]

The above grammar would allow the generation of the following strings:

- boy walks
- boy talks
- girl walks
- girl talks

The CFG notation is important to the flight certified compiler because using a CFG, it is possible to programmatically determine if a given string of input symbols (i.e., tokens generated from the program under review) constitutes a language within the definition of the CFG.

It is possible to programmatically determine if a set of input symbols represents an allowable string by the use of a derivation tree. A derivation is rooted at the start symbol and represents the hierarchical structure of the production rules - each leaf represents a terminal. The tree is generated by matching input symbols to the left side of a production and creating a higher level node representing the right side. This process stops when the start symbol is generated.

Depending on the basic structure of the desired language, it is possible to develop a CFG which has productions called "epsilon productions." Epsilon productions are productions which, when applied, do not reduce the input symbol set (i.e., we generate another layer in the derivation tree but do not reduce the input set). Epsilon moves occur naturally in many CFGs, but their inclusion does not assure us of always reducing the input set.
Chomsky Normal Form

During application of the grammar against a string of input symbols, it is possible within the definition of a CFG to have multiple derivations. If the derivation tree is applied starting at the left end of the input symbols, a left-most derivation tree is generated. Similarly, if the derivation tree is generated by examining the right-most of the input symbols first, a right-most derivation tree is generated. If the two derivations are not equivalent, we have an ambiguous grammar, that is, two paths representing a single string. Since it is not possible to determine programmatically which path was intended (i.e., by the programmer), an ambiguous grammar does not allow for certifiable software translation.

As stated previously, in order to develop a flight certified compiler, we must have grammar that is unambiguous. CFGs have the property that they will allow for ambiguities within the grammar specification. The following section discusses another grammar form which provides us more of the basic utility required to implement a flight certified compiler.

3.2 Chomsky Normal Form

Chomsky Normal Form (CNF) is any CFG without epsilon moves where the productions always have only either nonterminals on the right hand side or only a single terminal. Algorithms exist which will allow the conversion of a CFG to CNF. The motivation to convert from a CFG to a CNF is yet another notational form, Griebach Normal Form, which requires that we have a CFG with no epsilon moves. Epsilon moves are generated when a production is applied but the input set is not reduced by the new production (with equal number of terminals and nonterminals).

An example grammar in CNF form would be:

\[
\begin{align*}
S &::= BA | a \\
B &::= BB | b \\
A &::= a
\end{align*}
\]

with the set of nonterminals being \{S, A, B\}, the set of terminals being \{a, b\}, and the start symbol being S.

3.3 Griebach Normal Form

Griebach Normal Form (GNF) is any grammar which has no epsilon moves, and all productions start with a terminal symbol and are followed by the number of (possibly zero) nonterminal symbols. The advantage to having a grammar in GNF form is that the input set reduces with every application of a production which will assure that the parsing process will terminate.

An example grammar in GNF form would be:

\[
\begin{align*}
S &::= aAB \\
A &::= bB \\
B &::= c
\end{align*}
\]
LR Grammars

with the set of nonterminals being \{S, A, B\}, the set of terminals being \{a, b, c\}, and the start symbol \(S\).

Grammars in GNF form can be represented by deterministic and nondeterministic pushdown automata. An automaton is a finite state machine which can be used to represent a formal grammar definition. Automata are useful in this discussion because a variety of theorems and corollaries exist which deal with the properties associated with automata and prove correct the process by which automata recognizes strings from a GNF grammar and reject all others.

3.4 LR Grammars

The class of grammars known as LR grammars is a restricted notation of a CFG. LR grammar is defined as a CFG with the annotation that the start symbol does not appear on the right hand side of any production and that a set of nonterminals in each production can be uniquely generated from all productions of the grammar.

The major feature of an LR grammar to this paper is that an LR grammar is always unambiguous. Algorithms exist which can convert a deterministic push down to an LR grammar (refer to the bibliography for literature references).

3.5 Conclusion

Given a prospective grammar to be used for flight operations, the language can be analyzed and manipulated in order to structure the grammar in the forms previously discussed. Once the grammar is in one of the forms, certain assertions can be made about the grammar, for example, that the grammar will absolutely produce reliable and reproducible results. The following chapter of this document will discuss implementation techniques which if applied with these grammar constructs, will provide an environment in which flight certified code could be generated.
4.0 Language Implementation

The implementation of the flight certified compiler can be performed in a variety of computing environments. The certification required of the flight certified compiler falls into two major areas:

- **Language Specification**: The language should be specified in a BNF notation, and the notation should be carefully reviewed before the compiler implementation phase begins. The language should be reviewed for functional completeness by the user community. After review by the user community, the language should be scrutinized to assure that all ambiguities and useless productions are eliminated from the language definition.

- **Compiler Implementation**: The compiler which implements the flight certified language should be a flexible tool implemented to allow the language to be entered in a tabular fashion (i.e., the language constructs are specified in a BNF style so that language modifications are easily accomplished). The design would be to accept the language specification in a BNF form and apply the productions supplied.

Several different implementation techniques exist. This paper will present two different implementation techniques which would be applicable to the compiler. The following sections discuss implementation requirements and suggested strategies.

4.1 Language Specification

The language to be implemented by the flight certified compiler can be a dynamic language; that is, the flight certified compiler should be developed to accept the flight certified language in BNF form. By implementing the flight certified compiler in a table driven fashion, the language can be modified without having to modify the software which implemented the compiler. This implementation strategy will provide a flexible environment which can be changed as needs dictate without forcing the complete recertification of the compiler.

4.2 Implementation Alternatives

Several approaches to implementing the flight certified compiler are available. The language could be executed either in a traditional "compiled" mode (where the source program is translated into machine instructions) or the language could be executed in a "translated mode" (where each statement is interpreted at run-time). Each of the alternatives has advantages and disadvantages which are discussed in the following sections. If funding allows, there would be merit in prototyping both approaches and contrasting them in order to evaluate which provides the better solution.

4.2.1 Machine Code Generation

The first alternative for implementation is to compile the source language into machine language. Such an approach causes the compiler developed to become machine architecture/operating system dependent. In an effort to minimize the dependency risks, the
compiler may actually be developed to translate from the source language to a language already native to the host (hopefully the target language will be portable across host computers).

4.2.1.1 Advantages
Translating the source code to machine code (either directly or through the use of some intermediate high-level language) has several distinct advantages. These advantages are discussed in the following sections.

4.2.1.1.1 Implementation Simplicity
The compilation process from a source language to a target machine language is both mature and well understood. The techniques that would be required to implement the language could be based on proven software concepts.

The approach of translating from one language to another is a well understood and applied principle. Essentially, the compiler has a lookup table which maps symbols between the two languages. Once the original source program is converted to a target program the target program is compiled using an existing compiler. This approach places the overhead on the flight certified compiler to translate the source language to a target language before actually compiling the program.

4.2.1.1.2 Performance
No matter what approach is utilized to implement the flight certified compiler, a performance penalty will be incurred to translate the original source language into some target language. The approach of taking the original source language to machine language will provide an execution speed enhancement over any other alternative. Clearly, a target program in the form of machine code will execute optimally.

The resulting machine code should be optimized to execute in the native implementation environment so that the program will operate at peak efficiency.

4.2.1.2 Disadvantages
The machine code generation implementation strategy has several drawbacks which need to be evaluated. These drawbacks are discussed in the following sections.

4.2.1.2.1 Language Restrictions
A disadvantage to the direct machine code generation process is that the compiler implemented becomes hardware/operating system dependent. As new versions of the operating system, compiler’s native language (i.e., the implementing language of the compiler) and support hardware become available, the flight certified compiler would have to be carefully retested to assure that functionality is the same.

A disadvantage to the translation approach to another high order language is that the host language is limited to the functionality that exists within the target language. That is, the statements of the user input language (the source) will need to closely parallel program structures available within the target language.
4.2.1.2.2 Limited Value Added

If the desired implementation strategy was to simply translate the source language into a host defined language (and then use a COTS compiler to generate machine code), an argument would exist as to why not have the user use the COTS language to begin with. Such an argument would have merit because if we are only “front-ending” a language, this can typically be performed through the use of programming macros. A front-end editor could be developed which would provide a structured program.

4.2.1.2.3 Error Recovery

A distinct disadvantage of the machine code generation approach is the uncertainty of what the execution environment will do in the event of catastrophic program failure. In the event that a catastrophic error occurs, determining what actions should be performed is not always possible. In some instances, a catastrophic failure will abort the entire computer or, in many cases, at least the controlling software.

4.2.2 Table Driven Generation

An alternative approach would be to utilize a table driven execution environment. The table driven approach is a variant of an interpreted language, the primary difference being that in a table driven approach, all syntax analysis and variable binding is done before a program is "termed executable." However, in a table driven approach, the source program is represented in an internal table structure (similar to a parse tree), rather than machine code, and an execution executive exists which interprets the table entries during run-time in order to control the execution of the program.

Table-driven execution environments are not traditionally utilized in the implementation of typical higher order languages; rather, they are a useful implementation technique used with object oriented languages. They provide

the capability to perform upfront syntax analysis as well as variable location binding but do not perform the actual binding until run-time.

4.2.2.1 Advantages

The table driven approach to program execution has several advantages over the traditional generation of machine code. The advantages over the traditional generation of machine language are discussed in the following sections.

4.2.2.1.1 Error Recovery

In a table driven environment, the execution environment typically will perform many boundary analysis operations before a segment of code is allowed to execute. The execution environment should not allow a program to get into a state where abnormal termination would occur; rather, the environment would alert the user and prohibit the code from entering an "unsafe" state.

4.2.2.1.2 Semantic Analysis

One of the greater dilemmas facing the development of a flight certified compiler is the one of "How can I make the code do what I want rather than what I told it to do." Of course, this di-
lemma has plagued all language implementors for years. The table driven approach to implementing the flight certified compiler provides some framework to provide semantic analysis of the code before it is actually executed. In a traditional compiler, where machine code is generated from a source language, the resulting machine code should perform exactly what the programmer requested, no more or no less. Such an environment is not conducive to run time semantic analysis of a program.

The execution environment can be made "intelligent" with imposed operational guidelines which are continuously reviewed before actual execution of a statement begins. The execution environment would necessarily be slowed by the introduction of "computational rules" but the concept would provide a mechanism for NASA to place some type of software checks without actually having to modify a piece of source code explicitly.

4.2.2.1.3 Interactive Debugging

The table-driven approach provides the capabilities to provide a rich debugging environment. The execution of the software can be closely associated with specific source commands. As a result, providing informative diagnostics to the user is assured, as well as more accurate diagnostics.

4.2.2.1.4 Portability

Once a program has been converted to a table notation, the table can be ported to a variety of execution environments (e.g., UNIX, MVS, VM) and executed. This will allow flexibility for the development environment to utilize a variety of computer platforms and move code from machine to machine transparently.

4.2.2.2 Disadvantages

The table driven approach also has several disadvantages when compared to the machine code generation approach. These disadvantages are discussed in the following sections.

4.2.2.2.1 Performance

Since the actual execution environment is essentially an interpretive environment, execution performance will not match that of the machine code environment. If a significant number of "operational rules" are embedded into the execution environment, execution performance will degrade. A careful balance of necessary "operational rules" will need to be applied against performance requirements to determine the optimal mix.

4.3 Implementation Considerations

No matter which approach is to be utilized to implement the compiler, a good and robust parser will need to be developed which can provide a complete syntax analysis of the source code. Since the flight certified compiler is targeted for a nonprogramming user, the error reporting from the syntax analysis phase should be robust and helpful. The parser should pinpoint particular tokens (not simply lines of code) which cause the anomaly.

Additionally, since the trend in computer software technology is to lean toward CASE (Computer Aided Software Engineering), the flight certified compiler should be developed in conjunction with a friendly and robust user interface which provides a simplified programming approach. Such interfaces exist within various computing environments and have proven to
4.4 Conclusions

In order to develop a tool which provides maximum flexibility and feedback to the user, the desired approach would be to use a table driven execution environment. While such an environment imposes a small execution penalty, the benefits of dynamic semantic analysis and error recovery far out weigh the performance impact. Additionally, a table driven approach to implementation would provide a tool with maximum flexibility, which is necessary due to the dynamic software development environment present at NASA.
5.0 Verification

The most complicated and involved phase of the flight certified compiler is that of verification. The verification of the compiler will be intense and expensive to perform; however, having the availability of the flight certified compiler will be cost effective in the long run, because each individually developed program will not have to be certified (i.e., the price of verification is being paid for up front rather than over time).

5.1 Grammar Specification Verification

The first major step of the certification process would be to certify that the grammar developed is unambiguous in nature. The grammar has to be implemented in a fashion that allows all flight certified criteria mentioned in section 2.2 to be met.

The grammar which is decreed to be the final language to be implemented will need to be rigorously reviewed in order to assure that no ambiguities, recursive definitions and statements impossible to realize exist within the grammar specification. This process can be performed by defining the language utilizing traditional BNF specification techniques and then determining if the language is an LR grammar. If so, the grammar specification will meet the criteria that the same input always generates the same output (no ambiguous interpretation of the input data stream).

5.2 Language Implementation Verification

The most difficult phase in the development of the flight certified compiler is the actual verification that the implementation is complete and not subject to generating erroneous results.

The testing of the resulting flight certified compiler needs to be through a good demonstration of software metrics. A rigorous test plan will need to be developed which is capable of performing extensive corner case analysis of each construct associated with the flight certified language. Utilizing existing technology, the testing process will not be highly automated. While it is possible to utilize a computer in assisting with verifying that all possible corner cases are tested, a human being will be required to assure that the translation from specification to actual execution was performed correctly.

It should be noted that implementation verification only demonstrates that the language behaves as designed, it does not provide assurances that user developed programs are correct. While this comment may externally seem to minimize the usefulness of the flight certified compiler, it is actually a strong statement in support; that is, if the language is designed with constructs that will not allow a user to develop applications that will abnormally effect the system, we are assured that all programs written perform exactly what the user directed it to do (i.e., the program can be proven correct).
6.0 Conclusions

The flexibility that a flight certified compiler would provide NASA is worth the effort of continued research. Automating the software certification process will simplify the software development process and will simultaneously allow programs to be developed rapidly as the need arises. Providing a flight controller with the capability to efficiently and reliably generate programs would significantly reduce the typical program development costs which are currently incurred. Additionally, the functionality lost when a flight controller "translates" requirements to a programmer would be minimized.

Additionally, as the Space Station becomes a reality, the practice of having all software completed and certified prior to flight will become difficult. In order for the ground systems to support multi-year flights, they must be provided with the flexibility to generate programs as situations require.

The development of a flight certified compiler should be a task which will not push technology to any unknown limits; the development would primarily be the application of well understood language and compiler techniques. The major limitation of the flight certified compiler is that the compiler can only verify the syntax of the program and assure that the target code generated will not adversely effect the performance of the host computer.

The semantic implication of the program cannot be controlled programmatically; therefore, if an operator devises a program that computes an erroneous result, the flight certified compiler will generate code that reflects that design. However, with the introduction of an intelligent execution environment, partial semantic analysis of a program could be performed in an effort to reduce the incidence of semantic errors.
7.0 Bibliography

ARCHIVE

Purpose: If the choice is to create then all of the files associated with a group are written to a formatted floppy.
CodeGroups/GroupName/ *
AMSUPPORT/GroupName.dat

If the choice is to read, then first the algo_names.dat file is checked to see if that group already exists.
If it exists the user is asked if they want to continue.
If it doesn't exist, then it is added to the algo_names.dat file and all of the files are read into their directories.

If the choice is to list, the files on the floppy are listed in the work area.

Designer: Terri Murphy
Programmer: Terri Murphy
Date: 11/87
Version: 1.0
Project: CODE (Comp Development Environment)
Revised by: Terri Murphy

Reasons for Revision: Added capability for formatting a floppy and aborting. 12/18/87

Edit Box

Logic Box

Variables Box (MSID Signal Local Number)

Types Box (Short Integer Float Character)

Relational Operators (< <= => = <=)
That night in August, the trees were full, the boughs bent and heavy, and the apples -- all but the bright, waxy-green Gravensteins -- were a pale green-going-to-pink. The grass in the rows between the trees was knee-high; there would be one more mowing before the harvest. That night there was an owl hooting from the orchard called Cock Hill; Candy and Homer also heard a fox bark from the orchard called Frying Pan.

The Cider House Rules
John Irving
Purpose: code.c contains the main event loop which handles token processing.

----------------------------------------

External Interfaces

Subroutines:

initGraphics() -- inits windows,background
init_code() -- initializes CODE globals
cleanExit() -- exits code, restores original stuff
menu() -- loops to get moused token selection
msgif() -- MC: gets the active frame buffer
clearWA() -- clears work area window
displayWA() -- display text string in work area window
inform() -- display text in the message window
ask() -- inform(), then prompt for reply
msgfb() -- MC: select a frame buffer
put_if() -- puts the 'if' token
put endif() -- puts the 'endif' token into work area
put_maid() -- put a maid token into work area
put_signal() -- put a signal variable token into work area
put_local() -- put a local variable token into work area
put_lt() -- put a '<' token into work area
put_gt() -- put a '>' token into work area
put_le() -- put a '<=' token into work area
put_ge() -- put a '->' token into work area
put_ne() -- put an '8' token into work area
put_eq() -- put a '=' token into work area
put_add() -- put an '+' token into work area
put_subtract() -- put a '-' token into work area
put_multiply() -- put an '*' token into work area
put_divide() -- put an '/' token into work area
put_shiftL() -- put an 'shiftL' token into work area
put_shiftR() -- put an 'shiftR' token into work area
put_l_paren() -- put a '(' token into work area
put_r_paren() -- put a ')' token into work area
put_and() -- put an 'and' token into work area
put_or() -- put an 'or' token into work area
put_bitXor() -- put an 'bitXor' token into work area
put_bitOr() -- put an 'bitOr' token into work area
put_bitAnd() -- put an 'bitAnd' token into work area
put_then() -- put a 'then' token into work area
put_else() -- put an 'else' token into work area
put_not() -- put a 'not' token into work area
put_number() -- put a number into work area
put_str() -- put a string into work area
put_func() -- put a math function token into work area
put_comma() -- put a ',' token into work area
save() -- saves the current comp/group to file
edit() -- use vi,vred to edit comp's files
retrieve() -- reads comp names for a given group
readCompNames() -- gets comp header info from the user
hardcopy() -- reads comp names for a given group
new() -- creates a new comp or group
get_header() -- gets comp header info from the user
delete() -- deletes the last token from the Comp string
install() -- installs all completed comps
remove() -- removes a comp or a group
archive() -- tars a group to/from floppy
put_pi() -- put the constant pi into work area
token_help() -- provides token description (modal)
mgloadcurs() -- MC: loads in a new graphics cursor
color_valid() -- redraws tokens in correct color (yellow, or red)
put_status() -- puts the comp status on status line in bubble

/*
* Save the resulting new comp
*/
save();
inform("Copy Complete", PURPLE, 2); clearWA();
}

return (OK);
Purpose: Switch_name goes through the comp string and changes the old name to the new name. This routine puts the comp into a string until it finds the CompName, then it passes the comp name, and puts the rest of the Comp in another string. When finished doing this, it copies the first part of the comp into Comp, then cats the new comp name into Comp, then finally, cats the second part of the comp.

        & compLength)
    {
        tokenLength++;  
        compLength--; 
    }
    /* Count up the chars in the indent part */
    while (Comp[compLength-1] != ' ' 
        || Comp[compLength-1] != '
' 
        & compLength)
    {
        tokenLength++; 
        compLength--; 
    }
    return (tokenLength);  
}
Purpose: Demorgans converts a comp into a form that Troy's CLIPS help routine can deal with. Basically, it just puts double quotes around certain CLIPS key words.

Designer: J. Harold Taylor/SDC
Programmer: J. Harold Taylor/SDC
Date: 12/11/86
Version: 1.0
Project: CODE (Comp Development Environment)
Revised by:
Harold Taylor 1-21-87
Added double quotes around '{' and '}'

External Interfaces

Function: getwd

Description:
This function finds the current directory, it is based on the UCB getwd() routine. It was written to temporarily replace the same function in the Masscomp C library (which had severe problems on certain machines).

Inputs:
work_area Pointer-> work space to build path

Returns: Pointer-> work area with completed path

External references:
stat() fstat() bcopy() open() read() write() close() chdir() strings() strlen() exit()

Resources used: None
Limitations: None
Assumptions: None

Written by: Tom Silva, Bruce G. Jackson & Associates

Purpose: This file contains noise filtering routines. There is one noise filter routine for every output routine in the interface. For an explanation of these output routines see the user's guide for IESP. There are two different algorithms used in all the routines discounting types (i.e. short, float, etc.). The simpler routine handles string output, since we don't want to store and compare strings. The more complicated routine handles all numerical data.

/*************** RETRIEVE ***************

Purpose: Retrieve reads in the comp variable file into the CompVars struct, reads the comp language file into a temporary string which is passed to pretty_comp() for formatting and history set-up.

Returns: 0 - OK, no problems.
-1 - File i/o problem.

PRETTY_COMP

Purpose: Pretty_comp takes a temp_comp string from retrieve and formats it nicely. It also sets up the ChoiceCounter integer array which is a token history.

NOTE: This routine treats the comp file like a script and recreates the comp in the screen the same way as if a user were mousing tokens off the screen. The exceptions are: prints, comments, variables, numbers.

Function: strins

Entry specification:
char *strins(into, from)
register char *into, *from;

Description:
This routine inserts a string into another string, it is similar to the
strcat found in the C library (except strcat inserts after).

Inputs:
into Pointer-> target string
from Pointer-> string to insert

Returns:
Nothing

External references: None
Resources used: None
Limitations: None
Assumptions: None

Written by: Tom Silva, Bruce G. Jackson & Associates

Traceability:
Version Date Description
1.0 09/01/87 Initial version

Notes: None

char *strins(into, from)
register char *into, *from;
{
    register char *to;
    register int to_size, from_size;

    /*
    * Find the size of both strings. Include the zero byte for the size of
    * the 'into' string (the zero byte must be moved with the string).
    * Leave the pointers pointing at the zero bytes of the strings.
    */
    for (from_size = 0, *from; from++, from_size++);
    for (to = into, to_size = 1, *to; to++, to_size++);

    /*
    * Slide the 'into' string forward by copying it from it's tail to it's
    * head. It needs to be moved forward by the number of bytes in the 'from'
    * string. Then copy the 'from' string into the open slot.
    */
    for (into = to, to += from_size; to_size > 0; to--, into--, to_size--)
        *to = *into;
    for (from_size > 0; to--, from_size--)
        *to = *from;
Purpose: `wrt_to_doc` writes to the documentation window. It also creates the documentation window and deletes it after it has been written to. `wrt_to_doc` uses "More" to display the documentation.

Purpose: Translate takes the "Higher Level" language comp and creates a C file which is compatible with the INCO Algorithm Manager group/comp format. This routine figures out the spacing for the C file, so as to remove a dependency from the "Higher Level" comp file.

External Interfaces
None.

Global Variables

NumCompVars The number of variables in this comp.

Include files

#include "code.h"

var_check (name, local_index, global_index, class)
- char name[]; /* The name of the passed variable */
- int *local_index; /* The index into the CompVars struct */
- int *global_index; /* The index into the MSIDTable struct */
- char class[]; /* Either msid, signal, or local */

- int i; /* Counter */
- int defined_globally;
- int defined_locally;
- char msg_string[150];
- char temp[100];

Assume the worst--undefined variable

defined_globally = FALSE;
defined_locally = FALSE;
*local_index = -1;
*global_index = -1;

Look for the msid in the struct MSIDTable

if (strcmp (class, "msid") == 0)
{

If there is not MSIDTable then we can't look it up

if (MSIDTable[0].name)
    inform("MSID's will not be verified; the msid table was not found",PURPLE,2);
else
{
    Try to find the msid in the tag_MSIDTable
    for (i=0;i < MSIDCount;i++)
    {
        if (strcmp (name, MSIDTable[i].name) == 0)
            defined_globally = TRUE;
            *global_index = i;
            break;
        }
If we did not find the msid in the msid list
it is undefined and not usable.

if (!(defined_globally))
    {
        *global_index = ERROR;
    }

Look for signals in the struct SignalTable
for (i=0; i < SignalCount; i++)
    {
        if (strcmp (name, SignalTable[i].name) == 0)
            {
                defined_globally = TRUE;
                *global_index = i;
                break;
            }
    }

Always check to see whether the variable
is defined locally to this comp.
for (i=0; i < NumCompVars; i++)
    {
        if (strcmp (name, CompVars[i].name) == 0)
            {
                Return an ERROR if they are trying to use an msid
as a local, signal or something of the sort
if ((strcmp (class, CompVars[i].class) == 0) || (strcmp(class,"null") == 0))
        { *local_index = i;
            defined_locally = TRUE;
            break;
        }
        else /* It is a miss-classing e.g. a local as a signal */
        { return (ERROR);
        }
    }

return (OK); /* The variable is ok */

Purpose: funcCheck checks to see if a given unknown token is
defined in the function list. Return 1 if true, 0 otherwise.

**MODULE FUNCTION:**

Function determines if the user wants to read, write, or list the backup device.
Based on the user's desired action, this function accesses the necessary files
and the backup device. Display_file() is called to show the user the results
of the backup/restore operation.

#define MAX_HEAD_LEN 300

SWITCH_NAME

Purpose: Switch_name goes through the comp string and changes the old name to the new name. This routine puts the comp into a string until it finds the CompName, then it passes the comp name, and puts the rest of the Comp in another string. When finished doing this, it copies the first part of the comp into Comp, then cats the new comp name into Comp, then finally, cats the second part of the comp.

delete.c

 swore: dcrVarList

Purpose: dcrVarList decrements the occurrence of a passed
variable if it finds it in the CompVars structure.
It will also remove the variable from the CompVars
structure if the occurrence count is 0.

Returns: 0 if success, -1 if variable not found.

FILE NAME: graphics.c

FILE FUNCTION:

This file contains the routines which maintain the X Windows user interface. This file does not contain all the graphics routines, see the following files for additional X type stuff:

init_gp.c
utilities.c
window_io.c

SPECIFICATION DOCUMENTS:

/code/specs/code

FILE MODULES:

CreateDefaultImage - creates an image from a bit array
arm_toggle() - sets the toggle state to armed
disarm_toggle() - sets the toggle state to disarmed
get_height() - retrieves the height of the specified widget (pixels)
get_width() - retrieves the width of the specified widget (pixels)
get_x() - retrieves the x coordinate for the specified widget
get_y() - retrieves the y coordinate for the specified widget
popup_wait() - waits for user to select a button in the popup
process_popup() - handles display of popups
set_cycle_mode() - sets the cycle selection mode indicator of the current comp

cleanSlate();
displayWA(Comp);
put_status();

/* Set up the previous choice so the call to color valid in code.c will only allow the choices we allow on startup. */

PrevChoice[ChoiceCounter++] = 99;
RETRIEVE

Purpose: Retrieve reads in the comp variable file into the CompVars struct, reads the comp language file into a temporary string which is passed to pretty_comp() for formatting and history set-up.

Returns: 0 - OK, no problems.
-l - File i/o problem.

return (OK);
/* End of Retrieve */
_topology

Purpose: Pretty_comp takes a temp_comp string from retrieve and formats it nicely. It also sets up the ChoiceCounter integer array which is a token history.

NOTE: This routine treats the comp file like a script and recreates the comp in the screen the same way as if a user were mousing tokens off the screen. The exceptions are: prints, comments, variables, numbers.

* Function: strins
* Entry specification:
  char *strins(into, from)
  register char *into, *from;
* Description:
  This routine inserts a string into another string, it is similar to the
  strcat found in the C library (except strcat inserts after).

* Inputs:
  into Pointer-> target string
  from Pointer-> string to insert

* Returns: Nothing

* External references: None
* Resources used: None
* Limitations: None
* Assumptions: None

* Written by: Tom Silva, Bruce G. Jackson & Associates
* Traceability:
  Version Date Description
  1.0 09/01/87 Initial version

* Notes: None
```c
#define strins(into, from)

register char *into, *from;
{
    register char *to;
    register int to_size, from_size;

    /* Find the size of both strings. Include the zero byte for the size of
     * the 'into' string (the zero byte must be moved with the string).
     * Leave the pointers pointing at the zero bytes of the strings.
     */
    for (from_size = 0; *from; from++, from_size);
    for (to = into, to_size = 1; *to; to++, to_size++)

    /* Slide the 'into' string forward by copying it from it's tail to it's
     * head. It needs to be moved forward by the number of bytes in the 'from'
     * string. Then copy the 'from' string into the open slot.
     */
    for (into = to, to += from_size; to_size > 0; to--, into--, to_size--)
        *to = *into;
    for (from--; from_size > 0; to--, from--, from_size--)
        *to = *from;

FILE FUNCTION:

This file contains the tokens[] array which defines the following information for each CODE push button:

1) availability of help text
2) help text locater
3) comp token input function
4) comp token input function argument

NOTE: do not change the order of the structure elements, as they match the constants defined in: code_const.h

TRANSLATE

Purpose: Translate takes the "Higher Level" language comp and creates a C file which is compatible with the INCO Algorithm Manager group/comp format. This routine figures out the spacing for the C file, so as to remove a depency from the "Higher Level" comp file.

Designer: Troy Heindel
Programmer: Troy Heindel
Date: 7/6/87
Version: 1.0
Project: INCO Expert System Project

FILE NAME: utilities.c

FILE FUNCTION:

This file contains the routines which initialize the X Windows connections and define the X Windows widgets.

SPECIFICATION DOCUMENTS:
/code/specs/code

FILE MODULES:
cleanExit() - kills the X Window connection and exits the Comp Builder
cleanSlate() - initializes the variables used by a Comp
get_type() - determines the data type of currently selected Comp var
get_type_gc() - determines if user wants to del/create a comp or group
getVarIndex() - determines the data type of the variable
hardcopy() - prints the group files
indent() - maintains the indentation and spacing in the comp string
load_font() - loads a logical font
openFile() - opens the specified file and performs error processing
readCODEFile() - reads the CODE file into a given string
readCompNames() - extracts the names of the comps for the current group
readGroupNames() - extracts the names of the available groups
set_size() - sets the Work Area font
str_isalnum() - determines if a string is alphanumeric
writeGroupNames() - writes the group names back to the group name file

FILE NAME: window_io.c

FILE FUNCTION:
Contains the functions which prompt the user and display data to the user.

SPECIFICATION DOCUMENTS:
/code/specs/code

FILE MODULES:
ask () - processes the popup which asks a yes/no question
clear_inform () - takes down the inform() popup
display_file () - opens a disk file and displays it to the user in a popup
display_str () - displays a large string to the user via a popup
displayWA () - display a string to the user in the Work Area
get_string () - prompts the user to enter a string, processes the popup
inform () - displays a message to the user
set_device_tgl () - sets the state of the backup device toggles
set_font_tgl () - sets the state of the Work Area font selection toggles
updateWA () - adds a token to the Comp currently in the Work Area
user_ack () - displays a message to the user in a popup

FILE NAME: init_gp.c

FILE FUNCTION:

This file contains the routines which initialize the X Windows connections and define the X Windows widgets.

SPECIFICATION DOCUMENTS:

/code/specs/code

FILE MODULES:

build_get_name() - builds the get_name() popup
get_defaults() - gets the defaults for sizes, fonts, colors, etc.
init_graphics() - builds all the widgets and popups, opens connection to X
name_to_pixel() - converts a textual name to an X pixel value
select_cursor() - selects the specified cursor shape
set_btm_defaults() - sets the defaults
set_defaults() - sets defaults for the popups and main screen forms

Purpose: This routine does all the necessary stuff to move a comp built using CODE into a group of comps in the INCO Algorithm Manager.

Designer: Terri Murphy & Troy Heindel
Programmer: Terri Murphy & Troy Heindel
Date: 6/1/87
Version: 1.0
Project: CODE (Comp Development Environment)

External Interfaces

openFile() -- generic file opening routine.
save_CompInf0() -- save new comp dispositions.
inform() -- display text in the message window
ask() -- inform(), then prompt for reply
read_vars() -- read variables for a "complete" comp
variable_exist() -- see if the variable is already in the group vars list
write_comp() -- appends "complete" comps .c to group.c
config_mgmt() -- verify proper type of signals and msids
compile_group() -- Compiles the group.c file

SPECIFICATION DRIVEN LANGUAGE

SwRI PROJECT 05-2768
NASA GRANT NAG 3-339

FINAL REPORT

June 12, 1990

Steven W. Dellenback, Ph.D.
Timothy J. Barton
INTRODUCTION

The grant was awarded to perform basic research in the area of alternative methods to develop software programs.

Major efforts performed within the grant included:

- Investigate alternative languages currently in use (CODE, UIL, GOAL)
- Analysis and prototype implementation of CODE (or Comp Builder) in an X-Windows environment
- Investigated alternative user input techniques
- Investigated flight certified compiler concepts
AGENDA

Introduction

- Specification Driven Language Research

Flight Certified Compiler

Image Processing

Conclusion
Goals:

- Provide a screen oriented programming language and/or environment for flight controller applications
- Language and/or environment should be structured so that programs are flight certifiable
- Application must retrieve mission data in a safe and efficient manner
- Language should be portable to the following environments:
  - Space Shuttle (MCC)
  - Space Station (SSCC)
  - Payloads (TSS)
Project Activities:

- Investigated languages used by NASA and other organizations
  - User Interface Language (UIL)
  - Ground Operations Aerospace Language (GOAL)
  - Transportable Application Environment (TAE)
- Evaluated existing NASA prototype - Comp Builder (CODE)
  - Developed BNF representation of CODE language
  - Evaluated CODE software design and implementation
- Assisted in the definition of the environment requirements
  - NASA Computation Builder and Computation Manager Level B Requirements
  - Developed a BNF representation of the Mission Operations Application Language (MOAL)
Project Activities:

- Develop prototypes based on requirements

  - X Windows - HP Widget prototype
    Interface enhancements
    Implementation enhancements

  - X Windows - MOTIF prototype
    Continued interface enhancements
    Implemented MOAL language constructs
AGENDA

Introduction
Specification Driven Language Research

Flight Certified Compiler

Image Processing

Conclusion
Goal:
- To allow a user to develop "flight certified software" automatically (no human certification required).

Definition:
- Target language generation is reproducible
- Execution of the target language will cause no abnormal events on the host computer or any connected LANs (and computers)
- Program will always generate correct results
A language designed for the flight certified compiler should, at a minimum, include the following constructs:

- Named, strongly typed variables/constants
- Assignment operators
- Loop constructs (pre- and post-conditional loops)
- Conditional constructs (single and multi-case selection)
- Modularization constructs (e.g., functions)
- Data acquisition constructs (provide a mechanism for programs to efficiently and reliably acquire LAN data)
- Input/output constructs
Compilation Process
  - Lexical analysis
  - Parsing
  - Code generation
  - Binding
  - Representation Forms
    - Context Free Grammars
    - Chomsky Normal Form
    - Greibach Normal Form
    - LR Grammars
Flight certification will occur in two areas:
- Language Specification
- Language Implementation

Implementation Alternatives:
- Machine Code Generation
  . Generation options
    - Direct generation
    - Intermediate language
  . Advantages
  . Disadvantages
- Table-driven Execution
  . Concept
  . Advantages
  . Disadvantages
- Goal

- Grammar Specification Verification

- Language Implementation Verification
Goal:
- To determine the capabilities of image processing and to determine if an optical scanner COTS package exists which converts logic drawings into 'C' language programs.

Background:
- MCC Flight Control positions currently maintain various types of logic diagrams which are used to check the state of their system
- These logic diagrams are manually converted into Comps
- Several flight control positions manually generate test plans to ensure the logic contained in the Comps matches the logic diagram
- Does a COTS package exist which could automatically generate Comps from the diagrams?
/***************************************************/
Creation Time: 7208:16:42:36    Author: Troy Heindel
Group Name: DSC_STATUS         Comp Name: OF1
Purpose: DSC Status Indicator (p.1-1) (Algorithm #17)
***************************************************/
if V75X2171EC == 0
then print2 "DSC OF1 Byte"
endif
if V76V1500AC == 0 and
   V76V0120AC == 0 and
   V76V0120AD == 0
then print1 "DSC OF1 Fail"
endif
if V75X2171EC == 0 and
   V76V1500AC == 0 and
   V76V0120AC == 0 and
   V76V0120AD == 0
then print1 "OF1 Status"
endif
COTS Package Does Not Exist Which Meets Requirements

Available COTS Software And Hardware:

- Optical scanner hardware is a rapidly expanding market
  - Similar technology to photocopiers and laser printers
  - 250 percent annual growth since 1984
- Optical Character Recognition (OCR) Software
- Computer Aided Design (CAD) Software
- CAD overlay software
- Graphics drawing software
IEEE Transactions on Pattern Analysis and Machine Intelligence Identify Thousands of Research Projects

- Most address more fundamental aspects of image processing or image recognition:
  - Noise reduction and filtering
  - Edge enhancement and edge detection
  - Feature extraction
  - Raster-to-vector conversion
  - Dithering, gray scaling
- As fundamental aspects are established, various technologies are combined:
  - "A Robust Algorithm for Text String Separation From Mixed Text/Graphics Images" - Fletcher and Kasturi
  - "An Automatic Circuit Diagram Reader With Loop-Structure-Based Symbol Recognition" - Toshiba
Input by Drum Scanner

- Preprocessing
  - Component Separation
    - Loop-Symbol Recognition
      - Loop-Free Symbol and Rectangle Recognition
        - Line Analysis
          - Data Management

Data Transfer to CAD System
Conclusions:

- COTS package does not exist
- Technology is rapidly producing the required image processing/image recognition elements
- Research prototypes exist

Research Directions:

- Define drawing standard and prototype scanner/recognition process
- Computer based development environment
AGENDA

Introduction

Specification Driven Language Research

Flight Certified Compiler

Image Processing

Conclusion
- Alternative languages are valuable and useful tools
- Existing languages (e.g. CODE, GOAL) have demonstrated the benefits of utilizing alternative languages
- X-Windows provides a good environment to develop a user interface for program development applications
- Research efforts should continue in the following areas:
  - Alternative Input Techniques
  - Flight Certified Compiler
