PROCESSABLE POLYIMIDE ADHESIVE AND MATRIX COMPOSITE RESIN

ORIGIN OF THE INVENTION

The invention described herein was jointly made by employees of the United States Government and in the performance of work under a NASA contract and is subject to the provisions of Section 305 of the National Aeronautics and Space Act of 1958, as amended, Public Law 85-568 (72 Stat. 435; 42 USC 2457).

BACKGROUND OF THE INVENTION

1. Field of the Invention

This invention relates to the preparation of adhesives, matrix resins for composites, molding powders, films, and laminates, especially those showing enhanced flow with retention of mechanical and adhesive properties.

2. Description of the Related Art

High performance polyimide adhesives are used in the aerospace industry, for example, in joining metals to metals or metals to composite structures. In addition they are rapidly finding new uses as matrix resins for composites, molding powders, and films. These materials display a number of performance characteristics such as high temperature and solvent resistance, improved flow for better wetting and bonding, solvent resistance, high modulus, chemical and hot water resistance, etc. One area of application is in the manufacture of lighter and stronger aircraft and spacecraft structures.

Its structure, as shown below,

![LaRC TPI Structure](image)

is derived from 3,3',4,4'-benzophenonetetracarboxylic dianhydride (BTDA) and 3,3'-diaminobenzophenone (3,3'-DABP) and is prepared in 2-methoxyethyl ether (diglyme). It was invented at NASA Langley Research Center and is a commercially available product sold by Mitsui Toatsu (Mitsui Toatsu Chemicals, Inc., New York) and the Rogers Corporation (D.C. Sherman, C. Y. Chen, and J. L. Cerceca, SAMPE Preprints, 33, 134 (1988)) as a molding powder, poly(amic acid) solution, and film.

2

The commercialization of the 3,3'-DABP component of LaRC-TPI has not occurred in the United States because it has been shown to be a mutagen. (W. D. Ross, J. E. Nobel, J. A. Gridley, J. M. Fullenkamp, M. T. Winiger, and J. A. Graham, "Mutagenic Screening of Diamine Monomers", NASA Contractor Report 166085, Monsanto Research Corporation, February 1983.) Hence, only experimental samples of this chemical can be purchased for research purposes. One U.S. company prepares and polymerizes the 3,3'-DABP in situ, limiting the exposure of workers to this diamine. However, this process is costly.

In addition, the original version of LaRC-TPI (solution of poly(amic acid) in diglyme) appears to have an undesirably large and/or broad molecular weight distribution, containing amine and anhydride functional end groups such that the initial imidized powders do not mold well and exhibit poor melt stability.

We have discovered a way of producing high molecular weight 4,4'-isophthaloyldipthalic anhydride-metaphenylenediamine (IDPA-m-PDA) polyimides (henceforth referred to as LaRC-I-TPI) that have controlled molecular weight through end-capping. These materials are readily processed in their fully imidized form to afford well-consolidated composites, high quality moldings, high strength adhesive bonds, and tough flexible films and coatings.

SUMMARY OF THE INVENTION

An object of this invention is a novel polymer in an endcapped and uncapped form which exhibits melt flow and adhesive properties that make it attractive as a matrix resin for composites, a molding powder, an adhesive, a polymer film, and as a film for coatings.

Another object of this invention is to provide a process for preparing and using aromatic polyimides which reasonably process to make fiber-reinforced composites composed of an organic resin and a reinforcing fiber.

Another object of this invention is to provide a process for preparing and using aromatic polyimides as adhesives that can be reasonably processed to give materials with high bonding strengths and thermooxidative stability.

Another object of this invention is to provide a process for preparing well-consolidated polyimide moldings by heating imidized powders at high temperatures and pressures.

Another object of this invention is to provide a process for preparing thin films and coatings by heating a poly(amic acid) solution on a substrate.

The need for new and less expensive polyimide monomers of low toxicity for preparing high performance materials has been satisfied in the combination of 4,4'-isophthaloyldipthalic anhydride (IDPA) and metaphenylenediamine (m-PDA), which is designated LaRC-I-TPI and is shown below.
This new composition is based on a low toxicity, non-mutagenic, commodity diamine (metaphenylenediamine); the polyimide is an isomer of the commercially available LaRC-TPI, both being C_{30}H_{14}N_{2}O_{6} polyimides. The IDPA monomer is readily synthesized by standard techniques and is inexpensive. Because of similarities in the structures of LaRC-TPI and LaRC-I-TPI, one might expect them to have similar properties. Thus, one can obtain LaRC-I-TPI-like properties while avoiding the pitfalls of working with 3,3'-DABP, a suspect carcinogen.

This composition has been realized in LaRC-I-TPI (isomeric TPI), a material found to behave similarly to LaRC-TPI in certain properties such as Tg, film forming ability, solubility, and isothermal thermogravimetric analysis weight loss. Of special importance is the fact that by preparing isomeric TPI with suitable endcaps, we have generated adhesives, composite resins, cured in air for one hour each at 100° C., and showed no evidence of crystallinity.
EXAMPLE 4
IDPA-m-PDA, Offset Stoichiometry, 10 mol % Anisidine
A solution of m-PDA (0.0723 g, 6.68 x 10^{-4} mol, 95 mol % theoretical) and anisidine (0.0087 g, 7.06 x 10^{-5} mol, 10 mol %) end-cap was prepared in 1.5240 g of DMAc in a dried and stoppered vaccine bottle to give a final solution of 20% solids. The IDPA (0.3000 g, 7.036 x 10^{-4} mol, 100 mol % theoretical) was then added, and the mixture was allowed to stir at 25°C overnight with a magnetic stirrer. The inherent viscosity was 0.32 dl/g at 35°C in DMAc. A 20 mil wet film was cast onto glass, air dried, and cured to 300°C in air. Brittle pieces of film resulted, showing no crystallinity and having a Tg of 246°C. (DSC).

EXAMPLE 5
IDPA-m-PDA, Balanced Stoichiometry, No End-Cap
A solution of m-PDA (2.029 g, 0.01876 mol) in 40.12 g DMAc was prepared in a small screw-cap, dried glass bottle. IDPA (0.000 g, 0.01876 mol) was added in one charge, and the mixture was allowed to stir with a magnetic stirrer overnight at 25°C. The final poly(amic acid) solution had a concentration of 20% solids. The inherent viscosity was 0.52 dl/g, in DMAc at a concentration of 0.5% (wt/vol). The solution was stored in the refrigerator until needed.

EXAMPLE 6
Balanced Stoichiometry, 4 Mol% Aniline End-Cap
A solution of 0.5148 g DMAc and 0.0761 g m-PDA was prepared. IDPA (0.3000 g, 7.04 x 10^{-4} mol) was added and stirred at 25°C for one-half hour. The aniline end-cap (0.0026 g, 4.0 mol %) was then added and stirred overnight. The inherent viscosity of the resulting solution was 0.40 dl/g at 35°C in DMAc. A 20 mil wet thickness film was dried and cured to 300°C in air. The resulting gold-colored film was creasable and insoluble in refluxing DMAc, methylene chloride, and m-cresol. The DSC revealed no crystallinity and a Tg of 253°C.

EXAMPLE 7
Balanced Stoichiometry, 4 mol %, 4-Fluorophthalic Anhydride End-Cap
A solution of 1.5228 g DMAc and 0.0761 g m-PDA was prepared. IDPA (0.3000 g) was added and stirred one-half hour at 25°C. The end-cap, 4-fluorophthalic anhydride (0.0046 g, 4 mol %) was then added and the solution stirred at 25°C overnight to make the solution 20% solids. The inherent viscosity of the poly(amic acid) solution was 0.39 dl/g at 35°C in DMAc. A film (20 mil wet thickness) cast on soda-lime glass was dried in a low humidity chamber and cured for one hour each at 100°C, 200°C, and 300°C. The film was gold-colored and snapped on attempted creasing. It was insoluble at the 1% level in refluxing DMAc, methylene chloride, and m-cresol and had a Tg of 247°C. (DSC). No crystallinity was observed by DSC.

EXAMPLE 8
IDPA-m-PDA, Balanced Stoichiometry, 4 mol % Phthalic Anhydride End-Cap
A solution of 2-methoxethyl ether (diglyme), 39.00 g and DMAc, 111.4 g was mixed with m-PDA (7.6093 g, 0.070382 mol), Phthalic anhydride (0.4169 g, 4 mol %) was added and allowed to stir for one-half hour at 25°C. The IDPA (30.000 g, 0.070356 mol) was added and a large exotherm was observed. After three hours the 20% solution was refrigerated. The inherent viscosity was 0.43 dl/g at 35°C in DMAc. This poly(amic acid) solution was stored at 0°C until ready for adhesive bonding.

EXAMPLE 9
IDPA-m-PDA, Balanced Stoichiometry, 2.75 mol % Phthalic Anhydride End-Cap
The procedure of Example 8 was repeated except that 0.2866 g (2.75 mol %) of phthalic anhydride was used as the end-cap. After stirring at 25°C overnight the viscosity of the poly(amic acid) solution was determined to be 0.51 dl/g at 35°C in DMAc. The solution was stored at 0°C until used.

EXAMPLE 10
Preparation of Graphite Polyimide Prepreg
The composition according to Example 5 dissolved in N,N-dimethylacetamide, was coated on unidirectional graphite fiber at approximately 30% by volume (resin solids to fiber) to form a prepreg. This prepreg was air dried at ambient conditions until it was tack-free and then dried in a forced air oven at 191°C for one and one-half hours.

EXAMPLE 11
Preparation of Graphite Polyimide Prepreg
The composition according to Example 8 was dissolved in DMAc and was used to prepare prepreg according to Example 10.

EXAMPLE 12
Preparation of Composites
The prepregs from Examples 10 and 11 were placed in separate matched metal molds and each was heated to 204°C where 300 psi pressure was applied. They were further heated to 350°C and held under pressure at that final temperature for one hour. The molds were cooled under pressure to ambient temperature and the pressure was released. Well-consolidated composites resulted in both cases with the end-capped composition exhibiting the higher degree of flow.

EXAMPLE 13
A solution of the composition of Example 5, i.e., IDPA-m-PDA, 20 wt. % solids in DMAc, was used to prepare an adhesive tape as follows. The above solution was diluted to 7.5 wt. % solids in DMAc and applied to style 112, A1 100 ft E-glass cloth which had been obtained (1) room temperature, (RT), held approximately 50 minutes; (2) RT to 100°C, held one-half hour; (3) 100°C to 150°C, held one-half hour; (4) 150°C to 175°C, held one-half hour. The area to be bonded was coated (primed) on each adherend with the 20 wt. % solids solution of IDPA-m-PDA and air dried.
for one-half hour; it was heated 15 minutes at 100° C. and 15 minutes at 150° C. prior to bonding with the adhesive tape.

The above prepared adhesive tape was cut into strips sufficient to cover the bond area so as to give a 1.27 cm overlap for the previously prepared (Pasa Jell 107) titanium alloy (Ti-6Al-4V) four-fingered panel adherends. The tape was placed between the overlapped panels and the specimens were assembled in a bonding jig in a manner as to hold the specimens securely while being bonded. The assembly was placed in a hydraulic press and 2.07 MPa (300 psi) pressure was applied. The temperature, which was monitored by a thermocouple spotwelded next to the bondline of one of the specimens, was increased from RT to 343° C. over a period of approximately 40 minutes. The temperature of the specimen was held at 343° C. for one hour, while pressure was maintained at 2.07 MPa (300 psi). The heat was turned off and the press allowed to cool, under pressure, to less than 150° C. At that time the bonded panel was removed from the press and the bonding jig, the individual lap shear specimens were separated with a metal shearer, and the lap shear strengths were determined according to the procedure for ASTM D-1002.

Four specimens tested gave an average of 18.5 MPa (2680 psi) at RT, 22.9 MPa (3320 psi) at 204° C., and 20.8 MPa (3030 psi) at 232° C. Failures were primarily cohesive.

Example 14. Adhesive Tape Preparation and Bonding

A solution of the composition of Example 8, i.e., IDPA-m-PDA, 4 mol % PA, 20 wt. % solids in diglyme/DMAC, was used to prepare an adhesive tape and bond Ti-6Al-4V adherends in the same manner as in Example 13. At least four lap shear specimens were tested at each test temperature: RT, 204° C., and 232° C. Average lap shear strengths were: RT, 29.4 MPa (4260 psi); 204° C., 24.5 MPa (3560 psi); and 232° C., 18.0 MPa (2610 psi). Failures were primarily cohesive.

Example 15. Adhesive Tape Preparation and Bonding

A solution of the composition of Example 9, i.e., IDPA-m-PDA, 2.75 mol % phthalic anhydride, 20 wt. % solids in diglyme/DMAC, was used to prepare an adhesive tape and bond Ti-6Al-4V adherends in the same manner as in Example 13. Average lap shear strengths for four tested specimens at each test temperature were: RT, 25.0 MPa (3620 psi); 204° C., 24.3 MPa (3520 psi); and 232° C., 12.0 MPa (1740 psi). Failures were cohesive at 204° C. and a combination of cohesive/adhesive at RT and 232° C.

Example 16. Preparation of Neat Resin Mouldings from IDPA-m-PDA (Unencapped) and 2.75 mol % Phthalic Anhydride Endcapped Polyimides

The poly(malic acid) solutions from Examples 5 and 9 (unencapped and 2.75 mol % phthalic anhydride and endcapped, respectively) were separately precipitated in a blender from deionized water. The powders that resulted were washed twice each in a blender with water and air-dried overnight under the hood. They were then imidized for one hour each at 100° C., 150° C., and 300° C. One gram of each powder was introduced in a circular mold which had been pretreated with Frekote 33 releas-
13. A high temperature defect-free coating formed by coating a poly(amic acid) solution of the composition of claim 2 upon a substrate and thermally imidizing the coating.

14. A high temperature defect-free coating formed by coating a poly(amic acid) solution of the composition of claim 3 upon a substrate and thermally imidizing the coating.

15. A creasable, transparent, high temperature film formed by casting a poly(amic acid) solution of the composition of claim 1 upon a substrate, drying the cast solution to form a film, thermally imidizing the film, and removing the thermally imidized film from a substrate.

16. A creasable, transparent, high temperature film formed by casting a poly(amic acid) solution of the composition of claim 2 upon a substrate, drying the cast solution to form a film, thermally imidizing the film, and removing the thermally imidized film from a substrate.

17. A creasable, transparent, high temperature film formed by casting a poly(amic acid) solution of the composition of claim 3 upon a substrate, drying the cast solution to form a film, thermally imidizing the film, and removing the thermally imidized film from a substrate.

18. An adhesive prepared from metaphenylene diamine reacted with 4,4'-isophthaloyldipthalic anhydride.
