March 1990
Abstract

The ability to easily manipulate objects in a zero gravity environment will play a key role in future space activities. Emphasis will be placed on robotic manipulation. This will serve to increase astronaut safety and utility in addition to several other benefits. It is the aim of this research to develop control laws for the zero gravity robotic end effector designed by engineers at NASA Goddard. A hybrid force/position controller will be used. Sensory data available to the controller are obtained from an array of strain gauges and a linear potentiometer. Applying well known optimal control theoretic principles, the control which minimizes the transition time between positions is obtained. A robust force control scheme is developed which allows the desired holding force to be achieved smoothly without oscillation. In addition, an algorithm is found to determine contact force and contact location.

1 Introduction

There is no doubt that the task of gripping and handling objects in space is an important one. Much diagnostic servicing and repair of existing space structures (e.g. satellites) require physical manipulation of the structure. Processing materials in space is an essential step in the evolution of space technology. With the goal of constructing large space structures in mind, earth based processing becomes both physically and economically impractical. This fact demands that the processing of materials be moved to the construction site...into space.

It is evident, then, that robotic manipulation must play a vitally important role in the future of space activities. Already, telerobotic manipulators have been successfully employed in a full range of important space activities (e.g. satellite retrieval). Thus, the design of lightweight, dexterous robotic manipulators has become a significant and indispensable component of aerospace research and development in the past few years.

Designing the end effector portion of the space manipulator, one must address the problems associated with gripping objects in a zero gravity environment. Reaction forces and torques which are usually damped by various mechanisms (gravity, friction, interaction with the atmosphere) on earth, can create problems in space where these mechanisms are absent. For example, an astronaut attempting to turn a valve on a relatively large space vehicle must be securely attached to the vehicle, otherwise, instead of turning the valve, the torque created will serve to turn the astronaut relative to the vehicle. This is by no means the only difficulty. Consider the following scenario: A master slave arm is being used to link beams for a large space structure. The sockets used to link the beams are transported on trays to the locations of the beam joints. Due to the zero gravity environment, the sockets must be fixed in place by some type of fastener to ensure they remain on the tray. Designing the end effector to release the fastener while maintaining a firm grasp on the socket will solve both the problems associated with torques and reaction forces, as well as the problem of minor perturbations dispersing the sockets in random directions.

Along this line of thinking, NASA has developed the gripper/nut runner. This specially designed end effector has two fingers which together have one degree of freedom. Similar to a vice, the width of the opening is the only variable. Centered between the fingers is a device for unscrewing nuts. Having one degree of freedom, the nut runner will be actuated by wrist rotations.

The aim of this research is to develop control laws (in some optimal sense) for the gripper portion of the end effector. A hybrid force/position controller will be used. Sensory

\footnote{The term \textit{space} will be used synonymously with the term "zero gravity environment".}
data available to the controller are obtained from an array of strain gauges as well as a linear potentiometer. Applying well known optimal control theoretic principles, the control which minimizes the transition time between positions is obtained. A robust force control scheme is developed for smoothly achieving the desired holding force without oscillation. An algorithm is found to determine contact force and contact location in order to ensure a secure grasp.

2 End Effector Model

For analytical purposes it is necessary to establish a mathematical model of the system. The model development will be broken down into three sections. The first section details the actuator model. The basic model is standard and is available from various engineering texts. Added to the model in the second section are the effects of the gearing and the inertia of the mechanical system. Finally, the third section gives the complete system transfer function, as well as the position and force transfer functions.

2.1 Actuator Model

The finger actuator is a permanent-magnet DC motor. Models for these motors can be obtained from various sources [1], [2]. The equations for the motor are as follows:

\[
J_m \omega_m(t) = T_m(t) - T_L(t) \tag{2.1}
\]

\[
L_a i_a(t) = e_a(t) - R_a i_a(t) - e_b(t) \tag{2.2}
\]

\[
T_m(t) = k_i i_a(t) \tag{2.3}
\]

\[
e_b(t) = k_b \omega_m(t). \tag{2.4}
\]

Selected for the actuation, the TRW 5A540-10 MM Planetary Gearmotor is manufactured with gears inside the motor housing. The gearing has the effect of decreasing the angular velocity and increasing the torque. The gear ratio is 27.94 and the minimum efficiency is 0.6. A summary of the system constants can be found in Table 1; these constants include effects of the internal gearing. Motor variables are summarized in Table 2. Additional frictional terms have been neglected in the model development. They will be treated as disturbances to the control system.

#### 2.2 Mechanical Model

The transmission mechanism used is an acme screw. The acme screw serves to transform rotary motion of the motor to linear motion needed to move the fingers. A screw with a small lead angle, $\ell = 1.6 \text{ mm}$, was used so that larger finger tip forces could be developed while using a smaller motor. As a trade-off, the maximum velocity attained during opening and closing is lower. Another benefit of having a small lead angle is that the screw is self locking under reasonable load conditions. This is an important feature since it will allow the end effector to hold objects without using power. This property helps to eliminate problems created because of poor heat dissipation in space.

Used to link the motion of the fingers, the rack and pinion gear’s effect is to move the fingers at the same velocity in opposite directions. The model, which is developed for the force and velocity of one of the fingers, is affected only by the efficiency, $\rho$, of this gear.

Deformations of the finger components are assumed to be negligible. This assumption is reasonable since operating forces are far below the magnitude necessary to result in significant deflections of the aluminum body. Because the motion is strictly linear the moving parts in the finger assembly are treated as a point mass. The mass of the moving parts is approximately 1.14 kg.

Since the errors due to backlash caused by the gears (the motor’s internal gears, the acme screw, and the rack and pinion) will be within desired positioning accuracy of $\pm 0.25 \text{ cm}$, they can be ignored in the model development. Position control will be employed only to achieve an approximate desired finger opening; force control will be used upon encountering an object. Therefore, a coarse positioning scheme will be sufficient.

Ideal gears are initially assumed in the derivation. A gear is termed ideal if it has no moment of inertia, no friction, and a perfect meshing of teeth. For an ideal screw, the translation from angular velocity of the motor output shaft to linear velocity of the fingers is

$$ V_L(t) = \frac{\ell}{2\pi} \omega_m(t) \quad (2.5) $$

and the transformation from torque to force is

$$ F_c(t) = \frac{2\pi}{\ell} T_c(t) \quad (2.6) $$

where $T_c(\cdot)$ and $F_c(\cdot)$ denote the coupling torque and force respectively between the screw and the nut. Then from D’Alembert’s Law for torques and Newton’s Law for forces

$$ J_m \omega_m(t) = T_m(t) - T_c(t) \quad (2.7) $$
$$ F_L(t) = F_c(t) - m \ddot{V}_L(t). \quad (2.8) $$

3
Combining these equations and applying the screw equations 2.5 and 2.6 yields

\[ F_L(t) = \frac{2\pi}{\ell} T_m(t) - \left( \frac{2\pi}{\ell} \right)^2 J_m + m \dot{V}_L(t) \]  

(2.9)

Of course in reality gears are not ideal. To correct for this efficiency terms, \( \mu \) and \( \rho \), are incorporated into the model to account for the losses in the non-ideal screw and rack and pinion gears respectively. For an acme screw the efficiency is approximately 0.4, and for the rack and pinion 0.7.

\[ F_L(t) = \mu \rho \frac{2\pi}{\ell} T_m(t) - \left( \frac{2\pi}{\ell} \right)^2 J_m + m \dot{V}_L(t) \]  

(2.10)

For simplification define \( M \triangleq \left( \frac{2\pi}{\ell} \right)^2 J_m + m \) and \( F_m(t) \triangleq \mu \rho \frac{2\pi}{\ell} T_m(t) \) yielding the final dynamic equation

\[ F_L(t) = F_m(t) - M \dot{V}_L(t). \]  

(2.11)

By combining equations 2.2-2.5 the final electrical equation is found to be

\[ \mu \rho k_i e_a(t) = \frac{\ell}{2\pi} (L_a \dot{F}_m(t) + R_a F_m(t)) + \mu \rho k_i k_b \frac{2\pi}{\ell} V_L(t) \]  

(2.12)

A summary of the model constants is given in table 1.

2.3 System Transfer Functions

By taking the Laplace transform of equations 2.11 and 2.12 and rewriting them in matrix form, the system transfer matrix is:

\[ \begin{pmatrix} F_m(s) \\ F_L(s) \end{pmatrix} = \frac{1}{\frac{\ell}{2\pi} (L_a s + R_a) M s + \frac{2\pi}{\ell} \mu \rho k_i k_b} \begin{pmatrix} \frac{2\pi}{\ell} \mu \rho k_i k_b & \mu \rho k_i M s \\ -\frac{\ell}{2\pi} (L_a s + R_a) & \mu \rho k_i \end{pmatrix} \begin{pmatrix} F_m(s) \\ e_a(s) \end{pmatrix} \]  

(2.13)

When calculating the position transfer function, \( P(s) = s V_L(s) \), the load force, \( F_L(s) \), can be assumed to be identically zero. This is justifiable since position control mode will only be used if there are no external load forces. The position transfer function is

\[ P(s) = e_a(s) = \frac{\mu \rho k_i}{s \left( \frac{\ell}{2\pi} M L_a s^2 + \frac{\ell}{2\pi} M R_a s + \frac{2\pi}{\ell} \mu \rho k_i k_b \right)}. \]  

(2.14)

The force controller will only be used once a contact force has been detected on one of the fingers. Recall that the target object must be bolted firmly in place in a zero gravity environment. Thus once contact is made, position will become constant forcing the velocity to zero. From equation 2.11, this implies that the load force, \( F_L \), equals the motor force, \( F_m \). With these additional constraints the force transfer function is

\[ \frac{F_m(s)}{e_a(s)} = \frac{\frac{2\pi}{\ell} \mu \rho k_i}{L_a s + R_a}. \]  

(2.15)

3 Position Controller

Available from a linear resistive potentiometer, the position information is accurate to \( \pm 0.25 \) cm. For the purpose of controller development further mechanical detail of this sensor is not needed.
3.1 Model Verification

By measuring the gripper's response to a series of sine waves of varying frequencies, the true Bode plot for position may be obtained (figure 1). The accuracy of the true Bode plot for frequency greater than about 3 Hertz is extremely poor due to backlash in the system; this is essentially the mechanical cutoff frequency of the system. System performance will not be adversely affected by this low cutoff frequency since the fingers are not intended to make rapid changes in direction.

The actual Bode plot reveals that for the range of operation of the system, only first and possibly second order dynamics are evident. This implies that the third order dynamics caused by the nonzero inductance can be ignored, and thus it can be assumed that the inductance is zero when developing the position controller. Additional friction inherent in the system is apparent in the diminished response of the actual Bode plot.

3.2 State Space Realization

Substituting $L_a = 0$ into equation 2.14 gives:

$$P(s) = \frac{\mu p k_1}{s(\frac{1}{2} M R_a s + \frac{2\mu p k_1 k_b}{s} + s^2 + c_2)} = \frac{c_1}{s(s + c_2)}.$$  \hspace{1cm} (3.16)

This transfer function describes a stable linear time invariant system which has one input, the control voltage $e_a(\cdot)$, and one output, the finger position $P(\cdot)$. The minimal realization has two states, finger position $P(\cdot)$, and finger velocity $V_L(\cdot)$. In state space form, the minimal system is written as

$$\begin{cases} \dot{x}(t) = Ax(t) + bu(t) \\ y(t) = cx(t) \end{cases}$$ \hspace{1cm} (3.17)

where

$$A = \begin{pmatrix} 0 & 1 \\ 0 & -c_2 \end{pmatrix}, \quad b = \begin{pmatrix} 0 \\ c_1 \end{pmatrix}, \quad c = (1 \ 0).$$  \hspace{1cm} (3.18)

Note that since this realization is minimal, it is both controllable and observable. Also, stability of the system guarantees that the eigenvalues of $A$ have nonpositive real part.

3.3 Optimal Position Controller

It is desirable to determine the control which moves the fingers from the initial state (position, velocity), $x_0 = (x_0 \ 0)'$, to the desired final state, $x_f = (x_f \ 0)'$, in minimum
time with the constraint that $|u(t)| \leq M$. Such problems have been extensively studied in optimization theory. The solution to the minimum time problem follows from the well known Pontryagin Minimum Principle (PMP)\[3\].

Since the system is linear and controllable, a time optimal control, $u^*(t)$, that transfers the initial state $x_0$ to $x_f$ would clearly exist if there were no bounds on the control action. Even with the bounds on the control function, the reachable set at each finite time is convex and bounded and contains the origin. Therefore a time optimal control exists by simple translation of the origin.

Applying PMP it can be shown that the optimal control has the form $u^*(t) = -M \text{sgn}(b'p^*(t))$, where the costate $p^*(t)$ satisfies $\dot{p}^*(t) = -A^*p^*(t)$.

The Pontryagin Minimum Principle provides both necessary and sufficient conditions for optimality since the system is linear and the constraints convex. Finally the Hamiltonian has a unique global minimum (since it is a minimization of a linear function over a compact convex set). From this and the sufficiency it follows that the optimal control is unique.

3.3.1 Switching Time

The conditions of PMP do not contain any explicit information regarding either the initial costate, $p^*(0)$, or the terminal costate, $p^*(T^*)$. However, they do imply that the costate, $p^*(t)$, must be a nonzero vector $\forall t \in [0, T^*].$

The set of feasible controls, $\mathcal{F}$, is practically limited by the maximum armature voltage, which implies $M = 24V$. And since $b'p^*(t) = c_1p_2(t)$, and $c_1 > 0$, the set of feasible controls is

$$\mathcal{F} = \left\{ u : \begin{cases} u = M \text{sgn}(p_2(t)) & \text{if } p_2(t) \neq 0 \\ |u| \leq M & \text{if } p_2(t) = 0 \end{cases} \right\}. \quad (3.19)$$

Another physical constraint is that the control be continuous. Thus if $p_2$ changes sign the control must vary continuously from $M$ to $-M$. The times at which $p_2 = 0$ are termed the switching times. The switching times vary with the initial and final states.

The solution of the costate equation is

$$p_1^*(t) = p_1^*(0) = \text{constant} \quad (3.20)$$
$$p_2^*(t) = \left( p_2^*(0) - \frac{1}{c_2} p_1^*(0) \right) \exp(c_2) + \frac{1}{c_2} p_1^*(0) \quad (3.21)$$

Since $p_2^*(\cdot)$ is monotonic in $t$, the control voltage changes sign at most once. Without information of the initial or final costate, the switching time cannot be determined from these equations.

Disregarding the question of determining the initial or final costate, it is desirable to investigate which control among the feasible set, $\mathcal{F}$, steers the given initial state to the desired final state. Solving the state equation yields

$$x_1(t) = x_0 + \frac{c_1 u(t)}{c_2} t + \frac{c_1 u(t)}{c_2^2} (1 - \exp(-c_2 t)) \quad (3.22)$$
$$x_2(t) = -\frac{c_1 u(t)}{c_2} (1 - \exp(-c_2 t)). \quad (3.23)$$

By substituting for $u(\cdot)$ in equations 3.22 and 3.23, one can determine the feasible control which achieves the desired goal. This control is the optimal control.
Notice that the optimal control is directly a function of time, and indirectly a function of position. In order to make the controller robust to disturbances, it is necessary that the dependence on position be made more precise. That is, a more desirable form for the control would be

\[
u(x) = \begin{cases} 
24 & x_0 \leq x \leq \alpha \\
-24 & \alpha < x \leq x_f \\
0 & \text{elsewhere}
\end{cases}
\]  \hspace{1cm} (3.24)

where \(\alpha\) is the optimal switching position and \(x_0\) and \(x_f\) are the initial and final positions respectively.

Using CONSOLE\(^2\), a parametric optimization package, along with SIMNON, a non-linear simulator, the optimal switching position \(\alpha\) was determined. In every case the switching position was found to lie within the position error margins of \(\pm 0.25\) cm.

### 4 Force Controller

Strain gauges have been widely used in the field of stress analysis since 1940. They are one of the most accurate, sensitive, versatile and easy-to-use sensors available; but in spite of this, the proper and effective use of them requires a thorough understanding of their characteristics and performance [6].

Strain data is obtained from an array of four strain gauges on each finger (figure 2). From the strain data, both contact position and force can be calculated. This information will be used to control the holding force as well as to detect an improper grasp.

The ability to detect an improper grasp is important since a dropped object may not be easily retrieved. By calculating the contact force and contact locations the security of the grasp as well as the control action needed to correct any errors may be determined. Since the dimensions of the target objects are known, position information may be useful as well. Examples of possible grasp configurations are given in figure 2.

#### 4.1 Mechanical Model

In this section a functional mapping, \(H\), is derived to approximate the mapping

\[
e = H \begin{pmatrix} F \\ d \end{pmatrix} : \mathbb{R}^6 \times \mathbb{R}^6 \rightarrow \mathbb{R}^8
\]  \hspace{1cm} (4.25)

\(^2\)The implementation details of CONSOLE and SIMNON can be found in [4] and [5] respectively.

Table 3: Force Sensor Parameters
where

\[ \mathbf{F} = \begin{pmatrix} F_1 \\ F_2 \end{pmatrix}, \quad \mathbf{d} = \begin{pmatrix} d_1 \\ d_2 \end{pmatrix} \]

This mapping represents the continuous functional relation between the vector formed by the contact force and contact position on each finger, and the strains at the eight gauge locations. Taking into account the mechanical constraints of the physical situation, the dimensionality of this mapping can be reduced.

Assuming that the object has made contact with both fingers, the magnitude and direction of the x and z components of the contact force, with respect to each finger, will be the same. The y components will be equal in magnitude, but opposite in direction (figure 3). That is \( F_2 = (F_{1x}, -F_{1y}, F_{1z})' \). (To simplify notation the subscript 1 will be deleted henceforth). The location of the contact on the face of each finger may be different but the z component is constrained by the mechanics of the gripper. Approximating the face of the gripper to be flat allows the z constraint to be taken as constant, i.e. \( d_z = c \) and \( \mathbf{d}_i = (d_{ix}, d_{iz})' \) \( i = 1, 2 \). Thus knowledge of three force components and four position components is sufficient to approximate \( H \). Hence the mapping \( \mathcal{H} \) may be represented as

\[ \epsilon = \mathcal{H} \left( \begin{array}{c} \mathbf{F} \\ \mathbf{d} \end{array} \right) : \mathbb{R}^3 \times \mathbb{R}^5 \rightarrow \mathbb{R}^8 \]  

with

\[ \mathbf{F} \in \mathbb{R}^3, \quad \mathbf{d} = \begin{pmatrix} d_1 \\ d_2 \end{pmatrix} : \quad \mathbf{d}_i \in \mathbb{R}^2 \quad i = 1, 2. \]  

In order to determine the contact force and grip points given the strain gauge readings, the inverse mapping must be determined.

\[ \left( \begin{array}{c} \mathbf{F} \\ \mathbf{d} \end{array} \right) = \mathcal{H}^{-1}(\epsilon) : \mathbb{R}^8 \leftrightarrow \mathbb{R}^3 \times \mathbb{R}^5. \]  

The detailed derivation follows.

By locating the strain gauges on the rectangular portion of the gripper finger, any effect induced by the irregular shape of the upper finger is nullified, and thus the finger can be modeled by a beam of rectangular cross section with width \( a \), and depth \( b \). Problems related to calculating the strains in rectangular beams have already been studied in depth in the fields of mechanical and materials engineering [7]-[8].
A contact force consisting of any combination of point contacts, line contacts, and surface contacts, may be represented by an equivalent single point contact with a specified contact force magnitude and location; thus it is sufficient to consider only single point contact forces. Each contact force, \( F \), can be broken into three components, \([F_x, F_y, F_z] \). The \( z \) component is of greatest concern since this is the holding force. In a proper grasp both the \( x \) and \( y \) components should be zero.

To clarify the computations, the component forces and their induced moments will be treated separately (figure 3). The forces will be thought of as having equal magnitude and direction, but no horizontal offset from the vertical axis of the beam. In the \( y \) direction, the force causes tension or compression, while in the \( x \) and \( z \) directions, the forces induce bending. The corresponding moments, \( M_x = F_y d_x \), about the \( x \) axis, and \( M_y = F_x d_x + F_x d_z \), about the \( y \) axis, induce bending and torsion respectively (similarly for the moments \( M_x^2 \) and \( M_y^3 \) of finger 2). By applying superposition\(^3\) the resultant effect of the tension/compression, the bending, and the torsion can be calculated by summing their separate effects.

To begin calculation of the forward mapping, \( \bar{H} \), an explanation of the different types of strains caused by the contact force is given\(^8\). The strain due to bending moment \( M \) in a rectangular beam is

\[
\epsilon = \frac{6M}{ba^2E}.
\]  

(4.30)

In cases of nonuniform bending a shear strain is induced in the 'sides' of the beam. Nonuniform bending occurs if the moment is not constant throughout the beam. This is the case when the moment is generated by a force, \( F \), on the beam; the moment varies with distance from the force. For a rectangular beam this is

\[
\gamma_{xy} = \frac{3F}{2abG}.
\]  

(4.31)

The strain due to a tensile/compressive force, \( P \), in a rectangular beam is

\[
\epsilon = \frac{P}{Eba}.
\]  

(4.32)

The torsion created by the \( y \) axis moment, \( M \), will cause only shear strain in the \( xy \) coordinate reference frame. An approximation for the shear strain (on the front center of each finger) is given as in [8] by

\[
\gamma_{xy} = \frac{M}{0.235ba^2G}.
\]  

(4.33)

Oriented vertically on the finger, gauges 1, 2, 4, 5, 6, and 8 are not affected by torsion (figure 2). Gauges 3 and 7 though, are affected by the torsion as well as the other strains. Oriented at 45° to the coordinate axis, these gauges are aligned with the principle axis of pure torsion; thus the strain measured due to torsion is maximized.

Applying equations 4.30 and 4.32, equations for the strains\(^4\) at gauge location \( i \), \( i \in \{1, 2, 5, 6\} \) are as follows:

\[
\epsilon_i = \frac{6F_x d_x^4}{ba^2E} + \frac{F_z}{5aE} + \frac{6F_y d_z}{ba^2E}.
\]  

(4.34)

\(^3\)In general, the principle of superposition is valid for cases of loading where the magnitude of the stress and deflection is directly proportional to the load.

\(^4\)The sign convention adopted here assigns tensile strains a positive value. Care must be taken when developing the strain equations since a positive force may cause compression at the location on the finger where the measurement is taken.
\[ \epsilon_2 = \frac{6F_z(d_y^1 + d_{12})}{ba^2E} + \frac{F_y}{baE} + \frac{6F_y d_z}{ba^2E} \]  
(4.35)
\[ \epsilon_5 = \frac{6F_z d_y^2}{ba^2E} - \frac{F_y}{baE} \frac{6F_y d_z}{ba^2E} \]  
(4.36)
\[ \epsilon_6 = \frac{6F_z(d_y^2 + d_{12})}{ba^2E} - \frac{F_y}{baE} - \frac{6F_y d_z}{ba^2E} \]  
(4.37)

The first term in each equation is due to the nonuniform bending induced by the force \( F_z \). The second is due to the tension/compression induced by the force \( F_y \). And the third is due to the uniform bending moment about the \( x \) axis associated with \( F_y \).

The equations for the strains at gauge location \( i, i \in \{4,8\} \), on the side of the gripper finger, follow similarly from equations 4.30 and 4.32:
\[ \epsilon_4 = \frac{6F_z(d_y^1 + d_{14})}{ba^2E} + \frac{F_y}{baE} \]  
(4.38)
\[ \epsilon_8 = \frac{-6F_z(d_y^2 + d_{14})}{ba^2E} - \frac{F_y}{baE} \]  
(4.39)

Again, the first term is due to the nonuniform bending which, in this case, is induced by the force \( F_z \). And, just as above, the second term is due to the tensile strain induced by the force \( F_y \).

The calculations for gauges 3 and 7 are a little more complicated. The strains that are described thus far have been determined with respect to the \( xy \) coordinate reference frame. In order to derive a formula for the strain measured at strain gauges 3 and 7, the contribution of strains in the \( xy \) reference frame to the normal strain in a frame rotated \(-45^\circ\) must be determined. This derivation can be found in reference [8]. With \( \theta \) the angle of relative orientation of the coordinate frames, \( \epsilon_3 = \epsilon_x \cos^2(\theta) + \epsilon_y \sin^2(\theta) + \gamma_{xy} \sin(\theta) \cos(\theta) \). Letting \( \theta = -45^\circ \), and applying the equation at gauge locations 3 and 7
\[ \epsilon_3 = \frac{1}{2} \left( \frac{6F_z(d_y^1 + d_{13})}{ba^2E} + \frac{F_y}{baE} + \frac{6F_y d_z}{ba^2E} - \frac{3F_y}{2abG} \left( F_z d_y^1 + F_z d_z \right) \right) \]  
(4.40)
\[ \epsilon_7 = \frac{1}{2} \left( \frac{6F_z(d_y^2 + d_{13})}{ba^2E} - \frac{F_y}{baE} - \frac{6F_y d_z}{ba^2E} - \frac{3F_y}{2abG} \left( F_z d_y^2 + F_z d_z \right) \right) \]  
(4.41)

To help clarify this derivation, equation 4.40 has been broken down into its components.
\[ \epsilon_x = 0 \]  
(4.42)
\[ \epsilon_y = \frac{6F_z(d_y^1 + d_{13})}{ba^2E} + \frac{F_y}{baE} + \frac{6F_y d_z}{ba^2E} \]  
(4.43)
\[ \gamma_{xy} = \frac{3F_x}{2abG} + \frac{F_z d_y^1 + F_z d_z}{0.235ba^2G} \]  
(4.44)

The equation for \( \epsilon_y \) is derived exactly the same way as equations 4.34-4.37. The first shear strain term is caused by the nonuniform bending induced by the force \( F_z \). The second term is due to the torsion caused by the moment \( M_y \). The derivation is identical for \( \epsilon_7 \).

Now given the strain measurement from gauges 1 and 2, or gauges 5 and 6, the magnitude of the holding force, \( F_z \), can be calculated,
\[ F_z = \frac{ba^2E(\epsilon_2 - \epsilon_1)}{6d_{12}} = \frac{ba^2E(\epsilon_6 - \epsilon_5)}{6d_{12}} \]  
(4.45)
The calculation of the inverse mapping for the other components was accomplished using the symbolic algebra package MACSYMA. Due to the length and complexity of these equations, they will not be given here. Knowledge of their existence is sufficient for the purposes of this paper.

4.2 Determination of Holding Force and Contact Location

In the previous section it was proven theoretically that knowledge of the output of the eight strain gauges is sufficient to uniquely determine the location and magnitude of the contact force on both fingers. Unfortunately, the accuracy of the derived model may be affected by various disturbances caused by the unmodeled effects of transverse sensitivity, gauge misalignment, zero drift, and temperature dependence, the accuracy of the derived model may be effected. A controller design based on experimentally measured data should be more robust to these disturbances.

An experimental setup for accurately applying forces, $F_z$, perpendicular to the face of the gripper finger is depicted in figure 4. With this setup it is possible to empirically measure the sensor output for various holding force magnitudes and positions. Then, from the data, the functional relationship

$$\begin{align*}
\left( \frac{\dot{F}}{d} \right) &= \tilde{H}^{-1}(\epsilon) : \mathbb{R}^8 \rightarrow \mathbb{R}^3 \times \mathbb{R}^5
\end{align*}$$

(4.46)

can be determined. Note that for this setup $F_x$ and $F_y$ are both zero.

The equations developed in section 4.1 which express this relation mathematically are nonlinear (and continuous). The approximation of a continuous nonlinear function is a natural application for neural networks. It has been shown by Cybenko [10], that continuous functions of finite support may be approximated by a feed forward neural network with a single (finite) hidden layer. It is thus justified that this topology be used here. Whereas the functional approximation problem could be solved by choosing the form of the solution to be like the model and adjusting the parameters; the neural network solution has the additional advantage that the form of the solution need not be assumed.

The sufficiency proof in Cybenko's paper is nonconstructive and thus does not indicate the required number of neurons in the hidden layer. Using gradient descent (back propagation) to set the weights, the number of neurons is set by trial and error (i.e. If the network can converge to the solution given by the data in the training set, there are enough neurons in the hidden layer.).

For the case with $F_x$ and $F_y$ both zero, the network solution is found (see section 5).

---

5 An in depth discussion of neural networks is beyond the scope of this paper. An excellent introductory reference is the book by Rumelhart and McClelland [9].
4.3 Force Controller

Only knowledge of the holding force, \( F_z \), is necessary for force control. Once the desired holding force has been attained at both fingers the contact locations and other force components can be calculated. There are several reasons for this control scheme. First, knowledge of the holding force is sufficient for the task of securing the grasp; knowledge of the contact locations and other force components is necessary only for assuring a proper grasp. Second, the holding force can be calculated as linear combination of the readings from gauges 1 and 2, or gauges 5 and 6 (equation 4.45). The calculation complexity for the other variables is much higher, and involves readings from more of the strain gauges. Both the additional readings and calculations are time expensive and their incorporation into the control loop should be avoided if possible. Third, the contact locations and other force components cannot be determined unless contact is made to both fingers. In the case where contact is made to only one of the fingers, the gripper must be moved to center the object between the fingers before the contact location and other force components can be calculated.

Because the surfaces of the gripper fingers are not compliant, attempting to implement a minimum time controller may cause oscillation. Instead an attempt will be made to achieve a smooth response.

The model of the force response, as derived in section 2, is that of an asymptotically stable first order system. Such a system is robust to parameter variation, since the only effect of parameter variation would be to translate the poles of the force transfer function in the open left half plane. A typical controller for a first order system is a simple high gain controller. Theoretically, any finite positive gain could be chosen without destabilizing the system, however, choosing a gain which is too large may cause instability due to unmodeled dynamics. In addition, the gain is physically limited by the constraint on maximum armature voltage of 24V.

The force sensors are the most significant possible cause of feedback destabilization of the force control loop. This is due to the slow response exhibited by the strain gauges when a large force is applied then taken away. Once the force has been removed, the strain gauges may still detect its presence for a very short time. This could easily lead to oscillation. To avoid this a dead band can be put in the control algorithm such that if the measured force is close enough to the desired force, no control action will be taken.

5 Hardware Implementation

Developing hardware for space applications is a demanding task. In addition to those problems caused by a zero gravity environment, there are a host of others due to the harsh ambient variations associated with earth orbit. A satellite in geosynchronous orbit about the earth is subjected to variations in temperature alone in excess of several hundred degrees centigrade. Specifically, temperature specifications for the space station hardware state that all equipment must be able to withstand temperatures of \(-150^\circ C\) for 28 minutes and temperatures of \(200^\circ C\) for 55 minutes during each 83 minute orbit of the earth.

In such an environment, standard mechanical methods used for earth based devices are inappropriate. For instance, the viscosity of typical mechanical lubricants varies wildly with temperature rendering them useless in space.

Reliability becomes another significant concern in space engineering. From a purely monetary standpoint, an operation failure in a relatively inexpensive component can potentially disable the entire mechanism. Apart from fault-tolerant engineering considerations (e.g. redundant design), it is imperative that each component be of the highest quality.
Position information is measured using a linear potentiometer. With a minimum theoretical resolution of 0.025 cm, the errors in position due to the potentiometer will fall within the accepted position uncertainty of ±0.25 cm.

Using an analog to digital (A/D) converter the potentiometer output voltage is made available to the control algorithm. The equation which relates the sensor reading to gripper opening in centimeters was calculated by direct measurements to be:

\[
\text{opening} = 6.9 \times 10^{-3} (\text{sensor reading}) + 0.38
\]

(5.47)

The constants were chosen to emphasize accuracy in the range of the smaller openings.

Since potentiometer resistance is sensitive to temperature variations, a resistive position sensor would not be a wise choice on the final version. Alternatively, a similar sensor (perhaps capacitive) can be used without effecting the performance of the control.

Force information is obtained via an array of eight strain gauges. The calculation of the contact force and contact location from the strain data was described in section 4. A Wheatstone bridge (figure 4) is used to measure the small change in resistance of the strain gauge, \(R_1\), which occurs as the material is strained. A linear approximation of the relation between strain and measured output voltage is

\[
\varepsilon = \frac{(R_1 + R_4)(R_2 + R_3)}{V R_1 R_3} \frac{\Delta V_{AB}}{GF}.
\]

(5.48)

Again with the aid of an A/D converter the sensor data is made available to the control algorithm.

5.2 Neural Network

Using the experimental setup described in section 4, strain gauge readings were taken for various holding forces and contact locations.\(^6\) The tangential forces, \(F_x\) and \(F_y\), are

\(^6\) Data courtesy of Dr. Dipak Naik, Mechanical Engineering Department, University of North Carolina.
constrained by the experiment design to be zero. In addition, the face plate holds the z offset exactly constant. By imposing these three constraints, the problem is simplified considerably. In fact, the inverse mapping, $\mathbf{H}^{-1}$, can be completely decoupled. The inverse mapping for finger 1 is as follows:

\[
F_z = \frac{ba^2E(\epsilon_2 - \epsilon_1)}{6d_{12}} \quad (5.49)
\]
\[
d_y = \frac{d_{12}\epsilon_1}{(\epsilon_2 - \epsilon_1)} \quad (5.50)
\]
\[
d_x = \frac{7ba^2G}{2E(\epsilon_2 - \epsilon_1)}(\epsilon_1(d_{12} - d_{13}) + d_{13}\epsilon_2 - 2d_{12}\epsilon_3) \quad (5.51)
\]

The inverse mapping for finger 2 is similar.

The neural network weightings and biases for finger 1 (the long finger) were calculated by the back propagation method.\(^7\) To account for the software requirement that all inputs and outputs of the training data set be normalized to the interval (0,1) define $\tilde{\epsilon}_i \triangleq (\epsilon_i + 20)/300$. The neural network mapping is then described by

\[
F_z = \frac{25}{1 + \exp(-2.2 + 19.4\tilde{\epsilon}_1 - 20.8\tilde{\epsilon}_2 - .8\tilde{\epsilon}_3)} \quad (5.52)
\]
\[
d_y = \frac{8}{1 + \exp(-2.2 - 109.8\tilde{\epsilon}_1 + 85.5\tilde{\epsilon}_2 + 2.3\tilde{\epsilon}_3)} + 1 \quad (5.53)
\]
\[
d_x = \frac{8}{1 + \exp(1.3 + 11.7\tilde{\epsilon}_1 - 22.6\tilde{\epsilon}_2 + 31.3\tilde{\epsilon}_3)} + 1. \quad (5.54)
\]

Plots of the actual mapping versus the the neural network mapping are given in figure 5. These results are comparable to those obtained by Naik and Dehoff [11] using a truncated Taylor series approximation.

The apparent error is due not only to errors in the neural net approximation of the nonlinear function, but also to the inaccuracies in the training data. Some of the inaccuracies will be eliminated by the use of higher precision components for the circuit elements such as the Wheatstone bridge and the strain gauges themselves.

\(^7\)The software for this was taken from the Parallel Distributed Processing Software Package by Rumelhart and McClelland.
5.3 Computer Implementation

The time optimal position controller has been implemented on a Macintosh II equipped with a MacAdios board for D/A and A/D conversions. The controller can position to within ±0.25 cm of the desired position without overshoot. The accuracy of the positioning at various openings is reported in figure 6.

Several problems due to strain measurement noise have arisen while implementing the force controller. A significant improvement should be realized by use of higher quality components and wire wrapped circuits. Until the noise problems have been solved, implementation of the contact force and grip point calculation algorithm is virtually impossible. Variations in the strain gauge readings will cause significant errors in the calculations since the neural network mapping is based on a certain set of training data. In spite of this the force controller has been implemented but it cannot report an accurate holding force. The operator has the option of choosing one of three levels for the holding force: high, medium, or low. Addressing the problem of hitting an unexpected obstacle, the hybrid force/position controller stops if the prespecified force level is achieved during positioning.

Although the successful implementation of the neural network approximation of the mapping from strains to contact force and contact location has not been demonstrated, the approach seems to be a good one. This method offers a simple straightforward approach to this calculation which is unchanged by additional complexity of the mapping.

The control system block diagram along with flow diagrams of the control algorithm can be found in figure 7. Some of the notation used in these figures is summarized in table 5. The estimates are calculated as described in the previous sections.

6 Conclusions and Future Research

A controller has been developed and tested for the gripper portion of the zero gravity robotic end effector. It was determined that an optimal control exists which transfers the initial finger opening to the desired opening in minimum time. This time optimal control is unique and is constant with value equal to plus or minus maximum armature voltage, the value of the control depending on the relative location of the desired final position.

A force controller has been developed which is based only on the holding force, perpendicular to the finger face. The holding force on either finger can be calculated from

the output of two strain gauges on that finger by

$$F_z = \frac{ba^2E(e_2 - e_1)}{6d_{12}} = \frac{ba^2E(e_6 - e_5)}{6d_{12}}.$$  \hfill (6.55)

for finger 1 and 2 respectively (see figures 2 and 3). By including the output of two additional strain gauges on each finger the two tangential force components and the contact location may be calculated as well.

For the simplified case considered in section 5, where the tangential force components are constrained to be zero, the percent error between the actual mapping and the neural net mapping is similar to that achieved by the truncated Taylor series used by Naik and Dehoff [11]. It would be interesting to compare the results for a more general case.

The MacII design environment has been used for controller development and testing. The next logical step is to transfer the algorithm to a dedicated signal processing chip that can communicate with the central robot controller. Exact knowledge of the communication protocol of the system is required for the completion of this; however, transfer of the control algorithms should be straightforward since they are already coded in the C programming language.
