May, 1991

FINAL TECHNICAL REPORT
NATIONAL AERONAUTICS AND SPACE ADMINISTRATION
GRANT NAG-1-713
Acknowledgements

This report describes the research carried out under the most recent grant we received from NASA-Langley. The program started in 1964 and dealt with some experimental but mostly theoretical and computational aspects of a rather wide ranging topics related to the fatigue and fracture of aerospace structures. Some of the topics studied were fatigue crack propagation and fracture stability in plates and shells, delamination problems in layered materials, crack penetration problems in bonded dissimilar materials, stress intensity factors under thermal stresses and dynamic loading conditions, the interface crack in fiber reinforced materials, crack problems in bonded isotropic and orthotropic layers with periodic structure, the free end effect in layered materials, effect of various stiffeners and reinforcements on the stress intensity factors in plates and shells containing through or part-through cracks, plasticity effects on the crack opening displacements in plates and shells, multiple site surface and through cracks in plates and shells, modeling of interfacial zones in bonded materials, circumferential and axial surface crack problems in thick-walled cylinders, modeling and analysis of adhesively bonded joints, the effect of material nonhomogeneity on the stress intensity factors in debonding and fracture penetration problems, the effect of various end conditions on the stress intensity factors in cylindrical shells containing a through or part-through crack, toughening mechanisms in ceramics, surface and through crack problems in layered orthotropic plates, surface and through crack problems in plates and shells under mixed-mode loading conditions, development of function-theoretic methods to analyze mixed boundary value problems and to determine the nature of stress singularities, and development of computational techniques for solving singular integral equations arising from various kinds of crack problems. We would like to take this opportunity to thank the following individuals at the Materials Division, NASA-Langley who monitored the work and provided encouragement during the course of the research program: H. Hardrath, W. Illg, J. Davidson, J.H. Crews, Jr., W.B. Fichter, R.A. Everett, Jr., W. Elber, J.C. Newman, Jr., S. Johnson, C.C. Poe, Jr., C.A. Bigelow and C.E. Harris.

**Chapter 1. Transverse Shear Deformation Theories**

1.1 Introduction

1.2 Transverse shear Deformation Plate Theories

------ homogeneous isotropic plate
1.2.1 Mindlin's Displacement Based First-order Plate Theory

1.2.2 Reissner's Stress Based First-order Plate Theory

1.2.3 A Simple High-order Plate Theory

1.3 Transverse Shear Deformation Plate Theories

------ laminated or heterogeneous orthotropic plate
1.3.1 A General Linear Laminated or Heterogeneous Plate Theory

------ An Extended Mindlin's Approach

1.3.2 A Simple-higher-order Theory

------ Reddy's Approach

**Chapter 2. Laminated Plates with a Through Crack**

2.1 Introduction

2.2 Formulation of the Problem

2.2.1 Fourier Integral Transformation

2.2.2 Boundary Conditions
2.2.3 Singular Integral Equations

2.3 Stress Intensity Factor
   2.3.1 Solution of the Singular Integral Equation
   2.3.2 Displacement Component along the crack
   2.3.3 Stress Intensity Factor

2.4 Results and Discussions
   2.4.1 Homogeneous Plate
   2.4.2 Laminated Plate

Chapter 3. Stress Intensity Factors in Two-bonded Orthotropic Layers Containing a Crack Perpendicular to and on the Interface

3.1 Introduction
3.2 The Formulation of the Problem
   3.2.1 Solution of Differential Equations
   3.2.2 Displacements u(x,y) and v(x,y) for Material type I
   3.2.3 Stress Field
3.3 The Integral Equation
3.4 The Singularity at the Crack Tip
   3.4.1 Embedded Crack
   3.4.2 Edge Crack
   3.4.3 Crack Terminating at the Interface
3.5 Solution of the Singular Equation and the Stress Intensity Factor
   3.5.1 Embedded Crack
   3.5.2 Edge Crack
   3.5.3 Crack Terminating at the Interface
   3.5.4 The Stress Intensity Factors
3.6 Results and Discussions
3.7 Recommendations
Chapter 4. Surface Cracks in a Two-layer Orthotropic Plate

4.1 Introduction 118

4.2 The Line-Spring Model
   4.2.1 The Description of the Line-Spring Model 120
   4.2.2 The Compliance Functions 122

4.3 Singular Integral Equations
   4.3.1 The Singular Integral Equations 128
   4.3.2 The Stress Intensity Factors 129

4.4 Results and Discussions 131

Abstract

The main objective of this study is to develop an analytical method for a relatively accurate calculation of Stress Intensity Factors in a laminated orthotropic plate containing a through or a part-through crack. The laminated plate is assumed to be under bending or membrane loading and the mode I problem is considered.

First three transverse shear deformation plate theories (Mindlin's displacement based first-order theory, Reissner's stress-based first-order theory and a simple-higher order theory due to Reddy) are reviewed and examined for homogeneous, laminated and heterogeneous orthotropic plates. Then based on a general linear laminated plate theory, a method by which the stress intensity factors can be obtained in orthotropic laminated and heterogeneous plates with a through crack is developed. Examples are given for both symmetrically and unsymmetrically laminated plates and the effect of various material properties on the stress intensity factors are studied.

In order to implement the line-spring model which is used later to study the surface crack problem, the corresponding plane elasticity problem of a two-bonded orthotropic plate containing a crack perpendicular to the interface is also considered. Three different crack profiles: an internal crack, an edge crack and a crack terminating at the interface are considered. The effect of the different material combinations, geometries and material orthotropy on the stress intensity factors and on the power of stress singularity for a crack terminating at the interface is fully examined.

The Line Spring model of Rice and Levy is used for the part-through crack problem. The surface crack is assumed to lie in one of the two-layered laminated orthotropic plates due to the limitation of the available plane strain results. Rather extensive numerical results are given for both laminated composite and bonded metal-ceramic structural materials with various geometrical configurations. These results will be useful in brittle fracture analysis and more importantly, in subcritical crack growth studies.

All problems considered in this study are of the mixed boundary value type and are reduced to Cauchy type of singular integral equations which are then solved numerically.
Chapter 1. Transverse Shear Deformation Theories

1.1 INTRODUCTION

In recent years the potential of laminated composite materials for use as structural members has inspired considerable research activity in the study of the response of anisotropic laminated media. Because of the complicated internal structure of composites the stress field in the system is truly three-dimensional in character. One possible means of simplifying the three-dimensional equations of elasticity is to use the concept adopted in the formulation of plate theories. By following this approach various theories have been developed to treat the mechanical response of composite laminates. For example, classical laminated plate theory, which is an extension of the classical plate theory to laminated plates, was discussed by Lekhnitskii [1] by employing the Kirchhoff hypothesis in the analysis of symmetrical laminates. However, the classical laminate theory is inadequate for laminated plates made of advanced filamentary composite materials because most of these advanced composites have a low ratio of the transverse shear modulus to the in-plane modulus. Moreover, when we study the problem of a cracked plate under general loading conditions, the classical theory gives the following asymptotic results for the stress resultant distributions around the crack tip

\[
\begin{align*}
N_{ij} &\approx \frac{1}{\sqrt{2\pi}} \left[ k_1 f_{ij}^1(\theta) + k_2 f_{ij}^2(\theta) \right], \\
M_{ij} &\approx \frac{1}{\sqrt{2\pi}} \left[ k_1 g_{ij}^1(\theta,\nu) + k_2 g_{ij}^2(\theta,\nu) \right], \\
V_i &\approx \frac{1}{r^{3/2}} k_3 h_{ij}(\theta,\nu), \quad (i,j=1,2),
\end{align*}
\]

whereas an appropriate transverse shear deformation theory (such as that of Reissner's or Mindlin's) provides the corresponding fields as follows:
\[ N_{ij} \approx \frac{1}{\sqrt{2}r} \left[ k_1 f_{ij}^1(\theta) + k_2 f_{ij}^2(\theta) \right], \]

\[ M_{ij} \approx \frac{1}{\sqrt{2}r} \left[ k_1^b f_{ij}^1(\theta) + k_2^b f_{ij}^2(\theta) \right], \]

\[ V_i \approx \frac{1}{\sqrt{2}r} k_3 f_i^3(\theta), \quad (i,j = 1,2), \quad (1.1b) \]

where \( N_{ij}, M_{ij} \) and \( V_i \) are respectively membrane, bending and transverse shear components of the stress resultants, \( k_1, k_2 \) and \( k_3 \) are respectively the modes I, II, and III stress intensity factors, \( r \) and \( \theta \) are the local polar coordinates in \( x_1x_2 \) plane, and the angular expressions \( f_{ij}^1, f_{ij}^2 \) and \( f_i^3 \) are identical to the results given by the continuum elasticity solutions of crack problems [2] and [3].

Expressions (1.1a) clearly show that the solutions regarding the bending and transverse shear stress states at the crack tip given by classical theory do not conform to the standard results obtained from the elasticity solutions. That is, the angular distributions for \( M_{ij} \) and \( V_i \) differ from the expected elasticity results and are dependent on the Poisson's ratio, and the 3/2 singularity given for \( V_i \) is physically unacceptable. Furthermore, because of these discrepancies, the critical fracture mechanics parameters \( k_1^b, k_2^b \) and \( k_3 \) obtained from the classical theory are bound to be inaccurate. These inconsistencies are perhaps due to the fact that the classical theory can accommodate only two boundary conditions on the crack surface, namely the normal component of the bending moment and the Kirchhoff's effective transverse shear resultant combining the twisting moment and the transverse shear resultant, and it is likely to be inaccurate in the region of primary interest near the crack tip. All these shortcomings are seem to be removed when a transverse shear deformation theory is used.

Currently two groups of shear deformation plate theories are known in the literature: (1) stress-based theories and (2) displacement-based theories. The first stress-based shear deformation plate theory is due to Reissner [4], [5] and is based on a linear distribution of the in-plane normal and shear stresses through the thickness. The origin of displacement-based theories is attributed to Basset [6], and Hildebrand & Reissner & Thomas [7]. These first-order shear deformation theories assumed the following displacement field
\[ u_1 (x, y, z) = u(x, y) + z \psi_x (x, y), \]
\[ u_2 (x, y, z) = v(x, y) + z \psi_y (x, y), \]
\[ u_3 (x, y, z) = \omega (x, y). \quad (1.2) \]

The shear deformation theory based on equation (1.2) for plate is often referred to as the Mindlin plate theory [8]. Analogous to the approaches, which are based on introducing a priori plausible assumptions regarding the variation of displacement, strain and/or stresses in the thickness direction, Yang, Norris and Stavsky [9] presented a generalization of Mindlin's first order shear deformation plate theories for anisotropic plates. In Mindlin type of first-order theory a correction factor has to be introduced to account for the fact that it predicts a uniform shear stress through the thickness of the plate, which is obviously incorrect for most of cases.

For a more realistic evaluation of the stress fields and the shear stresses, high-order shear deformation theories have been proposed [10]. These high-order theories are cumbersome and computationally more demanding, because with each additional power of the thickness coordinate, an additional dependent unknowns is introduced into the theory. Recently Reddy [11] has extended the Levinson simple-high-order [12] approach of homogeneous isotropic plates to the laminated anisotropic composite plates. This simple-high-order laminated plate theory not only accounts for the parabolic variation of the transverse shear strains through the thickness, but also contains the same 5 dependent unknowns as in the first order theories.

These three above mentioned transverse shear deformation theories (Reissner's, Mindlin's and Reddy's) are reviewed and examined in this chapter. For each approach the basic assumptions, strain and stress fields, the plate constitutive equations and governing equations are examined. In addition, the controversies that definitely exist in the plate theory approach are explored. Homogeneous plate theories are studied first, then follows the extension to the laminated plate theories. Here, the laminated plate theories are the so-called single-layer laminate theories which are based on replacing the laminated plate by an equivalent single-layer anisotropic plate and introducing global displacement, strain and/or stress approximations in the thickness direction. It has been shown that these single-layer laminate theories, even the first-order theory, are adequate in representing global behavior, such as deflections
and stresses, of thin composites. If the local effects, such as interlaminar stress distributions, delaminations on fiber/matrix interface, etc, are to be studied one then has to consider the so-called multi-layer laminate theories, which are based on piecewise stress/ displacement approximations in the thickness direction. Here only single-layer laminate theories are studied.
1.2 TRANSVERSE SHEAR DEFORMATION PLATE THEORIES

HOMOGENEOUS ISOTROPIC PLATE

In this section the plate under consideration is assumed to be a thin elastic homogeneous isotropic plate of thickness $h$. The origin of a Cartesian coordinate system is located within the midplane $(x, y)$ with the $z$ axis being normal to this plane. As in the standard plate theory, it is also assumed that the plate surfaces $z = \pm h/2$ are subjected to surface traction defined by

\[
\begin{align*}
\sigma_{xz} (x, y, \pm h/2) &= 0, \\
\sigma_{yz} (x, y, \pm h/2) &= 0, \quad (1.3\text{ a})
\end{align*}
\]

and

\[
\begin{align*}
\sigma_z (x, y, + h/2) &= -q_1, \\
\sigma_z (x, y, - h/2) &= -q_2, \quad (1.3\text{ b})
\end{align*}
\]

where $q_1$ and $q_2$ can be arbitrary functions of $x$ and $y$.

The stress and moment resultants, each per unit length, are defined in the usual way, i.e.

\[
\begin{align*}
(Q_x, Q_y) &= \int_{-h/2}^{+h/2} (\sigma_{xz}, \sigma_{yz}) \, dz, \\
(M_x, M_y, M_{xy}) &= \int_{-h/2}^{+h/2} (\sigma_x, \sigma_y, \sigma_{xy}) \, z \, dz. \quad (1.4)
\end{align*}
\]

Because linear homogeneous plate bending theory is used, the in-plane stress resultants $N_x$, $N_y$ and $N_{xy}$, which are uncoupled with the bending resultant components, are not presented here.

Based on the above general assumptions, three different plate bending theories are discussed in detail in the following subsections.
1.2.1 Mindlin's Displacement Based First-order Plate Theory

1.2.1.1 The Assumed Displacement Field

In Mindlin's plate theory, the primary assumptions are based on the displacement fields [8], which, in the absence of the time parameter t, are described as follows:

\[
\begin{align*}
  u(x, y, z) &= z \psi_x(x, y), \\
  v(x, y, z) &= z \psi_y(x, y), \\
  \omega(x, y, z) &= \omega(x, y).
\end{align*}
\]  

(1.5)

Notice u and v are linear functions of z and \( \omega \) is independent of z. Here the three plate displacement components \( \psi_x, \psi_y \) and \( \omega \) are the unknown functions. Because of the linear features of \( u \) and \( v \), this theory is referred to as the first order theory.

1.2.1.2 The Strain Field

Using standard linear elasticity approach, the strain field can be obtained from (1.5) as

\[
\begin{align*}
  \epsilon_x &= \frac{\partial u}{\partial x} = z \frac{\partial \psi_x}{\partial x}, \\
  \epsilon_y &= \frac{\partial v}{\partial y} = z \frac{\partial \psi_y}{\partial y}, \\
  \gamma_{xy} &= \frac{\partial u}{\partial y} + \frac{\partial v}{\partial x} = z \left( \frac{\partial \psi_x}{\partial y} + \frac{\partial \psi_y}{\partial x} \right), \\
  \gamma_{xz} &= \frac{\partial u}{\partial z} + \frac{\partial \omega}{\partial x} = \psi_x + \frac{\partial \omega}{\partial x}, \\
  \gamma_{yz} &= \frac{\partial v}{\partial z} + \frac{\partial \omega}{\partial y} = \psi_y + \frac{\partial \omega}{\partial y}, \\
  \epsilon_z &= 0
\end{align*}
\]  

(1.6)
We can see that by using assumption (1.5) the in-plane strains are linear functions of \( z \) while the out-of-plane strains are constants through the thickness of the plate. Normal strain \( \varepsilon_z \) is neglected.

1.2.1.3 Constitutive Equations

For the thin plate, we assume the transverse normal stress may be neglected in comparison with the other stress components. Then the constitutive equations for the homogeneous isotropic plate can be obtained as follows:

\[
\varepsilon_x = \frac{1}{E} \left( \sigma_x - \nu \sigma_y \right), \\
\varepsilon_y = \frac{1}{E} \left( -\nu \sigma_x + \sigma_y \right), \\
\gamma_{yz} = \frac{1}{G} \sigma_{yz}, \quad \gamma_{xz} = \frac{1}{G} \sigma_{xz}, \quad \gamma_{xy} = \frac{1}{G} \sigma_{xy}, \\
\sigma_x = \frac{E}{1-\nu^2} \left( \varepsilon_x + \nu \varepsilon_y \right), \\
\sigma_y = \frac{E}{1-\nu^2} \left( \varepsilon_y + \nu \varepsilon_x \right), \\
\sigma_{yz} = G \gamma_{yz}, \quad \sigma_{xz} = G \gamma_{xz}, \quad \sigma_{xy} = G \gamma_{xy}.
\] (1.8)

1.2.1.4 The Stress Field

(a) Obtaining the stress fields from the constitutive equations

The general constitutive equations assume the linear strain-stress relationship. Considering expressions (1.6), (1.7) and (1.9) the stress field in the plate may be expressed as

\[
\sigma_x = z \left( -\frac{E}{1-\nu^2} \right) \left( \frac{\partial \psi_x}{\partial x} + \nu \frac{\partial \psi_y}{\partial y} \right) = c_1 (x, y) z
\]
\[
\sigma_y = z \left( \frac{E}{1 - \nu^2} \right) \left( \frac{\partial \psi_y}{\partial y} + \nu \frac{\partial \psi_x}{\partial x} \right) = c_2(x, y) z
\]

\[
\sigma_{xy} = z \ G \left( \frac{\partial \psi_x}{\partial y} + \frac{\partial \psi_y}{\partial x} \right) = c_3(x, y) z \quad (1.10)
\]

\[
\sigma_{xz} = G \left( \psi_x + \frac{\partial \omega}{\partial x} \right) = c_4(x, y)
\]

\[
\sigma_{yz} = G \left( \psi_y + \frac{\partial \omega}{\partial y} \right) = c_5(x, y) \quad (1.11)
\]

where \(c_i\ (i = 1, 5)\) are functions of \(x\) and \(y\) only.

Again, the in-plane stresses are linear functions of \(z\) and the out-of-plane stresses are constant through the thickness direction. Expressions (1.11) obviously violate the boundary conditions (1.3a).

(b) Obtaining stress field from the equilibrium equations:

Here the in-plane normal and shear stresses are the same as expressed in (1.10) but, we use a different approach, an equilibrium equation approach, to express the out-of-plane shear stresses. From the standard equilibrium equations in elasticity

\[
\frac{\partial \sigma_x}{\partial x} + \frac{\partial \sigma_{xy}}{\partial y} + \frac{\partial \sigma_{xz}}{\partial z} = 0, \quad (1.12)
\]

we have

\[
\frac{\partial \sigma_{xz}}{\partial z} = -\left( \frac{\partial \sigma_x}{\partial x} + \frac{\partial \sigma_{xy}}{\partial y} \right). \quad (1.13)
\]

Integrating (1.12) and using the expressions (1.10) we find
\[
\sigma_{xz}(x, y) = \int_{-h/2}^{h/2} \frac{\partial \sigma_{xz}}{\partial z} \, dz = \int_{-h/2}^{h/2} \left( \frac{\partial \sigma_x}{\partial x} + \frac{\partial \sigma_{xy}}{\partial y} \right) \, dz
\]

\[
= \int_{-h/2}^{h/2} \left( \frac{\partial c_1}{\partial x} + \frac{\partial c_3}{\partial y} \right) z \, dz . \quad (1.14)
\]

It can easily be seen that \( \sigma_{xz} \) has the term of \( z^2 \), i.e.

\[
\sigma_{xz} \propto z^2 + \ldots. \quad (1.15 \text{a})
\]

In the same manner, it can be shown that

\[
\sigma_{yz} \propto z^2 + \ldots. \quad (1.15 \text{b})
\]

Comparing (1.11) with (1.15), it is clear that in Mindlin's plate theory there is an inherent inconsistency regarding the stress field.

1.2.1.5 Plate Constitutive Equations

Substituting (1.6) and (1.7) into equations (1.9) and performing the integration from \((- h/2)\) to \((+ h/2)\), the following equations are obtained between the moment resultants to the plate-displacement components:

\[
\begin{bmatrix}
M_x \\
M_y \\
M_{xy}
\end{bmatrix}
= D \begin{bmatrix}
1 & \nu & 0 \\
\nu & 1 & 0 \\
0 & 0 & (1-\nu)/2
\end{bmatrix}
\begin{bmatrix}
k_x \\
k_y \\
k_{xy}
\end{bmatrix}, \quad (1.16)
\]

where

\[
D = \frac{E h^3}{12 (1 - \nu^2)}, \quad (1.17)
\]

and

\[
k_x = \frac{\partial \psi_x}{\partial x}, \quad k_y = \frac{\partial \psi_y}{\partial y}, \quad k_{xy} = \frac{\partial \psi_x}{\partial y} + \frac{\partial \psi_y}{\partial x},
\]
and

\[ Q_x = K G h \left( \psi_x + \frac{\partial \omega}{\partial x} \right), \]

\[ Q_y = K G h \left( \psi_y + \frac{\partial \omega}{\partial y} \right). \quad (1.18) \]

Notice that a parameter \( K \) has been introduced into the expressions for the transverse shear resultants. Here the constant, \( K \), commonly known as a correction factor, is used to account for the fact that the transverse shear stresses are constant through the thickness of the plate. By comparing to the exact theory various values of \( K \) has been used for homogeneous isotropic plates. For example Reissner [4], Mindlin [13], and Uflyand [14] used values of \( 5/6 \), \( \pi^2/12 \), and \( 3/2 \) respectively. The evaluation of \( K \) in a specific problem depends on either the exact elasticity solution of the problem or experimental evidence.

1.2.1.6 Governing Equations:

As in the standard plate theory, the stress resultants must satisfy the equilibrium equations:

\[ \frac{\partial M_x}{\partial x} + \frac{\partial M_{xy}}{\partial y} - Q_x = 0, \]

\[ \frac{\partial M_y}{\partial y} + \frac{\partial M_{xy}}{\partial x} - Q_y = 0, \]

\[ \frac{\partial Q_x}{\partial x} + \frac{\partial Q_y}{\partial y} = 0. \quad (1.19) \]

Substituting (1.16), (1.18) into (1.19) the governing equations can be obtained as
Under proper boundary conditions, the unknown functions $\omega$, $\psi_x$ and $\psi_y$ could be solved for various specific problems.

1.2.2 Reissner's Stress Based First-order Plate Theory

1.2.2.1 The Assumed Stress Field

Reissner's plate theory is based on a linear distribution of the in-plane normal and shear stresses through the thickness:

$$
\sigma_x = \frac{M_x}{h^2/6} \frac{z}{h/2},
$$

$$
\sigma_y = \frac{M_y}{h^2/6} \frac{z}{h/2},
$$

$$
\sigma_{xy} = \frac{M_{xy}}{h^2/6} \frac{z}{h/2}.
$$

The distribution of the transverse normal and shear stresses is determined from the equilibrium equations of the elasticity theory:

$$
\frac{\partial \sigma_x}{\partial x} + \frac{\partial \sigma_{xy}}{\partial y} + \frac{\partial \sigma_{xz}}{\partial z} = 0,
$$

$$
\frac{\partial \sigma_{xy}}{\partial x} + \frac{\partial \sigma_y}{\partial y} + \frac{\partial \sigma_{yz}}{\partial z} = 0,
$$

$$
\frac{\partial \sigma_{xz}}{\partial x} + \frac{\partial \sigma_{yz}}{\partial y} + \frac{\partial \sigma_z}{\partial z} = 0.
$$
Integrating equations (1.22) and using the boundary conditions, following (1.21) and the plate equilibrium equations (1.19) we can derive the expressions $\sigma_{xz}$ as follows:

$$\sigma_{xz} = - \int_{-h/2}^{h/2} \frac{\partial \sigma_{xz}}{\partial z} \, dz = - \int_{-h/2}^{h/2} \left( \frac{\partial \sigma_x}{\partial x} + \frac{\partial \sigma_{xy}}{\partial y} \right) \, dz$$

$$= - \int_{-h/2}^{h/2} \left( \frac{\partial M_x}{\partial x} + \frac{\partial M_{xy}}{\partial y} \right) \frac{z}{h^3/12} \, dz$$

$$= - Q_x \int_{-h/2}^{h/2} \frac{z}{h^3/12} \, dz,$$

$$\sigma_{xz} = \frac{3}{2} \frac{Q_x}{h} \left[ 1 - \left( \frac{2z}{h} \right)^2 \right]. \quad (1.23 \, a)$$

Similarly the transverse stress $\sigma_{yz}$ and the normal stress $\sigma_z$ can be obtained in term of their resultants and the coordinate $z$:

$$\sigma_{yz} = \frac{3}{2} \frac{Q_y}{h} \left[ 1 - \left( \frac{2z}{h} \right)^2 \right], \quad (1.23 \, b)$$

and

$$\sigma_z = \frac{3}{4} q \left[ \frac{2}{3} \cdot \frac{2z}{h} + \frac{1}{3} \left( \frac{2z}{h} \right)^3 \right],$$

where $q = q_1 - q_2. \quad (1.24 \, a, \, b)$

From expressions (1.21), it can be seen that in-plane normal and shear stress are linearly distributed through the thickness, which is the same as in Mindlin's theory (see expressions (1.10)). Because of this in literature both of these theories are often called Mindlin-Ressiner's first-order plate theory. On the other hand, in Reissner's theory the transverse shear stresses, obtained from the equilibrium equations, are parabolically distributed through the thickness. Therefore the boundary conditions at top and bottom of the plate [see (1.3 a)] are satisfied.
1.2.2.2 The Strain Field

Assuming an isotropic material and the displacements $u$, $v$ and $\omega$ of any point in the plate to be small as compared with its thickness $h$, we use the following general stress-strain relations:

\[
\epsilon_x = \frac{\partial u}{\partial x} = \frac{1}{E} \left[ \sigma_x - \nu (\sigma_y + \sigma_z) \right],
\]

\[
\epsilon_y = \frac{\partial v}{\partial y} = \frac{1}{E} \left[ \sigma_y - \nu (\sigma_x + \sigma_z) \right],
\]

\[
\gamma_{xy} = \frac{\partial u}{\partial y} + \frac{\partial v}{\partial x} = \frac{1}{G} \sigma_{xy}, \quad (1.25)
\]

\[
\gamma_{xz} = \frac{\partial u}{\partial z} + \frac{\partial \omega}{\partial x} = \frac{1}{G} \sigma_{xz},
\]

\[
\gamma_{yz} = \frac{\partial v}{\partial z} + \frac{\partial \omega}{\partial y} = \frac{1}{G} \sigma_{yz}, \quad (1.26)
\]

\[
\epsilon_z = \frac{\partial \omega}{\partial z} = -\frac{1}{E} \left[ \sigma_z - \nu (\sigma_x + \sigma_y) \right]. \quad (1.27)
\]

Notice that, for the case $q = 0$, the in-plane normal and shear stress are linear function of $z$, which is again the same as those in Mindlin's theory. However, as expressed in (1.26) and following (1.23) the transverse shear strains have the form of $az^2 + b$.

1.2.2.3 The Displacement Field

Substituting (1.21) into (1.25), letting $q = 0$ and performing the integrations we can easily see that the in-plane displacements $u$ and $v$ are linearly distributed through the thickness, which again are same as the expressions in Mindlin's theory. Unlike the assumption that the plate deflection $\omega$ is constant throughout the thickness of the plate in Mindlin's theory, the expression for $\omega$ in Reissner's theory has an inconsistency. Using the sixth relationship in the stress-strain relation
\[
\frac{\partial \omega}{\partial z} = \frac{1}{E} [ \sigma_z - \nu ( \sigma_x + \sigma_y ) ]
\]  

(1.27)

for \( q = 0 \), and the linear law for the distribution of the stresses \( \sigma_x \) and \( \sigma_y \), \( \omega \) will have the term of \( \sigma^2 \). Note that the same conclusion can be drawn from the expression (1.26). However in Reissner's original article [4], he stated that to be consistent with the assumption of linear bending stress distribution it is assumed that the displacement \( u \) and \( v \) vary linearly over the thickness of the plate and that \( \omega \) does not vary over the thickness of the plate. To overcome this inconsistency, some authors later (for example [15]) have introduced some average value \( \bar{\omega} \) of the transverse displacement, taken over the thickness of the plate, and then arrived at the governing equations in terms of this average value of \( \bar{\omega} \). In this way instead of finding the actual distribution of \( \omega (x, y, z) \), somehow the average value \( \omega \) as a function of \( x \) and \( y \) is sought.

1.2.2.4 Plate Constitutive Equations

Following [15], introducing some average value \( \omega \) of the transverse displacement, taken over the thickness of the plate, as well as some average values \( \psi_x \) and \( \psi_y \) of the rotation of the sections \( x = \text{constant} \) and \( y = \text{constant} \) respectively, and defining these quantities by equating the work of the resultant couples on the average rotations and the work of resultant forces on the average displacement to the work of the corresponding stresses on the actual displacements \( u_0(x, y, z) \), \( v_0(x, y, z) \) and \( w_0(x, y, z) \) in the same section, we find

\[
\int_{-h/2}^{+h/2} \sigma_x u_0 \, dz = M_x \psi_x,
\int_{-h/2}^{+h/2} \sigma_y v_0 \, dz = M_y \psi_y,
\int_{-h/2}^{+h/2} \sigma_{xy} v_0 \, dz = M_{xy} \psi_y,
\int_{-h/2}^{+h/2} \sigma_{xy} u_0 \, dz = M_{xy} \psi_x,
\int_{-h/2}^{+h/2} \sigma_{xz} w_0 \, dz = Q_x \omega,
\int_{-h/2}^{+h/2} \sigma_{yz} w_0 \, dz = Q_y \omega.
\]

(1.28)
Now substituting expressions (1.21) for the stresses into equations (1.28) the following relations between the average and actual displacement can be obtained

\[ \omega = \frac{3}{2h} \int_{-h/2}^{+h/2} \omega_0 \left[ 1 - \left( \frac{2z}{h} \right)^2 \right] dz , \]

\[ \psi_x = \frac{12}{h^2} \int_{-h/2}^{+h/2} \frac{u_0}{h} z \, dz , \]

\[ \psi_y = \frac{12}{h^2} \int_{-h/2}^{+h/2} \frac{v_0}{h} z \, dz . \]  

(1.29)

Using the stress-strain relations (1.25), for \( q = 0 \), we can express the in-plane stresses components \( \sigma_x, \sigma_y \) and \( \sigma_{xy} \) in terms of the actual displacements as follows:

\[ \sigma_x = \frac{E}{1 - \nu^2} \left( \frac{\partial u_0}{\partial x} + \nu \frac{\partial v_0}{\partial y} \right) , \]

\[ \sigma_y = \frac{E}{1 - \nu^2} \left( \frac{\partial v_0}{\partial y} + \nu \frac{\partial u_0}{\partial x} \right) , \]

\[ \sigma_{xy} = G \left( \frac{\partial u_0}{\partial y} + \frac{\partial v_0}{\partial x} \right) = \frac{E}{2 (1 + \nu)} \left( \frac{\partial u_0}{\partial y} + \frac{\partial v_0}{\partial x} \right) . \]  

(1.30)

Substituting (1.30) into (1.21), multiplying by \( \frac{12}{h^3} \) \( z \, dz \), integrating between

\[ z = -h/2 \text{ and } z = h/2, \]  

and observing relations (1.29), we arrive at the expressions

\[
\begin{bmatrix}
M_x \\
M_y \\
M_{xy}
\end{bmatrix}
= D
\begin{bmatrix}
1 & \nu & 0 \\
\nu & 1 & 0 \\
0 & 0 & (1-\nu)/2
\end{bmatrix}
\begin{bmatrix}
k_x \\
k_y \\
k_{xy}
\end{bmatrix},
\]

where

\[ D = \frac{E h^3}{12 (1 - \nu^2)} , \]

16
and
\[ k_x = \frac{\partial \psi_x}{\partial x}, \quad k_y = \frac{\partial \psi_y}{\partial y}, \quad k_{xy} = \frac{\partial \psi_x}{\partial y} + \frac{\partial \psi_y}{\partial x}. \]

(1.31)

In like manner, substituting expressions (1.23) into (1.26), multiplying the result by \( \frac{3}{2h} \left[ 1 - \left( \frac{2z}{h} \right)^2 \right] dz \), and integrating between the limits \( z = \pm h/2 \), we obtain:

\[
\begin{bmatrix}
Q_x \\
Q_y
\end{bmatrix} = \frac{5}{12} \frac{Eh}{1 + \nu} \begin{bmatrix}
\psi_x + \frac{\partial \omega}{\partial x} \\
\psi_y + \frac{\partial \omega}{\partial y}
\end{bmatrix} = \frac{5}{6} G h \begin{bmatrix}
\psi_x + \frac{\partial \omega}{\partial x} \\
\psi_y + \frac{\partial \omega}{\partial y}
\end{bmatrix}
\]

(1.32)

Reissner, in his treatment of this subject, makes use of Castigliano’s principle of least work to obtain the above expressions (1.31) and (1.32).

Comparing the plate constitutive equations (1.31) and (1.32) from Reissner's theory with (1.16) and (1.18) from Mindlin's theory we can see that for the bending moments' expressions, the two theories are exactly the same, whereas for the transverse shear resultants, if we let \( K = 5/6 \) in Mindlin's expressions, we arrive at the identical expressions of Reissner's expressions.

1.2.2.5 Governing Equations

Using the same equilibrium equations for stress resultants, for \( q = 0 \), we have

\[
\frac{\partial M_x}{\partial x} + \frac{\partial M_{xy}}{\partial y} - Q_x = 0,
\]

\[
\frac{\partial M_y}{\partial y} + \frac{\partial M_{xy}}{\partial x} - Q_y = 0,
\]
\[ \frac{\partial Q_x}{\partial x} + \frac{\partial Q_y}{\partial y} = 0. \] (1.33)

Now substituting (1.32) into (1.31), eliminating the quantities \( \psi_x \) and \( \psi_y \) from these equations, and taking into account the last equation of (1.33), we obtain

\[ M_x = -D \left( \frac{\partial^2 \omega}{\partial x^2} + \nu \frac{\partial^2 \omega}{\partial y^2} \right) + \frac{h^2}{5} \frac{\partial Q_x}{\partial x}, \]

\[ M_y = -D \left( \frac{\partial^2 \omega}{\partial y^2} + \nu \frac{\partial^2 \omega}{\partial x^2} \right) + \frac{h^2}{5} \frac{\partial Q_y}{\partial y}, \]

\[ M_{xy} = (1 - \nu) D \frac{\partial^2 \omega}{\partial x \partial y} - \frac{h^2}{10} \left( \frac{\partial Q_x}{\partial y} + \frac{\partial Q_y}{\partial x} \right). \] (1.34)

Substituting these expressions in (1.34) into the first two equations of (1.33), the following results can be obtained

\[ Q_x - \frac{h^2}{10} \nabla^2 Q_x = - D \frac{\partial (\nabla\omega)}{\partial x}, \]

\[ Q_y - \frac{h^2}{10} \nabla^2 Q_y = - D \frac{\partial (\nabla\omega)}{\partial y}. \] (1.35)

Observing the expressions (1.34) and (1.35), for the particular case of \( h \rightarrow 0 \), that is, of infinitely thin plates, the foregoing set of five equations gives the corresponding expressions in classical bending theory.

Introducing a new stress function \( \Phi \), after some manipulations (see [15] for details) the more convenient form for the governing equations can be obtained as follows

\[ \nabla^4 \omega = 0, \]

\[ \nabla^2 \Phi - \frac{10}{h^2} \Phi = 0, \] (1.36)

where
From equations (1.34) the expressions for $M_x$, $M_y$ and $M_{xy}$ can be obtained. For given boundary conditions, the plate bending problem can be solved for various specific cases.

1.2.3 A Simple Higher-order plate theory

1.2.3.1 The Assumed Displacement Field

In this simple higher-order plate theory, the primary assumptions based on the displacement field [11] in absence of the time parameter $t$, are the following:

\[
\begin{align*}
  u(x, y, z) &= z \psi_x(x, y) + z^2 \phi_x(x, y), \\
  v(x, y, z) &= z \psi_y(x, y) + z^2 \phi_y(x, y), \\
  \omega(x, y, z) &= \omega(x, y).
\end{align*}
\] (1.38)

As we can see in the sequel, these assumptions allow for the nonuniform shear stresses in the thickness direction of the plate, as well as the possibility of satisfying shear-free boundary conditions (1.3a) on the surface of the plate at $z = \pm h/2$.

Observing the boundary conditions

\[
\begin{align*}
  \sigma_{xz}(x, y, \pm h/2) &= 0, \\
  \sigma_{yz}(x, y, \pm h/2) &= 0. \quad \text{(1.3a)}
\end{align*}
\]

for an isotropic plate and possibly for an orthotropic plate, these conditions are equivalent to the requirement that the corresponding strains are zero on these surfaces. Then, we have
\[ \gamma_{xz} (x, y, \pm h/2) = 0, \]
\[ \gamma_{yz} (x, y, \pm h/2) = 0. \] (1.39)

From the strain-displacement relations and expressions (1.38) we find

\[ \gamma_{xz} = \frac{\partial u}{\partial z} + \frac{\partial \omega}{\partial x} = \psi_x + 3 z^2 \phi_x + \frac{\partial \omega}{\partial x}, \]
\[ \gamma_{yz} = \frac{\partial v}{\partial z} + \frac{\partial \omega}{\partial y} = \psi_y + 3 z^2 \phi_y + \frac{\partial \omega}{\partial y}. \] (1.40)

Thus using (1.2) or (1.39), we obtain

\[ \phi_x = -\frac{4}{3 h^2} (\psi_x + \frac{\partial \omega}{\partial x}), \]
\[ \phi_y = -\frac{4}{3 h^2} (\psi_y + \frac{\partial \omega}{\partial y}). \] (1.41)

Then, the displacements in equation (1.38) become

\[ u = z [\psi_x - \frac{4}{3 h^2} \frac{z^2}{h^2} (\psi_x + \frac{\partial \omega}{\partial x})], \]
\[ v = z [\psi_y - \frac{4}{3 h^2} \frac{z^2}{h^2} (\psi_y + \frac{\partial \omega}{\partial y})], \]
\[ \omega = \omega (x, y). \] (1.42)

These are the lowest order expressions antisymmetric in \( z \) which can be made to satisfy the shear-free conditions on \( z = \pm h/2 \). Also notice that there are still three unknown functions, \( \psi_x, \psi_y \) and \( \omega \).

1.2.3.2 The Strain Field

Introducing the following notation for convenience
\[ k_x = \frac{\partial \psi_x}{\partial x}, \quad k_x^{(2)} = -\frac{4}{3h^2} \left( \frac{\partial \psi_x}{\partial x} + \frac{\partial^2 \omega}{\partial x^2} \right), \]

\[ k_y = \frac{\partial \psi_y}{\partial y}, \quad k_y^{(2)} = -\frac{4}{3h^2} \left( \frac{\partial \psi_y}{\partial y} + \frac{\partial^2 \omega}{\partial y^2} \right), \]

\[ k_{xy} = \frac{\partial \psi_x}{\partial y} + \frac{\partial \psi_y}{\partial x}, \quad k_{xy}^{(2)} = -\frac{4}{3h^2} \left( \frac{\partial \psi_y}{\partial x} + \frac{\partial \psi_x}{\partial y} + 2 \frac{\partial^2 \omega}{\partial y \partial x} \right), \]

\[ k_{xz} = \psi_x + \frac{\partial \omega}{\partial x}, \quad k_{xz}^{(2)} = -\frac{4}{h^2} \left( \psi_x + \frac{\partial \omega}{\partial x} \right), \]

\[ k_{yz} = \psi_y + \frac{\partial \omega}{\partial y}, \quad k_{yz}^{(2)} = -\frac{4}{h^2} \left( \psi_y + \frac{\partial \omega}{\partial y} \right). \]

(1.43)

The strain field associated with the displacement given by equations (1.42) is found to be

\[ \epsilon_x = z \left( k_x + z^2 k_x^{(2)} \right), \]

\[ \epsilon_y = z \left( k_y + z^2 k_y^{(2)} \right), \]

\[ \epsilon_z = 0, \]

\[ \gamma_{xy} = z \left( k_{xy} + z^2 k_{xy}^{(2)} \right); \quad (1.44) \]

\[ \gamma_{xz} = k_{xz} + z^2 k_{xz}^{(2)}, \]

\[ \gamma_{yz} = k_{yz} + z^2 k_{yz}^{(2)}. \quad (1.45) \]

From the above expressions we can see that the in-plane strain will have the term of \( z^3 \) while the out-of-plane strains will have the term of \( z^2 \).
1.2.3.3 The Stress Field

As in Mindlin's theory, there are also inherent contradictions in the transverse stress expressions in this displacement based theory. If we use constitutive equation (1.9) to obtain the stress field, the transverse stresses $\sigma_{xz}$ and $\sigma_{yz}$ will have the term of $z^3$, the same order as $\gamma_{xz}$ and $\gamma_{yz}$. On the other hand, if we use equilibrium equation from elasticity in deriving the $\sigma_{xz}$ and $\sigma_{yz}$, observing that the in-plane stresses have the term of $z^3$, we would have a quadratic expressions of $\sigma_{xz}$ and $\sigma_{yz}$.

1.2.3.4 Plate Constitutive Equations

Substituting expressions (1.44) into equation (1.9) and performing the integration from $z = -h/2$ to $z = +h/2$, the following equations are obtained between the moment resultants and the plate-displacement components:

$$\{ C_m \} = [\mathbf{CD}] \{ C_k \}, \quad (1.46)$$

where

$$\mathbf{CD} = \begin{bmatrix}
D & \nu D & 0 & D_1 & \nu D_1 & 0 \\
\nu D & D & 0 & \nu D_1 & D_1 & 0 \\
0 & 0 & D (1-\nu)/2 & 0 & 0 & D_1(1-\nu)/2
\end{bmatrix},$$

$$\mathbf{C_m} = \begin{bmatrix}
M_x \\
M_y \\
M_{xy}
\end{bmatrix}, \quad \mathbf{C_k} = \begin{bmatrix}
k_x \\
k_y \\
k_{xy} \\
k_{x}^{(2)} \\
k_{y}^{(2)} \\
k_{xy}^{(2)}
\end{bmatrix},$$
\[ D = \frac{E h^3}{12 (1 - \nu^2)}, \quad D_1 = \frac{E h^5}{80 (1 - \nu^2)}. \quad (1.47) \]

In like manner, substituting expressions (1.45) into equations (1.9) performing the same integration, we arrive at the expressions:

\[
\begin{bmatrix}
Q_x \\
Q_y
\end{bmatrix} = G h \begin{bmatrix}
1 & 0 & \frac{h^2}{12} & 0 \\
0 & 1 & 0 & \frac{h^2}{12}
\end{bmatrix} \begin{bmatrix}
k_{xz} \\
k_{yz} \\
k_{xz}^{(2)} \\
k_{yz}^{(2)}
\end{bmatrix}
\]

\[ (1.48) \]

Notice that, due to the high-order terms introduced in the displacement field, as expected there are more terms involved in this plate constitutive equation, which differs greatly from the first-order theory.

1.2.3.5 Governing Equations

Using the standard plate theory approach, the stress resultants must satisfy the equilibrium equations as expressed before

\[
\frac{\partial M_x}{\partial x} + \frac{\partial M_{xy}}{\partial y} - Q_x = 0,
\]

\[
\frac{\partial M_y}{\partial y} + \frac{\partial M_{xy}}{\partial x} - Q_y = 0,
\]

\[
\frac{\partial Q_x}{\partial x} + \frac{\partial Q_y}{\partial y} = 0.
\quad (1.49)
\]

Substituting (1.47) and (1.48) into the above equations, the governing equations can be obtained for \(\omega, \psi_x, \text{and} \psi_y\).
1.3 TRANSVERSE SHEAR DEFORMATION PLATE THEORIES

----- LAMINATED OR HETEROGENEOUS ORTHOTROPIC PLATE

In the last section, three transverse shear deformation plate theories are studied for homogeneous isotropic plates. In this section these theories will be extended to deal with plates that are non-homogeneous in the thickness direction. The non-homogeneity of the plate may be of two types

(a) the elastic moduli vary continuously in the thickness direction of the so-called "heterogeneous plate";

(b) thin homogeneous layers of different elastic properties are assembled to form a "laminated plate" in which the moduli are piecewise constant.

It will be shown that these two types of nonhomogeneous plate problems could be solved in basically the same manner as the so-called "single layer laminated plate theory". In the case of a nonhomogeneous plate, the stiffness matrix is derived by continuous integration through the thickness for a heterogeneous plate and by stepwise integration for a laminated plate. In this study only laminated plates will be considered. The technique could easily be extended to heterogeneous plates.

The laminated plate under consideration consists of an arbitrary number of thin bonded orthotropic layers, with a total thickness \( h \). In the "single-layer" laminated plate theory we assume the individual lamina is elastic and the laminae are perfectly bonded along interfaces. Cartesian coordinate system is used with the \( z = 0 \) and \( z = h \) referred to lower and upper surfaces of the plate and cylindrical boundaries \( f_p(x,y) = 0 \) are defined by plane curves parallel to the \( x-y \) plane. As before, the top and bottom surfaces of the plate are assumed to be free of shear stresses but subjected to transverse normal stress, as follows:

\[
\begin{align*}
\sigma_{xz}(x,y,0) &= 0, & \sigma_{xz}(x,y,h) &= 0, \\
\sigma_{yz}(x,y,0) &= 0, & \sigma_{yz}(x,y,h) &= 0; \\
\sigma_z(x,y,0) &= 0, & \sigma_z(x,y,z) &= p_z.
\end{align*}
\]  

(1.50)  
(1.51)
Note that the lower surface of the plate is chosen as $z = 0$ plane which is call "reference plane". For a symmetrical laminated plate, for convenience, we usually choose the symmetry plane, the midplane, as the reference plane. However, for unsymmetrical laminated plate any plane parallel to the plate can be chosen as the reference plane (in practice the lower surface, the upper surface or the neutral plane of the plate). We choose $z = 0$ as reference plane because it is a general form for both laminated plate and heterogeneous plate.

It will also be shown in this section that the asymmetry in composition and geometry will introduce a coupling phenomenon between bending and stretching which was studied by Reissner and Stavsky [16] and [17] in conjunction with the classical bending theory. By assuming the symmetrical laminates the bending and stretching problem can be decoupled whereas the problem of unsymmetrical laminates are inherently coupled. In this section only two displacement based transverse shear deformation theories are studied for the laminated orthotropic plate. Because of the inconsistency in the displacement field, the Reissner's stress based plate theory will not be considered.

1.3.1 A General Linear Laminated or Heterogeneous Plate Theory

-------- An Extended Mindlin's Approach

1.3.1.1 The Assumed Displacement Field

The general linear laminated plate theory is attributed to Yang, Norris and Stavsky [9] who extended Mindlin's theory for homogeneous plate [8] to laminates consisting of an arbitrary number of bonded anisotropic layers and to heterogeneous plates. The assumed displacement field is:

$$ u(x, y, z) = u_0(x, y) + z \psi_x(x, y), $$

$$ v(x, y, z) = v_0(x, y) + z \psi_y(x, y), $$

$$ \omega(x, y, z) = \omega(x, y), \quad (0 < z < h), $$

(1.52)
where \( u, v, \) and \( \omega \) are the displacement components in the \( x, y \) and \( z \) directions, respectively, and \( u_0 \) and \( v_0 \) are the displacement components in \( x \) and \( y \) directions of reference plane (i.e. \( z = 0 \) plane). Note that these relations involve combined action of bending and extension which characterizes the general behavior of laminated and heterogeneous plates shown by Reissner and Stavsky [16], [17]. Comparing to the corresponding equations for a homogeneous plate, we can see that instead of three plate-displacement components here we have all five components \( u_0, v_0, \psi_x, \psi_y \) and \( \omega \) as the unknown functions.

### 1.3.1.2 The Strain Field

Again, using the standard linear elasticity approach, the strain field can be obtained from (1.52) as follows:

\[
\epsilon_x = \frac{\partial u}{\partial x} = \frac{\partial u_0}{\partial x} + z \frac{\partial \psi_x}{\partial x} = \epsilon_{x0} + z \kappa_x ,
\]

\[
\epsilon_y = \frac{\partial v}{\partial y} = \frac{\partial v_0}{\partial y} + z \frac{\partial \psi_y}{\partial y} = \epsilon_{y0} + z \kappa_y ,
\]

\[
\gamma_{xy} = \frac{\partial u}{\partial y} + \frac{\partial v}{\partial x} = \frac{\partial u_0}{\partial y} + \frac{\partial v_0}{\partial x} + z \left( \frac{\partial \psi_x}{\partial y} + \frac{\partial \psi_y}{\partial x} \right) = \gamma_{xy0} + z \kappa_{xy} ,
\]

(1.53)

\[
\gamma_{xz} = \frac{\partial u}{\partial z} + \frac{\partial \omega}{\partial x} = \psi_x + \frac{\partial \omega}{\partial x} = \gamma_{xz0} ,
\]

\[
\gamma_{yz} = \frac{\partial v}{\partial z} + \frac{\partial \omega}{\partial y} = \psi_y + \frac{\partial \omega}{\partial y} = \gamma_{yz0} ,
\]

\[
\epsilon_z = 0 ,
\]

(1.54)

where

\[
\epsilon_{x0} = \frac{\partial u_0}{\partial x} , \quad \epsilon_{y0} = \frac{\partial v_0}{\partial y} , \quad \gamma_{xy0} = \frac{\partial u_0}{\partial y} + \frac{\partial v_0}{\partial x} ,
\]

(1.55)
Besides the coupling characteristics the strain field has the same features as in the homogenous case.

1.3.1.3 Constitutive Equations for Any Layer

Assuming the generalized Hooke's law for the stress - strain relations, the constitutive relations of orthotropic materials for any layer are given by:

\[
\{ \Sigma \} = [ CE ] \{ \Omega \}, \quad \text{(1.57 a)}
\]

where

\[
CE = \begin{bmatrix}
C_{11} & C_{12} & C_{13} & 0 & 0 & 0 \\
C_{21} & C_{22} & C_{23} & 0 & 0 & 0 \\
C_{31} & C_{32} & C_{33} & 0 & 0 & 0 \\
0 & 0 & 0 & C_{44} & 0 & 0 \\
0 & 0 & 0 & 0 & C_{55} & 0 \\
0 & 0 & 0 & 0 & 0 & C_{66}
\end{bmatrix}
\]

\[
\Sigma = \begin{bmatrix}
\sigma_x \\
\sigma_y \\
\sigma_z \\
\sigma_{yz} \\
\sigma_{xz} \\
\sigma_{xy}
\end{bmatrix}, \quad \Omega = \begin{bmatrix}
\varepsilon_x \\
\varepsilon_y \\
\varepsilon_z \\
\gamma_{yz} \\
\gamma_{xz} \\
\gamma_{xy}
\end{bmatrix}, \quad \text{(1.57 b)}
\]
Observing that $C_{ij} = C_{ji}$, there are only 9 independent constants. For a heterogeneous plate, these 9 elastic coefficients $c_{ij}$ could be specified as functions of $z$ but do not vary in the $x, y$ directions. Following [18], for future convenience, we now employ a contracted notation to put the constitutive equation (1.57) into the form:

$$
\sigma_i = C_{ij} \epsilon_j \quad (i, j = 1, 2, 3),
$$

where

$$
\sigma_1 = \sigma_x, \quad \sigma_2 = \sigma_y, \quad \sigma_3 = \sigma_z,
$$

and the engineering strain $\epsilon_j$ are defined in an analogous manner. For the equation corresponding to $i = 3$ we then solve for $\epsilon_3$ and resubstitute it into equation (1.58), the results will be

$$
\sigma_i = Q_{i\alpha} \epsilon_{\alpha} + \frac{C_{i3}}{C_{33}} \sigma_3 \quad (i = 1, 2, 3), \quad (\alpha = 1, 2),
$$

where

$$
Q_{i\alpha} = C_{i\alpha} - \frac{C_{i3}}{C_{33}} C_{3\alpha}.
$$

The form of the constitutive relations given by equations (1.59) will be used in subsequent work. Integrals involving $\sigma_3$ will be dropped because for the thin plate in comparison with the other stress components $\sigma_2$ may be neglected.

Again as addressed in the subsection (2.1.4) the inconsistency for transverse shear stresses is still there.

1.3.1.4 Plate Constitutive Equations

The plate stress resultants and stress couples are defined as follows:

$$
(N_x, N_y, N_{xy}) = \int_0^h (\sigma_x, \sigma_y, \sigma_{xy}) \, dz,
$$

$$
(Q_x, Q_y) = \int_0^h (\sigma_{xz}, \sigma_{yz}) \, dz,
$$

28
\[
(M_x, M_y, M_{xy}) = \int_0^h (\sigma_x, \sigma_y, \sigma_{xy}) z \, dz .
\]

Substituting (1.53) and (1.54) into (1.57) and (1.59), and integrating, according to the definition (1.61 - 1.63) we obtain the plate constitutive equations as follows:

\[
\{ C_m \} = \begin{bmatrix} CC \end{bmatrix} \{ C_\epsilon \} ,
\]

where

\[
CC = \begin{bmatrix}
A_{11} & A_{12} & 0 & B_{11} & B_{12} & 0 \\
A_{21} & A_{22} & 0 & B_{21} & B_{22} & 0 \\
0 & 0 & A_{66} & 0 & 0 & B_{66} \\
B_{11} & B_{12} & 0 & D_{11} & D_{12} & 0 \\
B_{21} & B_{22} & 0 & D_{21} & D_{22} & 0 \\
0 & 0 & B_{66} & 0 & 0 & D_{66}
\end{bmatrix}
\]

\[
C_m = \begin{bmatrix}
N_x \\
N_y \\
N_{xy} \\
M_x \\
M_y \\
M_{xy}
\end{bmatrix}, \\
C_\epsilon = \begin{bmatrix}
\epsilon_x \\\n\epsilon_y \\
\gamma_{xy} \\
k_x \\
k_y \\
k_{xy}
\end{bmatrix},
\]

and

\[
\begin{bmatrix}
Q_x \\
Q_y
\end{bmatrix} = \begin{bmatrix}
A_{44} & 0 \\
0 & A_{55}
\end{bmatrix} \begin{bmatrix}
\gamma_{yz} \\
\gamma_{xz}
\end{bmatrix},
\]

where the reference plane strains \( \epsilon_x, \epsilon_y \), and \( \gamma_{xy} \), reference bending curvatures \( k_x \), \( k_y \) and \( k_{xy} \) and transverse shear strains \( \gamma_{xz0}, \gamma_{yz0} \) are defined in expressions (1.55).
(1.56) and (1.54) respectively, and for laminated plate

\[
(A_{ij}, B_{ij}, D_{ij}) = \sum_{k=1}^{n} \int_{h_{k-1}}^{h_k} Q_{ij}^{(k)}(1, z, z^2) \, dz,
\]

(1.66)

\[
(i, j = 1, 2),
\]

\[
(A_{66}, B_{66}, D_{66}) = \sum_{k=1}^{n} \int_{h_{k-1}}^{h_k} C_{66}^{(k)}(1, z, z^2) \, dz,
\]

(1.67)

\[
(A_{44}, A_{55}) = \sum_{k=1}^{n} \int_{h_{k-1}}^{h_k} (C_{44}^{(k)}, C_{55}^{(k)}) \, dz.
\]

(1.68)

where \( Q_{ij}^{(k)} \) and \( C_{mm}^{(k)} \) (\( m = 4, 5, 6 \)) are the material constants defined in (1.60) and (1.57) for the \( k \)th layer of the \( n \)-layer laminated plate.

1.3.1.5 Governing Equations

The stress and moment resultants must satisfy the following equilibrium equations:

\[
\frac{\partial N_x}{\partial x} + \frac{\partial N_{xy}}{\partial y} = 0,
\]

\[
\frac{\partial N_{xy}}{\partial x} + \frac{\partial N_y}{\partial y} = 0,
\]

\[
\frac{\partial M_x}{\partial x} + \frac{\partial M_{xy}}{\partial y} \cdot Q_x = 0,
\]

\[
\frac{\partial M_y}{\partial y} + \frac{\partial M_{xy}}{\partial x} \cdot Q_y = 0,
\]

\[
\frac{\partial Q_x}{\partial x} + \frac{\partial Q_y}{\partial y} = 0,
\]

(1.69)
where it is assumed that \( q = 0 \).

Substituting equations (1.63) and (1.64) into (1.69) the governing equations can then be obtained for the five unknown functions \( u_0, v_0, \psi_x, \psi_y \) and \( \omega \).

### 1.3.2 A Simple-higher-order Theory

---------- Reddy's Approach

#### 1.3.2.1 The assumed Displacement Field

This simple-higher order laminated plate theory is due to Reddy [11] which is based on the displacement field:

\[
\begin{align*}
    u(x, y, z) &= u_0(x, y) + z [ \psi_x - \frac{4}{3} \left( \frac{z}{h} \right)^2 ( \psi_x + \frac{\partial \omega}{\partial x} )], \\
    v(x, y, z) &= v_0(x, y) + z [ \psi_y - \frac{4}{3} \left( \frac{z}{h} \right)^2 ( \psi_y + \frac{\partial \omega}{\partial y} )], \\
    \omega(x, y, z) &= \omega(x, y). \quad (1.70)
\end{align*}
\]

Comparing to (1.42) for the homogeneous case, besides the reference plane displacement \( u_0 \) and \( v_0 \) which is due to the bending and stretching coupling, the two assumed displacement fields have the same \( z \) dependence. Here we have chosen the midplane of the plate as the reference plane for convenience. Again these are the lowest order expressions which can be made to satisfy the shear-free conditions on the lower and upper surfaces \( z = \pm h/2 \) with the same five unknown functions \( u_0, v_0, \psi_x, \psi_y \) and \( \omega \).

#### 1.3.2.2 The Strain Field and Constitutive Equations

Introducing the same notations as in the expressions (1.43) and the reference plane (here the midplane) strains as defined in (1.55), the strain field associated with the displacement given by equations (1.70) are
\[\varepsilon_x = \varepsilon_x^0 + z \left( k_x + z^2 k_x^{(2)} \right) ,\]
\[\varepsilon_y = \varepsilon_y^0 + z \left( k_y + z^2 k_y^{(2)} \right) ,\]
\[\varepsilon_z = 0 ; \quad (1.71)\]
\[\gamma_{xy} = \gamma_{xy}^0 + z \left( k_{xy} + z^2 k_{xy}^{(2)} \right) ,\]
\[\gamma_{xz} = k_{xz} + z^2 k_{xz}^{(2)} = \gamma_{xz0} ,\]
\[\gamma_{yz} = k_{yz} + z^2 k_{yz}^{(2)} = \gamma_{yz0} . \quad (1.72)\]

Besides the coupling phenomenon these strains have the same feature as discussed for the homogeneous case.

The constitutive equations for each layer will be the same as expressed in equations (1.57) and (1.59) because the physical properties of the laminated plate will remain the same regardless of what plate theory is used.

1.3.2.3 Equilibrium Equations and Plate Constitutive Equations

In this subsection we consider the plate constitutive equations and the equilibrium equations at the same time. Because two approaches are used to obtain the plate equilibrium equations which require different plate stress and moment resultants.

(a) Standard Plate Equilibrium Equations

As generally used for the plate problem, the standard equilibrium equations [15] are

\[\frac{\partial N_x}{\partial x} + \frac{\partial N_{xy}}{\partial y} = 0 ,\]
\[ \frac{\partial N_{xy}}{\partial x} + \frac{\partial N_y}{\partial y} = 0, \]
\[ \frac{\partial M_x}{\partial x} + \frac{\partial M_{xy}}{\partial y} - Q_x = 0, \]
\[ \frac{\partial M_y}{\partial y} + \frac{\partial M_{xy}}{\partial x} - Q_y = 0, \]
\[ \frac{\partial Q_x}{\partial x} + \frac{\partial Q_y}{\partial y} = 0. \quad (1.73) \]

These equations have been used by Levinson \[12\] for a homogeneous plate. Corresponding to the set of equilibrium equations (1.73), defining the stress resultants and stress couples \( N_x, N_y, N_{xy}, Q_x, Q_y \) and \( M_x, M_y, M_{xy} \) as in the expressions (1.61), (1.62) and (1.63), we could arrive at the same type of plate constitutive equations as expressed in (1.64) and (1.65), where the coefficients \( A_{ij}, B_{ij} \) and \( C_{ij} \) are defined exactly the same as in the expressions (1.66) - (1.68). Of course, the correction factor \( K \) is not needed any more.

\( \text{(b)} \) Using the Principle of Virtual Displacement to Derive the Plate Equilibrium Equations:

As could be seen later, the equilibrium equations (1.73) are variationally inconsistent with those derived from the principle of virtual displacements for the displacement field used in (1.70), because (1.73) is the equilibrium equations corresponding to the first-order plate theories. By using the equilibrium equations (1.73), the higher-order terms of the displacement field are accounted for only in the calculation of the strains but not in the governing differential equations. Reddy \[11\] corrected these equilibrium equations by deriving the plate equilibrium equations by means of the virtual work principle.

The principle of virtual displacement can be stated in analytical form as

\[ 0 = \int_{-h/2}^{+h/2} \int_{A} \left[ \sigma_x \delta \epsilon_x + \sigma_y \delta \epsilon_y + \sigma_{xy} \delta \gamma_{xy} + \sigma_{yz} \delta \gamma_{yz} + \sigma_{xz} \delta \gamma_{xz} \right] \, dA \, dz \]
\[ + \int_{A} q \delta \omega \, dx \, dy, \quad (1.74) \]
where \( h \Omega \) is the volume of the laminated plate and \( \delta \) denotes the variational symbol. Substituting the strains from (1.71) and (1.72) into (1.74), for example, we have for the first term:

\[
\int_{-h/2}^{+h/2} \int_{\Omega} \sigma_x \delta \epsilon_x \, dA \, dz = \int_{\Omega} \int_{-h/2}^{+h/2} \sigma_x \delta \epsilon_x \, dz \, dA
\]

\[
= \int_{\Omega} \int_{-h/2}^{+h/2} \sigma_x \delta [\epsilon_{x0} + z (k_x + z^2 k_x^{(2)})] \, dz \, dA
\]

\[
= \int_{\Omega} \{ \delta \epsilon_{x0} \left[ \int_{-h/2}^{+h/2} \sigma_x \, dz \right] + \delta k_x \left[ \int_{-h/2}^{+h/2} \sigma_x z \, dz \right]
\]

\[
+ \delta k_x^{(2)} \left[ \int_{-h/2}^{+h/2} \sigma_x z^3 \, dz \right] \} \, dA
\]

\[
= \int_{\Omega} \frac{\partial \delta u_0}{\partial x} N_x \, dA + \int_{\Omega} \frac{\partial \delta \psi_x}{\partial x} M_x \, dA
\]

\[
+ \int_{\Omega} \left[ -\frac{4}{3h^2} \left( \frac{\partial \delta \psi_x}{\partial x} + \frac{\partial^2 \delta \omega}{\partial x^2} \right) \right] P_x \, dA , \quad (1.75)
\]

where

\[
(N_x, M_x, P_{xy}) = \int_{-h/2}^{+h/2} \sigma_x (1, z, z^3) \, dz . \quad (1.76)
\]

Thus, defining the following stress resultants

\[
(N_x, N_y, N_{xy}) = \int_{-h/2}^{+h/2} (\sigma_x, \sigma_y, \sigma_{xy}) \, dz
\]

\[
(M_x, M_y, M_{xy}) = \int_{-h/2}^{+h/2} (\sigma_x, \sigma_y, \sigma_{xy}) \, z \, dz
\]

\[
(P_x, P_y, P_{xy}) = \int_{-h/2}^{+h/2} (\sigma_x, \sigma_y, \sigma_{xy}) \, z^3 \, dz
\]
\(( Q_x, Q_y ) = \int_{-h/2}^{+h/2} ( \sigma_{xz}, \sigma_{yz} ) \, dz \)

\(( R_x, R_y ) = \int_{-h/2}^{+h/2} ( \sigma_{xz}, \sigma_{yz} ) \, z^2 \, dz \) (1.77 a - e)

equation (1.74) can be written as

\[
0 = \int \left[ N_x \frac{\partial \delta u_0}{\partial x} + M_x \frac{\partial \delta \psi_x}{\partial x} + P_x \left[ -\frac{4}{3} h^2 \left( \frac{\partial \delta \psi_x}{\partial x} + \frac{\partial^2 \delta \omega}{\partial x^2} \right) \right] \\
+ N_y \frac{\partial \delta v_0}{\partial y} + M_y \frac{\partial \delta \psi_y}{\partial y} + P_y \left[ -\frac{4}{3} h^2 \left( \frac{\partial \delta \psi_y}{\partial y} + \frac{\partial^2 \delta \omega}{\partial y^2} \right) \right] \\
+ N_{xy} \left( \frac{\partial \delta u_0}{\partial y} + \frac{\partial \delta v_0}{\partial x} \right) + M_{xy} \left( \frac{\partial \delta \psi_x}{\partial y} + \frac{\partial \delta \psi_y}{\partial x} \right) \\
+ P_{xy} \left[ -\frac{4}{3} h^2 \left( \frac{\partial \delta \psi_x}{\partial y} + \frac{\partial \delta \psi_y}{\partial x} \right) + 2 \frac{\partial^2 \delta \omega}{\partial y \partial x} \right] \\
+ Q_y \left( \delta \psi_y + \frac{\partial \delta \omega}{\partial y} \right) + R_y \left[ -\frac{4}{h^2} \left( \delta \psi_y + \frac{\partial \delta \omega}{\partial y} \right) \right] \\
+ Q_x \left( \delta \psi_x + \frac{\partial \delta \omega}{\partial x} \right) + R_x \left[ -\frac{4}{h^2} \left( \delta \psi_x + \frac{\partial \delta \omega}{\partial x} \right) \right] + q \delta \omega \right] \, dx \, dy .
\] (1.78)

Integrating the expressions in equation (1.78) by parts, and collecting the coefficients of \( \delta u, \delta v, \delta \omega, \delta \psi_x \) and \( \delta \psi_y \), for \( q = 0 \) we obtain the following equilibrium in the domain \( \Omega \):

\[
\delta u : \quad \frac{\partial N_x}{\partial x} + \frac{\partial N_{xy}}{\partial y} = 0 ,
\]

\[
\delta v : \quad \frac{\partial N_{xy}}{\partial x} + \frac{\partial N_y}{\partial y} = 0 ,
\]
\[
\delta \omega : \quad \frac{\partial Q_x}{\partial x} + \frac{\partial Q_y}{\partial y} - \frac{4}{h^2} \left( \frac{\partial R_y}{\partial x} + \frac{\partial R_y}{\partial y} \right) \\
+ \frac{4}{3 h^2} \left( \frac{\partial^2 P_x}{\partial x^2} + 2 \frac{\partial^2 P_{xy}}{\partial y \partial x} + \frac{\partial^2 P_y}{\partial y^2} \right) = 0.
\]

\[
\delta \psi_x : \quad \frac{\partial M_x}{\partial x} + \frac{\partial M_{xy}}{\partial y} - Q_x + \frac{4}{h^2} R_x - \frac{4}{3 h^2} \left( \frac{\partial P_x}{\partial x} + \frac{\partial P_{xy}}{\partial y} \right) = 0,
\]

\[
\delta \psi_y : \quad \frac{\partial M_{xy}}{\partial x} + \frac{\partial M_y}{\partial y} - Q_y + \frac{4}{h^2} R_y - \frac{4}{3 h^2} \left( \frac{\partial P_{xy}}{\partial x} + \frac{\partial P_y}{\partial y} \right) = 0.
\]

Comparing to equations (1.73), the underlined terms are the consequence of the higher-order terms in the displacement expressions (1.70).

Corresponding to the equilibrium equations (1.79) the plate constitutive equations will have the following form:

\[
\{ CM \} = [ CC ] \{ CE \}, \quad (1.80 \text{a})
\]

where

\[
CC = \begin{bmatrix}
A_{11} & A_{12} & 0 & B_{11} & B_{12} & 0 & E_{11} & E_{12} & 0 \\
A_{21} & A_{22} & 0 & B_{21} & B_{22} & 0 & E_{21} & E_{22} & 0 \\
0 & 0 & A_{66} & 0 & 0 & B_{66} & 0 & 0 & E_{66} \\
B_{11} & B_{12} & 0 & D_{11} & D_{12} & 0 & F_{11} & F_{12} & 0 \\
B_{21} & B_{22} & 0 & D_{21} & D_{22} & 0 & F_{21} & F_{22} & 0 \\
0 & 0 & B_{66} & 0 & 0 & D_{66} & 0 & 0 & F_{66} \\
E_{11} & E_{12} & 0 & F_{11} & F_{12} & 0 & H_{11} & H_{12} & 0 \\
E_{21} & E_{22} & 0 & F_{21} & F_{22} & 0 & H_{21} & H_{22} & 0 \\
0 & 0 & E_{66} & 0 & 0 & F_{66} & 0 & 0 & H_{66}
\end{bmatrix}
\]
\[ CM = \begin{bmatrix} N_x & N_y & N_{xy} & M_x & M_y & M_{xy} & P_x & P_y & P_{xy} \end{bmatrix}^T, \]

\[ CE = \begin{bmatrix} \epsilon_{x0} & \epsilon_{y0} & \gamma_{xy0} & k_x & k_y & k_{xy} & k_x^{(2)} & k_y^{(2)} & k_{xy}^{(2)} \end{bmatrix}^T, \]

(1.80 b)

and

\[ \{ CQ \} = [ \text{CCR} ] \{ CK \}, \]

(1.81 a)

where

\[
\text{CCR} = \begin{bmatrix}
A_{44} & 0 & D_{44} & 0 \\
0 & A_{55} & 0 & D_{55} \\
D_{44} & 0 & F_{44} & 0 \\
0 & D_{55} & 0 & F_{55}
\end{bmatrix},
\]

\[
CQ = \begin{bmatrix}
Q_x \\
Q_y \\
R_x \\
R_y
\end{bmatrix}, \quad CK = \begin{bmatrix}
\gamma_{yz0} \\
\gamma_{xz0} \\
k_{yz}^{(2)} \\
k_{xz}^{(2)}
\end{bmatrix},
\]

(1.81 b)
where $A_{ij}$, $B_{ij}$, etc., are the plate stiffnesses, defined by

\[
( A_{ij}, B_{ij}, D_{ij}, E_{ij}, F_{ij}, H_{ij} )
= \int_{-h/2}^{+h/2} Q_{ij} ( 1, z, z^2, z^3, z^4, z^6 ) \, dz , \quad ( i, j = 1, 2 ),
\]

\[
( A_{44}, D_{44}, F_{44} )
= \int_{-h/2}^{+h/2} C_{44} ( 1, z^2, z^4 ) \, dz ,
\]

\[
( A_{55}, D_{55}, F_{55} )
= \int_{-h/2}^{+h/2} C_{55} ( 1, z^2, z^4 ) \, dz ,
\]

\[
( A_{66}, B_{66}, D_{66}, E_{66}, F_{66}, H_{66} )
= \int_{-h/2}^{+h/2} C_{66} ( 1, z, z^2, z^3, z^4, z^6 ) \, dz .
\]

(1.82 a - e)

### 1.3.2.4 Governing Equations:

For each set of equilibrium equations (1.73) and (1.79), substituting the corresponding plate constitutive equations, the governing partial differential equations in terms of the unknown functions $u_0$, $v_0$, $\omega$, $\psi_x$ and $\psi_y$ can be derived. It must be emphasized that in solving the governing equations derived from (1.79), the corresponding boundary conditions, which are also derived from the principle of virtual displacements, must be used. Upon solving the governing equations the five unknown functions $u_0$, $v_0$, $\omega$, $\psi_x$ and $\psi_y$ can be obtained and the corresponding elasticity problem can be solved.
Chapter 2. Laminated Plates with a Through Crack

2.1 INTRODUCTION

In chapter 1, prior to treating the more complicated problem of a laminated plate containing imperfections or cracks, a brief review of several commonly used transverse shear deformation plate theories were presented. In this chapter, the focus is on the laminated and heterogeneous plates containing a through thickness crack.

As we know the primary purpose of the stress analysis in structures is to study their strength and failure. In many cases the failure is attributed to the growth of cracks or crack-like flaws that exist in the structure. This requires, in addition to the application of standard failure theories specified by the traditional strength of material, the treatment of the problem of acceptance and safety from the viewpoint of fracture mechanics. Presently no complete solution of the plates failure problem in non-homogeneous or anisotropic plates is available because of the inherent difficulties in stress analysis and material characterization of such laminated structures. During the past two decades many investigators have studied the stress state in the immediate neighborhood of the crack tip in a homogeneous isotropic medium since the local fracture of the structure appears to be governed mainly by this stress field. The stress intensity factor, which represents the singular behavior of the stress state near the crack tip, has been used quite effectively as the primary load factor in the fracture analysis. Moreover, the knowledge of the stress intensity factors is a prerequisite for the fracture control, the residual strength, and subcritical crack growth analysis. The main interest in this chapter is in obtaining the stress intensity factors in laminated or heterogeneous plates containing a through thickness crack.

The orthotropic laminated plate, which could represent laminated composites or bonded materials, is composed of thin homogeneous layers of different orthotropic elastic properties. The heterogeneous plate may have continuously varying properties through the thickness. By using the so called “single-layer laminated plate theories” discussed in Chapter 1, we will assume that the individual lamina are elastic and are perfectly bonded along interfaces. Global laminated properties are obtained by integrating lamina properties through the thickness. The general linear laminated and
heterogeneous plate theory developed by Yang, Norris and Stavsky [7] and examined in Chapter 1 is used here, because it is believed that this theory is the best compromise between simplicity and accuracy. Some observations in this regard are given later in this chapter. The governing equations which are a set of partial differential equations will be solved by using Fourier Transformation technique. Finally a pair of singular integral equations will be derived to solve the related mixed boundary value problem. Then the stress intensity factors can be obtained for various geometries and bending or membrane loading conditions. Only the mode I crack problem will be considered.
2.2 FORMULATION OF THE PROBLEM

The problem of interest is shown in Figure 2.1. The "infinite" laminated plate consisting of an arbitrary number of bonded orthotropic layers contains a through crack of length 2a. The total thickness of the plate is \( h \). The system of coordinates and the definition of the variables are defined in the same way as in Chapter 1, particularly as in the general linear first order plate theory described in subsection (1.3.1) of Chapter 1. We also assume that the coordinates \( x \), \( y \), and \( z \) axes correspond to the principal orthotropy axes of each layer.

2.2.1 Fourier Integral Transformation

Following the general linear laminated plate theory reviewed in (1.3.1) of Chapter 1 the assumed displacement field is:

\[
\begin{align*}
    u(x, y, z) &= u_0(x, y) + z \psi_x(x, y), \\
    v(x, y, z) &= v_0(x, y) + z \psi_y(x, y), \\
    \omega(x, y, z) &= \omega(x, y), \\
    (0 < z < h),
\end{align*}
\]

(2.1)

where \( u \), \( v \), and \( \omega \) are the displacement components in the \( x \), \( y \) and \( z \) directions respectively, \( u_0 \) and \( v_0 \) are the displacement components in \( x \) and \( y \) directions of reference plane (i.e. \( z = 0 \) plane) and \( \psi_x \) and \( \psi_y \) are the rotations of the sections of \( x \)-constant and \( y \)-constant.

By defining the reference plane strains \( \epsilon_{x0} \), \( \epsilon_{y0} \), and \( \gamma_{xy0} \), reference bending curvatures \( k_x \), \( k_y \) and \( k_{xy} \) and transverse shear strains \( \gamma_{x20} \), \( \gamma_{y20} \) as follows:

\[
\begin{align*}
    \epsilon_{x0} &= \frac{\partial u_0}{\partial x}, & \epsilon_{y0} &= \frac{\partial v_0}{\partial y}, & \gamma_{xy0} &= \frac{\partial u_0}{\partial y} + \frac{\partial v_0}{\partial x}, \\
    k_x &= \frac{\partial \psi_x}{\partial x}, & k_y &= \frac{\partial \psi_y}{\partial y}, & k_{xy} &= \frac{\partial \psi_x}{\partial y} + \frac{\partial \psi_y}{\partial x}, \\
    \gamma_{x20} &= \psi_x + \frac{\partial \omega}{\partial x}, & \gamma_{y20} &= \psi_y + \frac{\partial \omega}{\partial y},
\end{align*}
\]

(2.2)
the plate constitutive equations can be written in the following form (see 1.64)

\[ \{ C_m \} = [ CC ] \{ C_\varepsilon \}, \quad (2.3 \text{ a}) \]

where

\[
CC = \begin{bmatrix}
A_{11} & A_{12} & 0 & B_{11} & B_{12} & 0 \\
A_{21} & A_{22} & 0 & B_{21} & B_{22} & 0 \\
0 & 0 & A_{66} & 0 & 0 & B_{66} \\
B_{11} & B_{12} & 0 & D_{11} & D_{12} & 0 \\
B_{21} & B_{22} & 0 & D_{21} & D_{22} & 0 \\
0 & 0 & B_{66} & 0 & 0 & D_{66}
\end{bmatrix}
\]

\[
C_m = \begin{bmatrix}
N_x \\
N_y \\
N_{xy} \\
M_x \\
M_y \\
M_{xy}
\end{bmatrix}, \quad C_\varepsilon = \begin{bmatrix}
\varepsilon_{x0} \\
\varepsilon_{y0} \\
\gamma_{xy0} \\
k_x \\
k_y \\
k_{xy}
\end{bmatrix}, \quad (2.3 \text{ b})
\]

and

\[
\begin{bmatrix}
Q_x \\
Q_y
\end{bmatrix} = \begin{bmatrix}
A_{44} & 0 \\
0 & A_{55}
\end{bmatrix} \begin{bmatrix}
\gamma_{y_0} \\
\gamma_{x_0}
\end{bmatrix}, \quad (2.3 \text{ c})
\]

where the stiffness constants \( A_{ij}, B_{ij} \) and \( D_{ij} \) (\( i, j = 1, 2 \)) are defined in (1.66) and \( A_{ij} \) (\( i = 4, 5, 6 \)) in (1.68) and (1.67). For example

\[
B_{ij} = \sum_{k=1}^{n} \int_{h_{k-1}}^{h_k} Q_{ij}^{(k)} z \, dz, \quad (i, j = 1, 2), \quad (2.4)
\]
for a laminated plate of n layers and $Q_{ij}$ of each layer are defined in (1.60).

Note that the bending - membrane coupling phenomenon, which was first studied by Reissner and Stavsky with classical bending theory, can be seen easily in the expressions (2.1) and (2.3). Unless $B_{ij}$ (i, j = 1, 2) are all zero, the problem will remain coupled. If the plate is symmetrically layered, and taking the plane of symmetry (i.e. the midplane) as the reference plane it may be shown that the $B_{ij}$'s (see expression (2.4)) are all zero, and consequently the problem becomes uncoupled.

For convenience, for this general linear laminated plate theory the five unknown functions, $u_0$, $v_0$, $\omega$, $\psi_x$ and $\psi_y$, are defined as the "displacement" vector $[U]$ as follows

$$[U] = \begin{bmatrix} u_1 & u_2 & u_3 & u_4 & u_5 \end{bmatrix}^T = \begin{bmatrix} u_0 & v_0 & \psi_x & \psi_y & \omega \end{bmatrix}^T.$$  

(2.5)

Substituting (2.3) into plate equilibrium equations (1.69) and considering (2.5), the governing partial differential equations in terms of the unknown functions $u_i$ are found to be

\[
A_{11}u_{1,xx} + (A_{12} + A_{66})u_{2,xy} + A_{66}u_{1,yy} \\
+ B_{11}u_{3,xx} + (B_{12} + B_{66})u_{4,xy} + B_{66}u_{3,yy} = 0,
\]

\[
A_{66}u_{2,xx} + (A_{12} + A_{66})u_{1,xy} + A_{22}u_{2,yy} \\
+ B_{66}u_{4,xx} + (B_{12} + B_{66})u_{3,xy} + B_{22}u_{4,yy} = 0,
\]

\[
B_{11}u_{1,xx} + (B_{12} + B_{66})u_{2,xy} + B_{66}u_{1,yy} \\
+ D_{11}u_{3,xx} + (D_{12} + D_{66})u_{4,xy} + D_{66}u_{3,yy} - A_{55}u_{3} - A_{55}u_{5,x} = 0,
\]
\[ B_{66}u_{2,xx} + (B_{12} + B_{66})u_{1,xy} + B_{22}u_{2,yy} + D_{66}u_{4,xx} + (D_{12} + D_{66})u_{3,xy} + D_{22}u_{4,yy} - A_{44}u_4 - A_{44}u_{5,y} = 0, \]
\[ A_{44}u_{4,y} + A_{44}u_{5,yy} + A_{55}u_{3,x} + A_{55}u_{5,xx} = 0. \]

(2.6 a - e)

Taking the Fourier Transforms of equations (2.6) and defining

\[ u_i = \frac{1}{2\pi} \int_{-\infty}^{\infty} \phi_i(x, \alpha) e^{-i\alpha y} d\alpha, \]

(2.7 a)

\[ \phi_i = \int_{-\infty}^{\infty} u_i(x,y) e^{i\alpha y} dy, \]

\[ i = 1, \ldots, 5, \]

(2.7 b)

we arrive at the following ordinary differential equations:

\[ CA \ddot{\phi} + CB \dot{\phi} + CD\phi = 0, \]

(2.8)

where

\[ [\Phi] = \begin{bmatrix} \phi_1 & \phi_2 & \phi_3 & \phi_4 & \phi_5 \end{bmatrix}^T, \]

(2.9)

\[ \ddot{\phi} = \Phi_{,xx}, \quad \dot{\phi} = \Phi_{,x}, \]

\[ CA = \begin{bmatrix} A_{11} & 0 & B_{11} & 0 & 0 \\ 0 & A_{66} & 0 & B_{66} & 0 \\ B_{11} & 0 & D_{11} & 0 & 0 \\ 0 & B_{66} & 0 & D_{66} & 0 \\ 0 & 0 & 0 & 0 & -A_{55} \end{bmatrix} \]
\[
\begin{bmatrix}
0 & A_{11} + A_{66} & 0 & B_{12} + B_{66} & 0 \\
A_{12} + A_{66} & 0 & B_{12} + B_{66} & 0 & 0 \\
0 & B_{12} + B_{66} & 0 & D_{12} + D_{66} & -A_{55} - \frac{i}{\alpha} \\
B_{12} + B_{66} & 0 & D_{12} + D_{66} & 0 & 0 \\
0 & 0 & -A_{55} \frac{i}{\alpha} & 0 & 0
\end{bmatrix}
\]

\[
\begin{bmatrix}
-\alpha^2 A_{66} & 0 & -\alpha^2 B_{66} & 0 & 0 \\
0 & -\alpha^2 A_{22} & 0 & -\alpha^2 B_{22} & 0 \\
-\alpha^2 B_{66} & 0 & -(\alpha^2 D_{66} + A_{44}) & 0 & 0 \\
0 & -\alpha^2 B_{22} & 0 & -(\alpha^2 D_{22} + A_{44}) & i\alpha A_{44} \\
0 & 0 & 0 & i\alpha A_{44} & \alpha^2 A_{44}
\end{bmatrix}
\]

(2.11 a-c)

Upon determining the eigenvalues \( s_i \) and the eigenfunctions \( C_{ij} \) of equations of (2.8), observing that \( \phi_i \) (\( i = 1, \ldots, 5 \)) must be finite when \( x \rightarrow \infty \), and thus taking the coefficients of the terms having \( e^{s_j x} \) with \( \text{Re}(s_j) > 0 \) to be zero, we finally obtain the solutions of equation (2.8) as:

\[
\phi_i = \sum_{j=1}^{5} C_{ij} A_j(\alpha) e^{s_j x}, \quad \text{Re}(s_j) < 0, \quad (i,j) = 1, \ldots, 5.
\]

(2.13)

Thus, the unknown displacement components \( u_i \) can be expressed as

\[
u_i = \frac{-1}{2\pi} \int_{-\infty}^{\infty} \phi_i(\alpha, x) e^{-i\alpha y} d\alpha
\]

45
where \( A_j \), \( (j = 1,..., 5) \) are the unknown functions which can be obtained by applying the boundary conditions. Substituting (2.13) into expressions (1.53 - 1.56) we obtain the strain components. Furthermore, substituting these into plate constitutive equation (2.3), the relevant expressions of stresses, moments, and transverse shear resultants can be obtained.

2.2.2 Boundary Conditions

Assuming that \( x = 0 \) and \( y = 0 \) are planes of symmetry with respect to loading and geometry and that the problem has been reduced to a perturbation problem in which the crack surface stress and moment resultants are the only nonzero external loads, the boundary conditions may be expressed as (Figure 2.1):

\[
N_{xy}(0^+, y) = 0, \\
M_{xy}(0^+, y) = 0, \\
Q_x(0^+, y) = 0, \quad (-\infty < y < \infty),
\]

(2.14 a-c)

\[
N_x(0^+, y) = f_1(y), \quad |y| < a, \\
u_0(0^+, y) = 0, \quad |y| > a,
\]

\[
M_x(0^+, y) = f_2(y), \quad |y| < a, \\
\psi_x(0^+, y) = 0, \quad |y| > a.
\]

(2.14 d,e)

46
Three of the unknown functions $A_1, \ldots, A_5$ maybe eliminated by using the homogeneous conditions (2.14 a-c). The remaining two are then obtained from the mixed boundary conditions (2.14 d,e).

2.2.3 Singular Integral Equations

To solve this mixed boundary value problem, we define the new unknown functions as follows:

$$\frac{\partial}{\partial y} \psi_x (0, y) = G_2(y), \quad (-\infty < y < \infty), \quad (2.15)$$

$$\frac{\partial}{\partial y} u_0 (0, y) = G_1(y), \quad (-\infty < y < \infty). \quad (2.16)$$

By using (2.4) and (2.13), it can be shown that

$$G_2(y) = \frac{\partial}{\partial y} \psi_x (0, y) = \frac{\partial}{\partial y} u_3$$

$$= \lim_{\alpha \to 0} \frac{1}{2\pi} \int_{-\infty}^{\infty} \sum_{j=1}^{5} C_{3j} A_j(\alpha) \cdot e^{\frac{i}{2}x} (-i\alpha) e^{-i\alpha y} d\alpha,$$

$$\sum_{j=1}^{5} C_{3j} A_j(\alpha) (-i\alpha) = \int_{-\infty}^{\infty} G_2(y) e^{i\alpha y} dy$$

$$= \int_{-\alpha}^{\alpha} G_2(t) e^{i\alpha t} dt = g_2(\alpha), \quad (2.17)$$
\[ G_1(y) = \frac{\partial}{\partial y} u_0(0,y) = \frac{\partial}{\partial y} u_1 \]

\[
= \lim_{x \to 0} \frac{1}{2\pi} \int_{-\infty}^{\infty} \sum_{j=1}^{5} C_{1j} A_j(\alpha) e^{s_j x} (-i\alpha) e^{-i\alpha y} d\alpha, \]

\[
\sum_{j=1}^{5} C_{1j} A_j(\alpha) (-i\alpha) = \int_{-\infty}^{\infty} G_1(y) e^{i\alpha y} dy
\]

\[
= \int_{-a}^{a} G_1(t) e^{i\alpha t} dt = g_1(\alpha). \quad (2.18)
\]

To obtain the unknown functions \( A_i(\alpha), \) \((i = 1, \ldots, 5),\) in terms of \( g_1 \) and \( g_2, \) the homogeneous boundary conditions (2.9 a-c) are applied first. Starting with

\[ N_{xy}(0^+, y) = 0, \]

and by substituting (2.13) into (2.3), we obtain

\[ N_{xy} = A_{66} u_{1,y} + A_{66} u_{2,x} + B_{66} u_{3,y} + B_{66} u_{4,x} \]

\[
= \frac{1}{2\pi} \int_{-\infty}^{\infty} \left[ A_{66} \sum_{j=1}^{5} C_{1j} A_j(\alpha) e^{s_j x} (-i\alpha) \right.
\]

\[
+ B_{66} \sum_{j=1}^{5} C_{3j} A_j(\alpha) e^{s_j x} (-i\alpha) + A_{66} \sum_{j=1}^{5} C_{2j} A_j(\alpha) e^{s_j x}(s_j)
\]

\[
+ B_{66} \sum_{j=1}^{5} C_{4j} A_j(\alpha) e^{s_j x}(s_j) \bigg] e^{-i\alpha y} d\alpha. \quad (2.19)
\]
By inverting the Fourier integral, we find

\[ \sum_{j=1}^{5} \left[ \begin{array}{c} C_{1j} A_{66} (-i\alpha) + C_{3j} B_{66} (-i\alpha) + C_{2j} A_{66} s_j \\ + C_{4j} B_{66} s_j \end{array} \right] A_j(\alpha) = 0. \]  

(2.20)

Similarly, from

\[ M_{xy}(0^+, y) = 0 \quad \text{and} \quad Q_x(0^+, y) = 0, \]

it can be shown that

\[ \sum_{j=1}^{5} \left[ \begin{array}{c} C_{1j} B_{66} (-i\alpha) + C_{3j} D_{66} (-i\alpha) + C_{2j} B_{66} s_j \\ + C_{4j} D_{66} s_j \end{array} \right] A_j(\alpha) = 0. \]  

(2.21)

\[ \sum_{j=1}^{5} \left[ \begin{array}{c} C_{3j} A_{55} + C_{5j} A_{55} s_j \end{array} \right] A_j(\alpha) = 0. \]  

(2.22)

Solving the system of linear algebraic equations (2.17 - 2.18) and (2.20 - 2.22) \( A_i(\alpha) \) may be expressed as follows:

\[ A_i(\alpha) = Q_{i1} g_1(\alpha) + Q_{i2} g_2(\alpha) \]
where \( Q_{i1} \) and \( Q_{i2} \) are the algebraic expressions from the solution of the equations (2.17-2.18) and (2.20-2.22).

Substituting (2.23) and (2.13) into the strain field (1.53) - (1.56), and using (2.31), the resultants \( N_x \) and \( M_x \) may be expressed as:

\[
M_x = B_{11} u_{1,x} + B_{12} u_{2,y} + D_{11} u_{3,x} + D_{12} u_{4,y},
\]

\[
M_x = \frac{1}{2 \pi} \int_{-\infty}^{\infty} \left[ B_{12} \sum_{j=1}^{5} C_{2j} A_j(\alpha) e^{sjx} \right] e^{i\alpha y} d\alpha
\]

\[
+ D_{12} \sum_{j=1}^{5} C_{4j} A_j(\alpha) e^{sjx} \right] e^{i\alpha y} d\alpha
\]

\[
= \frac{1}{2 \pi} \int_{-\infty}^{\infty} G_1(t) \ dt \int_{-\infty}^{\infty} H_{21}(\alpha, x) \ e^{i \alpha (t-y)} \ d\alpha
\]

\[
+ \frac{1}{2 \pi} \int_{-\infty}^{\infty} G_2(t) \ dt \int_{-\infty}^{\infty} H_{22}(\alpha, x) \ e^{i \alpha (t-y)} \ d\alpha,
\]

(2.25)
\[ H_{2k} = \sum_{j=1}^{5} \left\{ B_{11} C_{1j} s_j + B_{12} C_{2j} (-i \alpha) + D_{11} C_{3j} s_j + D_{12} C_{4j} (-i \alpha) \right\} Q_{jk} e^{s_j x}, \]
\[ (k = 1, 2), \]
\[ (2.26) \]

\[ N_x = A_{11} u_{1,x} + A_{12} u_{2,y} + B_{11} u_{3,x} + B_{12} u_{4,y}, \]
\[ (2.27) \]

\[ N_x = -\frac{1}{2\pi} \int_{-\alpha}^{\alpha} G_1(t) \, dt \int_{-\infty}^{\infty} H_{11}(\alpha, x) \, e^{i\alpha(t-y)} \, d\alpha \]
\[ + \frac{1}{2\pi} \int_{-\alpha}^{\alpha} G_2(t) \, dt \int_{-\infty}^{\infty} H_{12}(\alpha, x) \, e^{i\alpha(t-y)} \, d\alpha, \]
\[ (2.28) \]

\[ H_{1k} = \sum_{j=1}^{5} \left\{ A_{11} C_{1j} s_j + A_{12} C_{2j} (-i \alpha) + B_{11} C_{3j} s_j + B_{12} C_{4j} (-i \alpha) \right\} Q_{jk} e^{s_j x}, \]
\[ (k = 1, 2). \]
\[ (2.29) \]

Observing expressions (2.25) and (2.26) and applying the mixed boundary conditions (2.14 d, e), we finally obtain two integral equations to determine the new unknown functions \( G_1 \) and \( G_2 \) in the following form:
\[
\lim_{x \to 0} \int_{-a}^{a} \sum_{j=1}^{2} G_j(t) \int_{-\infty}^{\infty} H_{ij}(\alpha, x) e^{i \alpha (t-y)} d\alpha = f_i(y),
\]
\( (i = 1, 2), \quad |y| < a. \)  

By further examining the functions \( H_{ij} \), it can be shown that they are bounded everywhere for finite \( \alpha \). Therefore any possible singularity of the kernels in (2.30) at \( y = t \) must be due to the behavior of \( H_{ij}(\alpha, x) \) as \( \alpha \to \mp \infty \). Note that \( H_{ij} \) contains exponential damping terms of the form \( e^{s_j x} \), where \( \text{Re}(s_j) < 0 \). However, since in the limit \( x \) will go to zero, for \( y = t \) this damping does not insure the convergence of the inner integrals in (2.30). The major difficulty in this problem, of course, is that the functions \( s_j(x) \) are not known explicitly in terms of \( \alpha \). For the purpose of examining the singular behavior of the kernels in (2.30) and extracting the singular parts, all one needs, however, is the asymptotic behavior of \( s_j \) as \( |\alpha| \to \infty \). Thus, from (2.8) - (2.11) it can be shown that for large values of \( |\alpha| \) we have

\[
\frac{s_j(\alpha)}{|\alpha|} = \left( s_0 + \frac{s_{j1}}{\alpha} + \frac{s_{j2}}{\alpha^2} + \ldots \right),
\]

(2.31)

where \( s_0 \) is a constant.

Now using the relations (2.31) and separating the asymptotic values of \( H_{ij} \) for large \( |\alpha| \), the kernels in (2.30) may be expressed as:

\[
\int_{-\infty}^{\infty} H_{ij}(\alpha, x) e^{i \alpha (t-y)} d\alpha = \int_{-\infty}^{\infty} H_{ij}^\infty(\alpha, x) e^{i \alpha (t-y)} d\alpha
\]

\[
+ \int_{-\infty}^{\infty} \left[ H_{ij}(\alpha, x) - H_{ij}^\infty(\alpha, x) \right] e^{i \alpha (t-y)} d\alpha,
\]

where \( H_{ij}^\infty \) is the asymptotic value of \( H_{ij} \) for \( |\alpha| \to \infty \).
The first term on the right-hand gives Cauchy-type kernels \( \frac{1}{t - y} \), and the second integral is uniformly convergent for all \( t \) and \( y \) (in which the limit \( x = 0 \) can be therefore be put under the integral sign). After the asymptotic analysis and some lengthy but straightforward manipulations the integral equations and the kernels may then be expressed as follows:

\[
\sum_{j=1}^{2} \frac{\mu_{1j}}{\pi} \int_{-a}^{a} \frac{G_j(t)}{t - y} \, dt + \sum_{j=1}^{2} \int_{-a}^{a} k_{1j}(y, t) G_j(t) \, dt = f_1(y),
\]

\[
\sum_{j=1}^{2} \frac{\mu_{2j}}{\pi} \int_{-a}^{a} \frac{G_j(t)}{t - y} \, dt + \sum_{j=1}^{2} \int_{-a}^{a} k_{2j}(y, t) G_j(t) \, dt = f_2(y),
\]

(2.33 a, b)

where \( \mu_{ij} \) (\( i, j = 1, 2 \)) are material constants obtained from the asymptotic analysis, \( f_i(y), (i = 1, 2) \) are defined by (2.14 d, e) and the Fredholm kernels \( K_{ij} \) are obtained from

\[
k_{ij}(y, t) = \frac{1}{2\pi} \int_{-\infty}^{\infty} [H_{ij}(\alpha, 0) - H_{ij}(\alpha, 0)] e^{i\alpha(t-y)} \, d\alpha,
\]

(2.34)

From the definitions of \( G_1 \) and \( G_2 \) given by (2.15) and (2.16) it follows that (2.33) must be solved under the following single-valuedness conditions

\[
\int_{-a}^{a} G_j(y) \, dy = 0, \quad (i = 1, 2).
\]

(2.35)

Note that, when the plate is symmetrically layered about the \( z = 0 \) plane, by taking the plane of symmetry as the reference plane we find \( H_{12} = H_{21} = 0 \), and consequently \( \mu_{12} = \mu_{21} = 0 \) and \( k_{12} = k_{21} = 0 \). Thus, the bending and in-plane stretching problems would be decoupled.
2.3 STRESS INTENSITY FACTORS

2.3.1 Solution of the Singular Integral Equations

The two unknown density functions $G_1$ and $G_2$ can be obtained by solving the singular integral equations (2.33 a, b) numerically. The two most commonly known numerical methods for solving such singular integral equations are Quadrature method [19] and Collocation method [20], [21]. In this chapter, the singular integral equations are solved by collocation method (also called expansion method). To solve the integral equations:

\[
\begin{align*}
\sum_{j=1}^{2} \frac{\mu_{ij}}{\pi} \int_{-a}^{a} \frac{G_j(t)}{t-y} \, dt + \sum_{j=1}^{2} \int_{-a}^{a} k_{ij}(y, t) G_j(t) \, dt = f_1(y), \\
\sum_{j=1}^{2} \frac{\mu_{2j}}{\pi} \int_{-a}^{a} \frac{G_j(t)}{t-y} \, dt + \sum_{j=1}^{2} \int_{-a}^{a} k_{2j}(y, t) G_j(t) \, dt = f_2(y),
\end{align*}
\]

we first express the unknown functions in terms of their weight functions

\[
G_i(t) = \frac{g_i(t)}{(a^2 - t^2)^{1/2}},
\]

(2.36)

and then normalize the interval (-a, a) by defining

\[
t = ar, \quad (-a \leq t \leq a, \quad -1 \leq r \leq 1),
\]

\[
y = as, \quad (-a \leq y \leq a, \quad -1 \leq s \leq 1),
\]

54
\[ f_i(y) = \overline{f_i}(s), \]
\[ G_i(t) = \frac{g_i(r)}{(1 - r^2)^{1/2}}, \quad \overline{G_i}(t) = a_i g_i(r), \]
\[ L_{ij}(r,s) = a_{kj}(y,t). \]

By substituting (2.36) and (2.37) into (2.33), we obtain:

\[
\sum_{j=1}^{2} \frac{\mu_{1j}}{\pi} \int_{-a}^{a} \frac{g_j(r)}{(1 - r^2)^{1/2}(r-s)} dr + \sum_{j=1}^{2} \int_{-a}^{a} L_{1j}(r,s) g_j(r) dr = \overline{f_1}(s),
\]
\[
\sum_{j=1}^{2} \frac{\mu_{2j}}{\pi} \int_{-a}^{a} \frac{g_j(r)}{(1 - r^2)^{1/2}(r-s)} dr + \sum_{j=1}^{2} \int_{-a}^{a} L_{2j}(r,s) g_j(r) dr = \overline{f_2}(s),
\]

\[ |s| < 1. \]

In applying the collocation method, we choose

\[ g_1(r) = \sum_{j=1}^{N} a_j h_{j-1}(r), \]

55
\[ g_2(r) = \sum_{j=1}^{N} b_j h_{j-1}(r), \]  

(2.39)

where \( h_j(r) \) are linearly independent coordinate functions chosen to “fit the curve” and the \( a_j \) and \( b_j \) are coefficients to be determined. It is believed that the best choice of \( h_j(r) \) are orthogonal polynomials, because the coefficients show convergence as \( N \) is increased (see [21]).

Here, we let

\[ h_{j-i}(r) = T_{j-i}(r), \]

(2.40)

where \( T_{j-1}(r) \) are the Chebychev polynomial of the first kind corresponding to the weight function of expression (2.36). Note that these equations must be solved under the following single-valueness conditions:

\[
\begin{align*}
\int_{-1}^{1} G_1(t) \, dt &= 0, \quad \text{or} \quad \int_{-1}^{1} \frac{g_1(r)}{(1 - r^2)^{1/2}} \, dr = 0, \\
\int_{-1}^{1} G_2(t) \, dt &= 0, \quad \text{or} \quad \int_{-1}^{1} \frac{g_2(r)}{(1 - r^2)^{1/2}} \, dr = 0,
\end{align*}
\]

(2.41)

From (2.39) and (2.40) it can be seen that these extra conditions are:

\[
\sum_{j=1}^{N} a_j \int_{-1}^{1} \frac{T_{j-1}(r)}{(1 - r^2)^{1/2}} \, dr = 0,
\]
\[
\sum_{j=1}^{N} b_j \int_{-1}^{1} \frac{T_{j-1}(r)}{\sqrt{1-r^2}} \, dr = 0.
\]  
(2.42)

Using the orthogonal conditions:

\[
\int_{-1}^{1} \frac{T_n(r) T_0(r)}{\sqrt{1-r^2}} \, dr = 0, \quad n \neq 0,
\]
and observing that \( T_0(r) \equiv 1 \), we obtain

\[
a_1 \equiv 0,
\]
\[
b_1 \equiv 0,
\]  
(2.43)

Considering (2.44) for further convenience, we rewrite the unknown functions as follows:

\[
g_1(r) = \sum_{k=1}^{M} a_k T_k(r),
\]
\[
g_2(r) = \sum_{k=M+1}^{2M} a_k T_{k-M}(r).
\]  
(2.45)
Substituting (2.45) into (2.38) the singular integral equations can then be expressed as follows:

\[
\sum_{k=1}^{M} \frac{\mu_{11}}{\pi} a_k \int_{-1}^{1} \frac{T_k(r)}{(1 - r^2)^{1/2}(r - s)} \, dr \\
+ \sum_{k=M+1}^{2M} \frac{\mu_{12}}{\pi} a_k \int_{-1}^{1} \frac{T_{k-M}(r)}{(1 - r^2)^{1/2}(r - s)} \, dr \\
+ \sum_{k=1}^{M} a_k \int_{-1}^{1} L_{11}(r, s) \frac{T_k(r)}{(1 - r^2)^{1/2}} \, dr = T_1(s),
\]

\[
\sum_{k=1}^{M} \frac{\mu_{21}}{\pi} a_k \int_{-1}^{1} \frac{T_k(r)}{(1 - r^2)^{1/2}(r - s)} \, dr \\
+ \sum_{k=M+1}^{2M} \frac{\mu_{22}}{\pi} a_k \int_{-1}^{1} \frac{T_{k-M}(r)}{(1 - r^2)^{1/2}(r - s)} \, dr \\
+ \sum_{k=1}^{M} a_k \int_{-1}^{1} L_{21}(r, s) \frac{T_k(r)}{(1 - r^2)^{1/2}} \, dr \\
+ \sum_{k=M+1}^{2M} a_k \int_{-1}^{1} L_{22}(r, s) \frac{T_{k-M}(r)}{(1 - r^2)^{1/2}} \, dr = T_2(s),
\]

\(|s| < 1, \]

(2.46 a, b)
where the unknowns are $a_k$ ($k = 1, \ldots, 2M$).

In the collocation method there is no restriction on the choice of $s$. In this study we choose $T_M(s_i) = 0$ or

$$s_i = \cos\left(\frac{2i - 1}{2M}\pi\right), \quad (i = 1, \ldots, M).$$

(2.47)

In (2.46) for a given value of $s$ there are two integrations to be evaluated. Any standard technique can be used, for example, Gauss - Chebychev quadrature which takes advantage of the weight

$$\int_{-1}^{1} \frac{h(r)}{(1 - r^2)^{1/2}} dr = \sum_{j=1}^{N} W_j h(r_j),$$

(2.48)

where

$$r_j = \cos\left(\frac{j - 1}{N - 1}\pi\right),$$

$$\omega_1 = \frac{1}{2} \frac{\pi}{N - 1},$$

$$\omega_j = \frac{\pi}{N - 1}, \quad j = 2, \ldots, N - 1,$$

$$\omega_N = \frac{1}{2} \frac{\pi}{N - 1}.$$
For the singular integrals, such expansion function $T_j(\, r \,) \, \text{give the closed form expressions:}$

$$
\int_{-1}^{1} \frac{T_j(\, r \,)}{(1 - r^2)^{1/2}(\, r - s \,)} \, dr = \pi \, U_{j-1}(\, s \,),
$$

(2.50)

where $U_j(\, r \,)$ are the Chebychev polynomials of the second kind.

Using (2.49) and (2.50) with the collocation points $s_j$ as in the equation (2.47), the singular integral equations (2.46 a, b) can be evaluated at $M$ different points giving $2M$ linear algebraic equations for $a_1 \ldots a_{2M}$. The unknown functions $G_1(\, t \,)$ and $G_2(\, t \,)$ can then be obtained from (2.45) and (2.37).

### 2.3.2 Displacement Components along the Crack

From the previous subsection and (2.15) and (2.16) we could express the unknown functions as follows

$$
G_1(\, y \,) = \frac{\partial}{\partial y} \, u_0(\, 0, y \,) = \sum_{k=1}^{M} a_k \, \frac{T_k(\, y/a \,)}{(a^2 - y^2)^{1/2} \, a}, \quad |y| < a,
$$

$$
G_2(\, y \,) = \frac{\partial}{\partial y} \, \psi(\, 0, y \,) = \sum_{k=M+1}^{2M} a_k \, \frac{T_{k-M}(\, y/a \,)}{(a^2 - y^2)^{1/2} \, a},
$$

(2.51)

where $T_k$ are the Chebychev polynomial of first kind, $a_k (\, k = 1, \ldots, 2M \,)$ are the coefficients determined by solving the singular integral equations (2.46 a, b) numerically, and $a$ is the half crack length.
From the definition it is clear that for \( |y| \geq a \)

\[
G_1(y) = 0, \quad G_2(y) = 0. \tag{2.52}
\]

From (2.15), (2.16) and (2.52) we could then easily obtain the displacement components along the crack as follows

\[
u_0(0,y) = \int_{-a}^{y} G_1(y) \, dy \\
= a \sum_{k=1}^{M} a_k \int_{-a}^{y} \frac{T_k(y/a)}{(a^2 - y^2)^{1/2}} \, dy , \tag{2.53}
\]

\[
\psi_x(0,y) = \int_{-a}^{y} G_2(y) \, dy \\
= a \sum_{k=M+1}^{2M} a_k \int_{-a}^{y} \frac{T_{k-M}(y/a)}{(a^2 - y^2)^{1/2}} \, dy , \tag{2.54}
\]

Note that physically \( u_0 \) is the displacement in \( x \) direction in a given reference plane \( z = 0 \), and \( \psi_x \) is the rotation of \( x = \text{constant} \) plane in the plate. From the basic assumptions of the displacement-based plate theory (1.52) we obtain the displacement of the plate in \( x \)-direction as follows (see figure 2.1 and expressions (2.1)):

\[
u(x,y,z) = u_0(x,y) + z \psi_x(x,y). \tag{2.55}
\]
We also observe that due to the first order theory used the value of \( u_0(x, y) \) depends on the choice of the reference plane whereas the value of \( u(x, y, z) \) and \( \psi_x(x, y) \) will not do so. In this study for further convenience, and without any loss in generality, we choose the neutral plane of the laminated plate as reference plane. From (2.53), (2.54) and (2.55), the \( u(0, y, z) \) which is the displacement in \( x \)-direction along the \( y-z \) plane (i.e. the crack plane) can then be obtained as

\[
\begin{align*}
  u(0, y, z) &= u_0(0, y) + z \psi_x(0, y) \\
  &= \int_a^y \left[ G_1(y) + z G_2(y) \right] dy, \\
  &\quad |y| < a.
\end{align*}
\]

Since the laminated plate consists of layers with different material properties, the displacement component \( u(0, y, z) \) or \( u_0(0, y) \) and \( \psi_x(0, y) \), which are essential to describe the behavior of the through-thickness crack, will depend on the stacking order of the layers. In this work the nature of \( u(0, y, z) \) will be studied for the following combinations:

- i) symmetrically laminated plate;
- ii) unsymmetrically laminated plate;

under uniform tension or bending.

I. Symmetrically Laminated Plate

For a symmetrically laminated plate the neutral plane corresponds to the plane of symmetry of the plate. For such a plate by taking the symmetry plane as the reference plane, the bending and in-plane stretching problems may be decoupled. Therefore, the singular integral equations (2.33) become:

\[
\frac{\mu_{11}}{2} \int_a^y \frac{G_1(t)}{t - y} dt = f_1(y),
\]

(2.57)
for in-plane stretching problem,

\[
\frac{\mu_{22}}{\pi} \int_{-a}^{a} \frac{G_2(t)}{t-y} \, dt + \int_{-a}^{a} k_{22}(y,t) G_2(t) \, dt = f_2(y),
\]

\(|y| < a.

(2.58)

for bending problem. Here \(f_1(y)\) and \(f_2(y)\) are defined by equations (2.14).

From (2.57) and (2.58) we can easily see that the in-plane stretching problem and the bending problem are reduced to, respectively, a homogeneous single-layer plane stress problem and a bending problem for a plate with a central crack. This is expected because we have used the so-called single-layer laminated plate theory which is based on replacing the laminated plate by an equivalent single-layer anisotropic plate. Note that \(G_1(y), G_2(y)\) and \(u(0,y,z)\) are the global quantities introduced by this type of plate theory. After solving for the unknown functions \(G_1(y)\) and \(G_2(y)\), the displacement component along the crack \(u(0,y,z)\) can be obtained

\[
u(0,y,z) \equiv u_0(0,y),
\]

(2.59)

for the in-plane stretching problem, and

\[
u(0,y,z) \equiv z \psi_x(0,y),
\]

(2.60)

for the bending problem.

II. Unsymmetrically Laminated Plate

Unlike the symmetrically laminated plate problem, the unsymmetrical plate problem is inherently coupled. It is expected that for such a plate even if is under uniform tension applied in its neutral plane, there exist both the in-plane displacement \(u_0(0,y)\) and the rotation \(\psi_x(0,y)\). The singular integral equations in this case are
The problem will be solved separately under uniform tension and uniform bending defined by

\[
\begin{align*}
\Phi(y) &= N^\infty, \\
\Phi(y) &= 0,
\end{align*}
\]

(2.61)

and

\[
\begin{align*}
\Phi(y) &= 0, \\
\Phi(y) &= M^\infty,
\end{align*}
\]

(2.62)

respectively.

Again using the numerical procedure described in subsection (2.3.1), after obtaining the unknown function \( G_1(y) \) and \( G_2(y) \), the displacement component along the crack plane can be determined by the equation

\[
\begin{align*}
u(0, y, z) &= \int_{-a}^{a} \left[ G_1(y) + z G_2(y) \right] dy,
\end{align*}
\]

(2.56)
2.3.3 Stress Intensity Factor

It is well known that from the linear elastic theory of crack problem, the mode I stress intensity factor at the embedded crack tip can be obtained by one of the two alternate definitions

\[ k_I(z) = \lim_{y \to a^+} \sqrt{2(y-a)} \sigma_x(0,y,z), \]

(2.63)

\[ k_I(z) = \lim_{y \to a^-} \frac{\mu}{2} \sqrt{2(a-y)} \frac{\partial}{\partial y} u(0,y,z), \]

(2.64)

where \( \mu \) is a material constant defined by

\[ \mu = \frac{4\mu}{1+\kappa}, \quad \text{for isotropic material, where } \kappa = 3 - 4\nu \quad \text{for plane strain}, \]

and \( \kappa = \frac{3 - 4\nu}{1 + \nu} \quad \text{for plane strain}, \)

\[ \mu = \frac{E}{2}, \quad \text{for plane stress}, \]

\[ \mu = \frac{E}{2(1 - \nu^2)}, \quad \text{for plane strain}, \]

and

\[ \mu = \frac{1}{2} \left( \frac{d_{11} d_{12}}{2} \right)^{-1/2} \left[ \left( \frac{d_{11}}{d_{22}} \right)^{1/2} + \frac{2d_{12} + d_{56}}{2d_{22}} \right]^{-1/2}, \]

(2.65)

for orthotropic material when crack is located in yz plane and \( d_{ij} \) is defined in Appendix I.

Note that definition (2.63) is based on the stress distribution outside the crack, whereas definition (2.64) is based on the displacement component along the crack plane \( u(0,y,z) \) inside the crack. Naturally, for this displacement based plate
theory we use definition (2.64) to get the stress intensity factor at the crack tip as follows

\[ k_1(z) = \lim_{y \to a^-} \mu_m \cdot \sqrt{2(a-y)} \frac{\partial}{\partial y} u(0, y, z), \]

(2.66)

where \( \mu_m \) is a material constant defined by (2.65) for the mth layer of the laminated plate and the displacement component \( u(0, y, z) \) has been discussed in detail in the previous subsection (2.3.2).
2.4 RESULTS AND DISCUSSION

Two types of plate problems, a homogeneous plate and a laminated plate with a central crack, are studied in this chapter. The mode I stress intensity factors are obtained for each case. For homogeneous materials, we are interested in cracked plates subjected to bending only. Although in this chapter only the general linear laminated plate theory is implemented to solve the crack problem, in a similar manner, the other three transverse shear deformation plate theories reviewed and discussed in chapter 1 have been used to solve the crack problem in an isotropic homogeneous plate. This is done to investigate how different plate theories affect the description of crack tip stress behavior and to give an assessment to the plate theory used in solving the laminated plate problem. For a laminated plate the results given are by using the general linear laminated plate theory. As will be seen later, this approach can be justified from the homogeneous plate results. In this case the problem is solved under both tension and bending loads. It should be emphasized that when we say the plate is under bending it is always assumed that the plate is under membrane as well as bending loads so that there is no interference of the crack surfaces on the compressive side of the plate. This can be achieved by linear superposition.

The elastic constants of orthotropic materials used in the numerical examples are given in Table 2.1. These materials are all fiber reinforced graphite-epoxy composite laminates. Note that material B is the same as material A, except that the axes are rotated 90° about z, which is true also for materials D and C. For isotropic materials, $E_i$ and $\nu_i$ ( $i = 1, 2, 3$ ) represent the Young's modulus and Poisson's ratio of the $i$th layer in the plate. To study the effect of the material properties on the stress intensity factor, some hypothetical material constants are also used to solve the problem.

2.4.1 Homogeneous Plate

The elastic problem for the symmetric bending of a cracked homogeneous plate has been considered before. For example, with Reissner's stress-based first order plate theory, the problem was solved for an isotropic plate in [21] and for an orthotropic plate in [22]. In this study some additional results are given in conjunction with the displacement-based plate theories, namely, Mindlin's first-order
plate theory and a simple higher-order plate theory described in Chapter 1. Table 2.2 shows the effect of the thickness ratio $a/h$ on the stress intensity factor, which are obtained by different plate theories. Classical bending theory's results are included for the purpose of comparison. Because of the Kirchhoff assumption the classical theory gives rather inaccurate results near the boundaries. In a crack problem the crack surfaces are plate boundaries and the important part of the solution is its behavior very near the crack tip. Therefore, classical plate theory is somewhat inaccurate in solving the crack problem. This can be seen in Table 2.2, since it gives the same normalized stress intensity factors regardless of the value of $a/h$. Moreover, from Table 2.2, it can be seen that the other three transverse shear deformation theories give much the same values regarding the normalized stress intensity factor, with the variation of only about 1%. Later on, based on this observation, for computational convenience, a generalized Mindlin's displacement based first-order plate theory will be used for laminated plate problems. In the meantime, the effect of the transverse shear correction factor $K$ in Mindlin's theory [see (1.18)] on the stress intensity factor is also studied. The results are given in Table 2.3. As stated before, by taking $K$ as 1 and $5/6$, we could obtain Mindlin's and Reissner's theories (which are first order theories). In Table 2.3 some extreme values of $K$ are also considered in order to observe the trends.

### 2.4.2 Laminated Plates

In this part of the study, the results are given for both symmetric and unsymmetric bending as well as the membrane loading (i.e., for the neutral-plane tension). For convenience, we take the neutral plane of the laminated plate as the reference plane. In this case the corresponding boundary conditions are

\begin{align*}
    f_1 (y) &= N^\infty, \\
    f_2 (y) &= 0,
\end{align*}

(2.67)

for the membrane loading and
\[ f_1(y) = 0, \]
\[ f_2(y) = M^\infty, \]

for the bending case.

First a three-layer symmetric laminated plate is considered. This is a simplified model for a sandwich plate and a "honeycomb" structure. The notation of the plate is shown in Figure 2.2a.

Because of the nature of the plate theory used, the displacement components \( u, v \), the stress components \( \sigma_x, \sigma_y, \tau_{xy} \) as well as the stress intensity factor will be piecewise linear functions of \( z \). As expected, while the displacement components are continuous functions, the stress and stress intensity factor will have a discontinuity at \( z = \pm h_1/2 \), [ see (2.66) ] due to the nonhomogeneity of the laminated plate. Figures 2.3 and 2.4 show the effect of the thickness ratio \( a/h \) on the stress intensity factors at \( z = h_1/2 \) of Material I and \( z = h/2 \), respectively. The results are given for different material combinations with material I fixed as Material A and Material II being Material A, Material B and other hypothetical isotropic material (having a Young's modulus of 0.39, 3.9 and 390 GPA). Figure 2.5 and 2.6 show the effect of the thickness ratio \( a/h \) and ratio \( E_2/E_1 \) on the stress intensity factor. Here both materials are isotropic. Similar results are shown in Figures 2.7 and 2.8 with different \( h_1/h_2 \) ratios. From Figure 2.7 it may be observed that the variation in the stress intensity factors for different ratios \( E_2/E_1 \) is relatively insignificant. This is expected because with \( h_1 = 0.1 h_2 \), the core material near the symmetry plane have very little influence on the behavior of the plate when it is under bending only. On the other hand as shown in Figure 2.8, the thin layers on the outside will have a much more significant effect on the stress intensity factor.

A material of some considerable practical interest is a "honeycomb structure" which can be modeled as a 3-layer symmetric plate with the following features: (referring to Figure 2.2a)

a. \( h_1 \gg h_2 \),

b. \( E_2 \gg E_1 \),

c. for Material I the out-of-plane shear stiffnesses \( G_{xz} \) and \( G_{yz} \) are much
greater than the in-plane shear stiffness $G_{xy}$.

Figures 2.9 - 2.13 show the results for such a structure. Here, Material II is isotropic having the elastic constants $E_2$ and $\nu_2 = 0.3$, and Material I is assumed to have the properties $E_1$, $G_{xy} = \frac{E_1}{2(1+\nu_1)}$, $\nu_1 = 0.3$ and $G_{xz} = G_{yz} = \frac{1}{2} G_{xy}$. The results given in these figures are rather self-explanatory. While Figure 2.9 shows the effect of the thickness ratio $a/h$ and $TT$ on the stress intensity factors, Figures 2.10 and 2.11 show such effects due to the variation of $E_2/E_1$ and $TT$. The effect of $h_1/h_2$ for various values of $TT$ and $E_2/E_1$ is shown in Figures 2.12 and 2.13. It may be seen that for $h_1/h_2 \rightarrow 0$ the isotropic result $k/k_0 = 0.74$ is recovered.

As second example the bending and membrane loading of a two-layer unsymmetric plate problem is considered. The notation used is shown in Figure 2.2 b. Note that we choose the neutral plane of the plate as the reference plane, with $c_0$ being the vertical distance between the lower surface of the plate and the neutral plane.

Figures 2.14 - 2.18 are results obtained for such two-layer plate, which are all plotted as $k_2/k_0$ v.s. $a/h$. Here $a/h$ is the crack length and plate thickness ratio, $k_0 = \sigma_b \sqrt{a}$ with $\sigma_b = \frac{M}{h^2/6}$ when the plate is subjected to uniform bending moment $M$ at the infinity and $k_0 = \sigma_t \sqrt{a}$ with $\sigma_t = \frac{N}{h}$ when the plate is under the membrane load $N_x = N_\infty$ only, and $k_2$ is mode I stress intensity factor at the upper surface of the plate with $z = h - c_0$. Figure 2.14 gives the results obtained for different $E_2/E_1$ values where both materials are isotropic and $\nu_1$ is equal to $\nu_2$. The results given are for uniform bending moment. It is interesting to note that in this problem even though the singular integral equations are coupled, we obtain $\psi_x \equiv 0$ when the plate is under the in-plane tension and $u_0 \equiv 0$ when it is under bending. These are quite similar to the uncoupled case. Figure 2.15 and 2.16 show the effect of $\nu_2/\nu_1$ ratio on the stress intensity factor in a composite plate under bending and membrane loading respectively. It must be emphasized that for the membrane loading due to the coupling the stress intensity factor is still a linear function of $z$ despite the factor the external force $N_\infty$ is applied in the neutral plane of the plate. These results are quite significant because if we use a plane elasticity approach to solve this kind of problem it might give misleading results. Figures 2.17, 2.18 and 2.19 give the results for plates consisting of two bonded orthotropic layers.
In an attempt to determine the effect of the individual material constants on the stress intensity factors for the two-layer plate, the bending stress intensity factors for $a/h = 1$ and $h_2/h_1 = 1$ are calculated. In these examples, Material I is fixed as being an isotropic material in figure 2.20 or an orthotropic materials in Figures 2.21 and 2.22 and Material II is assumed to be a series of fictitious orthotropic materials where in each case only one or two material constants are varied. Here Material II with the exception of the particular material constant that is varied, is assumed to be "isotropic". For example, in Figure 2.20 for the curve of $R = G_{13}/G_{12}$ Material I is assumed to be isotropic with constants $E^{(1)}$ and $\nu_1 = 0.3$, whereas for the Material II we assumed that

\[ E^{(2)} = E^{(1)}, \]

and

\[ G_{12} = G_{23} = \frac{E^{(1)}}{2(1+0.3)}, \]

and only $G_{13}$ is varied relative to the remaining constants. It should be pointed out that in all cases, the stress intensity factor $k_2$ is a monotonically increasing or decreasing function of $R$ except for varying $G_{12}$ for which it seems to have a maximum for some value of $R > 1$. Similar results were observed in homogeneous orthotropic plates [22].

Figures 2.23 - 2.26 show the results regarding the distributions of the stress intensity factor along the plate thickness direction in the two-layer orthotropic plate, where Material I is Material A and Material II being Material B. For convenience the results given are $k(\tau^e)/k_0$ v.s. $\tau^e/h$, where

\[ \tau^e = z + c_0, \]

so that $\tau^e/h = 1$ and $\tau^e/h = 0$ correspond the upper and lower surfaces of the plate.

Figures 2.23 and 2.24 are results when the plate is subjected to uniform tension and pure bending respectively with the thickness ratio $h_2/h_1 = 1$. Notice that in Figure 2.24 the negative value of stress intensity factor, $k$, is due to the pure bending moment loading. Figures 2.25 and 2.26 show similar results with $h_2/h_1 = 10$. It is
clearly shown that due to the nature of the plate theory used, the stress intensity factors are linearly distributed along the thickness of the plate. In Figure 2.24 because the Material A in layer I is “stiffer” than Material B in layer II, it is expected that $|k(0)| = 0.833$ is larger than $|k(1)| = 0.792$. Similar trends may be find in other three figures too.

Finally we consider two examples concerning unsymmetric plates that consist of three layers subjected to both tension and bending. The geometry and the notation used are shown in Figure 2.2c. We use the same convention as in the two-layer case, namely

$$k_0 = \sigma_b \sqrt{a}, \quad \sigma_b = \frac{M^\infty}{h^2/6},$$

for the bending case, and

$$k_0 = \sigma_t \sqrt{a}, \quad \sigma_t = \frac{N^\infty}{h},$$

for the tension case.

Figures 2.27 and 2.28 are the stress intensity factor distributions in materials having the same Poisson’s ratio $\nu = 0.3$ and Figures 2.29 and 2.30 are the results for materials similar to that considered in Figure 2.27 and 2.28 with different $\nu_1$, $\nu_2$ and $\nu_3$. The same uncoupling features are observed as in the two-layer case. That is when all $\nu$’s are same in isotropic materials, $\psi_x \equiv 0$ for the membrane loading and $u_0 \equiv 0$ for bending. This uncoupling phenomenon disappears when the $\nu$’s are different. It is expected that the coupling becomes more significant when all the materials are orthotropic. In such cases it would be more appropriate to use a plate theory instead of plane elasticity theory to solve the crack problem under membrane loading.
Chapter 3. Stress Intensity Factor in Two-bonded Orthotropic Layers Containing a Crack Perpendicular to and on the Interface

3.1 INTRODUCTION

In modern engineering layered multimaterial systems have been widely used, ranging from laminated composites to microelectronic devices. In structural analysis and design of such systems, one of the most important considerations is the fracture of individual layers. It would be very attractive to develop special types of designs that improve the structural resistance to fracture failure. As one example of such design practice one may mention the process of manufacturing laminated composites in order to improve the structural resistance to unstable crack propagation by strengthening the material in certain directions, choosing the laminates with different material properties, and stacking the laminates in different sequences. All these increasing use of modern technologies have generated new problems for the structural design and failure analysis. Among the multitude of problems in this study we are mainly interested in the fracture analysis of a multilayered medium and specifically in the influence of material properties on the fracture behavior of the system.

If one examines the evolution of typical fracture failure in layered structural components, one may invariably trace the initial cause to a localized imperfection. One of the common forms of such imperfections is the surface flaw which may have the potential for growing into macroscopic cracks. Under cyclic loading and/or adverse environmental effects a surface flaw may grow into a part-through surface crack. Upon further application of the loads the surface crack may propagate subcritically through the thickness of the first layer which, in some cases, may cause the total failure of the system. In analyzing the subcritical growth of these surface cracks as well as the cracks imbedded into individual homogeneous layers, it is now generally accepted that the stress intensity factor can be used quite effectively as the primary correlation parameter. In studying the fracture of multilayered materials the basic mechanics problems is then the calculation of stress intensity factors along the crack front for physically relevant external loads and crack geometries. To do this, a mathematical model which may realistically take into account the geometrical and
physical properties of the medium and the real mechanism of fracture is needed. Because of mathematical difficulties, in recent studies the geometry and the material properties have been considerably simplified by introducing certain two-dimensional or axisymmetric approximations along with the material isotropy. In the early solutions the medium was generally assumed to be infinite consisting of either semi-infinite spaces with or without a layer in between, or periodically stacked laminates. For example, the plane and axisymmetric problems for a medium which consists of two or three different materials and which contains a crack perpendicular to the interfaces may be found in [23-26]. The layered composite which consists of periodically arranged two dissimilar orthotropic bonded layers was considered in [27]. The effect of the elastic properties and the thickness of the adhesive in bonded layered materials was studied in [28]. Later, the plane problem, which is somewhat closer to the actual problem, of two bonded layers containing cracks of various orientations and sizes was studied in [29] and [30]. In that study the individual layers were considered as being isotropic. Particularly in studying composites, the assumption clearly is not very realistic.

In this study the plane elasticity problem of two-bonded orthotropic layers containing a crack perpendicular to the interface is considered. It is assumed that the crack is located in one of the two layers and in a principal plane of orthotropy. The crack problem of a multi-layered medium can be treated as a two layer problem which consists of the layer that contains the crack and a homogenized composite layer representing the remaining part of the medium. Three different problems are studied: the internal or embedded crack problem, the edge crack problem and the problem of a crack terminating at the interface. A general formulation of the problems is given for plane strain case with the material type I. The singular behavior of the stress around crack tip and at the bimaterial interface is studied. The resulting singular integral equations are solved numerically and the stress intensity factors are calculated for various crack geometries and various material combinations. The effect of different material combinations and material orthotropy on the power of stress singularity for a crack terminating at the interface is fully examined.
3.2 THE FORMULATION OF THE PROBLEM

Consider a two-dimensional medium which is formed of two orthotropic infinite layers having thicknesses \( h_1 \) and \( h_2 \) as shown in Figure 3.1. Assume the layers are perfectly bonded along \( y=h_1 \) plane and contain a crack on the \( x=0 \) plane in the first layer. Further assume that by proper superposition the problem is reduced to a perturbation problem in which the crack surface tractions are the only external loads.

3.2.1 Solution of Differential Equations

Let the coordinate systems be selected as in Figure 3.1 and let \( u^{(i)}, v^{(i)}, \) (\( i=1,2 \)) be the \( x \) and \( y \) components of the displacement vector in the layers. The following differential equations which result from the plane theory of elasticity must be solved for each layer under appropriate boundary and continuity conditions:

\[
\begin{align*}
\beta_1 \frac{\partial^2 u}{\partial x^2} + \frac{\partial^2 u}{\partial y^2} + \beta_3 \frac{\partial^2 v}{\partial x \partial y} &= 0, \\
\frac{\partial^2 v}{\partial x^2} + \beta_2 \frac{\partial^2 v}{\partial y^2} + \beta_3 \frac{\partial^2 u}{\partial x \partial y} &= 0,
\end{align*}
\]

(3.1a, 3.1b)

where

\[
\beta_1 = \frac{b_{11}}{G_{xy}}, \quad \beta_2 = \frac{b_{22}}{G_{xy}}, \quad \beta_3 = 1 + \frac{b_{12}}{G_{xy}},
\]

(3.2a)

and

\[ [B] = [C]^{-1} \]

(3.2b)
and

\[ c_{11} = \frac{1 - \nu_{xz} \nu_{zx}}{E_x}, \quad c_{22} = \frac{1 - \nu_{yz} \nu_{zy}}{E_y}, \]

\[ c_{12} = c_{21} = -\frac{\nu_{yx} + \nu_{zx} \nu_{yz}}{E_y} = -\frac{\nu_{xy} + \nu_{zy} \nu_{xz}}{E_x}, \]

(3.3a)

for plane strain, and

\[ c_{11} = \frac{1}{E_x}, \quad c_{22} = \frac{1}{E_y}, \]

\[ c_{12} = c_{21} = -\frac{\nu_{yx}}{E_y} = -\frac{\nu_{xy}}{E_x}, \]

(3.3b)

for plane stress.

Because of symmetry, the problem will be considered for \( 0 > x > \infty \) only.

Let the solution of (3.1) be expressed in terms of the following Fourier integrals:

\[ u^{(i)}(x,y) = \frac{2}{\pi} \int_0^\infty f^{(i)}_1(y,\alpha) \sin \alpha x \, d\alpha + \frac{2}{\pi} \int_0^\infty g^{(i)}_1(x,\gamma) \cos \gamma y \, d\gamma \]

\[ = u_1^{(i)} + u_2^{(i)}, \]

\[ v^{(i)}(x,y) = \frac{2}{\pi} \int_0^\infty f^{(i)}_2(y,\alpha) \cos \alpha x \, d\alpha + \frac{2}{\pi} \int_0^\infty g^{(i)}_2(x,\gamma) \sin \gamma y \, d\gamma \]

\[ = v_1^{(i)} + v_2^{(i)}. \]

(3.4 a,b)
For simplicity at the beginning we will ignore the index \((i)\). Note that \(f_i\) and \(g_i\) \((i=1,2)\) are also functions of the material properties in each layer. By substituting from

\[
\begin{align*}
  u_1(x,y) &= 2 \int_0^\infty f_1(y, \alpha) \sin \alpha x \, d\alpha, \\
  v_1(x,y) &= 2 \int_0^\infty f_2(y, \alpha) \cos \alpha x \, d\alpha,
\end{align*}
\]

\(0 < x < \infty, \quad 0 < y < h,\)

(3.5)

into the equilibrium (3.1), we obtain

\[
\begin{align*}
  \beta_1 (\cdot \alpha^2) f_1 + f_1'' + \beta_3 f_2' (\cdot - \alpha) &= 0, \\
  f_2 (\cdot - \alpha^2) + \beta_2 f_2'' + \beta_3 f_1' (\cdot + \alpha) &= 0.
\end{align*}
\]

(3.6)

Assuming the solution of (3.6) in the form

\[
\begin{align*}
  f_1(y, \alpha) &= A(\alpha) e^{\gamma y \alpha}, \\
  f_2(y, \alpha) &= B(\alpha) e^{\gamma y \alpha},
\end{align*}
\]

(3.7)

we obtain the following characteristic equation:

\[
s^4 + \beta_4 s^2 + \beta_5 = 0,
\]

(3.8)

where \(\beta_4\) and \(\beta_5\) are defined as:

\[
\beta_4 = \frac{\beta_3^2 \cdot \beta_1 \beta_2 - 1}{\beta_2}, \quad \beta_5 = \frac{\beta_1}{\beta_2}.
\]

(3.9)
The roots of (3.8) are

\[ s^2 = \frac{-\beta_4 \pm \sqrt{\beta_4^2 - 4 \beta_5}}{2} . \]  

(3.10)

Defining

\[ \beta_6 = \sqrt{\beta_4^2 - 4 \beta_5} , \]  

(3.11)

we find

\[ s_1 = \omega_1 + i \omega_2 = \sqrt{(-\beta_4 + \beta_6)/2} , \quad s_3 = -s_1 , \]  

\[ s_2 = \omega_3 + i \omega_4 = \sqrt{(-\beta_4 - \beta_6)/2} , \quad s_4 = -s_2 , \]  

(3.12)

where \( \omega_1 \) and \( \omega_3 \) are assumed to be positive.

Thus, from (3.6), (3.7) and (3.12) it can be shown that

\[ f_1 (y, \alpha) = A_1(\alpha) e^{s_1y\alpha} + A_2(\alpha) e^{-s_1y\alpha} + A_3(\alpha) e^{s_2y\alpha} + A_4(\alpha) e^{-s_2y\alpha} , \]

\[ f_2 (y, \alpha) = \beta_7 \left[ A_1(\alpha) e^{s_1y\alpha} - A_2(\alpha) e^{-s_1y\alpha} \right] \]

\[ + \beta_8 \left[ A_3(\alpha) e^{s_2y\alpha} - A_4(\alpha) e^{-s_2y\alpha} \right] , \]

(3.13a, b)
where
\[ \beta_1 = \frac{\beta_3 s_1}{1 - \beta_2 s_1}, \quad \beta_2 = \frac{\beta_3 s_2}{1 - \beta_2 s_2}. \quad (3.14) \]

Similarly, substituting from
\[
\begin{align*}
    u_2(x,y) &= \frac{2}{\pi} \int_0^\infty g_1(x,\gamma) \cos \gamma y \, d\gamma, \\
    v_2(x,y) &= \frac{2}{\pi} \int_0^\infty g_2(x,\gamma) \sin \gamma y \, d\gamma, \quad 0 < x < 0^+, \quad 0 < y < h, \\
\end{align*}
\]
(3.15)

into equilibrium equations (3.1) it may be shown that
\[
\begin{align*}
    \beta_1 g_1'' - \gamma^2 g_1 + \beta_3 \gamma g_2' &= 0, \\
    g_2'' - \gamma^2 \beta_2 g_2 + \beta_3 g_1' (\gamma) &= 0. \quad (3.16)
\end{align*}
\]

If we now let
\[
\begin{align*}
    g_1(x,\gamma) &= C(\gamma) e^{mx\gamma}, \\
    g_2(x,\gamma) &= D(\gamma) e^{mx\gamma}. \quad (3.17)
\end{align*}
\]

the characteristic equation becomes
\[
m^4 + \frac{\beta_4}{\beta_5} m^2 + \frac{1}{\beta_5} = 0. \quad (3.18)
\]

From (3.18) it may be shown that
\[ m_1 = \frac{1}{\sqrt{\beta_5}} \sqrt{(-\beta_4 + \beta_6)/2}, \quad m_3 = -m_1, \]
\[ m_2 = \frac{1}{\sqrt{\beta_5}} \sqrt{(-\beta_4 - \beta_6)/2}, \quad m_4 = -m_2, \quad (\text{Re}(m_1, m_2) > 0). \]

(3.19)

Considering now the regularity conditions at \( x = \infty \), from (3.16), (3.17) and (3.19) it may be seen that
\[ g_1(x, \gamma) = C_1(\gamma) e^{-m_1x\gamma} + C_2(\gamma) e^{-m_2x\gamma}, \]
\[ g_2(x, \gamma) = \beta_9 C_1(\gamma) e^{-m_1x\gamma} - \beta_{10} C_2(\gamma) e^{-m_2x\gamma}, \quad (3.20 \text{ a, b}) \]

where
\[ \beta_9 = -\frac{1}{\beta_3} \left[ \frac{\beta_1 s_1}{\sqrt{\beta_5}} - \sqrt{s_1} \right], \]
\[ \beta_{10} = \frac{1}{\beta_3} \left[ \frac{\beta_1 s_2}{\sqrt{\beta_5}} - \sqrt{s_2} \right]. \quad (3.21) \]

3.2.2 Displacements \( u(x, \gamma) \) and \( v(x, \gamma) \) for Material type I:

Examining the following roots of the characteristic equation (3.6)
\[ s_1 = \sqrt{\beta_5} \quad m_1 = \omega_1 + i \omega_2 = \sqrt{(-\beta_4 + \beta_6)/2}, \]
\[ s_2 = \sqrt{\beta_5} \quad m_2 = \omega_3 + i \omega_4 = \sqrt{(-\beta_4 - \beta_6)/2}, \quad (3.22) \]

it can be shown that \( s_1 \) and \( s_2 \) are either real or complex conjugates. We define Materials type I and II as follows:
Material type I:

\[ s_1 = \sqrt{\beta_5} m_1 = \omega_1, \quad \omega_2 = 0, \]
\[ s_2 = \sqrt{\beta_5} m_2 = \omega_3, \quad \omega_4 = 0, \quad (3.23) \]

Material type II:

\[ s_1 = \sqrt{\beta_5} m_1 = \omega_1 + i \omega_2, \]
\[ s_2 = \sqrt{\beta_5} m_2 = \omega_3 + i \omega_4, \quad (3.24) \]

In this study we will assume that the material is of type I. The results for type II materials may be obtained with slight modification in the analysis. Note that \( s_1 \) and \( s_2 \) are the roots with positive real part and \( \beta_5 > 0 \). Defining now

\[ \beta_{11} = \frac{\omega_1}{\sqrt{\beta_5}}, \quad \beta_{12} = \frac{\omega_3}{\sqrt{\beta_5}}, \quad (3.25) \]

\[ K_1 = (A_1 - A_2), \quad K_2 = (A_1 + A_2), \]

\[ K_3 = (A_3 - A_4), \quad K_4 = (A_3 + A_4), \quad (3.26) \]

from (3.4), (3.13) and (3.20) it may be shown that

\[ u(x,y) = \frac{2}{\pi} \int_0^\infty \left[ K_1(\alpha) \sinh(\omega_1 \alpha y) + K_2(\alpha) \cosh(\omega_1 \alpha y) + K_3(\alpha) \sinh(\omega_3 \alpha y) \right. \]
\[ \left. + K_4(\alpha) \cosh(\omega_3 \alpha y) \right] \sin \alpha x \, d\alpha \]
\[ v(x,y) = \frac{2}{\pi} \int_0^\infty \left[ C_1(\gamma) \exp\left(-\frac{\omega_1 \cdot \gamma \cdot x}{\sqrt{\beta_5}}\right) + C_2(\gamma) \exp\left(-\frac{\omega_2 \cdot \gamma \cdot x}{\sqrt{\beta_5}}\right) \cos \gamma y \, d\gamma, \right. \\
\left. + \frac{2}{\pi} \int_0^\infty \left[ \beta_7 K_2(\alpha) \sinh(\omega_1 \alpha y) + \beta_7 K_1(\alpha) \cosh(\omega_1 \alpha y) + \beta_8 K_4(\alpha) \sinh(\omega_3 \alpha y) \\
+ \beta_8 K_3(\alpha) \cosh(\omega_3 \alpha y) \right] \cos \alpha x \, d\alpha \right. \\
- \frac{2}{\pi} \int_0^\infty \beta_9 C_1(\gamma) \exp\left(-\frac{\omega_1 \cdot \gamma \cdot x}{\sqrt{\beta_5}}\right) + \beta_0 C_2(\gamma) \exp\left(-\frac{\omega_3 \cdot \gamma \cdot x}{\sqrt{\beta_5}}\right) \sin \gamma y \, d\gamma, \right. \\
\right. \\
\left. (3.27 \text{ a, b}) \right. \\
\right. \\
\text{where } K_1(\alpha), K_2(\alpha), K_3(\alpha), K_4(\alpha), C_1(\gamma) \text{ and } C_2(\gamma) \text{ are the unknown functions to be determined from the boundary conditions.} \\
\right. \\
\right. \\
3.2.3 \textbf{Stress Field:} \\
\right. \\
\text{Using the following stress-strain and stress-displacement relations:} \\
\right. \\
\sigma_{xx} = b_{11} \epsilon_x + b_{12} \epsilon_y, \quad (3.28) \\
\sigma_{xx} = \frac{b_{12}}{b_{11}} \epsilon_y \\
= \frac{\partial u}{\partial x} + \frac{b_{12}}{b_{11}} \frac{\partial v}{\partial y} ; \quad (3.29) \\
\sigma_{yy} = b_{12} \epsilon_x + b_{22} \epsilon_y, \quad (3.30) \\
\frac{\sigma_{yy}}{b_{22}} = \frac{b_{12}}{b_{22}} \epsilon_x + \epsilon_y \\
= \frac{b_{12}}{b_{22}} \frac{\partial u}{\partial x} + \frac{\partial v}{\partial y} ; \quad (3.31) \]
\[ \sigma_{xy} = G_{xy} \gamma_{xy} = G_{xy} \left( \frac{\partial u}{\partial x} + \frac{\partial v}{\partial y} \right) \]  
\hfill (3.32)  

\[ \frac{1}{G_{xy}} \sigma_{xy} = \frac{\partial u}{\partial x} + \frac{\partial v}{\partial y} \quad ; \]  
\hfill (3.33)  

where

\[ [B] = [C]^{-1} \]  
\hfill (3.34)  

and \( c_{ij} \) are defined in (3.3),

from (3.17) we obtain the stress as follows:

\[ \frac{1}{b_{11}} \sigma_{xx} = \frac{2}{\pi} \int_{0}^{\infty} \left[ \lambda_1 K_1(\alpha) \sinh(\omega_1 ay) + \lambda_1 K_2(\alpha) \cosh(\omega_1 ay) \right. \]
\[ + \lambda_2 K_3(\alpha) \sinh(\omega_3 ay) + \lambda_2 K_4(\alpha) \cosh(\omega_3 ay) \]  
\[ \left. + \lambda_3 C_1 \gamma \exp(-\omega_1 \gamma \cdot x / \sqrt{\beta_5}) + \lambda_4 C_2 \gamma \exp(-\omega_1 \gamma \cdot x / \sqrt{\beta_5}) \cos \gamma y \right] \cos \alpha x \, d\alpha \]
\hfill (3.35)  

\[ \frac{1}{b_{22}} \sigma_{yy} = \frac{2}{\pi} \int_{0}^{\infty} \left[ \lambda_5 K_1(\alpha) \sinh(\omega_1 ay) + \lambda_5 K_2(\alpha) \cosh(\omega_1 ay) \right. \]
\[ + \lambda_6 K_3(\alpha) \sinh(\omega_3 ay) + \lambda_6 K_4(\alpha) \cosh(\omega_3 ay) \]  
\[ \left. + \lambda_7 C_1 \gamma \exp(-\omega_1 \gamma \cdot x / \sqrt{\beta_5}) + \lambda_8 C_2 \gamma \exp(-\omega_1 \gamma \cdot x / \sqrt{\beta_5}) \cos \gamma y \right] \cos \alpha x \, d\alpha \]
\hfill (3.36)  

83
\[
\frac{1}{G_{xy}} \sigma_{xy} = \frac{2}{\pi} \int_0^\infty \left[ \lambda_9 K_1(\alpha) \cosh(\omega_1 \alpha y) + \lambda_9 K_2(\alpha) \sinh(\omega_1 \alpha y) \\
+ \lambda_{10} K_3(\alpha) \cosh(\omega_3 \alpha y) + \lambda_{10} K_4(\alpha) \sinh(\omega_3 \alpha y) \right] \alpha \sin \alpha \, d\alpha
\]

\[- \frac{2}{\pi} \int_0^\infty \left[ \lambda_{11} C_1 \exp(-\omega_1 \gamma x / \sqrt{\beta_5}) + \lambda_{12} C_2 \exp(-\omega_1 \gamma x / \sqrt{\beta_5}) \gamma \sin \gamma \, d\gamma, \right. \]

(3.37)

where

\[
\lambda_1 = 1 + \beta_7 \omega_1 \frac{b_{12}}{b_{11}}, \quad \lambda_2 = 1 + \beta_8 \omega_3 \frac{b_{12}}{b_{11}},
\]

\[
\lambda_3 = \beta_{11} + \beta_9 \frac{b_{12}}{b_{11}}, \quad \lambda_4 = \beta_{12} + \beta_{10} \frac{b_{12}}{b_{11}}.
\]

\[
\lambda_5 = \frac{b_{12}}{b_{22}} + \beta_7 \omega_1, \quad \lambda_6 = \frac{b_{12}}{b_{22}} + \beta_8 \omega_3.
\]

\[
\lambda_7 = \frac{b_{12}}{b_{22}} \beta_{11} + \beta_9, \quad \lambda_8 = \frac{b_{12}}{b_{22}} \beta_{12} + \beta_{10}.
\]

\[
\lambda_9 = \omega_1 - \beta_7, \quad \lambda_{10} = \omega_3 - \beta_8.
\]

\[
\lambda_{11} = 1 - \beta_9 \beta_{11}, \quad \lambda_{12} = 1 - \beta_{10} \beta_{12}.
\]

(3.38)
3.3 THE INTEGRAL EQUATION

Using the condition that $\sigma_{xy}$ must vanish for $x = 0$, which follows from the assumed symmetry, from (3.37) we obtain

$$C_1 = -\frac{\lambda_{12}}{\lambda_{11}} C_2 .$$  \hspace{1cm} (3.39)

Defining the new unknown function

$$\frac{\partial u}{\partial y}(0, y) = \phi_1(y), \quad y \in L,$$

$$= 0, \quad y \in L', \hspace{1cm} (3.40)$$

where $(L + L') = (0, h_1)$, $L$ refers to the crack, from (3.27a) for layer 1, we find

$$\frac{2}{\pi} \int_0^\infty (C_1 + C_2)(-\gamma) \sin \gamma y \, d\gamma = \phi_1(y) .$$ \hspace{1cm} (3.41)

Inverting the Fourier integral, from (3.39) - (3.41) it follows that

$$C_1 = \lambda_{14} \frac{1}{2} \int_0^\infty \phi_1(t) \sin \gamma t \, dt = \lambda_{14} \frac{1}{2} \int_0^b \phi_1(t) \sin \gamma t \, dt ,$$

$$C_2 = \lambda_{13} \frac{1}{2} \int_0^\infty \phi_1(t) \sin \gamma t \, dt = \lambda_{13} \frac{1}{2} \int_0^b \phi_1(t) \sin \gamma t \, dt ,$$ \hspace{1cm} (3.42)

where

$$\lambda_{13} = \frac{\lambda_{11}}{\lambda_{12} - \lambda_{11}}, \quad \lambda_{14} = -\frac{\lambda_{12}}{\lambda_{11}} \lambda_{13} .$$ \hspace{1cm} (3.43)
We now use $u$, $v$, $\sigma_{xx}$, $\sigma_{yy}$ and $\sigma_{xy}$ to express the displacement and stress components in the first layer (that contains the cracks) and $u^*$, $v^*$, $\sigma_{xx}^*$, $\sigma_{yy}^*$ and $\sigma_{xy}^*$ in the second layer. Then, referring to Figure 1, we have the following boundary and continuity conditions:

\begin{align*}
\sigma_{yy} (0,x) &= 0 , & \sigma_{xy} (0,x) &= 0 , \\
\sigma_{yy}^* (h_2,x) &= 0 , & \sigma_{xy}^* (h_2,x) &= 0 ; \\
(3.44 \text{ a-d}) \\
u (h_1,x) &= u^* (0,x) , & v (h_1,x) &= v^* (0,x) , \\
\sigma_{yy}(h_1,x) &= \sigma_{yy}^* (0,x) , & \sigma_{xy}(h_1,x) &= \sigma_{xy}^* (0,x) . \\
(3.45 \text{ a-d})
\end{align*}

We observe that the displacement and stress expressions for layers 1 and 2 contain nine unknowns, $K_1$, $K_2$, $K_3$, $K_4$, $K_1^*$, $K_2^*$, $K_3^*$, $K_4^*$ and $\phi_1(t)$. Using the eight boundary and continuity conditions (3.44) and (3.45) we can obtain $K_i$ and $K_i^*$ ($i=1,4$) in terms of the unknown $\phi_1$. The function $\phi_1(t)$ can then be obtained from the following mixed boundary condition:

\begin{align*}
\sigma_{xx} (0,y) &= -p(y) , & y \in L \\
u (0,y) &= 0 , & y \in L' . \\
(3.46 \text{ a,b})
\end{align*}

By substituting from (3.36) into (3.44 a) and by inverting the Fourier integral, we find
\[ [\lambda_5 K_2 + \lambda_6 K_4] \alpha = \frac{2}{3} \int_0^\infty \int_0^\infty \left[ \lambda_7 C_1 e^{-\beta_{11} \gamma x} + \lambda_8 C_2 e^{-\beta_{12} \gamma x} \right] \gamma \cos \gamma y \cos \gamma x \, d\gamma \, dx. \]

(3.47)

After evaluating the integrals from (3.47) and (3.42), it may be shown that

\[ [\rho_3 K_2 + \rho_4 K_4] \alpha = \left[ -2 B_5 e^{-\alpha/\beta_{11} t} - 2 B_6 e^{-\alpha/\beta_{12} t} \right] \Phi, \]

(3.48)

where \[ \Phi = \int_L \phi_1(t) \, dt, \]

(3.49)

and see Appendix II for \( \rho_3 \) and \( \rho_4 \) and \( B_5 \) and \( B_6 \).

Similarly, from (3.44b) and (3.37) we obtain

\[ [\rho_5 K_1 + \rho_6 K_3] \alpha = 0. \]

(3.50)

By using again the general expressions (3.36) and (3.37), for layer 2 from the boundary conditions (3.44c) and (3.44d) we find

\[ \left[ \rho_3^* \sinh (\omega_1^* \alpha h_2) K_1^* + \rho_3^* \cosh (\omega_1^* \alpha h_2) K_2^* \right. \]
\[ + \rho_4^* \sinh (\omega_3^* \alpha h_2) K_3^* + \rho_4^* \cosh (\omega_3^* \alpha h_2) K_4^* \] \( \alpha \) = 0,

(3.51a)

\[ \left. \left[ \rho_5^* \cosh (\omega_1^* \alpha h_2) K_1^* + \rho_5^* \sinh (\omega_1^* \alpha h_2) K_2^* \right. \right. \]
\[ + \rho_6^* \cosh (\omega_3^* \alpha h_2) K_3^* + \rho_6^* \sinh (\omega_3^* \alpha h_2) K_4^* \] \( \alpha \) = 0.

(3.51b)

where the quantities with the superscript * are those in layer II having the same expressions with the quantities without * in layer I. For example, \( \omega_1^* \) is the characteristic root for the material in layer II with the same expression as in (3.12).
In a similar way, by substituting from the general displacement expressions (3.27) into the continuity conditions (3.45) and by evaluating the related integrals we obtain

\[ K_1 \sinh(\omega_1 \alpha h_1) + K_2 \cosh(\omega_1 \alpha h_1) + K_3 \sinh(\omega_3 \alpha h_1) + K_4 \cosh(\omega_3 \alpha h_1) \]

\[ - K_2^* - K_4^* = ( - \frac{1}{\alpha} ) \left[ B_1 \exp(-(h_1-t) \alpha/\beta_{11}) - \exp(-(h_1 + t) \alpha/\beta_{11}) \right] 
+ B_2 \left[ \exp(-(h_1-t) \alpha/\beta_{12}) - \exp(-(h_1 + t) \alpha/\beta_{12}) \right] \right] F, \]

\[ [ \rho_1 K_1 \cosh(\omega_1 \alpha h_1) + \rho_1 K_2 \sinh(\omega_1 \alpha h_1) + \rho_2 K_3 \cosh(\omega_3 \alpha h_1) 
+ \rho_2 K_4 \sinh(\omega_3 \alpha h_1) - \rho_1^* K_1^* - \rho_2^* K_4^* 
= ( - \frac{1}{\alpha} ) \left[ B_3 \exp(-(h_1-t) \alpha/\beta_{11}) - \exp(-(h_1 + t) \alpha/\beta_{11}) \right] 
+ B_4 \left[ \exp(-(h_1-t) \alpha/\beta_{12}) - \exp(-(h_1 + t) \alpha/\beta_{12}) \right] \right] F, \]

\[ [ \rho_3 K_1 \sinh(\omega_1 \alpha h_1) + \rho_3 K_2 \cosh(\omega_1 \alpha h_1) + \rho_4 K_3 \sinh(\omega_3 \alpha h_1) 
+ \rho_4 K_4 \cosh(\omega_3 \alpha h_1) - \rho_0 \rho_3^* K_2^* - \rho_0 \rho_4^* K_4^* 
= ( - \frac{1}{\alpha} ) \left[ B_5 \exp(-(h_1-t) \alpha/\beta_{11}) - \exp(-(h_1 + t) \alpha/\beta_{11}) \right] 
+ B_6 \left[ \exp(-(h_1-t) \alpha/\beta_{12}) - \exp(-(h_1 + t) \alpha/\beta_{12}) \right] \right] F, \]

\[ [ \rho_5 K_1 \cosh(\omega_1 \alpha h_1) + \rho_5 K_2 \sinh(\omega_1 \alpha h_1) + \rho_6 K_3 \cosh(\omega_3 \alpha h_1) 
+ \rho_6 K_4 \sinh(\omega_3 \alpha h_1) - \rho_0 \rho_5^* K_1^* - \rho_0 \rho_6^* K_3^* \]

88
\[
\begin{align*}
&= \left( \frac{1}{\alpha} \right) \left[ B_7 \left[ \exp\left( -(h_1 + t) \frac{\alpha}{\beta_{11}} \right) - \exp\left( -(h_1 + t) \frac{\alpha}{\beta_{11}} \right) \right] \\
&+ B_8 \left[ \exp\left( -(h_1 + t) \frac{\alpha}{\beta_{12}} \right) - \exp\left( -(h_1 + t) \frac{\alpha}{\beta_{12}} \right) \right] \right] \mathbf{F} ,
\end{align*}
\]

(3.52 a - d)

where

\[
\rho_{01} = \frac{b_{22}^*}{b_{22}}, \quad \rho_{02} = \frac{G_{xy}}{G_{xy}^*} .
\]

(3.53)

and see Appendix II for expressions \( \rho_i \) \( (i = 1, 6) \) and \( B_i \) \( (i = 1, 8) \).

In summary, the system of equations for the unknowns \( K_i(\alpha) \) and \( K_i^*(\alpha), (i = 1, \ldots, 4) \) may be expressed as follows:

\[
\alpha \mathbf{P} \mathbf{K} = \mathbf{F} \mathbf{f} ,
\]

(3.54)

\[
\mathbf{P} = (P_{ij}) ,
\]

\[
\mathbf{K} = [K_1 \ K_2 \ K_3 \ K_4 \ K_1^* \ K_2^* \ K_3^* \ K_4^*]^T ,
\]

\[
f = f_1 \exp \left[ -(\alpha/\beta_{11}) t \right] + f_2 \exp \left[ -(\alpha/\beta_{12}) t \right] + f_3 \exp \left[ -(\alpha/\beta_{11}) (h_1 - t) \right] + f_4 \exp \left[ -(\alpha/\beta_{12}) (h_1 - t) \right] + f_5 \exp \left[ -(\alpha/\beta_{11}) (h_1 + t) \right] + f_6 \exp \left[ -(\alpha/\beta_{12}) (h_1 + t) \right] ,
\]

(3.55)
where

\[
P_{35} = \rho_3^* \sinh (\omega_1^* \alpha h_2), \quad P_{36} = \rho_3^* \cosh (\omega_1^* \alpha h_2),
\]

\[
P_{37} = \rho_4^* \sinh (\omega_3^* \alpha h_2), \quad P_{38} = \rho_4^* \cosh (\omega_3^* \alpha h_2),
\]

\[
P_{45} = \rho_5^* \cosh (\omega_1^* \alpha h_2), \quad P_{46} = \rho_5^* \sinh (\omega_1^* \alpha h_2),
\]

\[
P_{47} = \rho_6^* \cosh (\omega_3^* \alpha h_2), \quad P_{48} = \rho_6^* \sinh (\omega_3^* \alpha h_2),
\]

\[
P_{51} = \sinh (\omega_1 \alpha h_1), \quad P_{52} = \cosh (\omega_1 \alpha h_1),
\]

\[
P_{53} = \sinh (\omega_3 \alpha h_1), \quad P_{54} = \cosh (\omega_3 \alpha h_1),
\]

\[
P_{61} = \rho_1 \cosh (\omega_1 \alpha h_1), \quad P_{62} = \rho_1 \sinh (\omega_1 \alpha h_1),
\]

\[
P_{63} = \rho_2 \cosh (\omega_3 \alpha h_1), \quad P_{64} = \rho_2 \sinh (\omega_3 \alpha h_1),
\]

\[
P_{71} = \rho_3 \sinh (\omega_1 \alpha h_1), \quad P_{72} = \rho_3 \cosh (\omega_1 \alpha h_1),
\]

\[
P_{73} = \rho_4 \sinh (\omega_3 \alpha h_1), \quad P_{74} = \rho_4 \cosh (\omega_3 \alpha h_1),
\]
\[ P_{81} = \rho_5 \cosh(\omega_1 h_1), \quad P_{82} = \rho_5 \sinh(\omega_1 h_1), \]
\[ P_{83} = \rho_6 \cosh(\omega_3 h_1), \quad P_{84} = \rho_6 \sinh(\omega_3 h_1), \]
\[ P_{85} = \rho_7 \cosh(\omega_5 h_1), \quad P_{86} = \rho_7 \sinh(\omega_5 h_1), \]

\[ P_{76} = \rho_{01} \rho_{03}^*, \quad P_{78} = \rho_{01} \rho_{04}^*, \]
\[ P_{85} = \rho_{02} \rho_{05}^*, \quad P_{87} = \rho_{02} \rho_{06}^*, \]

\( (3.56) \)

\[ f_1 = \begin{bmatrix} 2B_5 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \end{bmatrix}^T, \]
\[ f_2 = \begin{bmatrix} 2B_6 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \end{bmatrix}^T, \]
\[ f_3 = \begin{bmatrix} 0 & 0 & 0 & 0 & -B_1 & -B_3 & B_5 & -B_7 \end{bmatrix}^T, \]
\[ f_4 = \begin{bmatrix} 0 & 0 & 0 & 0 & -B_2 & -B_4 & B_6 & -B_8 \end{bmatrix}^T, \]
\[ f_5 = \begin{bmatrix} 0 & 0 & 0 & 0 & B_1 & B_3 & -B_5 & B_7 \end{bmatrix}^T, \]
\[ f_6 = \begin{bmatrix} 0 & 0 & 0 & 0 & B_2 & B_4 & -B_6 & B_8 \end{bmatrix}^T. \]

\( (3.57) \)

After determining \( K_i \) and \( K_i^* \), \( i = 1, \ldots, 4 \) by solving \( (3.54) \) in terms of \( \phi_1(y) \), this remaining unknown function may be obtained from the mixed boundary conditions \( (3.46) \). By substituting from \( (3.35) \) into \( (3.46a) \), using \( (3.42) \), and from \( (3.46b) \) by observing that \( \phi_1(y) = 0 \) on \( L' \) we find
\[ \frac{1}{2} \frac{1}{b_{11}} \sigma_{xx} = \int_0^\infty \left[ \lambda_1 K_1(\alpha) \sinh(\omega_1 \alpha y) + \lambda_1 K_2(\alpha) \cosh(\omega_1 \alpha y) \\
+ \lambda_2 K_3(\alpha) \sinh(\omega_3 \alpha y) + \lambda_2 K_4(\alpha) \cos(\omega_3 \alpha y) \right] \alpha \cos \alpha \ x \ d\alpha \\
+ B_{11} \int_L \phi_1(t) \ dt \left( \frac{1}{t - y} + \frac{1}{t + y} \right) = - \frac{\pi}{2} \frac{1}{b_{11}} p(y), \quad y \in L. \]

(3.58)

Finally, assuming that \( L = (a, b) \) or the crack is located along \( x = 0, a < y < b \), the integral equation (3.58) may be expressed in the following standard form:

\[ \int_a^b \left[ \frac{1}{t - y} + k(y, t) \right] \phi_1(t) \ dt = - \frac{\pi}{2} \frac{1}{b_{11}} \frac{1}{b_{11}} p(y). \quad a < y < b \]

(3.59)

where the Fredholm kernel, \( k(y, t) \), is defined as:

\[ k(y, t) = \frac{1}{t + y} + \frac{1}{b_{11}} \int_0^\infty \left[ E_1 e^{-\alpha/\beta_{11}t} + E_2 e^{-\alpha/\beta_{12}t} \\
+ E_3 e^{-\alpha/\beta_{11}(h_1 - t)} + E_4 e^{-\alpha/\beta_{12}(h_1 - t)} \\
+ E_5 e^{-\alpha/\beta_{11}(h_1 + t)} + E_6 e^{-\alpha/\beta_{12}(h_1 + t)} \right] d\alpha \]

(3.60)

where the \( E_i (i = 1, 6) \) are known functions of \( K_i, K_i^* \) (i = 1, 4) which may be obtained by solving the equations (3.54).
From the definition of the function $\phi_1$ given by (3.40) it is clear that for an imbedded crack the solution of the integral equation (3.59) must satisfy the following singlevaluedness condition:

$$\int_a^b \phi_1(t) \, dt = 0. \quad (3.61)$$
3.4 THE SINGULARITY AT THE CRACK TIP

It is well known that the stress field around a crack tip is proportional to \( r^{-s} \), where \( r \) is a small distance from the crack tip at which we measure the stress field, and \( s \) is called the power of singularity which should be between zero and one, i.e. \( 0 < s < 1 \). If \( s \) is less than zero, the stress is bounded as \( r \to 0 \) and there is no singularity at the crack tip. If \( s \) is greater than one, the strain energy density is unbounded as \( r \to 0 \), which is physically impossible.

The value of singularity \( s \) is dependent on the crack configuration as well as material properties. In this work, three crack configurations will be studied, namely: (referring to Figure 3.1)

i) embedded crack, \( a > 0, \ b < h_1 \),

ii) edge crack, \( a = 0, \ b < h_1 \),

iii) crack terminating at the interface, \( a \geq 0, \ b = h_1 \).

For each crack configuration, the singularity of the stress state around the crack tip or the irregular points \( a \) and \( b \) may be examined by using the function theoretic method described in [31], [32] and [33].

3.4.1 Embedded Crack

For the case of a crack embedded in a homogeneous material, the only singular term in the integral equation (3.32) is the dominant term \( \frac{1}{t-y} \) and the remaining kernels are bounded. The singular integral equations can thus be written in the form:

\[
\int_a^b \frac{\phi_1(t)}{t-y} \, dt + \text{B. T.} = - \frac{\pi}{2B_{11}} \frac{1}{b_{11}} \, p(y), \quad a > y > b.
\]

(3.62)

where B.T. corresponds to the bounded term.

To examine the behavior of the unknown function \( \phi_1(t) \) around the irregular points \( a \) and \( b \), following Muskhelishvili [31], we assume that the unknown function \( \phi_1 \) may be expressed as
\[ \phi_1(t) = \frac{g_1(t)}{(t-a)^\alpha (b-t)^\beta} = g_1(t) W_1(t) , \]  
(3.63)

where \( g_1(t) \) satisfies a Hölder condition in closed interval \( a \leq t \leq b \) and \( g_1(a) \neq 0, \ g_1(b) \neq 0 \). Also \( \alpha, \beta \) are the singularities at the irregular points which should satisfy the condition \( 0 < \Re (\alpha, \beta) < 1 \), and \( W_1(t) \) is any definite branch which varies continuously on the interval \( a < t < b \).

Define the following sectionally holomorphic function

\[ F_1(z) = \frac{1}{\pi} \int_a^b \frac{\phi_1(t)}{t-z} \, dt , \]  
(3.64)

substituting equation (3.63) into equation (3.64) we obtain

\[ F_1(z) = \frac{1}{\pi} \int_a^b \frac{g_1(t) \exp(i\pi\beta)}{(t-a)^\alpha (t-b)^\beta (t-z)} \, dt . \]  
(3.65)

Following Muskhelishvili, equation (3.65) can be written

\[ F_1(z) = \frac{g_1(a) \exp(i\pi\alpha)}{(b-a)^\beta (z-a)^\alpha \sin(\pi\alpha)} + \frac{g_1(b)}{(b-a)^\alpha (z-b)^\beta \sin(\pi\beta)} + F_{01}(z) . \]  
(3.66)

\( F_{01}(z) \) is bounded everywhere except possibly at the end points \( a, b \), where it has the following behavior

\[ |F_{01}(z)| < \frac{C_k}{|z-e_k|^{\beta_k}} , \quad k=1, 2 , \]  
(3.67)

95
\[ e_1 = a, \quad e_2 = b, \quad p_1 < \text{Re} (\alpha), \quad p_2 < \text{Re} (\beta) \text{ and } \epsilon_k, \rho_k \text{ are real constants}, \text{that is,} \]
\[ F_{01} (z) \text{ has singularities weaken than } \alpha, \beta. \]

Using the Plemelj formula \[31\]
\[ \frac{1}{\pi} \int_a^b \frac{\phi_1(t)}{t-z} \, dt = \frac{1}{2} \left[ F_1^+ (y) + F_1^- (y) \right], \quad a < y < b, \quad (3.68) \]
from (3.66) it follows that

\[ \frac{1}{\pi} \int_a^b \frac{\phi_1(t)}{t-y} \, dt = \frac{g_1(a) \cot (\pi \alpha)}{(b-a)\beta (y-a)\alpha} \]
\[ - \frac{g_1(b) \cot (\pi \beta)}{(b-a)\alpha (b-y)\beta} + F_{01} (y). \quad (3.69) \]

Substituting equation (3.69) into (3.62) we find

\[ \frac{g_1(a) \cot (\pi \alpha)}{(b-a)\beta (y-a)\alpha} - \frac{g_1(b) \cot (\pi \beta)}{(b-a)\alpha (b-y)\beta} = \psi_1 (y), \quad (3.70) \]

where \( \psi_1 (y) \) contain all the bounded functions.

By multiplying equation (3.70) first by \((y-a)\alpha\) and letting \(y \to a\), and then by \((b-y)\beta\) and letting \(y \to b\), we obtain the following characteristic equations for \( \alpha, \beta \),

\[ \frac{g_1(a) \cot (\pi \alpha)}{(b-a)\beta} = 0, \quad \text{or} \quad \cot (\pi \alpha) = 0, \]
\[ \frac{g_1(b) \cot (\pi \beta)}{(b-a)\alpha} = 0, \quad \text{or} \quad \cot (\pi \beta) = 0. \quad (3.71 \text{ a, b}) \]
The acceptable roots of these equations are \( \alpha = \frac{1}{2}, \beta = \frac{1}{2} \), which are the well known results in the crack problems. Hence, the fundamental function of the singular integral equation is

\[
W(t) = \frac{1}{(t - a)^{1/2} (b - t)^{1/2}}. \tag{3.72}
\]

Therefore as long as we have internal cracks, the power of singularity will be 1/2.

### 3.4.2 Edge Crack

This is the case that \( a = 0 \) and \( b < h_1 \). Now the crack is an edge crack with one crack tip in the medium and the other crack tip going to the boundary.

For this case the integrand of Fredholm kernel, \( k(y,t) \) expressed in (3.60), is no longer bounded as \( \alpha \to \infty \). Therefore the singular part of the kernel must be separated and evaluated in closed form. We can write the kernel \( k(y,t) \) in two parts.

\[
k(y,t) = k_s(y,t) + k_b(y,t). \tag{3.73}
\]

where \( k_s \) is the singular part and \( k_b \) is the bounded part of \( k \).

The singular integral equation can then be written as

\[
\int_0^b \left[ \frac{1}{t-y} + k_s(y,t) \right] \phi_1(t) \, dt + \int_0^b k_b(y,t) \phi_1(t) \, dt = -\frac{\pi}{2B_{11}} \frac{1}{b_{11}} p(y)
\]

\( 0 < y < b \). \tag{3.74}

Following the same function theoretic analysis as in the embedded crack case, the only acceptable roots for the characteristic equation are found to be \( \alpha = 0 \) and \( \beta = 1/2 \) (see [34] for details), that is, for the crack going to the free boundary, there is no singularity at the crack tip. Therefore the fundamental function of the singular
integral equation is

\[ W(t) = \frac{1}{(b - t)^{1/2}}. \]  \hspace{1cm} (3.75)

3.4.3 Crack Terminating at the Interface

This is the case that \( a \geq 0 \) and \( b = h_1 \). The problem of interest here is the singularity at the crack tip \( y = h_1 \). Thus, without any loss in generality we assume \( a > 0 \) and \( b = h_1 \) for the analysis. The similar problem has been studied by Delale in [27].

For this case the integrand of Fredholm kernel, \( k(y,t) \), expressed in (3.59), is no longer bounded as \( a \to \infty \) when \( y \to h_1 \) and \( t \to h_1 \), at the same time. Therefore, to study the singular behavior at the interface and to make the kernel numerically integrable, the singular part of the kernel must be separated and evaluated in the closed form. Again, we express the kernel \( k(y,t) \) as

\[ k(y,t) = k_s(y,t) + k_b(y,t). \]  \hspace{1cm} (3.76)

where \( k_s \) is the singular part and \( k_b \) is the bounded part.

To make the manipulations manageable without any loss in accuracy, we obtain the singular part from the symmetric crack problem shown in figure 3.2. In this case, the symmetry about the y axis is maintained and we have

\[ u(x,y) = u(x,-y), \]

\[ v(x,y) = -v(x,-y). \]  \hspace{1cm} (3.77)

Thus, it is sufficient to consider the problem for \( y > 0 \) only. Observing the general solution of the displacement \( u(x,y) \) as expressed in (3.27), the coefficients of the
nosymmetric terms sine and hyperbolic sine must be zero, i.e. $K_1 = 0$, $K_3 = 0$, $K_1^* = 0$ and $K_3^* = 0$, which makes the analysis considerably simpler and makes it possible to obtain the closed form expression of singular kernel $k_s(y, t)$.

Following the same procedure described in [27], it can be shown that $k_s(y, t)$ can be expressed as follows:

$$k_s = k_{s1} + k_{s2} + k_{s3} + k_{s4}$$

$$= P_{11} \frac{\omega_1 h_1 + (h_1 - t)/\beta_{11}}{(\omega_1 h_1 + (h_1 - t)/\beta_{11})^2 - (\omega_1 y)^2}$$

$$+ P_{12} \frac{\omega_1 h_1 + (h_1 - t)/\beta_{12}}{(\omega_1 h_1 + (h_1 - t)/\beta_{12})^2 - (\omega_1 y)^2}$$

$$+ P_{13} \frac{\omega_3 h_1 + (h_1 - t)/\beta_{11}}{(\omega_3 h_1 + (h_1 - t)/\beta_{11})^2 - (\omega_3 y)^2}$$

$$+ P_{14} \frac{\omega_3 h_1 + (h_1 - t)/\beta_{12}}{(\omega_3 h_1 + (h_1 - t)/\beta_{12})^2 - (\omega_3 y)^2}$$

(3.78)

where $P_{1i}$ ($i = 1, 4$) are the expressions of material constants which are obtained from the asymptotic analysis.

The governing singular integral equation then becomes:

$$\int_a^b \left[ \frac{1}{y} + \frac{1}{B_{11}} k_s(y, t) \right] \phi_1(t) \, dt + \int_a^b \frac{1}{B_{11}} k_b(y, t) \phi_1(t) \, dt$$

$$= -\frac{\pi}{2} B_{11} \frac{1}{b_{11}} p(y)$$

$$0 < y < b,$$

$$k_b(y, t) = k(y, t) - k_s(y, t).$$

(3.79)

We again define

99
\[ \phi_1(t) = \frac{g_1(t)}{(t - a)^{1/2} (h_1 - t)^\beta} = g_1(t) W_1(t). \] (3.80)

Here the singularity \( \beta \) will be different from 1/2 because of the additional singular kernel \( k_s(y, t) \).

To examine the singularity \( \beta \), we use the symmetric case as the illustration. Referring to Fig. 3.2 the singular integral equation may be expressed as

\[
\frac{1}{\pi} \int_{-h_1}^{h_1} \left[ \frac{1}{t-y} + \frac{1}{B_{11}} k_s(y, t) \right] \phi_1(t) \, dt = \text{bounded terms}.
\] (3.81)

Following Muskhelishvili, the unknown function \( \phi_1(t) \) can be written

\[ \phi_1(t) = \frac{F_1(t)}{(h_1^2 - t^2)^\beta}, \] (3.82)

where \( F_1(t) \) is bounded and Holder-continuous in the interval \( |t| < h_1 \), and \( 0 < \Re(\beta) < 1 \).

Define the sectionally holomorphic function:

\[
\Phi(z) = \frac{1}{\pi} \int_{-h_1}^{h_1} \frac{\phi_1(t)}{t-z} \, dt = \frac{1}{\pi} \int_{-h_1}^{h_1} \frac{F_1(t) \exp(i \pi \beta)}{(t-h_1)^\beta (t+h_1)^\beta (t-z)} \, dt,
\] (3.83a)

Then, the equation (3.83a) can be written as [31]

\[ \Phi(z) = \frac{F_1(-h_1) \exp(i \pi \gamma)}{(2 h_1)^\beta \sin(\pi \beta)(z + h_1)^\beta} - \frac{F_1(h_1)}{(2 h_1)^\beta \sin(\pi \beta)(z - h_1)^\beta} + \Phi_0(z) \] (3.83b)
where $\Phi_0(z)$ is bounded everywhere except at the end points $\pm h_1$, where it has the following behavior

$$|\Phi_0(z)| < \frac{F_1(\pm h)}{|z \pm h|^{\beta_0}}, \quad \text{Re}(\beta_0) < \text{Re}(\beta).$$

(3.84)

When $z = y$ is on the cut, using Plemelj formula:

$$\Phi(y) = \frac{F_1(-h_1) \cot(\frac{\pi \beta}{2})}{(2 h_1)^\beta (h_1 + y)^\beta} - \frac{F_1(-h_1) \cot(\frac{\pi \beta}{2})}{(2 h_1)^\beta (h_1 - y)^\beta} + \Phi^*(y)$$

$$|y| < h_1$$

(3.85)

Now consider the following integral

$$I_1 = \frac{1}{h} \int_{-h}^{h} k_{s_1}(y, t) \phi_1(t) \, dt$$

$$= \frac{1}{h} \int_{-h}^{h} P_{11} \frac{\omega_1 h_1 + (h_1 - t) / \beta_11}{(\omega_1 h_1 + (h_1 - t) / \beta_11)^2 - (\omega_1 y)^2} \phi_1(t) \, dt$$

$$= \frac{1}{h} \int_{-h}^{h} \left( -\frac{\beta_11 P_{11}}{2} \right) \frac{\phi_1(t)}{t - \left[ h_1 + \beta_11 \omega_1 (h_1 - y) \right]} \, dt$$

$$+ \frac{1}{h} \int_{-h}^{h} \left( -\frac{\beta_11 P_{11}}{2} \right) \frac{\phi_1(t)}{t - \left[ h_1 + \beta_11 \omega_1 (h_1 + y) \right]} \, dt,$$

(3.86a)
from (3.83 a)

\[
I_1 = -\frac{1}{\pi} \int_{-h_1}^{h_1} \left( \frac{\beta_{11} P_{11}}{2} \right) \frac{F_1(t) \exp(i \pi \beta)}{(t-h_1)^\beta (t+h_1)^\beta (t-[h_1+\beta_{11} \omega_1 (h_1-y)])} \, dt
\]

\[
+ \frac{1}{\pi} \int_{-h_1}^{h_1} \left( \frac{\beta_{11} P_{11}}{2} \right) \frac{F_1(t) \exp(i \beta \pi)}{(t-h_1)^\beta (t+h_1)^\beta (t-[h_1+\beta_{11} \omega_1 (h_1+y)])} \, dt,
\]

(3.86 b)

when \( z = h_1 + \beta_{11} \omega_1 (h_1 - y) \) and \( z = h_1 + \beta_{11} \omega_1 (h_1 + y) \) are outside the branch cut we have

\[
I_1 = -\frac{F_1(-h_1)}{(2 h_1)^\beta \sin(\pi \beta) [\beta_{11} \omega_1(h_1+y)]^\beta} + \Phi_1^*(y)
\]

\[
-\frac{F_1(-h_1)}{(2 h_1)^\beta \sin(\pi \beta) [\beta_{11} \omega_1(h_1-y)]^\beta} + \Phi_2^*(y),
\]

(3.83 c)

where \( \Phi_1^*(y) \) and \( \Phi_2^*(y) \) are similar to \( \Phi_0^*(y) \) in equation (3.83 b).

Observing that \( F_1(y) = -F_1(-y) \), the integration \( I_1 \) can be written as:

\[
I_1 = \left( \frac{\beta_{11} P_{11}}{2} \right) \frac{F_1(h_1)}{(2 h_1)^\beta \sin(\pi \beta) (\beta_{11} \omega_1)^\beta} \left[ \frac{1}{(h_1-y)^\beta} \right]
\]

102
Following the same procedure, we can obtain the following integrations:

\[ I_2 = \frac{1}{\pi} \int_{-h_1}^{h_1} k_{s2}(y, t) \phi_1(t) \, dt \]
\[ = \left( \frac{\beta_{12} P_{12}}{2} \right) \frac{F_1(h_1)}{(2 h_1)^\beta \sin(\pi \beta) (\beta_{12} \omega_1)^\beta} \left[ \frac{1}{(h_1 - y)^\beta} + \frac{1}{(h_1 + y)^\beta} \right], \]

(3.87 b)

\[ I_3 = \frac{1}{\pi} \int_{-h_1}^{h_1} k_{s3}(y, t) \phi_1(t) \, dt \]
\[ = \left( \frac{\beta_{11} P_{13}}{2} \right) \frac{F_1(h_1)}{(2 h_1)^\beta \sin(\pi \beta) (\beta_{11} \omega_3)^\beta} \left[ \frac{1}{(h_1 - y)^\beta} + \frac{1}{(h_1 + y)^\beta} \right], \]

(3.87 c)

\[ I_4 = \frac{1}{\pi} \int_{-h_1}^{h_1} k_{s4}(y, t) \phi_1(t) \, dt \]
\[ = \left( \frac{\beta_{12} P_{14}}{2} \right) \frac{F_1(h_1)}{(2 h_1)^\beta \sin(\pi \beta) (\beta_{12} \omega_3)^\beta} \left[ \frac{1}{(h_1 - y)^\beta} \right], \]
Substituting $I_1, I_2, I_3, I_4$ and (3.85) into (3.81) and letting $y \to h_1$ and noting that $F_1(h_1) \neq 0$, the characteristic equation for $\beta$ becomes:

\[
-2 \cos (\pi \beta) + \beta_{11} P_{11} \frac{1}{(\beta_{11} \omega_1)^\beta} + \beta_{12} P_{12} \frac{1}{(\beta_{12} \omega_1)^\beta} + \beta_{11} P_{13} \frac{1}{(\beta_{11} \omega_3)^\beta} + \beta_{12} P_{14} \frac{1}{(\beta_{12} \omega_3)^\beta} = 0.
\]

(3.88)

This is the same equation found in [27]. Choosing the orthotropic elastic constants close to isotropic constants numerically we find the same singularity power computed in [23] and [30]. The characteristic equation (3.88) can be solved numerically to obtain $\beta$. For practical orthotropic materials equation (3.88) has only one root between 0 and 1. If material II is stiffer than material I, the root will be less than 1/2. But if material I is stiffer than material II, then the root will be greater than 1/2.

For the two bonded strip problem, when $a > 0$ and $b = h_1$, the fundamental function is

\[
W_1(t) = \frac{1}{(t - a)^{1/2} (h_1 - t)^{\beta}},
\]

(3.89)

where $\beta$ is the root of equation (3.88).
3.5 SOLUTION OF THE SINGULAR INTEGRAL EQUATION AND THE STRESS INTENSITY FACTOR

The solution of the problem depends on the unknown density function $\phi_1$ which can be obtained by solving the singular integral equation (3.59) numerically using any one of the known techniques [35], [33]. In this work the quadrature method described in [33] is used. To solve the integral equation:

$$\int_a^b \left[ \frac{1}{t-y} + k(y, t) \right] \phi_1(t) \, dt = - \frac{\pi}{2 B_{11}} \frac{1}{b_1} p(y),$$

$$a < y < b,$$

(3.90)

we first normalize the interval $(a, b)$ by defining:

$$t = \frac{b-a}{2} r + \frac{b+a}{2}, \quad (a \leq t \leq b, \ -1 \leq r \leq 1)$$

$$y = \frac{b-a}{2} s + \frac{b+a}{2}, \quad (a \leq y \leq b, \ -1 \leq s \leq 1)$$

$$\phi_1(t) = F(r),$$

$$\frac{b-a}{2} k(y, t) = k(r, s),$$

$$- \frac{\pi}{2 B_{11}} \frac{1}{b_1} p(y) = p(s).$$

(3.91 a - e)

Equation (3.90) may then be expressed as
The unique solution of the singular integral equation (3.92) can be obtained for given crack configuration. Three typical crack geometries will be investigated separately in the following subsections.

3.5.1 Embedded Crack

In this case the solution of the singular integral equation (3.92) will be obtained under the single-valuedness condition

$$\int_{-1}^{1} F(r) \, dr = 0. \quad (3.93)$$

Since \( F(r) \) has a power singularity 1/2 at the end points the solution will be sought in the form

$$F(r) = \frac{f(r)}{\sqrt{1-r^2}} \quad (3.94)$$

where \( f(r) \) is Holder continuous in the interval \(-1 \leq r \leq 1\).

Following the procedure described in [33] we get the system as follows

\[
\frac{1}{2} K^* (s_k, r_1) f(r_1) + \sum_{i=2}^{n-1} K^* (s_k, r_i) f(r_i) + \frac{1}{2} K^* (s_k, r_n) f(r_n) = -\frac{1}{n-1} p(s_k), \quad (k = 1, ..., n-1),
\]

(3.95)

and

\[
\frac{1}{2} f(r_1) + \sum_{i=2}^{n-1} f(r_i) + \frac{1}{2} f(r_n) = 0,
\]

(3.96)
where

\[ K^* (s, r) = \frac{1}{r^s} + k (r, s), \]

\[ r_i = \cos \left( \frac{i-1}{n-1} \pi \right), \quad i = 1, \ldots, n \]

\[ s_k = \cos \left( \frac{2k-1}{2n-1} \pi \right), \quad k = 1, \ldots, n-1. \quad (3.97 \text{ a - c}) \]

From (3.95) and (3.96) n unknowns \( f(r_i), \ i = 1, \ldots, n \) can be solved.

3.5.2 Edge Crack

For the case of an edge crack the singular integral equation (3.92) will be the same but the single-valuedness condition (3.93) for the displacement will not be valid anymore. The unknown function \( F(r) \) will have a 1/2 power singularity at one end and no singularity at the other.

Considering an edge crack \( a = 0 \), \( F(r) \) will be singular only for \( r = 1 \). Therefore in (3.94) \( (1 + r)^{1/2} \) is included with the extra condition that

\[ f(-1) = f(r_n) = 0. \quad (3.98) \]

Given this condition the number of unknown is reduced to \( n - 1 \) and using equations (3.95), \( f(r_i), (i = 1, \ldots, n - 1) \) can be easily solved.

3.5.3 Crack Terminating at the Interface

For the case in which \( a > 0, b = h_1 \), the singularity at the end points are \( \alpha = 1/2 \) and \( \beta \), where \( \beta \) is obtained from equation (3.88). Therefore the solution will be sought in the form
\[ F(r) = \frac{f(r)}{(1 + r)^{1/2}(1 - r)^{\beta}}. \]  

(3.99)

Again, the single-valuedness condition will be

\[ \int_{-1}^{1} F(r) \, dr = 0. \]  

(3.100)

Following [33], we obtain:

\[ \sum_{i=1}^{n} K^* \left( s_k, r_i \right) W \left( r_i \right) f \left( r_i \right) = p \left( s_k \right), \]

\[ k = 1, \ldots, n-1, \]  

(3.101)

and

\[ \sum_{i=1}^{n} W \left( r_i \right) f \left( r_i \right) = 0, \]  

(3.102)

where

\[ P_n^{\left( -1/2, -\beta \right)} \left( r_i \right) = 0, \quad i = 1, \ldots, n, \]

(3.103a)

\[ P_{n-1}^{\left( 1/2, 1 - \beta \right)} \left( s_k \right) = 0, \quad k = 1, \ldots, n-1, \]  

(3.103b)

and \( W(\ r \) is the weight of the Jacobi polynomials

\[ P_n^{\left( -1/2, -\beta \right)} \left( r \right). \]
Solving the $n \times n$ system of linear equations, the $n$ unknowns $f(r_i)$, ($i = 1, \ldots, n$), can be obtained.

3.5.4 The Stress Intensity Factors

In this problem we are mostly interested in the computation of the stress intensity factors which may be expressed in terms of the density function $F(r)$.

For the embedded crack where $0 < a < b < h_1$ the stress intensity factors are defined as follows:

$$K(a) = \lim_{y \to a} \sqrt{2(a-y)} \sigma_x(0,y),$$

$$K(b) = \lim_{y \to b} \sqrt{2(b-y)} \sigma_x(0,y).$$

Using the above definition and as described in [34] we obtain:

$$K(a) = 2B_{11} b_{11} \lim_{y \to a} \sqrt{2(a-y)} \sigma_x(0,y)$$

$$= 2B_{11} b_{11} f(-1) \sqrt{(b-a)/2},$$

$$K(b) = -2B_{11} b_{11} \lim_{y \to b} \sqrt{2(b-y)} \sigma_x(0,y)$$

$$= -2B_{11} b_{11} f(1) \sqrt{(b-a)/2},$$

where

$$B_{11} b_{11} = \frac{2\mu}{1+k},$$

when the material is isotropic.
For the case of an edge crack \( (a = 0) \) the stress intensity factor becomes

\[
k(b) = -2B_{11}b_{11}f(1)\sqrt{b}.
\] (3.106)

For a crack terminating at the interface, the stress intensity factor \( b = h_1 \) can be obtained from simplified symmetric crack problem (see Figure 3.2), described in subsection 3.4.3, when \( a = h_1 \), we have

\[
\frac{1}{b_{11}}\sigma_{xx} = \frac{2}{\pi} \int_0^\infty \left[ \lambda_1 K_2(\alpha)\cosh(\omega_1^*\alpha y_2) + \lambda_2 K_4^*(\alpha)\cosh(\omega_3^*\alpha y_2) \right] \alpha \cos\alpha x d\alpha,
\]

\[
\lim_{x \to 0} \frac{1}{b_{11}}\sigma_{xx} = \frac{2}{\pi} \int_0^\infty \left[ \lambda_1 K_2(\alpha)\cosh(\omega_1^*\alpha y_2) + \lambda_2 K_4^*(\alpha)\cosh(\omega_3^*\alpha y_2) \right] \alpha d\alpha
\]

\[
= \int_{-h_1}^{h_1} k^*_s(y_2, t) \phi_1(t) dt,
\] (3.107)

where, the quantities with * represent the corresponding quantities in the second layer and \( k^*_s \) is as follows (see [27] for details)

\[
k^*_s = k^*_{s1} + k^*_{s2} + k^*_{s3} + k^*_{s4}
\]

\[
= P_{11}^* \frac{\omega_1^* h_1 + (h_1 + t)/\beta_{11}}{(\omega_1^* h_1 + (h_1 + t)/\beta_{11})^2 - (\omega_1^* y_2)^2}
\]

\[
+ P_{12}^* \frac{\omega_1^* h_1 + (h_1 + t)/\beta_{12}}{(\omega_1^* h_1 + (h_1 + t)/\beta_{12})^2 - (\omega_1^* y_2)^2}
\]

\[
+ P_{13}^* \frac{\omega_3^* h_1 + (h_1 + t)/\beta_{11}}{(\omega_3^* h_1 + (h_1 + t)/\beta_{11})^2 - (\omega_3^* y_2)^2}
\]

\[
+ P_{14}^* \frac{\omega_3^* h_1 + (h_1 + t)/\beta_{12}}{(\omega_3^* h_1 + (h_1 + t)/\beta_{12})^2 - (\omega_3^* y_2)^2}.
\] (3.108)

110
Defining
\[ k(\ h_1) = \lim_{y \to h_2} 2^\beta (y_2 + h_2)^\beta \sigma_x^*(0,y), \quad (3.109 \ a) \]

and following a procedure similar to that used in obtaining (3.86), the stress intensity factor at the crack tip \( h_1 \) is found to be
\[
k(\ h_1) = B_{11}^* b_{11}^* \frac{f(1)}{h_1^\beta} \frac{1}{\sin \pi \beta} \times \left\{ \beta_{11} P_{11}^* \frac{1}{(\beta_{11} \omega_1^*)^\beta} + \beta_{12} P_{12}^* \frac{1}{(\beta_{12} \omega_1^*)^\beta} + \beta_{11} P_{13}^* \frac{1}{(\beta_{11} \omega_3^*)^\beta} + \beta_{12} P_{14}^* \frac{1}{(\beta_{12} \omega_3^*)^\beta} \right\}.
\quad (3.109 \ b)\]

111
3.6 RESULTS AND DISCUSSION

The problem is solved numerically for three particular crack configurations which are, referring to Figure 3.1, the embedded crack (0 < a < b < h₁), the edge crack (a = 0, b < h₁) and the crack terminating at the interface (a = 0, b = h₁). The results referring to the stress intensity factors are shown in Figures 3.3-3.7 and Table 3.3. Generally the results presented in these figures and the table are self-explanatory.

The results given in this study are obtained for self equilibrating crack surface tractions. If the external loads are applied to the layered material at locations sufficiently far from the region of cracks, the crack surface tractions in the perturbation problem would be uniform. For example, if the medium is loaded in tension parallel to the x-axis away from the crack region the crack surface tractions are constant and are related by

\[ \frac{1 - \nu_{x_1} \nu_{x_1}^1}{E_{x_1}} p_1 = \frac{1 - \nu_{x_2} \nu_{x_2}^2}{E_{x_2}} p_2 , \quad (3.110) \]

for plane strain and

\[ \frac{p_1}{E_{x_1}} = \frac{p_2}{E_{x_2}} , \quad (3.111) \]

for plane stress. Here the subscripts 1 stands for the properties in material I and 2 for material II. In this study only plane strain case is considered.

To investigate the effect of orthotropic material properties on stress intensity factor in the cracked plane, we first rewrite the singular integral equation (3.90) in the following form:

112
\[ \frac{1}{\pi} \int_a^b \left[ \frac{1}{t^2} + k(y, t) \right] \phi_1(t) \, dt = \frac{1}{\mu_1^*} p(y), \]
\[ a < y < b, \]

(3.112)

Here \( \mu_1^* = 2 B_{11} b_{11} \), \( \phi_1(y) = \frac{\partial u_1}{\partial y} (0, y) \),

and \( p(y) \) is the self equilibrating crack surface traction in material I, and the subscript 1 again refers to the material I.

The physical meaning of \( \mu^* \) in this general form of a crack problem is revealed in the following relationship (see [36])

\[ G = \frac{1}{2 \mu^*} \pi k_1^2, \]

(3.113)

Here \( G \) is the energy release rate, and \( k_1 \) is the stress intensity factor for mode I crack.

For isotropic material \( \mu^* \) is given as:

\[ \mu^* = \frac{4 \mu}{1 + \kappa}, \quad \text{where} \quad \kappa = 3 - 4\nu \quad \text{for plane strain}, \]

and \( \kappa = \frac{3 - \nu}{1 + \nu} \quad \text{for plane strain}, \)

\[ \mu^* = \frac{E}{2}, \quad \text{for plane stress}, \]

\[ \mu^* = \frac{E}{2(1 - \nu^2)}, \quad \text{for plane strain}, \]

(3.114 a)

And for orthotropic materials

\[ \mu^* = 2 B_{11} b_{11}, \]

(3.114 b)

Where \( b_{11} \) is defined in (3.2) and \( B_{11} \) in Appendix II. It can be seen that \( \mu^* \) is
somehow a measurement of material orthotropy in the crack problem. Greater $\mu^*$ stands for "stiffer" material.

Table 3.1 shows the different elastic constants used throughout the analysis. Materials 1 and 2 are orthotropic which are fiber-reinforced composite laminates. Note that material 2 is the same as material 1, except that the axes are rotated 90° about the z axis. Materials 3, 4 and 5 are isotropic. Generally speaking, material 3 is steel, 4 is zirconia and 5 is Alumina, both 4 and 5 are ceramics. Table 3.2 shows the material pairs A to I for which extensive numerical results are given. Choosing the same materials and letting $a$, $b$, $h_1$ or $h_2$ go to proper limits we recover all the special cases considered in [23], [30] and [34].

Figure 3.3 shows the stress intensity factors in two-orthotropic bonded layers with an embedded crack of half length $l = \frac{b - a}{2} = \frac{h_1}{4}$. Note that as the crack tip $b$ approaches the interface (i.e., as $c/l \to 3$) $k_b$ tends to zero for $\mu_2^* > \mu_1^*$ and to infinity for $\mu_2^* < \mu_1^*$. This well-known behavior is due to the fact that for $b = h_1$ the power of the stress singularity $\beta$ is less than 0.5 for $\mu_2^* > \mu_1^*$ and greater than 0.5 if $\mu_2^* < \mu_1^*$. For these cases, the definition of the stress intensity factors are given by equation (3.104). For the material combinations used in this figure $\beta = 0.520$ for pair A and $\beta = 0.481$ for pair B. Also note that as the crack tip approaches the free boundary as expected $K_a$ tends to infinity.

Stress intensity factors for an edge crack in two-orthotropic layers and two-isotropic layers are shown in Figures 3.4 and 3.5. In these cases too note that as the crack tip $b$ approaches the interface $k_b$ tends to zero for $\mu_2^* > \mu_1^*$ and to infinity for $\mu_2^* < \mu_1^*$. Also note that as the crack length decreases the stress intensity factor approaches 1.1215 for isotropic material in Figure 3.5 and 1.101 for orthotropic material in Figure 3.4 which are the value obtained for the semi-infinite plane having an edge crack of length $b$. Figure 3.6 shows the effect of thickness ratio on the stress intensity factor in two-orthotropic layers with a pressurized edge crack. The results for the crack terminating at the interface are shown in figure 3.6 (the curve corresponding to $\frac{b}{h_1} = 1$). In all these figures the Stress Intensity Factors are obtained from (3.106) for edge crack and (3.109) for crack terminating at the interface.

Figure 3.7 shows the Stress Intensity factor in two-orthotropic layers.
containing an edge crack and subjected to uniform bending away from the crack region. In the uncracked two-layer plate the relevant stress is given by

\[ \sigma_{x1} (y_1) = -p_1 (y_1) = -p_b \left( 1 - \frac{y_1}{c_1} \right), \]

\[ 0 < y_1 < h_1, \]

\[ c_1 = \frac{E_{x1}^* h_1^2 + 2 E_{x2}^* h_1 h_2 + E_{x2}^* h_2^2}{2 (E_{x1} h_1 + E_{x2} h_2)}, \]

(3.115 a, b)

\[ E_x^* = E_x, \] for plane stress

\[ = \frac{E_x}{1 - \nu_{xz} \nu_{zx}}, \] for plane strain

where \( y_1 = c_1 \) determines the location of the neutral axis and the constant \( p_b \) is the magnitude of the stress at the plate surface which is related to the bending moment \( M \) by

\[ p_b = \frac{3 c_1 M}{c_1^3 + (E_{x2}^* / E_{x1}^* - 1) (c_1 - h_1)^3 + E_{x2}^* / E_{x1}^* (h_1 + h_2 - c_1)^3}. \]

(3.116)

Table 3.3 shows the Stress Intensity Factors for an edge crack under constant pressure and bending conditions for material pair I, that is, for a homogeneous isotropic strip. These results are given here for the purpose of comparison. Tables 3.4-3.7 show the effects of material combinations and properties on the power of stress singularity \( \beta \) which is obtained from equation (3.88) for a crack terminating at the interface. All the results are obtained for plane strain case. Results in Tables 3.4 and 3.5 are given for fixed elastic properties in material I and varying elastic properties in material II. These results are for both isotropic and orthotropic material pairs. To
give some idea about how the material constants in material II effect \( \beta \) for a full range of \( \mu_2^* \) hypothetical material constants are used. Here \( \mu^* \) are calculated from (3.114). From these tables note that as the second material becomes “stiffer”, i.e. as \( \mu_2^*/\mu_1^* \) increases, the value \( \beta \) decreases in a certain range of \( \mu_2^*/\mu_1^* \). Beyond that range, the ratio \( \mu_2^*/\mu_1^* \) has almost no effect on \( \beta \). It is also important to note that the value \( \beta \) is heavily dependent on the material parameters in the first layer due to the fact that the crack is in the first layer. For the orthotropic material pairs results in Tables 3.4 and 3.5 correspond to three different orthotropic material pairs with \( \mu_1^* \) values of 1.35, 12.078 and 61.6 (GPa). It is clearly seen that when the “stiffness” in the first layer decreases, \( \beta \) becomes smaller.

The effect of individual material constants in the second layer on the power of stress singularity \( \beta \) are examined in Tables 3.6 and 3.7. The results are only done for partial variations of the variable \( c \) because materials with the other half variations are material of type II. In Tables 3.6 and 3.7 material I is fixed as an isotropic material and material II is the same as material I except one material constant is changed which is \( E_Y \) in Table 3.6a and \( G_{xy} \) in Table 3.6b. We can see that \( E_Y \) in the second layer almost have no effect on \( \beta \) because the crack located in the \( y-z \) plane. In contrast to this \( G_{xy} \) in second layer has much large effect on \( \beta \). Similar effects are studied for the fixed orthotropic materials I. The results are shown in Tables 3.7. As expected \( E_{x2}/E_{x1} \) has the most significant effect on \( \beta \). The effect of \( G_{xy2}/G_{xy1} \) on \( \beta \) is similar to the isotropic cracked layer.

Finally it should be pointed out that the accuracy of the numerical results for Stress Intensity Factors is not uniform. For Stress Intensity Factors at an imbedded crack the convergence was relatively fast. However, in the calculation of the Stress Intensity Factors for an edge crack, particularly for \( \mu_1^* > \mu_2^* \), there were convergence difficulties for \( b \rightarrow h_1 \) and \( b = h_1 \).
3.7 RECOMMENDATIONS

In the present work, a general formulation of the fracture problem of layered orthotropic strips with a crack perpendicular to the interface is given. The formulations done only for the case where both materials are of type I. This would have a limitation on the choice of the materials. Following the same procedure, the problem can also be studied for orthotropic materials of type II, or for the combination of type I and type II.

In this study the crack is limited in the first layer only. A further study could be done for the case when the crack crosses the interface, when there is a T shaped crack with the crack going along the interface and when there are cracks in both layers.

In our formulation the thickness of the adhesive bonding the layers has been neglected. The study of the adhesive also can be recommended. Also, the bonded materials with more than two-layers could more realistic for the study of the composite materials, but it requires lengthy algebra.

There are many other problems to be studied in the fracture of bonded materials. We hope that our work will have its contributions in the study of these problems.
Chapter 4. Surface Cracks in a Two-layer Orthotropic Plate

4.1 INTRODUCTION

The surface or part-through crack problem in a structural component which may locally be represented by a "plate" or a "shell" is certainly one of the most important problems in Fracture Mechanics. It is a truly three-dimensional problem in which the stress field perturbed by the crack interacts very strongly with the surfaces of the solid. Because of its complexity generally the problem seems to lend itself only to numerical techniques. At the present, a neat analytical treatment of surface crack problem, even for the linear elastic isotropic solids, appears to be intractable. Consequently, the available solutions of the problem very heavily rely on some kind of numerical technique such as the finite element method [37, 38], the alternating method [39, 40], the boundary integral method [41], the finite element alternating method [42], the method of weight functions [43], and the body force method [44]. For reviews of various methods and solutions see [45, 46]. Also see [21] for the extension of various methods to the shell problem.

The line-spring model, proposed by Rice and Levy [47, 48] and incorporated in a plate theory that allows for transverse shear deformation [2, 3], competes with these methods because of its simplicity and relatively high accuracy. Basically this model transforms the part-through crack problem into a through crack problem by making use of the corresponding plane strain edge crack solution. Figures 4.2-4.5 show the comparisons of Line-Spring model with the finite element method and the effect of transverse shear in a homogeneous plate containing a surface crack and subjected to membrane and bending loads. It may be seen that this model indeed gives very good results.

Because Line-Spring model allows for the solution of the three-dimensional surface crack problem within the two-dimensional plate theory, it reduces the computational effort considerably. Once the verification of this model has been established more extensive parameter studies can be made. Due to the lack of other solutions for the non-homogeneous plate, this verification is done only for the homogeneous plate [21, 49]. Also it is important to point out that for surface cracks
the most important point is the deepest penetration point of the crack front which lie in the center of the more accurate and applicable area of this model. In this study most of the results are given for quantities at the deepest penetration point. We refer to [21] for the behavior of the surface crack around the end points.

In this study the surface crack problems (Figure 4.1) are solved for a two-layer orthotropic plate under uniform tension and bending moment with the surface crack penetrating only through one of the two layers. This restriction is due to the fact that the corresponding two-layer edge-notched orthotropic plane strain results are available only for this geometry and that the line spring model for cracks intersecting the bimaterial interfaces has not yet been formulated. The solution of the plane strain problem needed in this study is given in Chapter 3 where extensive numerical results are provided for various material combinations. Among these material combinations considered the following are of considerable practical interest: (a) fiber reinforced laminated composite materials; (b) ceramic and metal bonded structural components, and (c) the films on elastic substrates used in the microelectronic devices. The results given for all these material combinations are for various geometrical parameters of plates and cracks. Also the effects of material orthotropy on the stress intensity factors are examined.
4.2 THE LINE-SPRING MODEL

4.2.1 The Description of Line - Spring Model

The Line - Spring model was first proposed by Rice and Levy [47] in 1972 and since then many improvements and modifications have been made. We refer to [21] for a literature survey and for various modifications of the model.

Briefly, the model allows one to use a plate theory to formulate the problem by removing the "net ligament", and replacing it by unknown, thickness averaged stress resultants which may then be treated as crack surface loads in a through crack problem. Figure 4.6 illustrates this process for Mode I crack problem. This technique reduces by one dimension the complexity of the analysis. Moreover, it allows both through and part-through crack problems to be solved with the same plate theory formulation.

Recall that in Chapter 2, the two-dimensional formulation of through crack problem in a plate is solved as a mixed boundary value problem with the mixed boundary conditions as follows:

\[ N_x (0, y) = -N_x^\infty, \quad |y| < a, \]
\[ u_0 (0, y) = 0, \quad |y| > a, \]

and

\[ M_x (0, y) = -M_x^\infty, \quad |y| < a, \]
\[ \phi_x (0, y) = 0, \quad |y| > a, \]

(4.1)

where the general principle of superposition is used to account for the loading \( N_x^\infty \) and \( M_x^\infty \) applied to the structure at "infinity" or away from the crack region.

In the case of part-through crack problem the net ligament is replaced by appropriate resultants \( N \) and \( M \) (Figure 4.6) and therefore, the corresponding mixed boundary value problem must be solved under the conditions:

120
\[ N_x (0, y) = - N_x^\infty + N, \quad |y| < a, \]
\[ u_0 (0, y) = 0, \quad |y| > a, \]

and
\[ M_x (0, y) = - M_x^\infty + M, \quad |y| < a, \]
\[ \phi_x (0, y) = 0, \quad |y| > a. \quad (4.2) \]

Thus referring to (2.33) for the corresponding through crack formulation, the governing equations for the two-layer plate with a surface crack may be expressed as:

\[ \frac{\mu_{11}}{\pi} \int_{-a}^{a} \left[ \frac{1}{t - y} + k_{11}(y, t) \right] g_1(t) \, dt + \frac{\mu_{12}}{\pi} \int_{-a}^{a} \left[ \frac{1}{t - y} + k_{12}(y, t) \right] g_2(t) \, dt = - N_x^\infty + N, \]

\[ \frac{\mu_{12}}{\pi} \int_{-a}^{a} \left[ \frac{1}{t - y} + k_{12}(y, t) \right] g_1(t) \, dt + \frac{\mu_{22}}{\pi} \int_{-a}^{a} \left[ \frac{1}{t - y} + k_{22}(y, t) \right] g_2(t) \, dt = - N_x^\infty + M, \quad |y| < a, \quad (4.3) \]

where

\[ g_1(t) = \frac{\partial u_0(t)}{\partial t}, \]
\[ g_2(t) = \frac{\partial \psi_x(t)}{\partial t}. \quad (4.4) \]
The unknowns in equations (4.3) are $N$, $M$, $u_0$ and $\psi_x$, where $N$ and $M$ are net ligament stress resultants illustrated in Figure 4.6, $u_0$ is the in-plane displacement of the $x$ direction in neutral plane and $\psi_x$ is the rotation of the section $x=\text{constant}$. Since there are four unknowns and only two equations more information is needed. In the line-spring model, $N$ and $M$ are linearly related to $u_0$ and $\psi_x$ in the manner of a spring. After substitution of these relationships into equation (4.3), $g_1$ or $g_2$ (or $u_x$ or $\psi_x$) can be numerically determined from which all quantities of interest can be calculated.

### 4.2.2 The Compliance Functions

The Line-Spring model is based on two assumptions. The first, previously stated and illustrated in Figure 4.6, involves replacing the net ligament (in which the state of stress is two-dimensional) by resultant forces which are functions of $y$ only. The second assumption is that the stress intensity factors along the crack front may be obtained from these resultant forces as though the stress state were one of plane strain. Clearly, very near the end points the assumption would not be valid. Therefore, this model is most accurate in the center of the crack and improves as the crack gets longer for a given crack depth, i.e. as plane strain conditions are approached.

In order to make use of this analogy, the plane strain stress intensity factor solutions for the corresponding two-layer edge-notched strip must be available. Such solutions used in this study are obtained from the results of Chapter 3 and along with a curve fit in the form of:

\[
g_t (\xi) = \frac{k_1}{\sigma_t \sqrt{h}} \sqrt{\pi \xi} \sum_{k=0}^{n} c_{tk} \xi^k,
\]

\[
g_b (\xi) = \frac{k_1}{\sigma_b \sqrt{h}} \sqrt{\pi \xi} \sum_{k=0}^{n} c_{bk} \xi^k,
\]

\[0 \leq \xi \leq 0.9,
\]

(4.5)

where
\[ \xi = \frac{L(y)}{h}, \quad (\text{Figure 4.6}). \]

In the literature, \( g_b \) and \( g_t \) are often referred to as shape functions which can be obtained once the edge cracked plane-strain results are given. Then, the stress intensity factor for the strip can be expressed as

\[ K_1 = \sqrt{\frac{h}{\xi}} \left( \sigma_t g_t + \sigma_b g_b \right). \quad (4.6) \]

In these expressions \( \sigma_t(y) \) and \( \sigma_b(y) \) represents the averaged net ligament stresses as follows:

\[ \sigma_t = \frac{N}{h}, \quad \text{and} \quad \sigma_b = -\frac{M}{h^2/6}. \quad (4.7) \]

The derivation is based on expressing the energy available for fracture along the crack front in two different ways. First, in a plate with an edge crack subjected to a uniform tension \( N \) and bending moment \( M \) (Figure 4.7(a)), if \( K \) is the stress intensity factor given by the plane strain solution, from the crack closure energy, the energy (per unit width) available for fracture may be obtained as [50, 51]

\[ G = \frac{\partial}{\partial L} \left( U - V \right) = \lambda K_1^2, \quad (4.8) \]

where

\[ \lambda = \frac{1 - \nu^2}{E}, \quad \text{for isotropic materials}, \]

or

\[ \lambda = \left( \frac{\epsilon_{11} \epsilon_{33}}{2} \right)^{1/2} \left[ \left( \frac{\epsilon_{11}}{\epsilon_{33}} \right)^{1/2} + \frac{2 \epsilon_{13} + \epsilon_{55}}{2 \epsilon_{33}} \right]^{1/2}, \quad (4.9) \]

for orthotropic materials.
See Appendix I for expressions of \( e_{ij} \). With the assumption of coplanar crack growth, equation (4.6) are substituted into (4.8) to obtain,

\[
G = -\frac{\partial}{\partial L} (U - V) = h \lambda (\sigma_t^2 g_t^2 + 2\sigma_b \sigma_t g_t g_b + \sigma_b^2 g_b^2).
\]

(4.10)

Next consider the crack to extend from \( L \) to \( L + \Delta L \) under "fixed load" conditions. The resulting changes in \( U \) and \( V \) are as follows (Figure 4.7 b):

\[
dU = N \, d\delta + M \, d\theta,
\]

\[
dV = \frac{1}{2} \left[ N (\delta + d\delta) + M (\theta + d\theta) \right] - \frac{1}{2} (N \, d\delta + M \, d\theta).
\]

(4.11)

Equations (4.11) give the energy available for a crack growth \( dL \) as follows:

\[
d(U - V) = \frac{1}{2} (N \, d\delta + M \, d\theta).
\]

(4.12)

Note that \( N \) and \( M \) are fixed loads, and for a change of \( dL \) in the crack length we have

\[
d\delta = \frac{\partial \delta}{\partial L} \, dL, \quad d\theta = \frac{\partial \theta}{\partial L} \, dL.
\]

(4.13)

Thus, from (4.12) and (4.13) it follows that

\[
G = \frac{\partial}{\partial L} (U - V) = \frac{1}{2} (N \frac{\partial \delta}{\partial L} + M \frac{\partial \theta}{\partial L}).
\]

(4.14)

and by using (4.9) we find

\[
\frac{1}{2} (N \frac{\partial \delta}{\partial L} + M \frac{\partial \delta}{\partial L}) = h \lambda (\sigma_t^2 g_t^2 + 2\sigma_b \sigma_t g_t g_b + \sigma_b^2 g_b^2),
\]

(4.15)
where \( g_t \) and \( g_b \) are known functions and expressions of \( \sigma_t \) and \( \sigma_b \) are given in (4.7).

Assuming

\[
\tau = \begin{bmatrix} \tau_1 \\ \tau_2 \end{bmatrix} = \begin{bmatrix} \sigma_t \\ \sigma_b \end{bmatrix},
\]

\[
\omega = \begin{bmatrix} \omega_1 \\ \omega_2 \end{bmatrix} = \begin{bmatrix} \delta \\ \frac{h}{6} \theta \end{bmatrix},
\]

and

\[
G(\xi) = \begin{bmatrix} g_t^2 & g_t g_b \\ g_t g_b & g_b^2 \end{bmatrix},
\]  

(4.16)

equation (4.15) may be written as

\[
\frac{h}{2} \tau^T \frac{\partial \omega}{\partial L} = h \lambda \tau^T G \tau.
\]  

(4.17)

From (4.17) it is seen that

\[
\frac{\partial \omega}{\partial L} = 2 \lambda G \tau.
\]  

(4.18)

By observing that \( G \) is a function of \( L \), \( \tau \) is independent of \( L \) and \( \omega = 0 \), for \( L = 0 \), from (4.18) we find:

\[
\omega = 2 \lambda h \left( \frac{1}{h} \int_0^L G \, dL \right) \tau = 2 h \lambda [ A ] \tau.
\]  

(4.19)
where

\[
\begin{align*}
[ A ] &= \frac{1}{h} \int_0^L G \, dL = \begin{bmatrix} a_{ij} \end{bmatrix}, \\
\end{align*}
\]

\[
\begin{align*}
a_{11} &= \frac{1}{h} \int_0^L g_t^2 \, dL, & a_{12} = a_{21} &= \frac{1}{h} \int_0^L g_t \, g_b \, dL, \\
a_{22} &= \frac{1}{h} \int_0^L g_b^2 \, dL. \\
\end{align*}
\]

(4.20)

From (4.19) and (4.20) one may write

\[
\tau = \begin{bmatrix} \sigma_t \\ \sigma_b \end{bmatrix} = -\frac{1}{2} \frac{1}{h \lambda} \Gamma \begin{bmatrix} \delta \\ \frac{h}{\theta} \end{bmatrix}
\]

where

\[
\Gamma = \begin{bmatrix} \gamma_{ij} \end{bmatrix} = [ A ]^{-1}.
\]

(4.21)

Thus, the relationship between \((N, M)\) and \((\delta, \theta)\) may be expressed as follows:

\[
\begin{bmatrix} N \\ M \end{bmatrix} = \begin{bmatrix} \sigma_t \\ h^2/6 \sigma_b \end{bmatrix} = -\frac{1}{2} \frac{1}{h \lambda} C \begin{bmatrix} \delta \\ \theta \end{bmatrix}
\]

where

\[
C = \begin{bmatrix} c_{ij} \end{bmatrix},
\]

126
and

\[ c_{11} = \gamma_{11}, \quad c_{12} = c_{21} = \frac{1}{6} \gamma_{12}, \]

\[ c_{22} = \frac{1}{30} \gamma_{22}. \]  

(4.22)

From definition (4.4) and observing that (Figure 4.7),

\[ \delta = 2 u_0 (0, y), \]

\[ \theta = 2 \psi_x (0, y). \]  

(4.23)

we obtain

\[
\begin{bmatrix}
N \\
M
\end{bmatrix} = \frac{1}{\lambda} \begin{bmatrix}
c_{11} & c_{12} \\
c_{12} & c_{22}
\end{bmatrix} \begin{bmatrix}
g_{c1} \\
g_{c2}
\end{bmatrix},
\]

\[ g_{c1} = \int_{-a}^{y} g_1(t) \, dt, \]

\[ g_{c2} = \int_{-a}^{y} g_2(t) \, dt. \]  

(4.24)

Equation (4.24) gives the information that is needed for substitution into integral equations (4.3). From this the surface crack problem may be solved numerically in a manner similar to the case of the through crack problem.
4.3 SINGULAR INTEGRAL EQUATIONS

4.3.1 The Singular Integral Equations

As mentioned in subsection (4.2), the singular integral equations for part-through crack problems may be obtained directly from the corresponding through crack equations combined with the compliance function (4.24). From (4.3) and (4.24), they may be expressed as follows:

\[
\frac{\mu_1}{\pi} \int_{-a}^{a} \left[ \frac{1}{t-y} + k_{11}(y,t) \right] g_1(t) \, dt + \frac{\mu_2}{\pi} \int_{-a}^{a} \left[ \frac{1}{t-y} + k_{12}(y,t) \right] g_2(t) \, dt
\]
\[
- \frac{c_{11}}{\lambda} \int_{-a}^{Y} g_1(t) \, dt - \frac{c_{12}}{\lambda} \int_{-a}^{Y} g_2(t) \, dt = -N_x^\infty,
\]
\[
\frac{\mu_2}{\pi} \int_{-a}^{a} \left[ \frac{1}{t-y} + k_{12}(y,t) \right] g_1(t) \, dt + \frac{\mu_2}{\pi} \int_{-a}^{a} \left[ \frac{1}{t-y} + k_{22}(y,t) \right] g_2(t) \, dt
\]
\[
- \frac{c_{21}}{\lambda} \int_{-a}^{Y} g_1(t) \, dt - \frac{c_{22}}{\lambda} \int_{-a}^{Y} g_2(t) \, dt = -M_x^\infty,
\]
\[
|Y| < a.
\]  

(4.25)

We refer to (2.33) and (2.34) for the expressions of \( \mu_{ij} \) and \( k_{ij} \), \( \lambda \) can be obtained from (4.8), and \( g_1(t) \) and \( g_2(t) \) are the unknown functions defined in (4.4).

Also these singular integral equations must be solved under the following single-valuedness conditions:
\[ \int_{-a}^{a} g_1(t) \, dt = 0, \quad \text{and} \quad \int_{-a}^{a} g_2(t) \, dt = 0. \]

Since the dominant part of the system of integral equations (4.25) has only a Cauchy kernel (which is the same as in the through crack case), the solution is of the following form:

\[ g_i(t) = \frac{f_i(t)}{\sqrt{a^2 - t^2}}, \quad (i = 1, 2), \]

where the function \( f_1 \) and \( f_2 \) are bounded in the closed interval \( |t| < a \).

Following similar numerical procedures as in the through crack case, described in subsection (2.3.1) of Chapter 2, by first normalizing the equations from \(-a < y < a\) to \(-1 < s < 1\), and then using the collocation method, the unknown functions \( g_1(y) \) and \( g_2(y) \) or \( f_1(y) \) and \( f_2(y) \) may easily be determined numerically.

### 4.3.2 The Stress Intensity Factors

After solving the singular integral equations (4.25) under the single-valuedness conditions (4.26), the unknown functions \( g_1(y) \) and \( g_2(y) \) can be obtained. Then, using the expressions (4.24), the stress intensity factor \( K(y) \) along the crack front may be determined as follows:

\[ K_i = \sqrt{h} \left( \sigma_t g_t + \sigma_b g_b \right), \]

where \( \sigma_t = \frac{N}{h} \), and \( \sigma_b = \frac{M}{h^2/6} \), which are equivalent net-ligament stresses and \( g_t \) and \( g_b \) are known functions obtained from the corresponding edge-notched plane strain results.

Notice that while the solution of a through crack gives the stress intensity factor at \( y = \pm a \), the line-spring model provides stress intensity factors along the front of a surface crack, that is \(-a < y < a\).
Since the model is most accurate in the central portion of the crack, it is best applied to problems where failure occurs when the surface crack grows through the thickness leading either to leaking or to the development of a through crack which then grows in length to a critical size. Because of the plane strain assumption, the model becomes less applicable near the ends of the crack. Because of this the results given in these study are mostly at the maximum penetration point and for $a/h \geq 0.5$. 
4.4 RESULTS AND DISCUSSION

The main interest of the study in this chapter is in evaluating the stress intensity factors in a two-layer isotropic and orthotropic plates with a surface crack. The similar problems for homogeneous one-layer isotropic and orthotropic plates have been considered before in [21], [49], [22] and elsewhere. Some of those results are shown here for the purpose of comparison.

The elastic constants of the material combinations used in the numerical examples are given in Tables 4.1 and 4.2. The material combinations considered here are of important practical interest: Material Pair A and B are fiber reinforced laminated (graphite-epoxy) composites, which have long been widely used in aerospace industry; Material Pairs C, D and E are ceramic and steel bonded structural components, which have recently been receiving increasing attention in a number of applications of metal/ceramics joints [52, 53]. Material Pair I represents an isotropic homogeneous plate which is included here for the purpose of comparison. Extensive numerical results are given for all these material combinations with various geometrical configurations.

As in previous studies, the stress intensity factors are given in their normalized form. For the Line-Spring model, the stress intensity factors are normalized in two different ways. First, they are normalized with respect to the corresponding plane strain values (corresponding to the limiting values when \( a/h \rightarrow \infty \)), namely

\[
\frac{k_t (0)}{k_t^\infty}, \quad \text{and} \quad \frac{k_b (0)}{k_b^\infty},
\]

where \( k_t^\infty \) and \( k_b^\infty \) are the corresponding values for an edge-cracked strip under plane strain conditions with the same \( L_0/h \) ratio (Figure 4.1). These normalizations show how the constraining effect of the ends affect the crack driving force. For the same \( a/h \) value, when the value \( L_0/h \) increases \( \frac{k_i (0)}{k_i^\infty} \) may decrease, this is because \( k_i^\infty \) are relatively more rapidly increasing functions of \( L_0/h \). To give some idea about the absolute values of the stress intensity factors, part of the results are given for a fixed normalizing stress intensity factor, i.e.,

\[
131
\]
\[
\frac{k_t(0)}{\sigma_t^\infty \sqrt{h_1}}, \quad \text{and} \quad \frac{k_b(0)}{\sigma_b^\infty \sqrt{h_1}},
\]

where
\[
\sigma_t^\infty = \frac{N^\infty}{h}, \quad \sigma_b^\infty = \frac{6M^\infty}{h^2},
\]

and \( h_1 \) is the thickness of the first layer of the plate.

In this form it is expected that for a given \( a/h \) when \( L_0/h \) increases (i.e., the surface crack gets deeper) the normalized stress intensity factor \( \frac{k_i(0)}{\sigma_i^\infty \sqrt{h_1}} \) (\( i = t, b \)) would also increase.

In both normalization forms, the stress intensity factor \( k_t(0) \) and \( k_b(0) \) are the values calculated at the maximum penetration point of the crack under the membrane and bending loads respectively. Here it should be observed that, as in the through crack case, when we say the plate is under the bending load we always assume that the plate is under membrane load of sufficiently high magnitude as well, so that there is no interference of the crack surfaces on the compressive side of the plate. In the case of a part-through crack, as can be seen from the results later, under bending the stress intensity factors change sign as the crack gets deeper. Since a negative stress intensity factor has no meaning, these solutions, similar to the through crack case, require a superposition of a tensile solution to make \( k_i > 0, (i = t, b) \).

As noted before, for the application of the line-spring model, the contour of the part-through crack can be any reasonable curve. Elliptic cracks are mainly studied here since it is believed that the ellipse is the closest contour for the actual shape of the crack which may be encountered in practical application. One could refer to [21] for results of some different contours and their effects on the convergence of the results. Here for elliptical contour, the crack depth for any cross section is defined by (Figure 4.1)

\[
L(y) = L_0 \sqrt{1 - (y/a)^2}, \quad |y| < a,
\]

(4.29)

where \( L_0 \) is the crack depth at the midsection \((y = 0)\).
Tables 4.3 - 4.8 show the stress intensity factors in the two-layer strip containing an edge crack under membrane loading $N$ and bending moment $M$ for the material pairs given in Table 4.2. These are the actual values for $k_t^\infty$ and $k_b^\infty$ (see the first normalization form) and are calculated from the results of Chapter 3. Based on these plane strain results the coefficients $c_{bk}$ and $c_{tk}$ in the shape function $g_t(\xi)$ and $g_b(\xi)$ of the corresponding material pairs are given in Tables 4.9 - 4.14.

To make a better curve fit in all material pairs considered $g_b(\xi)$ has the form of

$$g_b(\xi) = \sqrt{\pi} \xi \sum_{k=1}^{n} c_{bk} \xi^{(k-1)},$$

(4.30)

while

$$g_t(\xi) = \sqrt{\pi} \xi \sum_{k=1}^{n} c_{tk} \xi^{2(k-1)},$$

(4.31a)

for $h_2/h_1 = 1., 0.2,$ and

$$g_t(\xi) = \sqrt{\pi} \xi \sum_{k=1}^{n} c_{tk} \xi^{(k-1)},$$

(4.31b)

for $h_2/h_1 = 10., 5.$

The extensive numerical surface crack results are given in Figures 4.8 - 4.17 and Tables 4.15 - 4.42, which are very much self-explanatory. Before giving further results about two-layer orthotropic plates, the surface crack results for a homogeneous isotropic plate (Material Pair I) are shown first in Figures 4.8 - 4.11, which correspond to the two normalization forms under bending and tension respectively. The trends discussed before for these two stress intensity factor normalization forms can be clearly observed in these figures. Figures 4.12 - 4.16 are the results for Material Pair B and Figure 4.17 is the comparison of the Material Pair I (i.e. the homogeneous isotropic plate) and Material Pair B (which consist of fiber reinforce composites). As we can see here the material orthotropy does have a
significant effect on the normalized stress intensity factor, especially when $L_0/h_1$ increases.

Tables 4.15 - 4.38 show the results for all the material pairs given in Table 4.2, which are given again in both normalization forms. Based on all these results the surface crack behavior could be observed and moreover, combining with proper crack propagation model the subcritical crack growth and fatigue crack growth problem, which are very important practical problems, can be studied. Tables 4.39-4.42 give the results regarding the distribution of the normalized stress intensity factor at the crack front for Material B under bending and tension respectively. Tables 4.39 and 4.40 are results for a semi-elliptic surface crack and Tables 4.41 and 4.42 are for a rectangular surface crack. Here the rectangular surface crack contour for any cross section is defined by (Figure 4.1)

$$L(y) = L_0 \quad |y| < a,$$

(4.30)

where $L_0$ is the crack depth at the midsection ($y = 0$).

Finally it must be noted that, due to the lack of available surface crack results in the layered orthotropic plate, the comparison with other results is made only with homogeneous material, which has been shown to give very good results (figures 4.2 - 4.5). Because of the relative simplicity and high accuracy of the model more extensive parameter studies for wider range of orthotropic and isotropic material combinations can be done whenever it is needed.

Appendix I

Expressions $\bar{\mu}$ and $\lambda$

A. The general Hooke's law for an orthotropic plate can be expressed as follows:

$$\epsilon_x = \frac{1}{E_x} \sigma_x - \frac{\nu_{xy}}{E_x} \sigma_y - \frac{\nu_{xz}}{E_x} \sigma_z = c_{11} \sigma_x + c_{12} \sigma_y + c_{13} \sigma_z,$$

$$\epsilon_y = \frac{-\nu_{yx}}{E_y} \sigma_x + \frac{1}{E_y} \sigma_y - \frac{\nu_{yz}}{E_y} \sigma_z = c_{21} \sigma_x + c_{22} \sigma_y + c_{23} \sigma_z,$$

$$\epsilon_z = \frac{-\nu_{zx}}{E_z} \sigma_x - \frac{\nu_{zy}}{E_z} \sigma_y + \frac{1}{E_z} \sigma_z = c_{31} \sigma_x + c_{32} \sigma_y + c_{33} \sigma_z,$$

$$\gamma_{yz} = c_{44} \sigma_{yz}, \quad \gamma_{zx} = c_{55} \sigma_{zx}, \quad \gamma_{xy} = c_{66} \sigma_{xy}.$$
B. When a crack is located in the position as shown in Fig. 2.1 it can be shown that

\[ \tilde{\mu} = \frac{1}{2} \left( \frac{d_{11} d_{22}}{2} \right)^{-1/2} \left[ \left( \frac{d_{11}}{d_{22}} \right)^{1/2} + \frac{2 d_{12} + d_{66}}{2 d_{22}} \right]^{-1/2}, \]

where

- \( d_{11} = c_{11}, \quad d_{22} = c_{22}, \)
- \( d_{12} = c_{12}, \quad d_{66} = c_{66}, \)

for general plane stress,

- \( d_{11} = \frac{c_{11} c_{33} - c_{13} c_{33}^2}{c_{33}}, \)
- \( d_{22} = \frac{c_{22} c_{33} - c_{23} c_{33}^2}{c_{33}}, \)
- \( d_{12} = \frac{c_{12} c_{33} - c_{13} c_{23}}{c_{33}}, \)
- \( d_{66} = c_{66}, \)

for plane strain.
C. When a crack is located in the position as shown in Fig. 4.1(b) it can be shown that

$$\lambda = \left( \frac{e_{11} e_{33}}{2} \right)^{1/2} \left[ \left( \frac{e_{11}}{e_{33}} \right)^{1/2} + \frac{2 e_{13} + e_{55}}{2 e_{33}} \right]^{1/2},$$

where

$$e_{11} = \frac{c_{11} c_{22} - c_{12}^2}{c_{22}} ,$$

$$e_{33} = \frac{c_{33} c_{22} - c_{23}^2}{c_{22}} ,$$

$$e_{13} = \frac{c_{13} c_{22} - c_{12} c_{32}}{c_{22}} ,$$

$$e_{55} = c_{55} ,$$

for plane strain.
