Verification of the FtCayuga Fault-Tolerant Microprocessor System

Volume 2: Formal Specification
and Correctness Theorems

Mark Bickford and Mandayam Srivas

ORA Corporation
Ithaca, New York

Contract NAS1-18972
July 1991
Abstract

This is the second volume of a two-volume report that presents a formal specification and verification of a property of a quadruplicately redundant fault-tolerant microprocessor system design. This volume gives a complete listing of the formal specification of the system and the correctness theorems that were proved. The system performs the task of attaining interactive consistency among the processors using a special instruction on the processors. The design is based on an algorithm proposed by Pease, Shostak and Lamport. The microprocessor used in the system is called FtCayuga, which was designed by extending another formally verified microprocessor MiniCayuga. The property verified ensures that an execution of the special instruction by the processors correctly accomplishes interactive consistency, provided certain preconditions hold, using a computer-aided hardware design verification tool, Spectool, and the theorem prover, Clio, both of which were developed at ORA. A major contribution of the work is the demonstration of a significant fault-tolerant hardware design that is mechanically verified by a theorem prover.

Key Words: Fault-tolerance, hardware verification, mechanical theorem proving.

1 Introduction

NASA Langley Research Center has recently initiated a research effort to develop a validation methodology for life-critical digital (fly-by-wire) flight control systems. Such systems must meet stringent reliability requirements. The systems are expected to have a probability of failure as low as $10^{-9}$ for a 10 hour mission. Hence, as has been well-argued in [6], the design and validation methods employed for such systems must meet high standards. The designs must use fault-tolerant strategies to enable the continued operation of the system in the presence of component failures. The validation methods must ensure that there are no design errors in the system.

The process of formal verification is capable of showing that a system design satisfies a specified property for all inputs and initial conditions of the design. Hence it is a promising candidate for consideration as a validation technology for flight control systems. Digital control systems are implemented using a combination of hardware and software components. Hence, a formal verification technology for flight control systems must be applicable to both software and hardware designs. This work is concerned with the formal verification of a hardware design.

This report presents the formal verification of a hardware system for a task that is an important component of a fault-tolerant computer architecture for flight control systems. The hardware system implements an algorithm for attaining interactive consistency (byzantine agreement) [2] among four microprocessors as a special instruction on the processors. The property verified ensures that an execution of the special instruction by the processors correctly accomplishes interactive consistency, provided certain preconditions hold. An assumption is made that the processors execute synchronously. For verification, we used a computer-aided hardware design verification tool, Spectool [3], and the theorem prover, Clio [1], both of which were developed at ORA. The microprocessor used in the system is called FtCayuga, which we designed by extending the the formally verified microprocessor MiniCayuga [4].

A major contribution of the work is the demonstration of a significant fault-tolerant hardware design that is mechanically verified by a theorem prover. The work illustrates the advantage of using hierarchy and abstraction in system design specification to manage the complexity of formal verification. The work demonstrates the value of a special-purpose tool that tailors the use of a theorem prover to a hardware domain in order to reduce the effort
required for formal verification.

This is the second volume of a two-volume report. The first volume [5] contains an overview of the work and an informal description of the specification and the proof of correctness. This volume contains the entire specification of the system and the definitions of all the correctness theorems and lemmas we proved. This volume is intended as a supplement to Volume 1, and, hence, the presentation in this volume assumes that you have read Volume 1.

The next section describes the general structure of a specification generated by Spec
tool, which also appeared as appendix section A in Volume 1. We repeat this description here for easy reference. The description is useful in understanding the design specifications of the main blocks—

1. The Voter Specification section contains the design and abstract specifications of the Voter.
2. The FtCayuga Specification section contains the design and abstract specifications of FtCayuga.
3. The IcNet Specification section contains the design and abstract specifications of IcNet.
4. The Common Theory section contains definitions of the data types and primitive functions on the data types that are used in the previous specifications. Some of these types are unimplemented abstract types which are specified by axiomatizing the operations on them.
5. The Main Lemmas section contains the definitions of the main theorem and the main lemmas with the help of which the main theorem was proved. The bridge theorems that connect the two levels of descriptions of IcNet and Voter appear as part of the abstraction specifications of the respective components. Since we did not prove the bridge theorems for FtCayuga, we have not included them here.
6. The General Lemmas section contains the set of basic lemmas that were used in proving one or more of the lemmas in the Main Lemmas section.
2 General Structure of a Specification Generated by Spectool

A design specification generated by Spectool consists of the parts described in the following sections.

2.1 Structural Specification Part

This part specifies the data path architecture. It defines a set of types to model the data path state and a set of functions to specify the connections between the data path components. Spectool generates this part in a generic fashion from the following structural information about the data path provided by the user:

1. the names of components and component classes,
2. the names of the actions defined on components,
3. the types that model the internal states of components,
4. the types of the external inputs to the circuit, and
5. the graphical connections between components.

To give the reader an idea of this part of a design specification, a fragment of the structural specification part of the voter circuit is shown below.

∥∥ Generic part of the data path state definition
type SYSTEM_STATE = COMP->LOCAL_STATE
type INPUT_STREAM = NAT->EXTSTATE
type CHANGE = <<COMP,NAT,LOCAL_STATE>>
type STATE = <<SYSTEM_STATE, [CHANGE], INPUT_STREAM>>

∥∥ A type for every component class. The type defines the names of ∥∥ all the components used in the data path that belong to the class.
majority ::= MAJ1 | MAJ2 | MAJ3
bytereg ::= PR1 | PR2 | PR3 | R12 | R13 | R23 | R31 | R32
bitlatch ::= VS | ST

|| A labeled union type of all the component class types
COMP ::= Controller | C_majority !majority | C_mux4 !mux4
| C_bytereg !bytereg | C_bitlatch !bitlatch

|| A labeled union type of all local states of components
LOCAL_STATE ::= S_Controller !CONTROLSTATE
| S_majority !majority_localstate
| S_mux4 !mux4_localstate
| S_bytereg !bytereg_localstate
| S_bitlatch !bitlatch_localstate

ACTION ::= A_majority !majority_ACT
| A_mux4 !mux4_ACT
| A_bytereg !bytereg_ACT
| A_bitlatch !bitlatch_ACT

|| The following specifies the input connections to the component MAJ2
majorityinput s (C_majority MAJ2) =
<<getbyteregoutO (current s (C_bytereg R32)),
getbyteregoutO (current s (C_bytereg R12)),
getbyteregoutO (current s (C_bytereg PR2))>>

The type STATE defines the data path state as a tuple: <<SYSTEM_STATE, [CHANGE],
INPUT_STREAM>>. SYSTEM_STATE maps every component (an element of type COMP) in the
data path to its LOCAL_STATE. [CHANGE] is the list of pending actions on the data path
components. This list is maintained to simulate the effect of delays on actions. The list
contains an update record for each of the actions that has been triggered by the controller
on components, but is yet to be completed. The first two fields of STATE define a snapshot
in time of the data path state. The state of a component is given by SYSTEM_STATE unless
an action is pending on the component, in which case the state is bottom.

The third field of the tuple, INPUT_STREAM, specifies the values of the external inputs
to the circuit as function of time. INPUT_STREAM is a function type from time (NAT) to
EXTSTATE, where EXTSTATE is a type that combines all the external inputs into a tuple.
The type LOCAL\_STATE is a labeled union of the local states of all the components of the data path (and the controller). The local state type of a component is a tuple of its internal state and (a tuple of) its outputs. The definition of the local state type of a component appears as part of the component class specification.

The set of components in a data path is organized so that every component is an instance of a component class. The type COMP groups together the names of all the components in a data path. It is defined as a labeled union of all the component class types, where a component class type is an enumerated type of the names of all the components belonging to the corresponding class.

Similarly, the type ACTION groups together the names of the action types of the component classes, where the action type of a component class is an enumerated type of the names of all the actions defined for the class. The definition of the action type of a component appears as part of the component class specification.

Connections between data path components are specified by defining, for every component, a function that determines the inputs to the component in a given data path state.

### 2.2 Component Classes Specification Part

Every component in the data path is an instance of a component class. The components belonging to the same class share several attributes. This part specifies the shared attributes of a class for every class used in a design. A component class specification defines the type that denotes the internal state of a components of the class, the types of the outputs, a type denoting the names of the actions on the components, and the effects of the actions on the components. For every action, it defines three functions: "state" and "output" functions return, respectively, the new state and the new outputs of a component after an action is performed; and the "delay" function gives the delay associated with the action. For illustration, a part of the specification of the majority component class used in the voter circuit is given below.

```plaintext
|| The component class majority.
|| Local state of majority: <<internal state type, <<output types>>>>
type majority_localstate = <<<<data, BOOL>>, <<(byte), (BOOL)>>>
```
|| Type denoting the actions on the components of the class

majority_ACT ::= 
    select3 !majority | 
    select2 !majority | 
    select0 !majority | 
    select1 !majority | 
    comp !majority

majoritydelay (select3 c) = #0
majoritycomp (select3 c) = C_majority c
majorityout (select3 c) s <<in1,in2,in3>> = <<get_byte 3 (dataof s), bitof s>>
majoritystate (select3 c) s <<in1,in2,in3>> = s

majoritydelay (select2 c) = #0
majoritycomp (select2 c) = C_majority c
majorityout (select2 c) s <<in1,in2,in3>> = <<get_byte 2 (dataof s), bitof s>>
majoritystate (select2 c) s <<in1,in2,in3>> = s

2.3 Controller Specification Part

A controller is specified by means of two functions nextstate and scheduler. The nextstate function gives the next controller state as a function of the current state and controller inputs. The nextstate function is used at the end of each cycle to advance the controller state. The function scheduler returns a list of actions as a function of the controller state, controller inputs, and the phase. For illustration, a part of the specification of the controller for the voter circuit is shown below.

CONTROLSTATE ::= LDP1 | LDP2 | XNG11 | XNG12 | XNG21 | XNG22 | XNG31 
                  | XNG32 | CMPP | OUT1 | OUT2

nextstate LDP1 in = ("(startedof in))->(LDP1);(LDP2)
nextstate LDP2 in = XNG11

... scheduler XNG11 <<<vstart, started>> 0 = (selprvtbyte0)
selprvtlbyteO = [A_bytereg(read0 PRI), A_mux4(choose3 MUX)]

scheduler XNG12 «vstart, started» 0 = (selprvtlbyte2)

selprvtlbyte2 = [A_bytereg(read2 PR1), A_mux4(choose3 MUX)]

... || Some of the details specific to the voter design
|| There are 4 clock phases per cycle.
num_phases = 4

2.4 Composite Behavior Specification Part

This part defines a set of functions that derive the composite behavior of a design using the information expressed in the rest of the specification. This part formalizes in Caliban the operational model of the behavior of a finite state controller system. This part is identical for every circuit since Spectool generates it in a completely generic fashion. The higher-order function definition capability of Caliban is a primary reason why it is possible to express this part in a generic fashion. A top level fragment of this part of the specification is shown below.

Execute s = do_phases 0 s

Output s = generate_output 0 s

do_phases n s = update_state s , n = num_phases
do_phases (n+1) (do_phase n s)

do_phase n «<s,p,in>> =
advance_inputstream (do_actions (current_schedule s2 n) s2)
where s2 = update_state «<s,p,in>>

The two main functions defined in this part are Execute and Output. Execute advances the state of the system across a single cycle. Output returns the (tuple of) external outputs produced by the circuit over the next cycle. Output actually returns a list outputs, one for every phase in a cycle. The two functions are defined hierarchically in terms of several other functions, some of which are described below.
To simulate the effect of delays on component actions, the specification maintains a list of records of pending updates that have been triggered by the controller, but are yet to take effect on the circuit state. The update record for an action contains the component on which the update is pending, a time-out counter that is initialized to the delay of the action and decremented after every phase, and the result of the update. The function update_state causes the result of all the update records on the list that have timed out to take effect on the circuit state. The function also decrements the time-out counter of the update records that have not yet timed-out by one unit of time. The purposes of the rest of the functions should be apparent from the names of the functions. They are summarized below.

- The function do_phases updates the state for all the phases in a cycle.
- The function do_phase updates the state for a single phase. It causes (using update_state) the pending updates that have timed out to take effect; gets the current_schedule from the controller, makes new update records (using do_actions) for all the actions in the schedule, and then advances the input stream by a time unit.

Proper_state 's' => 'VoterABS (Execute s)'
= 'VoterStep (VoterABS s) (Voter_from_proc s) (Voter_from_voters s)'

*********** Correspondence between the levels:***********

Voter output functions. We define one function for every output
of the Voter. The function defines the list of output signals
produced at that port in the "output phases" (0 and 2) of a cycle.

maj_out n <<cstate,array,maj,go>>
= low_half (get_maj_val n maj) , (cstate = OUT1)
high_half (get_maj_val n maj) , (cstate = OUT2)
dont_care || don't care in other cases

dont_care = <<bottom,bottom>>

get_maj_val 1 <<<<b0,b1>>,<<c0,c1>>,<<d0,d1>>> = b0
get_maj_val 2 <<<<b1,b0>>,<<c0,c1>>,<<d0,d1>>> = c0
get_maj_val 3 <<<<b0,b1>>,<<c0,c1>>,<<d0,d1>>> = d0

low_half (DATUM (Word byte3 byte2 byte1 byte0)) = <<byte0, byte1>>
high_half (DATUM (Word byte3 byte2 byte1 byte0)) = <<byte2, byte3>>
crossout <<cstate,array,maj,go>>
= xng_out cstate array || depends only on cstate and array

xng_out cs array
= sendlow 1 array, (cs = XNG11)
sendhigh 1 array, (cs = XNG12)
sendlow 2 array, (cs = XNG21)
sendhigh 2 array, (cs = XNG22)
sendlow 3 array, (cs = XNG31)
sendhigh 3 array, (cs = XNG32)
dont_care || don't care, otherwise

sendlow n array = <<get_byte 0 (array 1 n), get_byte 1 (array 1 n)>>
sendhigh n array = <<get_byte 2 (array 1 n), get_byte 3 (array 1 n)>>

statusout <<cstate, array, maj, go>> = getstatus maj, (cstate = CMPP) dont_care

gSTATUS <<<maj11, maj12>>, <<<maj21, maj22>>, <<<maj31, maj32>>>

= <<<maj12, maj22, maj32>>, <<<maj12, maj22, maj32>>>

sndngout <<cstate, array, maj, go>>
= <<-True, True>>, (cstate = OUT1)
<<True, True>>, (cstate = OUT2)
<<False, False>>

freeout <<cstate, array, maj, go>>
= <<-True, True>>, (cstate = LDP1)
<<False, False>>

Now the tuple <<maj_out 1 s, maj_out 2 s, ...., freeout s>> will be a tuple of lists of length two. The output function at the lower level gives a list of tuples of length two. To compare the two levels, we must "transpose" one of the representations.

transpose [ <<a0, b0, c0, d0, e0, f0, g0>>, <<a1, b1, c1, d1, e1, f1, g1>>] = << <<a0, a1>>, <<b0, b1>>, <<c0, c1>>, <<d0, d1>>, <<e0, e1>>, 
<<f0, f1>>, <<g0, g1>> >

VoterOut s = <<maj_out 1 s, maj_out 2 s, maj_out 3 s, statusout s, crossout s, sndngout s, freeout s>>

VoterOut_Lemma := 'VoterOut (VoterABS s)'
<= 'transpose (Output s)', Proper state 's'

Now we will write another description of the voter, similar to the one above, but with the inputs and outputs grouped differently and with the input stream separated from the state. This description is used when the voter is thought of as a component in a larger system.

type ARRAY = NUM->NUM->data
type MAJSTATE = <<data, BOOL>>
type MAJROW = <<MAJSTATE, MAJSTATE, MAJSTATE>>
type VOTERSTATE = <<CONTROLSTATE, ARRAY, MAJROW, BOOL>>

The input tuple used above has the form <<pvt1, pvt2, pvt3, v1, v2, v3, b>>, and each cycle consumes four such tuples from the input stream.

The new description of the voter as a component having four inputs from_proc = <<go, pvt1, pvt2, pvt3>>, and v1, v2, and v3, each of which is a four tuple (representing the values on the input wires in each of the four phases).

serial_from_proc <<<<<go0, go1, go2, go3>>, <<pvt10, pvt11, pvt12, pvt13>>, 
<<pvt20, pvt21, pvt22, pvt23>>, 
<<pvt30, pvt31, pvt32, pvt33>>>>, v1, v2, v3>> =

[[<pvt10, pvt20, pvt30, go0>>, 
<pvt11, pvt21, pvt31, go1>>, 
<pvt12, pvt22, pvt32, go2>>, 
<pvt12, pvt22, pvt32, go2>>]

serial_from_voter <<pr, <<v10, v11, v12, v13>>, <<v20, v21, v22, v23>>, 
<<v30, v31, v32, v33>>> >

= [[<v10, v20, v30>>, 
<v11, v21, v31>>, 
<v12, v22, v32>>, 
<v13, v23, v33>>]

So, in the new description, the voter has a state s : : VOTERSTATE and it gets an input in = <<from_proc, from_v1, from_v2, from_v3>>.
We can define its new state by using the function VoteStep defined above.

\[
\text{voterstep } s \text{ in } = \text{VoterStep } s \text{ (serial_from_proc in)}(\text{serial_from_voter in})
\]

The voter-component will have four output ports: to_proc, cross1, cross2, and cross3. The "cross" outputs will all be the same:

\[
\text{cross_out } \langle \text{cs, array, mj, b} \rangle = \text{pad } (\text{xng_out cs array})
\]

\[
\text{pad } \langle a, b \rangle = \langle a, a, b, b \rangle
\]

The output "to_proc" contains all the other output of the voter:

\[
\text{to_proc } s = \text{drop_cross } (\text{VoterOut } s)
\]

\[
\text{drop_cross } \langle m_1, m_2, m_3, \text{status, cross, sndng, free} \rangle = \\
\langle m_1, m_2, m_3, \text{status, sndng, free} \rangle
\]

\[
\text{good_array } a = \\
\text{good (a 1 1)} \& \text{good (a 1 2)} \& \text{good (a 1 3)} \\
\& \text{good (a 2 1)} \& \text{good (a 2 2)} \& \text{good (a 2 3)} \\
\& \text{good (a 3 1)} \& \text{good (a 3 2)} \& \text{good (a 3 3)}
\]

\[
\text{good_maj_row } \langle a, b, c \rangle = \text{good_maj a } \& \text{good_maj b } \& \text{good_maj c}
\]

\[
\text{good_maj } \langle a, b \rangle = \text{good a } \& \! b
\]

\[
\text{control } \langle \text{cs, array, maj, go} \rangle = \text{cs}
\]

\[
\text{arrayof } \langle \text{cs, array, maj, go} \rangle = \text{array}
\]

\[
\text{maj_of } \langle \text{cs, array, maj, go} \rangle = \text{maj}
\]

\[
\text{go_of } \langle \text{cs, array, maj, go} \rangle = \text{go}
\]

\[
\text{row_of } \langle \text{cs, array, maj, go} \rangle = \langle \text{array 1 1, array 1 2, array 1 3} \rangle
\]

Now we'll define a predicate that says how well defined the inputs to the voter need to be in order to result in a Proper_voterstate.

\[
\text{good_voter_in } \text{cs in } = \text{(!}(\text{serial_from_voter in}) , \text{xng_cycle cs \!
\text{!!}(\text{serial_from_proc in})
\]

\[
\text{xng_cycle XNG11 } = \text{True}
\]

\[
\text{xng_cycle XNG12 } = \text{True}
\]

\[
\text{xng_cycle XNG21 } = \text{True}
\]

\[
\text{xng_cycle XNG22 } = \text{True}
\]

\[
\text{xng_cycle XNG31 } = \text{True}
\]

\[
\text{xng_cycle XNG32 } = \text{True}
\]

\[
\text{xng_cycle cs } = \text{False}
\]

\[
\text{Proper_voterstate_lemma } := \\
(\text{Proper_voterstate } 's' \& \text{'good_voter_in (control s) in'='True'}) \\
\Rightarrow \text{Proper_voterstate } '\text{voterstep s in'}
\]
When the voter state is not LDP1 the nextstate is a function of the current state only. We need to export this function:

\[ \text{next\_voterstate} \, s = \text{nextstate} \, s \, \text{bottom} \]

### 3.2 Design Specification

Some generic functions we need.

Iterate Zero f x = x
Iterate (Succ n) f x = Iterate n f (f x)

select Zero (a:x) = a
select (Succ n) (a:x) = select n x

The successor relation on the indicies.

suc ONE = TWO
suc TWO = THREE
suc THREE = FOUR
suc FOUR = ONE
suc2 = suc.suc
suc3 = suc2.suc

Fault modelling

Everything is defined in terms of the parameter "faulty" which is a
predicate on the type INDEX which tells us which fault regions are faulty.
The possible faults are listed in the following enumerated type:

FAULT ::= Region !INDEX | NO_FAULT

To model the fact that we are assuming at most one fault, we can suppose
that there is a constant, "the_fault" of type FAULT, and then define the
predicate "faulty" in terms of that constant.

theFault :: FAULT
AXIOM '!theFault'='True'

faulty index = (theFault = (Region index))

This abstraction function lets us view the state of the ic-net
as a function from indicies to ftcayuga states, a function from indicies to voter states, and an input stream.

We wouldn’t need this step if the spectool supported indexed components.

\[ \text{IcNetABS} = \langle \text{FTCStates} \ s, \ \text{VoterStates} \ s, \ \text{inlist}_\text{from} \ s \rangle \]

\[
\begin{align*}
\text{FTCStates} \ s \ \text{ONE} &= \text{get}\_\text{FTC1\_state} \ s \\
\text{FTCStates} \ s \ \text{TWO} &= \text{get}\_\text{FTC2\_state} \ s \\
\text{FTCStates} \ s \ \text{THREE} &= \text{get}\_\text{FTC3\_state} \ s \\
\text{FTCStates} \ s \ \text{FOUR} &= \text{get}\_\text{FTC4\_state} \ s \\
\text{VoterStates} \ s \ \text{ONE} &= \text{get}\_\text{V1\_state} \ s \\
\text{VoterStates} \ s \ \text{TWO} &= \text{get}\_\text{V2\_state} \ s \\
\text{VoterStates} \ s \ \text{THREE} &= \text{get}\_\text{V3\_state} \ s \\
\text{VoterStates} \ s \ \text{FOUR} &= \text{get}\_\text{V4\_state} \ s
\end{align*}
\]

************************** Step function for IcNet **************************

The abstract state change (behavior) of the voter-net.

What happens at each index depends on whether that index is faulty.

\[
\text{IcNetStep} \ \langle \text{ftc}, \ \text{vtr}, \ \text{int}:\text{rest} \rangle =
\langle \text{newftc}, \ \text{newvtr}, \ \text{rest} \rangle
\]

where \( \text{newftc\ index} = \text{fault}_\text{ftc\ step\ index\ ftc} \) (ftcin\ input\ index) 
\[
\text{newvtr\ index} = \text{fault}_\text{vtr\ step\ index\ vtr} \) (vtrin\ input\ index) 
\]

ftcin\ input\ index = \text{make}\_\text{ftc\ in\ (select\_int\ index\ int)}
\[
\text{(fault\_to\_proc\ index\ ftc\ vtr)}
\]

vtrin\ input\ index = \text{Voterinput}\ index\ ftc\ vtr

-----------------------------

\[
\begin{align*}
\text{fault}_\text{ftc\ step\ index\ s\ in} &= \text{FtCayugaStep} \ (s\ index) \ in, (\text{faulty}\ index) \\
&\text{byzCayugaStep} \ (s\ index) \ in \\
\text{fault}_\text{vtr\ step\ index\ s} &= \text{voterstep} \ (s\ index), (\text{faulty}\ index) \\
&\text{byzstep} \ (s\ index)
\end{align*}
\]

select\_int\ ONE \ \langle a, b, c, d \rangle = a \\
select\_int\ TWO \ \langle a, b, c, d \rangle = b \\
select\_int\ THREE \ \langle a, b, c, d \rangle = c \\
select\_int\ FOUR \ \langle a, b, c, d \rangle = d

fault\_to\_proc\ index\ ftc\ vtr =
\[
\text{to\_proc} \ (vtr\ index), (\text{faulty}\ index) \\
&\text{byz\_to\_proc} \ (vtr\ index)
\]

Voterinput\ index\ ftc\ vtr =
\[
\langle \text{fault\_from\_proc\ index\ ftc}, \\
\text{fault\_cross\ THREE} \ (\text{succ3}\ index) \ vtr, \\
\text{fault\_cross\ TWO} \ (\text{succ2}\ index) \ vtr, \\
\text{fault\_cross\ ONE} \ (\text{succ}\ index) \ vtr \rangle
\]

The function "fault\_from\_proc" gives the input tuple of values coming from the processors to the voter whose index is "index".

fault\_from\_proc\ index\ ftc =
\[
\langle \text{fault\_vstart\ index\ ftc}, \\
\text{fault\_prvt} \ (\text{whichprvt}\ index\ (\text{succ}\ index) \ (\text{succ}\ index)) \ ftc, \\
\text{fault\_prvt} \ (\text{whichprvt}\ index\ (\text{succ2}\ index)) \ (\text{succ2}\ index) \ ftc, \\
\text{fault\_prvt} \ (\text{whichprvt}\ index\ (\text{succ3}\ index)) \ (\text{succ3}\ index) \ ftc \rangle
\]

The expression "whichprvt\ i\ j" tells us which replica of the private value of processor j is connected to voter i. This is only used when processor j is faulty, and tells us which of byzpvt1, byzpvt2, and byzpvt3 was used.

whichprvt\ ONE\ i = 1 \\
whichprvt\ TWO\ ONE = 1 \\
whichprvt\ TWO\ i = 2 \\
whichprvt\ THREE\ FOUR = 3
whichprvt THREE \( i = 2 \)
whichprvt FOUR \( i = 3 \)

\[
\text{fault}_\text{vstart} \ i \ ftc = \text{vstart}_\text{out}(ftc \ i), \text{faulty} \ i
\]
\[
\text{byz}_\text{go} \ (ftc \ i)
\]

\[
\text{fault}_\text{prvt} \ i1 \ i2 \ s = \text{prvt}_\text{out}(s \ i2), \text{faulty} \ i2
\]
\[
\text{byz}_\text{pvt} \ i1 \ (s \ i2)
\]

\[
\text{fault}_\text{cross} \ i1 \ i2 \ s = \text{cross}_\text{out}(s \ i2), \text{faulty} \ i2
\]
\[
\text{byz}_\text{cross} \ i1 \ (s \ i2)
\]

\[
\text{byz}_\text{cross} \ \text{ONE} = \text{byz}_\text{cross1}
\]
\[
\text{byz}_\text{cross} \ \text{TWO} = \text{byz}_\text{cross2}
\]
\[
\text{byz}_\text{cross} \ \text{THREE} = \text{byz}_\text{cross3}
\]

\[
\text{byz}_\text{pvt} \ 1 = \text{byz}_\text{pvt1}
\]
\[
\text{byz}_\text{pvt} \ 2 = \text{byz}_\text{pvt2}
\]
\[
\text{byz}_\text{pvt} \ 3 = \text{byz}_\text{pvt3}
\]

\[
\text{icNetStepLemma} :=
\]
\[
\left( \text{icNet}_\text{ABS} \ (\text{Execute} \ s) \right) = \left( \text{icNet}_\text{Step} \ (\text{icNet}_\text{ABS} \ s) \right), \text{Proper}_\text{state} \ s
\]

\|\| \text{What we have done with this abstraction step is to organize the}
\|\| \text{state of the ic-net as a function on indices,}
\|\| \text{and to hide the cross connections.}

\|\| \text{Here is the translation of the Proper}_\text{state predicate for the ic-net}

7 The Main Lemmas Proved

MainTheorem defines the main correctness property that we proved. It expresses the 12-cycle interactive consistency property for the entire system, which was described in detail in sections 5.2 and 9.1 of Volume 1. In the following, we describe some of the main lemmas that we proved in constructing a proof of MainTheorem.

MainTheorem states the interactive consistency property for the actual value (defined by the function actualPVT) that the processor sends to the voter. Since the processor sends the value to the voter over two cycles, we define one half of this value based on the contents of the special register PVT in the cycle in which ICOP is executed and the other half based on the contents of PVT in the following cycle. To ensure that the IC computation is performed on a consistent value of PVT, the programmer must make sure that the content of PVT will not change before the processor sends it to the voter. One way a programmer can ensure this is by not having a SADD instruction, which is the only instruction that can change the special register PVT, immediately following ICOP. AnotherMainTheorem formally states this condition. We have not proved this theorem, which should follow from the MainTheorem.

To decompose the proof of MainTheorem into smaller proofs, we divided the 12-cycle IC computation into a sequence of six stages of smaller duration. For each of these stages, we proved a stage lemma that defines the expected behavior for that stage. The different stages we used and their corresponding lemmas are enumerated below.
1. **Load stage** represents the first three cycles of IC computation in which the contents of the private register is moved from the processor to the voter. The lemma corresponding to this stage is **Load_correct_lemma**.

2. **Exchange stage** represents the next six cycles of the computation in which the voters exchange values between each other. This stage is further divided into a sequence of three 2-cycle computations, with one lemma for each of them: **Xng1_correct_lemma**, **Xng2_correct_lemma** and **Xng3_correct_lemma**.

3. **Compute stage** represents the single cycle in which majority computation is performed. The lemma corresponding to this stage is **Compute_correct_lemma**.

4. **Output stage** represents the last two cycle of the computation in which the results are written into the processor. The lemma corresponding to this stage is **Output_correct_lemma**.

We "chained" the stage lemmas together, in order, to prove the **MainTheorem**. We proved another set of lemmas, called **connect lemmas**, to assist us in the chaining process. That is, we used the connect lemmas to prove that the antecedent of a stage lemma implies the consequent of a succeeding stage lemma in the chain. The list given below shows the order in which we used the lemmas for proving the **MainTheorem**. In the following, **CL** is an abbreviation for "**Connect_lemma**," and \( \rightarrow \) is used to indicate the chronological order in which two lemmas are proved when the lemmas appear within the same item in the list.

1. **Load_correct_lemma**

2. **CL.1.4 \( \rightarrow \) (CL.1.5, CL.1.3) \( \rightarrow \) (CL.1.1, CL.1.2)**

3. **Xng1_correct_lemma**

4. (CL.1.1, CL.1.2) \( \rightarrow \) CL.3

5. **Xng2_correct_lemma**

6. (CL.1.1, CL.1.2) \( \rightarrow \) CL.4

7. **Xng_correct_lemma**

8. (CL.1.1, CL.1.2) \( \rightarrow \) CL.5

9. **Compute_correct_lemma**.
Now we specify the multi-cycle behavior of the ic net.

We only expect it to perform correctly under certain assumptions. First, at the beginning of the multi-cycle computation, all the non-faulty voters should be synchronized in their LDP1 state, and be waiting for the go-signal. And all the non-faulty processors should have their bytecounter at BYTE1. Using the following predicates, we can assert this condition on the voternet state, s, as: Sync 'LDP1' 's' & All_go 's'

```plaintext
Sync 'cs' '<<ftc,vtr,inlist>>' :=
  ('faulty ONE'='False' => 'control (vtr ONE)'='cs')
  & ('faulty TWO'='False' => 'control (vtr TWO)'='cs')
  & ('faulty THREE'='False' => 'control (vtr THREE)'='cs')
  & ('faulty FOUR'='False' => 'control (vtr FOUR)'='cs')

vtr '<<f,v,in>>' = v
ftc '<<f,v,in>>' = f
inlist '<<f,v,in>>' = in
GO = '<<True,True,True,True>>'
go_signal '<<ftc,vtr,int:rest>>' index = vstartout (ftc index)

All_go 's' :=
  ('faulty ONE'='False' =>
    ('go_of (vtr s ONE)'='False'
    & 'go_signal s ONE'='GO' & 'bytecount (ftc s ONE)'='BYTE1'))
  & ('faulty TWO'='False' =>
    ('go_of (vtr s TWO)'='False'
    & 'go_signal s TWO'='GO' & 'bytecount (ftc s TWO)'='BYTE1'))
  & ('faulty THREE'='False' =>
    ('go_of (vtr s THREE)'='False'
    & 'go_signal s THREE'='GO' & 'bytecount (ftc s THREE)'='BYTE1'))
  & ('faulty FOUR'='False' =>
    ('go_of (vtr s FOUR)'='False'
    & 'go_signal s FOUR'='GO' & 'bytecount (ftc s FOUR)'='BYTE1'))

Bytecount_sync 'b' 's' :=
  ('faulty ONE'='False' => 'bytecount (ftc s ONE)'='b')
  & ('faulty TWO'='False' => 'bytecount (ftc s TWO)'='b')
  & ('faulty THREE'='False' => 'bytecount (ftc s THREE)'='b')
  & ('faulty FOUR'='False' => 'bytecount (ftc s FOUR)'='b')

So, the preconditions to the main correctness theorem are:

Preconditions 's' :=
  Propicnet 's' & Sync 'LDP1' 's' & All_go 's'

Some intermediate results.

Specification of the load cycles.

Xng3_correct 's' :=
'faulty ONE'='False' => xng3_correct 's' 'ONE'
& 'faulty TWO'='False' => xng3_correct 's' 'TWO'
& 'faulty THREE'='False' => xng3_correct 's' 'THREE'
& 'faulty FOUR'='False' => xng3_correct 's' 'FOUR'

Xng = Iterate (#3) IcNetStep
Xng1_correct_lemma :=
(proper_icnet 's' & sync 'XNG11' 's') =>
(proper_icnet 'Xng s' & sync 'XNG21' 'Xng s')

Xng2_correct_lemma :=
(proper_icnet 's' & sync 'XNG21' 's' & xng1_correct 's') =>
(xng2_correct 'Xng s' & sync 'XNG31' 'Xng s' & xng1_correct 'Xng s')

Xng3_correct_lemma :=
(proper_icnet 's' & sync 'XNG31' 's' & xng1_correct 's' & xng2_correct 's') =>
(xng3_correct 'Xng s' & sync 'CMPP' 'Xng s' & xng1_correct 'Xng s' & xng2_correct 'Xng s')

The compute and output cycles:
An array is a function of type :: INDEX->INDEX->data
If A is an array and i is an index, the A i has type :: INDEX->data
so it represents a vector of four values, one for each index.
This representation makes it easy to rotate the vector, since the
rotated vector is obtained by composing with the function "succ".
Now we can say that an array A is consistent if, for all non-faulty
indices, i and j, the vectors , A i and A j, are related by the appropriate
rotation, e.g. if j = succ2 i then (A i).succ2 equals (A j).

IndexConsistent 'array' 'index' :=
('faulty (succ index)'='False'=>'(array index).succ='array (succ index)'
& ('faulty (succ2 index)'='False'=>'(array index).succ2='array (succ2 index)'
& ('faulty (succ3 index)'='False'=>'(array index).succ3='array (succ3 index)'

Consistent 'array' :=
'faulty ONE'='False'=> IndexConsistent 'array' 'ONE'
& 'faulty TWO'='False'=> IndexConsistent 'array' 'TWO'
& 'faulty THREE'='False'=> IndexConsistent 'array' 'THREE'
& 'faulty FOUR'='False'=> IndexConsistent 'array' 'FOUR'

a_icvec init final index ONE = actualPVT init index
a_icvec init final index TWO = maj_val 1 final index
a_icvec init final index THREE = maj_val 2 final index
a_icvec init final index FOUR = maj_val 3 final index

maj_val i <<ftc,vtr,in>> index = get_maj_val i (maj_of (vtr index))
Compute = Iterate (#1) IcNetStep

Compute_correct_lemma :=
(proper_icnet 's' & sync 'CMPP' 's'
  & proper_icnet 'before' & load_correct 'before' 's'
  & xng1_correct 's' & xng2_correct 's' & xng3_correct 's')
=> (consistent 'a_icvec before (compute s)'
  & sync 'OUTI' 'compute s')

We want the final correctness condition to refer only to the
states of the processors, not the voters. So the icvec that
we state the condition on is:

icvec init final index ONE = actualPVT init index
icvec init final index TWO = get_special_register VT1 final index
icvec init final index THREE = get_special_register VT2 final index
icvec init final index FOUR = get_special_register VT3 final index

get_special_register saddr <<ftc,vtr,inlist>> index = sregof (ftc index) saddr

So to finish of the proof of correctness we need only show that
for non-faulty index, 'icvec init (output s) index'='a_icvec init s index'
Output = Iterate (#2) IcNetStep

output_correct 's' 'index' :=
'icvec init (Output s) index'= 'a_icvec init s index'

Output_correct 's' :=
('faulty ONE'= 'False' => output_correct 's' 'ONE')
& ('faulty TWO'= 'False' => output_correct 's' 'TWO')
& ('faulty THREE'= 'False' => output_correct 's' 'THREE')
& ('faulty FOUR'= 'False' => output_correct 's' 'FOUR')

Output_correct_lemma :=
(Proper_icnet 's' & Sync 'OUT1' 's' & Bytecount_sync 'BYTE1' 's')
=> Output_correct 's'

Twelve_cycle = Output.Compute.Xng.Xng.Xng.Load

MainTheorem := Preconditions 's' => Consistent 'icvec s (Twelve_cycle s)'

Here's another theorem that expresses a property useful from the point of view of a programmer using ICOP. It ensures that the system performs IC computation on the contents of SREG[PVT] in the cycle in which ICOP was executed, provided the instruction immediately following ICOP is not SADD. The following theorem, which has not been proved yet, can be proved using the above MainTheorem as a lemma.
and the final values in the special register VT1, VT2, and VT3.
Among the non-faulty processors, these vectors should be related
by a rotation.

anothericvec init final index ONE = get_special_register PVT init index
anothericvec init final index TWO = get_special_register VT1 final index
anothericvec init final index THREE = get_special_register VT2 final index
anothericvec init final index FOUR = get_special_register VT3 final index

Note that the expression "icvec init final index" is actually
a function on the type INDEX, and represents the vector of four values.

ResultConsistent 's' := Consistent anothericvec s (Iterate #12 IcNetStep s)

AnotherMainTheorem :=
Preconditions 's' & Next_instrn_isnot_SADD 's' => ResultConsistent 's'

Array s = arrayof.(vtr s)
ItStep n = Iterate n IcNetStep

Task 1 Final Report
Volume 1 published as NASA CR-4381.

This is the second volume of a two-volume report that presents a formal specification and verification of a property of a quadruplicately redundant fault-tolerant microprocessor system design. This volume gives a complete listing of the formal specification of the system and the correctness theorems that were proved. The system performs the task of attaining interactive consistency among the processors using a special instruction on the processors. The design is based on an algorithm proposed by Pease, Shostak and Lamport. The microprocessor used in the system is called FtCayuga, which was designed by extending another formally verified microprocessor MiniCayuga. The property verified ensures that an execution of the special instruction by the processors correctly accomplishes interactive consistency, provided certain preconditions hold, using a computer-aided hardware design verification tool, Spec tool, and the theorem prover, Clio, both of which were developed at ORA. A major contribution of the work is the demonstration of a significant fault-tolerant hardware design that is mechanically verified by a theorem prover.
